The movement of microorganisms has been extensively modeled by stochastic active particle models. In three dimensions, both swimming microorganisms, like sperm cells and some bacteria, and gliding microorganisms, like malaria sporozoites in the skin, often exhibit helical trajectories. If the internal driving force is the primary source of noise in the system, it induces random, yet time-correlated variations in the torque. To investigate this effect, we introduce a three-dimensional active rotational Ornstein-Uhlenbeck particle model. We find that the presence of a rotational component and the resulting helical path can mitigate the effect of intrinsic noise in the drive, allowing for larger long-time mean square displacements than straight movement at the same speed. The model not only provides qualitative insights into the constraints faced by microbes that may have led to the evolutionary selection of certain motility patterns, but also presents an analytical, quantitative tool for extracting information from these movements. We present and analyze corresponding data for malaria parasites gliding through hydrogels.

Corrugated channels can filter ciliated microorganisms based on the metachronal wavelength — •Gonçalo Antunes and Holger Stark — Technische Universität Berlin, Institute of Theoretical Physics, Hardenbergstr. 36, 10623 Berlin, Germany

Many microorganisms (e.g. Paramecium) move by a carpet of cyclically beating cilia that cover their surface. These cilia often beat in an organized fashion, such that the beating phases form a traveling wave, referred to as a metachronal wave. In this study, we investigate the swimming of such microorganisms in corrugated microchannels. We model the motion of the cilia via a time-varying effective slip velocity applied on the microorganism's surface, which we approximate as an infinite slab. By employing the lubrication approximation, we show analytically that the swimming speed of ciliated microorganisms placed inside a corrugated channel is sensitive to the corrugation height, provided that the wavelength of the corrugation matches that of the metachronal wave. Indeed, the direction of motion itself may invert with respect to swimming in bulk fluid, with the channel acting as a virtual barrier which blocks microorganisms under specific conditions for corrugation and slip-velocity modulations, but allow others to pass through. We also show that the interplay between the corrugation and the slip velocity profile allows for the swimming of microorganisms with zero time-averaged slip velocity, which thus cannot swim in bulk fluid. Finally, we complement our theory with preliminary results from hydrodynamic simulations for radially-symmetric microorganisms of finite length in radially-symmetric corrugated channels.

DY 36.7 Thu 17:00 H37

Motion of a single particle partially exposed in a simple shear flow — •Dominik Geyer[1,2], Aouane Othmane[1], and Jens Harting[1,2] — [1]Helmholtz-Institut Erlangen-Nürnberg for Renewable Energy (IET-2), FZ Jülich — [2]Department of Physcis, FAU Erlangen-Nürnberg

Sand immersed in the water can be imagined as a wet granular matter. Besides sedimentation, friction, and surface roughness are two relevant physical phonemes within this system. Many body systems in a turbulent regime have been studied using discrete elements methods for a long time, but a single particle in the Stokes flow regime is particularly interesting for biological systems and microfluidic devices.

A layer of quadratic-arranged spheres models the rough surface. The question arises of how to describe the motion of a single traveling particle over this substrate.

We choose a combined numerical and analytical approach. The Stokes equation is solved analytically for the sphere near a rough wall. Lattice Boltzmann simulations with momentum-exchange particle coupling are performed for different wall roughness and friction coefficients.

Although, the Stokes equation assumes that the particle Reynolds number is zero. Surprisingly, the numerical results match our theoretical description until a particle Reynolds number of two. In this regime, friction between the moving particle and the substrate significantly influences the angular velocity but has a minor influence on the traveling velocity in the flow direction.

DY 36.8 Thu 17:15 H37

Rational Design of Smart Microfluidics in Responsive Channels — •Arwin Marbini — Albert-Ludwigs Universität Freiburg

Responsive microfluidics offers exciting potential for self-regulating biomimetic systems. This study explores bifurcating microchannel networks with pressure-sensitive resistances, combining experiments with simulations based on the Hagen-Poiseuille equation and a linear model. These methods extract critical, experimentally inaccessible parameters under steady-state and dynamic conditions. Our findings enable the design of adaptable microfluidic networks, unlocking precise flow control for future applications in biology, soft robotics, and advanced material systems.

DY 36.9 Thu 17:30 H37

Blue Water: A passive, reusable microfiltration device for water purification — •Tim R. Baumann, Ioannis Gkekas, Martina Viefhues, and Dario Anselmetti — Experimental Biophysics, Bielefeld University

Water is the most vital resource for life on Earth. Due to pollution of freshwater and oceans, this valuable resource has become globally endangered. The effects

of microplastic pollution are widely discussed in scientific, political, and socioeconomic contexts. Despite regulations on single-use plastics and microplastic output, efforts should also focus on reintegrating microplastics to achieve a sustainable circular economy. Furthermore, microplastic-sized particles can migrate through organic tissue and can therefore be classified as contaminants of emerging concern. However, filtering plastics of this size is a challenging task.

Thus, this work examines and extends the findings of Divi et al. regarding the suspension feeding mechanisms of various ray species. We studied the filtration performance and efficiency for different geometric ratios of channel widths in simulations and laboratory environments. First, we have the main inner channel connected to the pressure inlet. From this, two rows of tilted lamellae structures branch off laterally to the outer secondary channels.

By applying sufficiently high pressure ($> 6 \cdot 10^5\ Pa$) to the inlet and achieving flow and particle velocities of $> 35\ \frac{m}{s}$, we can purify 82 % of half of the initial fluid. To prevent rupturing of our microfluidic chip under this pressure, we further investigated using glass fiber reinforced PDMS and lowering the operating pressure.

DY 37: Brownian Motion and Anomalous Diffusion

DY 37.1 Thu 15:00 H43

A universal class of exactly solvable diffusions — •Costantino Di Bello[1], Edgar Roldan[2], and Ralf Metzler[1] — [1]Potsdam University, Institute of Physics and Astronomy, Potsdam-Golm, Germany — [2]ICTP, Quantitative Life Sciences section, Trieste, Italy

We consider a general one-dimensional overdamped diffusion model described by the Ito stochastic differential equation (SDE) $dX_t = \mu(X_t, t)dt + \sigma(X_t, t)dW_t$, where W_t is the standard Wiener process. We obtain a specific condition that μ and σ must fulfill in order to be possible to solve the SDE via mapping the generic process, using a suitable space-time transformation, into the simpler Wiener process. By taking advantage of this transformation, we obtain the propagator in the case of open, reflecting, and absorbing boundary conditions for a large class of diffusion processes. With the same technique, we were also able to derive the first passage time (FPT) statistics of a large class of models. Moreover, as many physical observables in stochastic thermodynamics are described by an SDE of the same form, our result can provide the analytical expression of the probability distribution of many observables like work, entropy et similia. We stress the fact that our results are valid for many non-autonomous, non-linear and non-homogeneous processes.

DY 37.2 Thu 15:15 H43

Thermodynamic bounds on generalized transport: From single-molecule to bulk observables — •Cai Dieball and Aljaž Godec — Mathematical biophysics group, Max Planck Institute for Multidisciplinary Sciences, 37077 Göttingen, Germany

We prove that the transport of any scalar observable in d-dimensional nonequilibrium systems is bounded from above by the total entropy production scaled by the amount the observation "stretches" microscopic coordinates. The result, a time-integrated generalized speed limit, reflects the thermodynamic cost of transport of observables, and places underdamped and overdamped stochastic dynamics as well as deterministic motion on equal footing. Our work fills an important gap in thermodynamic inference, since microscopic dynamics is, at least for short times, underdamped. Requiring only averages but not sample-to-sample fluctuations, the proven transport bound is practical and applicable not only to single-molecule but also bulk experiments where only averages are observed, which we demonstrate by examples.

[1] Phys. Rev. Lett. 133, 067101 (2024)

DY 37.3 Thu 15:30 H43

Foundation of classical dynamical density functional theory: uniqueness of time-dependent density–potential mappings — Michael Andreas Klatt[2,3,1], •Christian Bair[1], Hartmut Löwen[1], and René Wittmann[1,4] — [1]Institut für Theoretische Physik II: Weiche Materie, Heinrich-Heine-Universität, Düsseldorf, Germany — [2]Deutsches Zentrum für Luft- und Raumfahrt (DLR), Institut für KI Sicherheit, Ulm, Germany — [3]DLR, Institut für Materialphysik im Weltraum, Köln, Germany — [4]Institut für Sicherheit und Qualität bei Fleisch, Max Rubner-Institut, Kulmbach, Germany

When can we uniquely map a classical density profile to an external potential? In equilibrium, without time dependence, the one-body density is known to uniquely specify the external potential that is applied to the many-body system. This mapping from a density to the potential is the cornerstone of classical density functional theory (DFT). Here, we consider non-equilibrium, time-dependent many-body systems that evolve from a given initial condition. We derive explicit conditions, for example, no flux at the boundary, that ensure that the mapping from the density to a time-dependent external potential is unique. We thus prove the underlying assertion of dynamical density functional theory (DDFT) - without resorting to the so-called adiabatic approximation often used in applications. By ascertaining uniqueness for all n-body densities, we ensure that the proof - and the physical conclusions drawn from it - hold for general superadiabatic dynamics of interacting systems.

DY 37.4 Thu 15:45 H43

Phase locking and fractional Shapiro steps in collective dynamics of microparticles — •Seemant Mishra[1], Artem Ryabov[2], and Philipp Maass[1] — [1]Institut für Physik, Universität Osnabrück, Germany — [2]Charles University, Faculty of Mathematics and Physics, Czech Republic

Nonlinear systems under time-periodic driving often exhibit phase locking, where synchronization between the system's dynamics and driving leads to robust stationary states. In this work, we show that phase-locked dynamics in a driven system of hardcore-interacting microparticles arises from running solitary cluster waves. Such cluster waves were recently predicted to occur in overdamped Brownian motion [1,2] and shortly after confirmed in experiments [3]. Particle currents are related to soliton velocities due to a unit displacement law saying that the total average shift of all particle positions per soliton period equals one wavelength of the periodic potential. The collective particle dynamics synchronize with the driving for certain particle diameters only. Based on an effective potential for solitary wave propagation, we derive dynamical phase diagrams of integer and fractional synchronization modes.

DY 37.5 Thu 16:00 H43

Modeling charge attachment induced ion transport in glasses — •Quinn Emilia Fischer and Philipp Maass — Department of Physics, Universität Osnabrück, Germany

In charge attachment induced ion transport (CAIT), material foreign mobile ions can replace native mobile ions near the surface of a glass below the glass transition temperature. Insight into the ion dynamics during CAIT experiments is provided by measurements of near-surface concentration profiles.

We discuss the modeling of concentration profiles by coupling the Poisson equation to kinetic equations of linear irreversible thermodynamics. Solving the kinetic equations requires knowledge on the dependance of both the Onsager coefficients and chemical potentials of the mobile ions on the ion concentrations.

We show how chemical potentials can be derived for a model, where mobile ions occupy sites in a disordered energy landscape, and how Fermi energies are generalized to a system of multiple ion types. We further explain the determination of Onsager coefficients by modeling thermally activated hopping motion in the energy landscape and the relation between the coefficients and ion mobilities.

The dependence of both the Onsager coefficients and the chemical potentials on mobile ion concentration is sensitive to the form of the energy landscape. It is argued that this sensitivity needs to be taken into account in a consistent theoretical modeling of CAIT experiments, which requires solutions of the coupled Poisson and kinetic equations to reproduce measured concentration profiles.

DY 37.6 Thu 16:15 H43

Local and Diffusive Dynamics of Interlayer Lithium ions in Synthetic Fluoro-Hectorites: ^{2}H and ^{7}Li NMR-Study — •Jepsinraj Kakkuzhiyulla Parambath and Michael Vogel — TU Darmstadt, Institut for Condensed Matter Physics, Hochschulstr. 6, 64289, Darmstadt, Germany

Investigating ion transport is a crucial part of developing robust devices for energy storage and sensors. Fluoro-Hectorite, a clay mineral of the Smectite group serves as a model material for this investigation, specifically Lithium Hectorite with the structural formula of $Li_{0.5}[Mg_{2.5}Li_{0.5}]Si_4O_{10}F_2$ and a layered structure. Due to the swelling properties of the Hectorites, the interlayer spacing and thus the degree of confinement can be varied with water content. The charge transports results from interlayer lithium ions, which are dissolved in water. The Hectorite confinements provide mechanical stability and guide the charge carriers over long distances, leading to fast ion transport [Hiebl et al., Chem. Mater. 2020, 32, 7445]. We use ^{2}H and ^{7}Li NMR to study the dynamics of the interlayer water molecules and lithium ions. Spin lattice relaxometry studies of local dynamics, including field cycling and static field gradient(SFG) measurements of diffusive dynamics show a strong dependence on the interlayer spacing.

DY 37.7 Thu 16:30 H43

Random Walks of Intermittently Self-Propelled Particles — Agniva Datta[1], Carsten Beta[1,2], and •Robert Grossmann[1] — [1]University of Potsdam, Potsdam, Germany — [2]Kanazawa University, Kanazawa, Japan

We present a dynamical model of intermittently self-propelled particles: active particles that recurrently switch between two modes of motion, namely an active run-state and a turn state, in which self-propulsion is absent. The durations of these motility modes are drawn from arbitrary waiting-time distributions. We derive the expressions for exact forms of transport characteristics like mean-square displacements and diffusion coefficients to describe such processes. Furthermore, the conditions for the emergence of sub- and superdiffusion in the long-time limit are presented. We give examples of some important processes that occur as limiting cases of our system, including run-and-tumble motion of bacteria, Lévy walks, hop-and-trap dynamics, intermittent diffusion and continuous time random walks. We eventually apply this modeling framework to describe bacterial swimming in polysaccharide matrices.

DY 37.8 Thu 16:45 H43

First-passage time for generalized telegrapher's processes under stochastic resetting — •Trifce Sandev — Macedonian Academy of Sciences and Arts, Skopje, Macedonia — Ss. Cyril and Methodius University in Skopje, Macedonia — Korea University, Seoul, Korea

We consider different generalizations of the telegrapher's process. One possible generalization is the so-called subordinated telegrapher's process, which can be obtained from the standard telegrapher's process subordinated by Lévy noise. Another possible generalization is a heterogeneous telegrapher's process which is a stochastic process with a multiplicative dichotomic noise and a position-dependent velocity. For both cases we analyze the non-equilibrium stationary states approached in the long time limit, as well as the survival probability, the first-passage time density and the mean first-passage time in the presence of Poissonian stochastic resetting of the particle to the initial position.

Diffusion and Homogeneous Linewidth – Phthalocyanine on Solid Rare-Gas Clusters — •Philipp Elsässer, Arne Morlok, Ulrich Bangert, Li Yilin, Felix Riedel, Lukas Bruder, Frank Stienkemeier, and Tanja Schilling — Institute of Physics, University of Freiburg, Hermann-Herder-Straße 3, 79104 Freiburg, Germany

Doped clusters are an important tool in the spectroscopy of organic molecules and the study of basic properties of confined quantum systems. It is crucial in these structures to understand the characteristics of the configurations between dopant and cluster. The binding sites may vary over time due to diffusion. Because of this, the diffusion behavior is valuable to characterize doped clusters.

We have studied the diffusion of free-base phthalocyanine (H_2Pc) on solid, icosahedral, rare-gas clusters of argon and neon by molecular dynamics simulations. We observe on both systems that the spacial motion of H_2Pc is confined on a single face of the icosahedron. The rotational movement of the molecule shows a cluster-size dependent anomalous-diffusive behavior on a picosecond timescale. This overall anomalous diffusion is in agreement with the homogeneous line width broadening observed in action-based two-dimensional electronic spectroscopy experiments.

DY 38: Focus Session: Innovations in Research Software Engineering (joint session BP/DY)

Research software engineering (RSE) is an emerging field in science, with practitioners spanning a continuous spectrum from "researchers who code" to "software engineers developing for science". In Germany, a growing movement supported by deRSE e.V. is gaining recognition, and more institutions are acknowledging the increasing demand across various disciplines. This focus session will provide a platform to highlight recent advances in applications, tooling, and software in the fields of biophysics, dynamics, and statistical physics, as well as developments in the recognition and proliferation of RSE as a profession within our field and academia in general.

Organized by Simon Christ and Sophia Rudorf (Hannover).

Time: Thursday 15:00–18:00 Location: H44

Community-driven software and data training for computational biology — •Toby Hodges — The Carpentries, Oakland, CA, USA

The Carpentries is a global community teaching essential software and data skills for research. Certified Instructors teach hundreds of workshops to thousands of learners all over the world every year, introducing them to essential skills for computational research such as programming, version control, and data organisation. In recent years, the community has also begun to develop and deliver lessons that build on these foundations, teaching more intermediate and advanced Research Software Engineering skills such as HPC, parallel programming, and containerised computing. This talk will explore how open source, collaborative training efforts can build capacity for computational research, discuss what makes this model work and some lessons learned along the way, and finish with a look at what the community plans to do next.

DY 38.2 Thu 15:30 H44

Python-based interface to micromagnetic simulation software: Ubermag — •Hans Fangohr[1,2,3], Martin Lang[1,2], Samuel J.R. Holt[1,2], Swapneel Amit Pathak[1,2], Kauser Zulfiqar[1,2,4], and Marijan Beg[5] — [1]MPSD, Hamburg, Germany — [2]CFEL, Hamburg, Germany — [3]Univ. Southampton, UK — [4]Univ. Hamburg, Germany — [5]Imperial College London, UK

We describe the Python-based user environment "Ubermag" to help scientists use well-established (micromagnetic) simulation packages.

Within Ubermag [1], researchers can express the physics problem they want to simulate in a scientist-friendly but machine readable problem definition based on Python syntax [2]. Ubermag translates this problem into the configuration files needed for micromagnetic simulation packages such as OOMMF or mumax3. On completion of the simulation, the computed data is presented back to the user at the Python level. Ubermag is often used in Jupyter Notebooks, and supports rich media to provide figures and equations within the notebook.

We report on the motivation for Ubermag, the design and implementation process, and our experiences made both from the perspective of science users and from the research software engineers. We touch on a range of topics, including interface design, domain specific languages, testing, packaging, Jupyter, and reproducibility.

This work was supported by EPSRC UK Skyrmion Grant EP/N032128/1, and the European research projects OpenDreamKit (676541) and MaMMoS (101135546).

OCTOPOS.jl: A Julia-based tool for synonymous codon optimization — Simon Christ[1], Jan-Hendrik Trösemeier[2], and •Sophia Rudorf[1] — [1]Institute of Cell Biology and Biophysics, Leibniz University Hannover, Germany — [2]independent researcher

OCTOPOS.jl is a research software designed to optimize synonymous mRNA sequences for improved heterologous gene expression in various host organisms. Combining a detailed mechanistic model of in-vivo protein synthesis with machine learning, OCTOPOS.jl predicts protein expression based on codon choice. Originally developed as a Java desktop application, the software has been reimplemented in the Julia programming language to enhance performance, modularity, and scalability. The new implementation serves as the foundation for a graphical user interface and a web application, accessible at https://octopos.cell.uni-hannover.de/. These updates improve accessibility and usability, broadening its appeal to both computational and experimental biologists. OCTOPOS.jl supports organism-specific genetic sequence engineering and detailed analysis of translation dynamics, thus providing a valuable resource for the synthetic biology and biotechnology communities.

DY 38.4 Thu 16:00 H44

Invert pattern forming systems with BayesFlow to bridge the gap from simulation to experimental observation — •Hans Olischläger — Interdisciplinary Center for Scientific Computing (IWR) — Heidelberg University

The description of experimental systems by complex spatial models, be it with (stochastic) partial differential equations, agent-based simulation or otherwise, is often the condensation of all the central scientific hypotheses regarding a particular object of study.

I argue, that making progress in this kind of modelling is currently hindered by the lack of a tool that enables solving the following inverse problem: Given an observation, determine all the model configurations that are able to produce

it. In other words, what is the posterior probability of all model configurations given some (set of) experimental data.

Instead of just preaching that in theory a Bayesian treatment would be nice, I will then continue to present such a tool: amortized Bayesian inference (as implemented in the software package BayesFlow). I will give examples on the classical Gierer-Meinhardt pattern forming PDE and a biophysical model, the Min system, which is used by E. coli to control cell division.

I will also take a step back to give a broader picture of the newly available statistical methods that support complex spatial modelling and their limitations. The aim is to provide some guidance on what you can and cannot infer from your state-of-the-art scientific simulator given observations, and how to do it.

DY 38.5 Thu 16:15 H44

FAIR Data Management for Soft Matter Simulations using NOMAD — •Bernadette Mohr[1], Esma Boydas[1], Nathan Daelman[1], José M. Pizarro[1], Tristan Bereau[3], Claudia Draxl[1], Luca M. Ghiringhelli[4], Martin Girard[2], Denis Usvyat[6], Roser Valentí[7], Silvana Botti[5], and Joseph F. Rudzinski[1,2] — [1]CSMB, HU Berlin — [2]MPIP Mainz — [3]ITP, Heidelberg Uni. — [4]Dept. of Mater. Sci. and Eng., FAU Erlangen — [5]RC-FEMS and Faculty of Physics, RUB Bochum — [6]Inst. für Chem., HU Berlin — [7]ITP, GU FfM

NOMAD [nomad-lab.eu][1, 2] is an open-source, community-driven data infrastructure designed to facilitate FAIR data management in materials science. Currently, it supports over 60 computational codes and encompasses DFT, classical MD, and many-body methods. This contribution will focus on recent developments, following modern software practices, to enhance NOMAD's applicability to soft matter and biological systems, including support for coarse-grained representations and advanced workflows such as free energy calculations. Combined with a schema for representing force fields, molecular topologies, and hierarchical system structures, NOMAD tracks data provenance and streamlines data analysis and the creation of AI-ready datasets. The NOMAD framework meets the classical simulation community's needs for improved data management standards and provides a foundation for building a cohesive, interconnected scientific data ecosystem. [1] Scheidgen, M. et al., JOSS 8, 5388 (2023).

[2] Scheffler, M. et al., Nature 604, 635-642 (2022).

DY 38.6 Thu 16:30 H44

Estimation of kinetic rates by constrained optimization — •Federico Marotta[1], Maria Zimmermann-Kogadeeva[1], Peer Bork[1], Julia Mahamid[1], and Sophia Rudorf[2] — [1]European Molecular Biology Laboratory — [2]Leibniz Universität Hannover

Biological systems often rely on molecular motors to perform useful work. The kinetics of the reactions in a motor's cycle can be easily investigated *in vitro* or in model organisms, but it is difficult to generalize them to a different system. We present a method to estimate the transition kinetics in an uncharacterized system, where minimal data are available, by leveraging a reference system where the kinetics have been elucidated. The motor's activity is represented as a continuous-time Markov chain, characterized by an infinitesimal generator matrix Q whose entries are functions of the transition rates of the cycle (the vector ω) and possibly of the concentrations of external molecules. In the uncharacterized system, the available data induce a constraint on the admissible rates. By employing an extremum principle, we estimate the rates ω_{unc} that minimize the kinetic distance with respect to the reference rates ω_{ref} while respecting such constraint. As an application of this strategy, we describe a model of the translation elongation cycle, where reference data are available for *E. coli in vitro*, and estimate the rates either *in vivo* or in a different organism, under constraints on the total elongation time or the steady-state occupancies, respectively.

DY 38.7 Thu 16:45 H44

Software provisioning for HPC and RSE — •Martin Lang[1,2], Henning Glawe[1,2], Jehferson Mello[1,2], and Hans Fangohr[1,2,3] — [1]Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — [2]Center for Free-Electron Laser Science, Hamburg, Germany — [3]University of Southampton, Southampton, UK

All research software relies on existing libraries for various functionalities such as low-level math operations, FFTs, IO, or other domain-specific operations. Installing these dependencies, potentially based on different compilers or in multiple versions, with all inter-dependencies fulfilled is notoriously difficult.

In the first part of this talk we introduce the open-source package manager Spack, which has a strong focus on HPC and research software. Spack can install software in multiple versions and variants, and supports optimised compilation for the underlying hardware, including compiling on exotic hardware. It comes with a large, community-provided collection of commonly used packages. Spack's packaging files make it easy to specify required dependencies, provide optional features of a software, and ensure compatibility with other libraries.

In the second part we present the concrete setup at our institute. We use Spack to provide the software stack on the local HPC, including pre-compiled packages and toolchains (sets of compilers and libraries) for users to compile their own software. We report on requirements and challenges, and how we address these with Spack. We also touch on scripting the Spack-based installation process including the option to recreate the HPC software environment on a scientist's laptop.

DY 38.8 Thu 17:00 H44

Small scale Research Software Engineering — •Simon Christ — Leibniz Universität Hannover, Institut für Zellbiologie und Biophysik, Computational Biology

While we are in dire need of research software organizations on a faculty level or larger, small scale software engineering, that is one research software engineer in a group or institute, is something that can be achieved in a short time frame and is probably the most common form today. A field report from Computational Biology where research software engineers are involved in modeling, developing solutions, teaching and maintenance.

DY 38.9 Thu 17:15 H44

Estimation of pKa values in membrane bound proteins — •Jesse Jones[1], Nereu Montserrat i Busquets[1,2], Ana Gamiz Hernandez[3], Ville Kaila[3], and Maria Andrea Mroginski[1] — [1]Technische Universität Berlin, Berlin — [2]Freie Universität Berlin, Berlin — [3]Stockholm Universität, Stockholm

Many key bioenergetic processes involving electron and proton reactions take place in membrane bound protein complexes, generating a proton motive force. Yet the ionizable groups which facilitate these reactions are often buried in hydrophobic pockets in the membrane. These processes are mainly described through pK_a values, which continue to be poorly understood and difficult to obtain despite structural, biochemical and computational advances. Hence, estimating pK_a values of these residues without the need for weeks of work in a laboratory, is important to describe the dynamics of the system, providing information on possible proton pathways. In this work we preview Karlsberg3, a software which uses a Poisson Boltzmann Equation solver (APBS) for proteins and calculates pKa values. Karlsberg3 is, in contrast to its predecessor Karlsberg2+, parallelized, running in modern software environments, and able to take membranes into consideration.

DY 38.10 Thu 17:30 H44

The teachingRSE project - Towards a professionalization of RSE education. — •Florian Goth[1] and Simon Christ[2] — [1]Universität Würzburg, Institut für theoretische Physik und Astrophysik, Am Hubland, 97074 Würzburg — [2]Leibniz Universität Hannover, Institut für Zellbiologie und Biophysik, Herrenhäuser Str. 2 30419 Hannover

At the deRSE23, the second conference for research software engineering(RSE) in Germany, a group of people came together for a small workshop to discuss how to deal with questions revolving around RSE education. Overwhelmed by the immense resonance to that workshop we took home a tremendous amount of feedback that made obvious that a short blog post will not suffice to adequately represent it. Now it is two years later, and the project produced its first output, the second position paper https://arxiv.org/abs/2311.11457 of de-RSE e.V. and it has sprawled out into a multitude of follow-up projects. In this talk, I will give an overview over the original ideas that we tried to convey in the position paper, and go into more detail on how domain sciences like physics need to change in light of this new specialization.

DY 38.11 Thu 17:45 H44

Python-Based Analysis Pipeline for the Quantification of Mechanics in Neural Organoids — •Michael Frischmann[1,2], Elijah R. Shelton[1], Achim T. Brinkop[1,2], and Friedhelm Serwane[1,2,3] — [1]Faculty of Physics & Center for NanoScience, LMU Munich, Germany — [2]Institute of Biophysics, Ulm University, Ulm, Germany — [3]SyNergy & GSN, Munich, Germany

Neuronal tissues form under the influence of mechanical forces guiding cellular movements. In the mammalian retina, neuronal translocations occur over hours. However, mechanical probing at those timescales in situ have posed experimental challenges. We employed magnetic ferrofluid droplets in mouse stem cell-derived retinal organoids to probe tissue mechanics from seconds to hours. To quantify tissue strain we have developed a Python-based analysis pipeline featuring an accessible graphical user interface (GUI). This pipeline automates strain quantification, image segmentation, and fitting procedures, enabling high-fidelity creep compliance measurements over extended durations. Our measurements reveal power-law scaling of dynamic compliance as well as tensile loss and storage modulus, consistent with soft glassy rheology just above the glass transition. These results demonstrate that neuronal tissues remodel in a scale-free manner while maintaining solid-like properties. This discovery provides a framework for understanding how mechanical signals may govern connectivity in the central nervous system. Integrating neural organoid models, mechanical probing, and computational methods, prepares us to investigate the interplay between biomechanics and neurodevelopment.

DY 39: Machine Learning in Dynamics and Statistical Physics II

Time: Thursday 15:00–16:30 Location: H47

DY 39.1 Thu 15:00 H47

Fast and energy-efficient reservoir computing using a resonant-tunneling diode — •Osamah Sufyan[1], Antonio Hurtado[2], and Kathy Lüdge[1] — [1]Technische Universität Ilmenau, Institut für Physik, Weimarer Straße 25, 98693 Ilmenau, Germany — [2]University of Strathclyde, Institute of Photonics, Glasgow, United Kingdom

Resonant-tunneling diodes (RTDs) have garnered significant attention as platforms for neuromorphic computing, owing to their fast operation and intricate nonlinear dynamics. Among the most hardware-friendly and energy-efficient paradigms in this domain is reservoir computing (RC), where the nonlinear dynamics of a physical system are leveraged to perform complex computational tasks.

In this work, we explore the use of a single RTD as a reservoir, employing time-multiplexing techniques for chaotic time-series prediction achieving similar performance to previous RC approaches [1]. Our findings highlight the relationship between the RTD's distinct dynamical regimes and the reservoir's performance in predicting future values of the Mackey-Glass and Lorenz system time series. Additionally, we investigate the RTD as an excitable system, demonstrating its potential for spiking neural network applications. We examine various data encoding and decoding strategies for spike-based operations, further underscoring the versatility of RTDs in neuromorphic computing.

DY 39.2 Thu 15:15 H47

Tailored minimal reservoir computing: Connecting nonlinearities in the input data with nonlinearities in the reservoir — Davide Prosperino[1], Haochun Ma[1], Vincent Gross[2], and •Christoph Räth[3,2] — [1]Allianz Global Investors (AGI) — [2]Ludwig-Maximilians-Universität (LMU) — [3]Deutsches Zentrum für Luft- und Raumfahrt (DLR)

The traditional setup of reservoir computing (RC) for predicting time series uses random matrices to define the underlying network and the input layer. Here, we show that a few modifications, which eliminate randomness and minimize computational resources and data requirements, lead to significant and robust improvements in short- and long-term predictive performance. We introduce block-diagonal reservoirs, which implies that a reservoir can be composed of multiple smaller reservoirs. Further, the non-linear activation function at the nodes can be dispensed with if the non-linear step in the analysis chain is shifted to the output layer. The input weights are determined according to well-defined rules. Any random initialization has thus been eliminated. By varying the remaining four hyperparameters, it is now possible to systematically investigate the transition from a linear, disjunct mapping of the input data to the output data to a combined nonlinear one. It is further demonstrated that there is a connection between the nonlinearities in the input data and the nonlinearities in the reservoir such that the best prediction results are obtained when both nonlinearities match. It becomes thus possible to define an optimally tailored setup for minimal RC for data sets with given nonlinearities.

DY 39.3 Thu 15:30 H47

Physical Reservoir Computing with Ferroelectric Oxides — •Atreya Majumdar[1], Yan Meng Chong[2], Dennis Meier[2], and Karin Everschor-Sitte[1] — [1]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Duisburg, Germany — [2]Department of Materials Science and Engineering, Norwegian University of Science and Technology (NTNU), Trondheim, Norway

Physical reservoir computing has shown remarkable potential in magnetic systems by utilizing their complex, non-linear, and history-dependent intrinsic dynamics for machine learning tasks [1]. More recently, ferroelectric materials - the electrical analogs of magnetic systems - have garnered attention. These materials not only meet all the essential criteria for reservoir computing but also bring unique advantages [2]. Here, we introduce the ferroelectric semiconductor ErMnO3 as a novel physical reservoir. By utilizing the material's non-linear and history-dependent photocurrent response, we demonstrate its capability to recognize varying input light pulse intensities. This study highlights the potential of ferroelectric materials in physical reservoir computing, paving the way for energy-efficient and scalable computing architectures.

Describing heat transport in crystalline polymers in real and reciprocal space — Lukas Reicht[1], Lukas Legenstein[1], Sandro Wieser[2], and •Egbert Zojer[1] — [1]Graz University of Technology, Austria — [2]TU Wien, Austria

Heat transport modelling either relies on describing the propagation of phonons employing the Boltzmann transport equation or on simulating the real-space dynamics of atoms using (non)-equilibrium molecular dynamics techniques. Due to the structural complexity of crystalline polymers both approaches call for a highly accurate but at the same time numerically extremely efficient strategy for describing inter-atomic interactions. This is achieved via machine-learned potentials, where we combine an efficient active-learning strategy with moment-tensor potentials.[1,2] Additionally, real-space and reciprocal space approaches make fundamentally different approximations regarding anharmonicities and phonon occupations. Here, we show that for polymers of intermediate complexity, like crystalline polythiophene, real- and reciprocal space approaches yield consistent values of the thermal conductivities at least when using an accurate machine-learned potential. Interestingly, for the seemingly much simpler crystalline polyethylene such an agreement is only obtained when higher-order phonon scattering is considered. This can be traced back to a selection rule arising from the comparably simple phonon band structure of polyethylene. [1] npj Comput Mater 10, 18 (2024); [2] Molecules 29, 3724 (2024)

Reinforcement learning for autonomous navigation of active particles in complex flow fields — •Diptabrata Paul and Frank Cichos — Peter Debye Institute for Soft Matter Physics, Universität Leipzig, 04103 Leipzig, Germany

Sensing and feedback on environmental stimuli are integral to regulating diverse functions in living systems, ranging from sub-cellular processes to evolution of navigation strategies such as chemotaxis and phototaxis. Unlike living systems, noisy artificial microswimmers have limited ability to adapt to various stationary and dynamic environmental perturbations to yield optimized behaviour for a given task. Consequently, reacting to such environmental cues becomes indispensable for achieving effective navigation and control in complex and noisy settings. In this context, we explore incorporation of machine learning algorithm for autonomous decision making for navigation of an active microswimmer within noisy environments. While naive navigation policies yield inefficient and ineffective solutions under changing conditions, employing actor-critic reinforcement learning (RL) framework trained in experiments leads us to quasi-optimal policies that are capable of navigating, even in presence of complex flow fields. Our study exhibits that a model trained under noisy conditions successfully learns effective navigation policies and are robust with respect to environmental perturbations such as hydrodynamic flow fields as well as varying initial conditions. This work paves the way for development of online RL for modelling adaptive behaviour and navigation of active microswimmers in complex fluidic scenarios.

Predictability Analysis of Discrete Time-Series Data with a Hamiltonian-Based Filter-Projection Approach — •Henrik Kiefer and Roland Netz — Freie Universität Berlin, Fachbereich Physik, Berlin, Deutschland

The generalized Langevin equation (GLE), derived by projection from a general many-body Hamiltonian, exactly describes the dynamics of an arbitrary coarse-grained variable in a complex environment. However, analysis and prediction of real-world data with the GLE is hampered by slow transient or seasonal data components and time-discretization effects. Machine-learning (ML) techniques work but are computer-resource demanding and difficult to interpret. We show that by convolution filtering, time-series data decompose into fast, transient and seasonal components that each obey Hamiltonian dynamics and, thus, can be separately analyzed by projection techniques. We introduce methods to extract all GLE parameters from highly discretized time-series data and to forecast future data including the environmental stochasticity. For daily-resolved weather data, our analysis reveals non-Markovian memory that decays over a few days. Our prediction accuracy is comparable to ML long short-term memory (LSTM) methods at a reduced computational cost compared to LSTM. For financial data, memory is very short-ranged and the dynamics effectively is Markovian, in agreement with the efficient-market hypothesis; consequently, models simpler than the GLE are sufficient. Our GLE framework is an efficient and interpretable method for the analysis and prediction of complex time-series data.

Entanglement phase transitions in unitary circuit games with free fermions — •Raúl Morral-Yepes[1,2], Marc Langer[1,2], Adam Smith[3,4], Barbara Kraus[1,2], and Frank Pollmann[1,2] — [1]Technical University of Munich, TUM School of Natural Sciences — [2]Munich Center for Quantum Science and Technology (MCQST) — [3]School of Physics and Astronomy, University of Nottingham — [4]Centre for the Mathematics and Theoretical Physics of Quantum Non-Equilibrium Systems

In the recently introduced framework of unitary circuit games, two competing parties an entangler and a disentangler can induce an entanglement phase transition, distinct from measurement-induced transitions. In this work, we study such games within the context of matchgate dynamics, which correspond to free fermion systems. First, we investigate the entanglement properties of fermionic Gaussian states (FGS) and explore different methods for their disentangling. We propose a representation of FGS using a minimal matchgate circuit in a standard form, and introduce algorithms for updating this representation as unitary operations are applied. Within this framework, we define a natural disentangling procedure that reduces the number of gates in the circuit, thereby decreasing the system's entanglement. We then analyze the unitary game using this gate disentangler, observing a phase transition between a volume-law and area-law entanglement phase. The nature of this transition differs depending on whether we examine Rényi-0 or other entanglement entropies.

DY 41.2 Fri 9:45 H37

Measurement Induced Entanglement Transitions in Random Qudit Clifford Circuits — •Aamod Vinayak Atre, Raúl Morral Yepes, and Frank Pollmann — Department of Physics, Technical University of Munich

Random quantum circuits with local projective measurements uncover the universal dynamical properties of generic chaotic quantum many-body systems, as their unitary evolution is independent of the microscopic features of Hamiltonians. Entanglement measures characterize these universal dynamics into volume-law and area-law regimes, which exhibit bipartite entropy scaling proportional to the system volume and system boundary respectively. This continuous entanglement scaling transition, driven by the rate of measurement, has been extensively studied in spin-1/2 (qubit) systems of various spatial geometries. In this talk, we discuss the characterization the entanglement transitions in 1D random quantum circuits of spins (qudits) with arbitrary local Hilbert-space dimension d. This work employs the generalized stabilizer formalism, taking advantage of the Clifford group which forms a unitary 2-design on the space of unitaries. We find the nature of the entanglement transition, from volume-law to area-law regimes, to be preserved for $d > 2$. The critical measurement density increases, converging to $1/2$ in the limit $d \to \infty$. Lastly, we describe the stabilizer dynamics in the limit $d \to \infty$, by a dynamical classical model.

DY 41.3 Fri 10:00 H37

Entanglement phases, localization and ergodicity of monitored free fermions in 2D — •Karim Chahine and Michael Buchhold — Institut für Theoretische Physik, Universität zu Köln, D-50937 Cologne, Germany

Monitored quantum systems, characterized by the interplay between unitary evolution and mid-circuit measurements, have recently emerged as a novel expression of quantum dynamics. Despite their inherently out-of-equilibrium nature, these systems can host robust quantum phases and display measurement-induced phase transitions (MIPT) in the entanglement entropy. Remarkably, they are also unique in providing a link between quantum dynamics in D dimensions and quantum statistical mechanics in $D+1$ dimensions. In this talk, I will present our recent work on a new arena with a rich phenomenology: continuously monitored, $U(1)$-symmetric free fermions in 2D. I will address the emerging MIPT and its similarities and differences with Anderson-type localization transitions. Some emphasis will be put on the low-measurement regime, where intriguing features in the entanglement structure and ergodic properties emerge, revealing a richer phenomenology than previously anticipated.

DY 41.4 Fri 10:15 H37

Spectral Properties and Magic generation of T-doped Random Clifford Circuits — •Dominik Szombathy — Budapest University of Technology and Economics

We investigate the spectral properties and magic generation of T-doped random Clifford circuits. There is a direct relation between the structure of Pauli string orbits and the eigenvalue spectrum of a Clifford circuit. Operatively, we sample the closed trajectories with brick-wall circuits and determine the distribution of the eigenvalues $\lambda = e^{i\Theta}$. The autocorrelation function of the phases of the eigenvalues displays peculiar properties: extreme degeneracies as well as some level-repulsion, and features reminiscent of a fractal pattern.

To investigate the stability of orbits and head towards universal quantum computation, we introduce $\pi/4$ phase shift gates (T-gates). We find that even a single T-gate completely changes the properties of the circuit. By increasing the number of T-gates (N_T), the correlation function rapidly approaches that of the random unitary circuits. Nevertheless, some statistically significant fraction of non-trivial orbits persists at low T-gate densities (N_T/N).

We observe a similar phenomenology in the magic generation as a function of T-gate density. In particular, we find universal scaling of the maximum and mean magic as a function of N_T/N . We also highlight the structure of magic generated by these circuits. Injecting a few T-gates the distribution is discrete but becomes continuous as N_T increases. At large densities N_T/N , most of the weight is found in a sharp peak well below the theoretical maximum.

DY 41.5 Fri 10:30 H37

Magic transition in measurement-only circuits — •Poetri Sonya Tarabunga[1,2] and Emanuele Tirrito[3,4] — [1]Technical University of Munich, Physics Department, 85748 Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), 80799 München, Germany — [3]The Abdus Salam International Centre for Theoretical Physics (ICTP), 34151 Trieste, Italy — [4]Dipartimento di Fisica "E. Pancini", Università di Napoli "Federico II", 80126 Napoli, Italy

Magic quantifies the distance of a quantum state to the set of stabilizer states, and it serves as a necessary resource for potential quantum advantage over classical computing. In this work, we study magic in a measurement-only quantum circuit with competing types of Clifford and non-Clifford measurements, where magic is injected through the non-Clifford measurements. This circuit can be mapped to a classical model that can be simulated efficiently, and the magic can be characterized using any magic measure that is additive for tensor product of single-qubit states. Leveraging this observation, we study the magic transition in this circuit in both one- and two-dimensional lattices using large-scale numerical simulations. Our results demonstrate the presence of a magic transition between two different phases with extensive magic scaling, separated by a critical point in which the mutual magic exhibits scaling behavior analogous to entanglement. We further show that these two distinct phases can be distinguished by the topological magic. In a different regime, with a vanishing rate of non-Clifford measurements, we find that the magic saturates in both phases.

DY 41.6 Fri 10:45 H37

Developing a Framework for Predicting Useful Quantum Advantage in the Calculation of Molecular NMR Spectra — •Keith Fratus, Andisheh Khedri, Juha Leppäkangas, Michael Marthaler, and Jan Reiner — HQS Quantum Simulations GmbH, Karlsruhe, Germany

Demonstrating useful quantum advantage remains a primary goal of quantum computing efforts in the NISQ era. Key to such efforts is the ability to estimate the accuracy and performance of competing classical approximation methods when exact comparisons are not available. In this talk we report on our efforts to develop and understand the behaviour of various classical approximation methods which aim to solve a specific class of chemical simulation problems. In particular, we develop classical simulation methods designed to predict molecular NMR spectra, with the aim of being able to quantify the accuracy and computational requirements of performing these simulations, even for parameter regimes which we do not directly simulate. Using such methods, we work towards a framework for predicting in which parameter regimes, system sizes, and target accuracies one can expect the failure of classical methods for this class of systems, thus allowing for the possibility of quantum advantage.

DY 41.7 Fri 11:00 H37

Linear differential equation approach to the Loschmidt amplitude — •Michael Vogl — King Fahd University of Petroleum and Minerals, Dhahran, Saudi Arabia

The Loschmidt amplitude is a popular quantity that allows making predictions about the stability of quantum states under time evolution. We present an approach that allows us to find a linear differential equation that can be used to

compute the Loschmidt amplitude. This approach, while in essence perturbative, has the advantage that it converges at finite order. We demonstrate that the approach for generically chosen matrix Hamiltonians often offers advantages over Taylor and cumulant expansions even when we truncate at finite order. Even in low dimensional systems such as two band Hamiltonians (multi-Weyl semimetals and AB bilayer graphene) it can be used to obtain general formulas for the Loschmidt amplitude after a quench. Results readily generalize to find transmission amplitudes and specific contributions of the partition function, too. Our method can also be applied to many body spin and fermionic Hamiltonians. Here, while the approach still offers advantages, more care has to be taken than in a generic case. We also provide an estimate for a breakdown time of the approximation.

DY 42.1 Fri 9:30 H43

Stochastic Thermodynamics of the Interacting Non-reciprocal Particles and Fields — •Atul Tanaji Mohite and Heiko Rieger — Saarland University, Saarbrücken, Germany

Non-reciprocal interactions that violate Newtons law 'actio=reactio' are ubiquitous in nature and are currently intensively investigated in active matter, chemical reaction networks, population dynamics and many other fields. An outstanding challenge is the thermodynamically consistent formulation of the underlying stochastic dynamics that obeys local detailed balance and allows for a rigorous analysis of the stochastic thermodynamics of non-reciprocally interacting particles. Here we present such a framework for a broad class of active systems and derive by systematic coarse-graining exact expressions for the macroscopic entropy production. Four independent contributions to the thermodynamic dissipation can be identified, among which the energy flux sustaining vorticity currents manifests the presence of non-reciprocal interactions. Then, Onsager's non-reciprocal relations, the fluctuation-response relation, the fluctuation relation and the thermodynamic uncertainty relations for non-reciprocal systems are derived. Finally, we demonstrate that our general framework is applicable to a plethora of active matter systems and chemical reaction networks and opens new paths to understand the stochastic thermodynamics of non-reciprocally interacting many-body systems.

DY 42.2 Fri 9:45 H43

Staying on Time: Precision and Cost of a Controlled Clock — •Till Welker and Patrick Pietzonka — School of Physics and Astronomy, University of Edinburgh, United Kingdom

The precision of an autonomous clock is associated with an entropic cost. In overdamped systems, the precision-cost tradeoff is bounded by the thermodynamic uncertainty relation (TUR). To avoid paying immense costs while staying accurate over an extended period, the clocks in our phones, radios, and computers adapt their dynamics according to a precise reference clock.

We study the minimal model of the two-state controlled clock with one state running slower and one state running faster than the reference clock. At a rate R, the controlled clock reads out the reference clock and adjusts its state accordingly. While the clock hand progresses, the offset reaches an analytically solvable steady state, and the clock's error remains bounded.

The combined cost of the controlled and reference clock obeys the TUR. However, the operator of the controlled clock only needs to pay a part of that cost, namely the driving of the controlled clock and the cost of state adjustment. We show that there is an R-dependent tradeoff between the controlled clock's cost and its total error, and we explore the Pareto front of optimal clocks.

DY 42.3 Fri 10:00 H43

Active Brownian information engine: Self-propulsion induced colossal performance — •Rafna Rafeek and Debasish Mondal — Department of Chemistry and Center for Molecular and Optical Sciences and Technologies, Indian Institute of Technology Tirupati, Yerpedu 517619, Andhra Pradesh, India

Many biological systems operating in athermal (active) environments, can be modeled as an information engine, with the key aspect of utilizing information on the fluctuation to extort work from the noisy environment. In this study, we propose a feedback-driven information engine operating in a Gaussian-correlated active reservoir with characteristic strength (D_a) and correlation time (τ_a), which outperforms its thermal counterpart. We obtain the optimal functioning criteria for the enhanced performance of the active Brownian information engine (ABIE), reliant on the dispersion of the steady state, which is analogous to its passive analog. We notice that a weakly correlated active bath extracts colossal work due to the reduced relative loss of information in the relaxation process. In the limit of fractionally smaller correlation time ($t_a/t_r \rightarrow 0$, t_a is thermal relaxation time), the upper bound on colossal work extraction is $0.202(D+D_a)$. The excess amount of extracted work reduces and converges to its passive counterpart in the higher limit of correlation time ($t_a/t_r \rightarrow high$). Interestingly, when correlation time is equivalent to relaxation time ($t_a/t_r = 1$), half the upper bound of excess work is achieved irrespective of activity strength. This study provides a new insight into understanding and designing the information-energy exchange of biological submicrometer motors.

DY 42.4 Fri 10:15 H43

Entropy estimation for partially accessible Markov networks based on imperfect observations: Role of finite resolution and finite statistics — •Jonas H. Fritz, Benjamin Ertel, and Udo Seifert — II. Institut für Theoretische Physik, Universität Stuttgart, 70550 Stuttgart, Germany

Estimating entropy production from real observation data can be difficult due to finite resolution in both space and time and finite measurement statistics. We characterize the statistical error introduced by finite sample size and compare the performance of three different entropy estimators under these limitations for two different paradigmatic systems, a four-state Markov network and an augmented Michaelis-Menten reaction scheme. We consider the thermodynamic uncertainty relation, a waiting-time based estimator for resolved transitions and a waiting-time based estimator for blurred transitions in imperfect observation scenarios. For perfect measurement statistics and finite temporal resolution, the estimator based on resolved transitions performs best in all considered scenarios. The thermodynamic uncertainty relation gives a better estimate than the estimator based on blurred transitions at low driving affinities, whereas the latter performs better at high driving affinities. Furthermore, we find that a higher temporal and spatial resolution leads to slower convergence of measurement statistics, implying that for short measurement times, a lower resolution may be beneficial. Additionally, we identify a self-averaging effect for the waiting-time based entropy estimators that can reduce their variance for observations with finite statistics.

DY 42.5 Fri 10:30 H43

Stochastic Calculus Approach to Thermodynamic Bounds for Jump Processes — •Lars Stutzer, Cai Dieball, and Aljaž Godec — Mathematical bioPhysics Group, Max Planck Institute for Multidisciplinary Sciences, 37077 Göttingen, Germany

Thermodynamic inequalities bound dissipation from below in terms of fluctuations of, and correlations between, observable currents and densities. They are at the heart of thermodynamic inference. By establishing a stochastic-calculus for functionals of Markov-jump dynamics, we allow for immediate extensions of results derived for overdamped diffusion to discrete state spaces, which expands the range of bounds available for jump processes. Moreover, we use the calculus to prove new bounds for jump-processes, including transient thermodynamic uncertainty relations, finite-time correlation bounds, and the recently established transport bounds. While it was expected for these results carry over to discrete spaces, the methodological advance establishes them as an inherent property of stochastic equations of motion. Our results put Langevin and Markov-jump dynamics on a common footing on the level of individual stochastic trajectories. We illustrate the results by means of biologically motivated examples.

DY 42.6 Fri 10:45 H43

Is learning in Neural Networks just very high dimensional parameter fitting? — •Ibrahim Talha Ersoy — Universität Potsdam, Institut für Astronomie und Physik, Potsdam, Deutschland

Neural Networks (NNs) are known for their highly non-convex loss landscapes, shaped by the data and the error function. Unlike in convex optimization, the model navigates regions of changing curvature to find the global minimum. We anticipate qualitative changes in the model occurring at points where new error basins are explored. In information bottleneck settings, Tishby et al. (2015) suggested that transitions between distinct loss regions are associated with phase transitions, a concept proven in L2 setups by Ziyin et al. (2023), where they examined the onset of learning when varying the L2 regularizer strength. We extend the findings of Ziyin et al. (2023), interpreting them from an information geometric perspective and demonstrate further phase transitions when model changes. By distinguishing between the loss and error landscapes, we provide a rigorous argument that extends the scope of our results beyond the L2 setup. This approach enables a better understanding of the limitations of the free energy interpretation of the L2 loss function and provides a more accurate depiction. Finally, our results suggest a clear distinction between learning, characterised by phase transitions at points of model change, and fitting, where the model remains qualitatively fixed, lacking phase transitions.

DY 42.7 Fri 11:00 H43

Coherent effects in the semiclassical limit of quantum work — •Nicolás Torres-Domínguez[1], Carlos Viviescas[2], and JD Urbina[3] — [1]Chalmers tekniska högskola, Göteborg, Sweden — [2]Universidad Nacional de Colombia, Bogotá, Colombia — [3]Universität Regensburg, Institut für Theoretische Physik

Within the framework of quantum thermodynamics, the use of quasiprobabilities can provide a comprehensive approach to the work statistics of quantum systems. In this formulation the effects of coherences in the initial state of the system are accounted in a natural way for all protocols and are expected to be displayed in the quantum features of the chosen quasidistribution [1]; yet clear examples of this are scarce in the literature. In this work we consider the semiclassical limit of the quantum work distribution obtained using the Kirkwood-Dirac quasiprobability, highlighting the effects of initial coherences on the energetics of the system and on the quantum behavior of the quasidistribution. We illustrate our results in a study of the work distribution of a forced quantum harmonic oscillator [2] in the Weyl-Wigner representation in phase space.

DY 43: Active Matter IV (joint session BP/CPP/DY)

Time: Friday 9:30–13:00 Location: H44

Invited Talk DY 43.1 Fri 9:30 H44

Wave propagation in systems of active filaments — •Kirsty Y. Wan — Living Systems Institute, University of Exeter, UK

Active hair-like protrusions called cilia are found in many eukaryotes where they produce physiological flows for a variety of functions. Cilia assume a myriad of configurations both external to an organism for the purposes of feeding or swimming motility, but also internally where they mediate mucociliary clearance in vertebrate tissues. Single cilia can propagate large-amplitude non-decaying bending waves, even in the absence of a cell body. These waves assume a variety of stereotyped forms and frequencies, depending on the species. Multiple cilia also interact to produce different types of local and global coordination patterns, including robust metachronal waves. Do these dynamic states of coordination arise spontaneously, or do they require some form of internal control by the cell or animal? We propose new and emerging organisms to address these questions.

DY 43.2 Fri 10:00 H44

Metabolic activity controls the emergence of coherent flows in microbial suspensions — •Florian Böhme[1], Alexandros Fragkopoulos[1,2], Nicole Drewes[2], and Oliver Bäumchen[1,2] — [1]University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany — [2]Max Planck Institute for Dynamics and Self-Organization (MPIDS), 37077 Göttingen, Germany

Photosynthetic microbes have evolved and successfully adapted to the spatio-temporal variations of environmental parameters within their habitat. In the absence of light, they can still sustain their biological functionality and metabolic activity through aerobic respiration. However, for the soil-dwelling microalga *Chlamydomonas reinhardtii*, their environment may be deprived of both oxygen and light, resulting in a significant reduction of their swimming velocity [1]. Here, we study the effect of motility and cell density of *C. reinhardtii* in a confined system, on the emergence of bioconvection [2]. This collective phenomenon can be reversibly switched by light and arises due to the natural tendency of the bottom-heavy cells to move against gravity. We show that the rate at which the system evolves, as well as the dominant wavelength of the instability can both be directly controlled by the number density of cells. Further, we provide insights on the internal flow fields and density profiles of single bioconvection plumes for different parameters.

[1] A.A. Fragkopoulos et al., *J. R. Soc. Interface* **18**, 20210553 (2021).

DY 43.3 Fri 10:15 H44

Tumbling *E.coli* in bulk and close to surfaces — •Pierre Martin[1], Tapan Chandra Adhyapak[2], and Holger Stark[1] — [1]Institute of Theoretical Physics, Hardenbergstr. 36, 10623 Berlin, Germany — [2]Indian institute of science education and research (IISER), Tirupati, India

Escherichia coli (*E. coli*) swims by rotating multiple flagella which are connected to the cell body forming a thick bundle. To change direction, *E. coli* performs tumble events by reversing the rotation of one or more flagella. The involved filaments undergo a series of polymorphic transformations, altering both their helicity and handedness. This complex phenomenon involves the interplay of semiflexible filaments and hydrodynamic flow fields.

Here, we have developed a detailed numerical framework to simulate *E. coli*, capturing the full dynamics of flexible flagella, including their polymorphism and their hydrodynamic interactions. The filaments and the cell body are embedded in a viscous fluid, which we model using multi-particle collision dynamics. We analyzed a large number of tumble events, with fixed tumble time or taken from a gamma distribution, exploring the roles of hook and flagellar flexibility as well as flagellar polymorphism. We find that they strongly influence the distribution of tumble angles. Finally, we also show that close to a flat surface the mean tumble angle is strongly shifted to smaller values. This indicates that tumble events may not be recognized, which could give the impression of suppressed tumbling near surfaces.

DY 43.4 Fri 10:30 H44

***Trypanosoma brucei* (un)chained - effects of confinement on a parasitic microswimmer** — •Hannes Wunderlich[1], Marinus Thein[2], Lucas Brehm[2], Klaus Ersfeld[2], and Matthias Weiss[1] — [1]Experimental Physics I, University of Bayreuth — [2]Laboratory of Molecular Parasitology, University of Bayreuth

Trypanosoma brucei is a parasitic unicellular microswimmer that causes the African sleeping sickness. An active spiral movement of the parasite, mediated by a microtubule-driven flagellum that wraps around the cell body, is mandatory to evade the host's immune system while exploring tissues and blood vessels. In addition, the nematic subpellicular micotubule array plays a pivotal role in the elasticity, propulsion, and navigation of the parasite. To study the features and mechanisms behind the cell's motion in such complex environments, we have mimicked spatial confinement in microfluidic devices with different geometries. Our data show that spatial constraints in narrow channels and channel networks can improve cell locomotion of wild-type trypanosomes, supposedly due to the interaction of the elastic cell body and nearby walls. The addition of microtubule-disrupting drugs or the use of mutant strains with altered post-translational modifications of microtubules resulted in significantly altered swimming velocities and marked changes in the intermittent switching between run and tumble phases. Shape analyses of individual cells suggest that microtubules in the sub-pellicular array, the corset that keeps trypanosomes in their native spindle-like shape, are most affected in these cases.

DY 43.5 Fri 10:45 H44

Micro-swimmer motility in presence of signaling factors — Agniva Datta, Robert Grossmann, and •Carsten Beta — Institute of Physics and Astronomy, University of Potsdam, Germany

The navigation of bacteria through aqueous environments, driven by the rotation of helical flagella, has been a significant region of interest in the biophysics community for the last few decades. In this study, we focus on the motility of our model organism, Pseudomonas putida, which exhibits persistent mobile episodes (Active Brownian motion) interrupted by stochastic reorientation events (turns), driven by flagellar self-propulsion, thereby leading to a run-and-turn motility.

Key motility parameters including tumbling rates, run lengths, trajectory persistence (rotational diffusion coefficient), and the characteristics of the self-propulsion force*are hypothesized to depend on the density of quorum-sensing autoinducer molecules, produced by the bacteria themselves as signaling factors. To test this hypothesis, we expose swimming bacteria to aqueous environments with controlled autoinducer concentrations and analyze the resulting changes in motility patterns. Through a combination of experimental data and theoretical modeling, we aim to elucidate the principles of micro-swimmer motility in presence of signaling molecules.

DY 43.6 Fri 11:00 H44

Collective dynamics of active dumbbells near a circular obstacle — •Chandranshu Tiwari[1] and Sunil Singh[2] — [1]Department of Physics, Indian Institute of Science Education and Research, Bhopal 462066, India. — [2]Department of Physics, Indian Institute of Science Education and Research, Bhopal 462066, India.

We present the collective dynamics of active dumbbells in the presence of a static circular obstacle using Brownian dynamics simulation. The active dumbbells aggregate on the surface of a circular obstacle beyond a critical radius, and the aggregate size increases with the activity and the curvature radius. The dense aggregate of active dumbbells displays persistent rotational motion with a certain angular speed, which linearly increases with activity. Furthermore, we show a strong polar ordering of the active dumbbells within the aggregate. The polar ordering exhibits long-range correlation, with the correlation length corresponding to the aggregate size. Additionally, we show that the residence time of an active dumbbell on the obstacle surface increases rapidly with area fraction due to many-body interactions that lead to a slowdown of the rotational diffusion. This article further considers the dynamical behavior of a tracer particle in the solu-

tion of active dumbbells. Interestingly, the speed of the passive tracer particle displays a crossover from monotonically decreasing to increasing with the size of the tracer particle upon increasing the dumbbells' speed. Furthermore, the effective diffusion of the tracer particle displays non-monotonic behavior with the area fraction; the initial increase in diffusivity is followed by a decrease for a larger area fraction.

Free growth under tension — •Chenyun Yao and Jens Elgeti — Forschungszentrum Jülich GmbH, Jülich, Germany

Ever since the ground breaking work of Trepat et al. in 2009, we know that cell colonies growing on a substrate can be under tensile mechanical stress. The origin of tension has so far been attributed to cellular motility forces being oriented outward of the colony. Works in the field mainly revolve around how this orientation of the forces can be explained, ranging from velocity alignment, self-sorting due to self-propulsion, to kenotaxis.

In this work, we demonstrate that tension in growing colonies can also be explained without cellular motility forces! Using a combination of well established tissue growth simulation technique and analytical modelling, we show how tension can arise as a consequence of simple mechanics of growing tissues. Combining these models with a minimalistic motility model shows how colonies can expand while under even larger tension. Furthermore, our results and analytical models provide novel analysis procedures to identify the underlying mechanics.

A route to active turbulence in circular activity spots — •Arghavan Partovifard and Holger Stark — Institute of Theoretical Physics, Institut für Theoretische Physik, Technische Universität Berlin, Hardenbergstr. 36, 10623Berlin, Germany.

Active nematics exhibit distinctive behavior such as active turbulence and regular flow patterns under spatially varying activity [1]. Utilizing the Doi-Edwards theory supplemented by an active stress tensor [1], we investigate active nematics confined to a circular spot by switching off activity outside the spot. The open boundary allows topological defects to enter and leave the spot.

We calculate the total topological defect charge inside the spot using three approaches: counting all defects, measuring the rotation of the director field along the rim of the spot, and integrating the diffusive charge density. All methods agree that for spot radii just larger than the nematic coherence length, the system has a total topological charge of +1, where two +1/2 defects perform a regular swirling motion. As the radius increases, more defects enter and their motion becomes more and more chaotic. Ultimately, the charge per unit area saturates at the value characteristic of bulk active turbulence. For the range of radii where the total charge in the spot is +1, the nematic director exhibits shear-induced anchoring at an angle of 45° with respect to the tangent at the spot rim. With increasing radius, when more defects enter, the anchoring angle deviates from 45° but its distribution still peaks around this value.

Cognitive flocks: order-disorder transitions and threat evasion — •Priyanka Iyer[1], Cecilia Soroco[2], and Gerhard Gompper[1] — [1]Forschungszentrum Jülich — [2]University of British Columbia, Canada

Directed self-propulsion is ubiquitous in living organisms. From E.Coli dispersing in biofilms to migrating bird flocks, living organisms are constantly out-of equilibrium. By sensing their environment and adjusting their movement, organisms can exhibit emergent patterns and collective behaviors, such as self-organization in human crowds [1], bird flocks, and fish schools. The Inertial Spin Model (ISM) was introduced to explain the fast and robust propagation of information in bird flocks [2], when only alignment interactions are considered. However, more generally, agents exhibit a variety of interactions like local avoidance, cohesion and threat evasion. We show how such behaviors can be incorporated within the framework of the ISM. It is found that local avoidance introduces emergent noise in the system, triggering an order-disorder transition. Exploring the flock dynamics near this transition reveals a complex interplay between cohesion, alignment, and local avoidance, resulting in diverse behaviors such as pronounced shape and density fluctuations, and diffusive motion of the flock. Lastly, by applying the model to a stationary threat scenario, we analyze flock properties that govern threat information propagation in the flock.

Myosin-independent amoeboid cell motility — •Winfried Schmidt, Alexander Farutin, and Chaouqi Misbah — Univ. Grenoble Alpes, CNRS, LIPhy, F-38000 Grenoble, France

Mammalian cell motility is essential for many physiological and pathological processes, such as the immune system, embryonic development, wound healing, and cancer metastasis. Cells have developed the amoeboid migration mode which allows them to move rapidly in a variety of different environments, including two-dimensional confinement, three-dimensional matrix, and bulk fluids. We introduce a model for an amoeboid cell where the cortex is described as a thin shell along the cell surface. The cell shape evolves due to polymerization of actin filaments and the forces acting on the cortex. We find analytically and numerically that the state of a resting, non-polarized cell can become unstable for sufficiently large actin polymerization velocities, resulting in the spontaneous onset of cell polarity, migration, and dynamical shape changes. Notably, this transition only relies on actin polymerization and does not necessitate molecular motors, such as myosin. These findings yield a deeper understanding of the fundamental mechanisms of cell movement and simultaneously provide a simple mechanism for cell motility in diverse configurations.

DY 43.11 Fri 12:30 H44

Active membrane deformations of a synthetic cell-mimicking system — Alfredo Sciortino[1], •Dmitry Fedosov[2], Gerhard Gompper[2], and Andreas Bausch[1] — [1]Physik Department, Technische Universität München, Garching bei München, Germany — [2]Institute for Advanced Simulation, Forschungszentrum Jülich, Jülich, Germany

Biological cells are fascinating micromachines capable of adapting their shape due to the complex interaction between a deformable membrane and the dynamic activity of the cytoskeleton. We investigate the behavior of an active synthetic cell-mimicking system using simulations and experiments. In simulations, the model consists of a fluid vesicle with a few encapsulated growing filaments. In experiments, giant vesicles contain an active cytoskeletal network composed of microtubules, crosslinkers, and molecular motors. These active vesicles show strong shape fluctuations reminiscent of shape changes of biological cells. We analyze membrane fluctuations and show how the intricate coupling between soft confinement and internal active forces results in fluctuation spectra with distinct spatial and temporal scales, differing significantly from those of passive vesicles. Simulations demonstrate the universality of this behavior, quantifying the impact of correlated activity on the dynamics of membrane deformations. This model makes a step toward quantitative description of shape-morphing artificial and living systems.

Force Generation by Enhanced Diffusion in Enzyme-Loaded Vesicles — Eike Eberhard, •Ludwig Burger, Cesar Pastrana, Giovanni Giunta, and Ulrich Gerland — Physik komplexer Biosysteme, Technische Universität München, Deutschland

Recent experiments show that the diffusion coefficient of some metabolic enzymes increases with the concentration of their cognate substrate, a phenomenon known as enhanced diffusion. In the presence of substrate gradients, enhanced diffusion induces enzymatic drift, resulting in a non-homogeneous enzyme distribution. In this work, we study the behavior of enzyme-loaded vesicles exposed to external substrate gradients using a combination of computer simulations and analytical modeling. We observe that the spatially inhomogeneous enzyme profiles generated by enhanced diffusion result in a pressure gradient across the vesicle, which leads to macroscopically observable effects, such as deformation and self-propulsion of the vesicle. Our analytical model allows us to characterize dependence of the velocity of propulsion on experimentally tunable parameters. The effects predicted by our work provide an avenue for further validation of enhanced diffusion, and might be leveraged for the design of novel synthetic cargo transporters, such as targeted drug delivery systems.

From Cavitation in Soft Matter to Erosion on Hard Matter — •Claus-Dieter Ohl — Institute of Physics, Otto-von-Guericke University, Magdeburg, Germany

Cavitation is the technical term for the formation of empty spaces in a liquid. These unstable voids eventually implode and focus energy on small volumes. Shock wave emission, light emission, erosion, and even nuclear reactions are the consequence of this near singular energy focusing. Here, I will present recent

research related to cavitation not only in liquids but also in elastic solids and particularly at the interface of both materials. Singularities developing on the axis of symmetry in non-spherical collapses near boundaries are able to amplify shock waves through self focusing. We think that this mechanism is the primary cause for erosion. In contrast, the non-spherical collapse and shock wave focusing near a tissue allows for the penetration of the tissue with liquid jets at 1000m/s and above. The mechanism at play may be relevant in sports and battle zones, as they could lead to traumatic brain injuries.

DY 44.2 Fri 10:00 H47

Shape switching and tunable oscillations in adaptive droplets — •Tim Dullweber[1,2], Roman Belousov[1], Camilla Autorino[1,4], Nicoletta Petridou[1], and Anna Erzberger[1,3] — [1]European Molecular Biology Laboratory, Heidelberg, Germany — [2]University Heidelberg, Heidelberg, Germany — [3]Institute for Theoretical Physics, Heidelberg University, Heidelberg, Germany — [4]Faculty of Biosciences, Heidelberg University, Heidelberg, Germany

Soft materials can undergo irreversible shape changes when driven out of equilibrium. When shape changes are triggered by processes at the surface, geometry-dependent feedback can arise. Motivated by the mechanochemical feedback observed in multicellular systems, we study incompressible droplets that adjust their interfacial tensions in response to shape-dependent signals. We derive a minimal set of equations governing the mesoscopic droplet states, controlled by just two dimensionless feedback parameters. We find that interacting droplets exhibit bistability, symmetry-breaking, excitability and tunable shape oscillations ranging from near-sinusoidal to relaxation-type. We apply our framework to model shape measurements in zebrafish embryos and identify a shape-switching mechanism promoting boundary formation. The underlying critical points reveal novel mechanisms for physical signal processing through shape adaptation in soft active materials, and suggest new modes of self-organization at the collective scale.

DY 44.3 Fri 10:15 H47

Impact of the history force on the motion of droplets in shaken liquids — •Frederik Gareis and Walter Zimmermann — Theoretical Physics, University of Bayreuth

The Basset-Boussinesq history (BBH) force acts on droplets and solid particles in flows, alongside stationary viscous friction, inertia, and gravitational forces. This force arises from vortex shedding around objects undergoing unsteady acceleration. In this study, we analytically calculate the BBH force for spherical, sedimenting heavy particles in horizontally shaken (periodically accelerated) fluids at low Reynolds numbers and identify the parameter ranges where BBH effects are significant. Our results reveal that BBH can increase particle displacement amplitude by over 60 percent, particularly in the transition region between the low-frequency viscous Stokes regime and the high-frequency inertia-dominated regime. Additionally, we derive a power law for the oscillatory displacement amplitude of a particle around its mean position in a horizontally shaken fluid, facilitating clear experimental identification of BBH effects.

DY 44.4 Fri 10:30 H47

Bubble Dynamics and Transport in Porous Structures: Insights from Mesoscale Simulations — •Qingguang Xie[1], Othmane Aouane[1], and Jens Harting[1,2] — [1]Forschungszentrum Jülich GmbH, Helmholtz-Institut Erlangen-Nürnberg (IET-2), Erlangen, Germany — [2]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany

Bubble formation, detachment, and transport within porous structures are critical phenomena in various applications, including electrolyzers and chemical reactors. We numerically investigate the dynamics of bubble growth and detachment at a catalytic surface using the lattice Boltzmann method. The departure radius of a bubble, growing with either a pinned or moving contact line, shows good agreement with theoretical predictions. Beyond detachment, we examine the subsequent transport of bubbles through a porous transport layer, systematically evaluating transport efficiency by considering factors such as pressure gradients, reaction rates, and pore wettability. Our findings provide valuable insights for optimizing the design of porous structures, potentially resulting in enhanced performance in electrolyzers and other gas-evolving devices.

DY 44.5 Fri 10:45 H47

Displacements in thin fluid and elastic films — •Andreas M. Menzel — Otto von Guericke University Magdeburg, Germany

We address the displacements of comparatively small objects in flat thin fluid films under low-Reynolds-number conditions or in flat thin elastic sheets under linear elasticity.

It is well-known that the fundamental solution of the corresponding continuum equations for forced in-plane displacements diverges logarithmically in strictly two-dimensional systems, the so-called Stokes paradox. We provide an illustrative way of interpretation and demonstrate how the divergence cancels under pairwise interactions and confinement [1,2]. Interestingly, logarithmic spatial dependencies prevail under rectangular clamping of elastic membranes [3]. Moreover, the divergence is still present in free-standing sheets of finite thickness, unless they are stabilized, for instance, by substrates [4,5].

We are confident that our analytical results will prove useful in corresponding quantitative experimental evaluations.

DY 44.6 Fri 11:00 H47

Magnetic dynamics in ferromagnetic liquid crystal emulsions — •Christoph Klopp[1], Hajnalka Nádasi[1], Darja Lisjak[2], and Alexey Eremin[1] — [1]Otto von Guericke University, Institute of Physics, 39106 Magdeburg, Germany — [2]Jozef Stefan Institute, Department for Materials Synthesis, 1000 Ljubljana, Slovenia

We explore magnetic liquid crystal (LC) emulsions for applications as manipulatable chemical sensors in giant cells of Characean algae. Such emulsions can be controlled by magnetic fields and provide targeted drug delivery or sensing [1]. The investigated emulsions consist of a ferromagnetic liquid crystal [2] dispersed in an aqueous solution. We investigate the dynamic magnetic response using AC-susceptometry [3] as a function of the carrier medium viscosity and the particle or droplet size distribution. The emulsions' magnetic spectra differ drastically from those in the bulk of the hybrid liquid crystal mixture. We demonstrate the influence of the liquid crystal director configuration at the water-droplet interface by analyzing the effect of different surfactants (mainly SDS and PVA) in the aqueous phase.

DY 44.7 Fri 11:30 H47

Drying effects in soft colloidal monolayers — •Kai Luca Spanheimer[1], Matthias Karg[2], Nicolas Vogel[3], Liesbeth Janssen[4], and Hartmut Löwen[1] — [1]Institut für Theoretische Physik II: Weiche Materie Heinrich-Heine-Universität, 40225 Düsseldorf, Germany — [2]Physikalische Chemie I: Kolloide und Nanooptik Heinrich-Heine-Universität, 40225 Düsseldorf, Germany — [3]Lehrstuhl für Partikelsynthese Friedrich-Alexander-Universität,91058 Erlangen, Germany — [4]Soft Matter and Biological Physics Eindhoven University of Technology, 5600 MB Eindhoven, The Netherlands

Langmuir-Blodgett deposition is a staple of colloidal monolayer research. It is used in sample preparation for imaging techniques, that spatially resolve colloid patterns. Recent experimental observations have shown that drying can strongly rearrange micron sized microgel patterns after their deposition. The usual dictum that these drying effects do not play a role for colloidal deposition can thus not be held up as a general rule. While capillary effects are well known to be strong at microscopic length scales and play a significant role in drying processes they have been mostly neglected concerning Langmuir-Blodgett deposition. In order to better understand the mechanism of drying we propose a model based on capillary attraction as well as hard core and soft shell repulsion. This model reproduces colloid patterns observed at interfaces as well as ones that occur after drying in the corresponding parameter regimes. From here we are able to derive parameter ranges where drying can play a role in rearranging patterns of colloids and where it can't.

DY 44.8 Fri 11:45 H47

Interplay of Elasticity and Capillarity in Droplets on Flexible Sheets — •Salik Sultan and Holger Stark — Technische Universität Berlin, Institute of Theoretical Physics, Hardenbergstr. 36, 10623 Berlin, Germany

Droplets resting on flexible sheets deform into lens-like shapes, offering promising applications in areas like tunable liquid lenses. We have extended and employ our fully three-dimensional Boundary Element Method (BEM) simulation framework [1] to investigate dynamic wetting on thin flexible sheets. Our study focuses on the intricate interplay between the mechanical properties of the sheet and droplet behavior, particularly emphasizing contact angle and droplet shape. By varying the tension and mechanical properties of the sheet, our model demonstrates how we can control and tune the shape of the droplet. Additionally, by introducing stiffness gradients, we aim to explore the potential to steer droplets along the sheet via durotaxis. The versatility of our model suggests potential extensions to other soft material and droplet interactions, such as capillary origami. This work sheds light on the complex interactions between soft substrates and liquid interfaces, leading the way for advancements in material science and interfacial biology.

Cluster quasicrystals composed of ultrasoft particles vs. soft quasicrystals built of colloids with hard cores — Robert F.B. Weigel and •Michael Schmiedeberg — Theoretical Physics: Lab for Emergent Phenomena, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

We study and compare two different approaches for the stabilization of quasicrystals:

First, we consider a Phase Field Crystal model of complex patterns that self-assemble in systems consisting of ultrasoft colloids. Quasicrystals can be either stabilized by interactions with multiple length scales [1,2] or by preferred binding angles as in patchy colloids [3].

Second, we study a system with patchy colloids with a hard core with a Density Functional Theory. The hard-core is implemented by using a variant of the Fundamental Measure Theory [4] that probably is the best mean field approach to hard particles.

While the ultrasoft particles assemble in cluster quasicrystals where the particles can completely overlap, in case of hard cores we observe structures that are rather dominated by the tiles that occur on a local level. Our results explain the differences between quasicrystlas that occur in different systems.

Beyond rings and chains: exploring porous crystals and flexible networks with magnetic colloids — •Carina Karner — Technische Universität Wien

We report on the self-assembly of magnetic colloids engineered with two distinct magnetic patches positioned at their poles, an advancement from traditional Janus particles with a single magnetic dipole. While Janus particles are known to form a variety of superstructures including chains, rings, and close-packed arrangements [1], the two-patch design significantly expands the range of achievable structures. Our simulation study reveals the formation of porous networks with adjustable flexibility, variable pore sizes, and controllable crystalline order. Notably, we observe the formation of a porous Kagome lattice, reminiscent of the experimental Kagome lattice observed colloids with two hydrophobic patches, the well known Janus-triblock system [2]. This enhanced self-assembly behavior in two-patch magnetic particles opens up further possibilities for creating fully tunable, field-responsive ferrofluids. Such systems could useful for applications requiring externally modulated viscosity, such as adaptive damping systems in automotive and aerospace engineering. [1] Vega-Bellido, G. I., DeLaCruz-Araujo, R. A., Kretzschmar, I., & Córdova-Figueroa, U. M. (2019). Self-assembly of magnetic colloids with shifted dipoles. Soft Matter, 15(20), 4078-4086. [2] Chen, Q., Bae, S. C., & Granick, S. (2011). Directed self-assembly of a colloidal kagome lattice.Nature,469(7330), 381-384.

DY 44.11 Fri 12:30 H47

Effect of geometrical confinement on friction in soft solids — •Aashna Chawla and Deepak Kumar — Department of Physics, Indian Institute of Technology Delhi, New Delhi 110016, India

Soft and biological materials come in a variety of shapes and geometries. When two soft surfaces with mismatched Gaussian curvatures are forced to fit together, beautiful patterns emerge at the interface due to geometry-induced stress. In this study, we explore the effect of geometrically incompatible confinement of a thin sheet on a soft hydrogel substrate on friction. We use a novel experimental setup to measure the friction between a thin flat elastic sheet placed on a low-friction hydrogel substrate. We show that the frictional force at the interface strongly depends on the geometry and is significantly larger for the geometrically incompatible configuration of a flat sheet on a spherical substrate compared to the other two geometrically compatible configurations: flat sheet on a flat substrate and flat sheet on a cylindrical substrate. Furthermore, for the incompatible configuration of the flat sheet on a spherical substrate, we observe that the frictional force increases monotonically with the sheet radius, with a transition in the behavior at an intermediate radius. We show that these effects arise from the coupling of the stress developed in the sheet due to its geometrically incompatible confinement with the curvature of the interface, resulting in an increased normal force, thereby increasing friction. The insights gained from this study could have significant implications for our understanding of friction in various biological, nanoscale, and other soft systems.

DY 45: Quantum Chaos (joint session DY/TT)

Time: Friday 11:30–13:00 Location: H37

DY 45.1 Fri 11:30 H37

Semiclassical foundation of universality in many-body quantum circuits — •Maximilian Kieler[1], Felix Fritzsch[2], and Arnd Bäcker[1] — [1]TU Dresden, Institut für Theoretische Physik, Dresden, Germany — [2]Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Straße 38, 01187 Dresden, Germany

For single particle systems the fundamental equivalence of quantum chaotic systems and random matrix theory is well-understood by means of semiclassical periodic orbit theory. We propose an extension to spatially local many-body systems by incorporating the concept of symmetry-breaking. Using this we show that random matrix behavior arises generically in quantum chaotic many-body systems in the form of a symmetry breaking of local time-translation symmetries. This general framework is applied to quantum circuits where an explicit correspondence to the random matrix result for the spectral form factor can be shown.

DY 45.2 Fri 11:45 H37

Distribution of resonance poles of chaotic scattering systems — •Jan Robert Schmidt, Florian Lorenz, and Roland Ketzmerick — TU Dresden, Institute of Theoretical Physics, Dresden, Germany

The distribution of resonance poles of chaotic scattering systems is investigated in the semiclassical limit at unprecedented small wavelengths. For the paradigmatic three-disk scattering system, we study the spectral gap towards the real axis, the fractal Weyl law, which counts the number of resonance poles, and the distribution of decay rates. These properties are compared to previous analytical results, e.g. from random matrix theory. In contrast to this system with full escape, systems with partial escape have significantly different properties. For the example of a dielectric cavity, we show that results from random matrix theory cannot explain the distribution of decay rates.

DY 45.3 Fri 12:00 H37

Solved after 60 years: Exact Derivation of the Ericson Transition in Quantum Chaotic Scattering — •Simon Köhnes and Thomas Guhr — University of Duisburg-Essen, Lotharstr. 1, 47048 Duisburg, Germany

Scattering experiments are the prime source of information on the quantum world. Scattering theory nowadays has numerous applications in various branches of physics and beyond, even including classical wave phenomena. We analyze chaotic scattering systems in the framework of Random Matrix Theory. The distribution of the scattering matrix elements is the key quantity. A strong sign of chaos in complex quantum systems is the Ericson regime of strongly overlapping resonances in which the cross sections exhibit random behavior. We apply the Supersymmetry Method. For the three Wigner-Dyson symmetry classes, we analytically calculate the transition to the Ericson regime, facilitating direct comparison with experimental results. In the course of doing so, we also gather new information on features of the underlying supersymmetric non-linear sigma model.

DY 45.4 Fri 12:15 H37

Chaotic Quantum Scattering: Exact Solutions for Systems with Spin — •Nils Gluth and Thomas Guhr — Universität Duisburg-Essen, Duisburg, Germany

Scattering experiments facilitate access to quantum systems. Scattering theory is needed to fully describe the involved experimental situations. Over the years, it became a powerful tool with applications to a large variety of different systems, such as for example compound nuclei, atoms, molecules, quantum graphs or even microwave networks and cavities. These systems are typically complex or in a broad sense chaotic, calling for statistical approaches, in particular Random Matrix Theory. Considerably extending our previous work, we calculate the distribution of scattering matrix elements and cross sections using Supersymmetry. We focus on the symplectic symmetry class which had not yet been solved, because a theoretical understanding is needed in view of recent experiments. We provide a comparison of our results with experimental data.

DY 45.5 Fri 12:30 H37

Phase-space representations and exceptional points of coupled polarized modes in cylindrical cavities — •Tom Rodemund[1], Shilong Li[2], Síle Nic Chormaic[3], and Martina Hentschel[1] — [1]Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany — [2]College of Information Science and Electronic Engineering, Zhejiang University, Hangzhou, China — [3]Okinawa Institute of Science and Technology Graduate University, Okinawa, Japan

Optical microcavities are often assumed to be two-dimensional (2D). This allows a convenient phase-space representation in 2D, where Poincaré surface of section for particle dynamics and the Husimi function for their wave counterpart are prominent methods. Here we extend the concept of Husimi functions for open systems [1] to three-dimensional (3D) optical microcavities of arbitrary

shape. In particular we study deformed cylindrical cavities and illustrate their mode dynamics in terms of generalized Husimi functions.

The coupling between the two different polarizations (TE and TM) is a new feature in realistic 3D optical cavities that is not present in 2D. We find the interaction of polarized modes to be governed by a network of exceptional points that reflects the openness, or non-Hermiticity, of the system. The mode coupling is analyzed using the extended Husimi formalism that we find to be a comprehensive and useful way to represent the mode structure of 3D microcavities [2].

DY 45.6 Fri 12:45 H37

The classical Maldacena-Shenker-Standford bound — •Gerrit Caspari, Fabian Haneder, Juan-Diego Urbina, and Klaus Richter — University of Regensburg, Regensburg, Deutschland

The Maldacena-Shenker-Stanford (MSS) bound [1] is a condition on a system's quantum Lyapunov exponent, defined as half the growth rate of the regularised out-of-time-ordered correlator (OTOC), which states that said exponent is bounded by the system's temperature, with, e.g., black holes as characteristic systems saturating the bound.

From the perspective of classical chaos, this is surprising, since the classical Lyapunov exponent seems not to be bounded. We study chaotic quantum systems in a hyperbolic geometry with and without cusps and magnetic fields [2][3] via Selberg's Trace Formula (STF). Through this we derive bounds on the classical Lyapunov exponent from analyticity conditions in the trace formula and relate them to the MSS bound.

We report our progress in studying these bounds using the STF, which entails an investigation of the analyticity condition needed to prove the STF for the partition function of our systems and its relation to possible phase transitions.

Equilibrium and non-equilibrium dynamics of biological systems with memory — •Roland Netz — Freie Universität Berlin, Fachbereich Physik, Berlin

Biological systems are many-body systems. Thus, their dynamics, when described in terms of a low-dimensional reaction coordinate, is governed by the generalized Langevin equation (GLE), an integro-differential equation of motion which contains friction memory [1]. Two examples will be discussed:

Protein-folding kinetics is standardly described as Markovian (i.e., memoryless) diffusion in a one-dimensional free-energy landscape. By analysis of molecular-dynamics simulation trajectories of fast-folding proteins the friction is demonstrated to exhibit significant memory with a decay time of the same order as the folding and unfolding times [2,3,4]. Memory friction leads to anomalous and drastically modified protein kinetics: the folding and unfolding times are not dominated by free-energy barriers but rather by non-Markovian friction.

Active motion of organisms obviously is far from equilibrium. The parameters of an appropriate non-equilibrium GLE are extracted from trajectories. It is demonstrated that the motion of single-cellular algae is characterized by pronounced memory friction, which allows to classify and sort individual cells.

DY 46.2 Fri 12:00 H43

Mean transient drift of synaptic weights in feed-forward spiking neural networks with spike-timing-dependent plasticity — •Jakob Stubenrauch and Benjamin Lindner — BCCN Berlin and Physics Department HU Berlin, Germany

Spike-timing dependent plasticity (STDP) [1] is a phenomenological model for the dynamics of single synaptic weights. This concise microscopic (single-synapse) description allows for the derivation of macroscopic network theories, capturing for instance learning, forgetting, and representational drift.

For the development of such theories it is important to characterize the stochastic process of synaptic weights. Early attempts capture this process for Poissonian presynaptic spikes and conditionally Poissonian postsynaptic spikes [2]. However, since STDP depends on fine spike-timing differences below 20 ms [1], it is important to characterize the synaptic dynamics for neuron models that describe the fast response mechanistically.

Leveraging a recent theory [3] as well as established results for the leaky integrate-and-fire neuron [4,5], we analytically compute the drift and diffusion of feed-forward synapses in a setup where a layer of presynaptic Poisson processes feeds into a recurrent network of leaky integrate-and-fire neurons.

DY 46.3 Fri 12:15 H43

A Biophysical Model for Temperature-Sensitivity of Neurons — •Julian Voits[1], Wojciech Ambroziak[2,3], Jan Siemens[2,4], and Ulrich S. Schwarz[1,5] — [1]Institute for Theoretical Physics, University of Heidelberg, Germany — [2]Department of Pharmacology, University of Heidelberg, Germany — [3]Department of Translational Disease Understanding, Grünenthal GmbH, Aachen, Germany — [4]Molecular Medicine Partnership Unit (MMPU), European Molecular Biology Laboratory (EMBL), Heidelberg, Germany — [5]BioQuant-Center for Quantitative Biology, University of Heidelberg, Germany

Control of body temperature is essential for our well-being and especially important during periods of fever or heat acclimation, e.g. due to traveling or climate change. An essential element of body temperature control are temperature-sensitive neurons, particularly warm-sensitive ones in the preoptic area of the hypothalamus. Since the discovery of temperature-sensitive ion channels, it has become clear that the underlying molecular mechanisms are rather diverse. In this work, we introduce a mathematical model based on a reduced version of the Hodgkin-Huxley model that can predict the frequently observed linear dependence of spiking rates on temperature in warm-sensitive neurons. Additionally, we present data showing how neurons adapt to varying temperatures over time, along with evidence of hysteresis in many temperature-sensitive neurons.

DY 46.4 Fri 12:30 H43

Position-Dependent Non-Markovian Effects Improve Protein Folding Simulations — •Lucas Tepper, Cihan Ayaz, Benjamin Dalton, and Roland Nezt — Freie Universität Berlin

It's common to project a protein's full atomic resolution onto a one-dimensional reaction coordinate to capture key aspects of its folding process. As a direct consequence of this dimensionality reduction, non-Markovian memory effects emerge. Accounting for memory effects in the framework of the generalized Langevin equation (GLE) with linear friction has proven efficient, accurate and insightful. However, recent advances in deriving GLEs with non-linear, position-dependent friction kernels raise questions about their applicability to protein folding simulations. We derive a novel method to extract position-dependent friction kernels from time series data via conditional Volterra equations. When applied to two protein test systems, the position- and time-dependent friction is strongest for long memory times in the folded states, where atoms are tightly packed. Additionally, we propose a novel and numerically efficient GLE simulation setup, confirming the accuracy of the extracted kernels. Compared to linear friction GLE simulations, our results show that position-dependent non-Markovian effects are critical for accurately reproducing protein folding kinetics when using low-dimensional reaction coordinates.

DY 46.5 Fri 12:45 H43

Multicomponent mixtures exhibit a vast nucleation-and-growth regime — •Yicheng Qiang, Chengjie Luo, and David Zwicker — Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, 37077 Göttingen, Germany

Phase coexistence is crucial for understanding how cells regulate biomolecular condensates. Despite of the multicomponent and multiphase nature of such condensates, the direct study of coexisting phases is limited to only few components since the parameter space is high-dimensional. So far, no theory provides a direct and concrete estimation of the phase coexistence behavior of multicomponent mixtures. As a first-level description of multicomponent phase behavior, we derive scaling relations for the number of coexisting phases in typical multicomponent mixtures in equilibrium. The scaling relations reveal that the interactions required to have many coexisting phases only scales very weakly with the number of components, whereas the stability analysis of the homogeneous state suggests a much stronger scaling. This discrepancy implies that large parts of the phase diagram of multicomponent mixture are in the nucleation-and-growth regime, where the homogeneous state is locally stable while multiple coexisting phases are preferred energetically. This suggests that multicomponent mixtures can achieve versatility and controllability in phase behavior with moderate interactions, which might be utilized by cells to create or destroy biomolecular condensates.

DY 47: Closing Talk (joint session BP/CPP/DY)

Time: Friday 13:15–14:00 Location: H2

Invited Talk DY 47.1 Fri 13:15 H2

Active control of forces, movement and shape: from biological to non-living systems — •Ulrich S. Schwarz — Heidelberg University, Heidelberg, Germany

Animal cells are highly dynamic and continuously generate force, for example for division, migration and mechanosensing. Their main force generators are myosin II molecular motors, whose activity is precisely controlled by biochemical circuitry. We first discuss how this system can be hijacked by optogenetics, thus that cellular force generation can be controlled in time and space using light. Next, we use active gel theory combined with van der Waals theory for myosin II molecules to demonstrate that cell contractility is sufficient to explain cell migration and that optogenetics can be used to initiate and revert migration. For two myosin II species, we predict the possibility of oscillations. We then move up in scale and analyze force generation in intestinal organoids, which are epithelia with the topology of a sphere. Combining experimental data, image processing and the bubbly vertex model, we show how apico-basal asymmetries can lead to cell extrusion and budding. We finally discuss how force generation and shape changes can be achieved in non-living systems, in particular for nematic elastomers, in which the direction of contraction is imprinted during polymerization and actuation is achieved by temperature control.

Overview of Invited Talks and Sessions

(Lecture halls H13, H14, H15, and H17; Poster P1 and P3)

Invited and Prize Talks

HL 3.1	Mon	9:30–10:00	H17	**Alexandria Database - Improving machine-learning models in materials science through large datasets** — •Jonathan Schmidt, Tiago Cerqueira, Aldo Romero, Silvana Botti, Miguel Marques
HL 3.2	Mon	10:00–10:30	H17	**Generative Models on the Rise - Which one shall I pick for my Inverse Design Problem?** — •Hanna Türk, Elisabetta Landini, Christian Kunkel, Patricia König, Christoph Scheurer, Karsten Reuter, Johannes Margraf
HL 3.3	Mon	10:30–11:00	H17	**Machine-learning accelerated prediction of two-dimensional conventional superconductors** — Thalis H. B. da Silva, Théo Cavignac, Tiago F. T. Cerqueira, •Haichen Wang, Miguel A. L. Marques
HL 3.4	Mon	11:15–11:45	H17	**Machine Learning for Design, Understanding, and Discovery of (Semiconducting) Materials** — •Pascal Friederich
HL 3.5	Mon	11:45–12:15	H17	**OptiMate: Artificial intelligence for optical spectra** — •Malte Grunert, Max Grossmann
HL 18.1	Tue	9:30–10:00	H17	**Ultrafast Nano-Spectroscopy of Photo-Induced Dynamics in Low-Dimensional Materials** — •Takashi Kumagai
HL 18.2	Tue	10:00–10:30	H17	**Landau level Nanoscopy of charge and heat transport in low-dimensional heterostructures** — •Mengkun Liu
HL 18.3	Tue	10:30–11:00	H17	**Real space mapping of electrically tunable anisotropic THz plasmon polaritons in hBN encapsulated black phosphorus** — •Eva Pogna
HL 18.4	Tue	11:15–11:45	H17	**Ultra-confined THz hyperbolic phonon polaritons in a transition metal dichalcogenide** — Ryan A. Kowalski, Niclas S. Mueller, Gonzalo Alvarez-Perez, Maximilian Obst, Katja D. Granados, Giulia Carini, Aditha Senarath, Saurabh Dixit, Richarda Niemann, Ragu B. Iyer, Felix Kaps, Jakob Wetzel, J. Michael Klopf, Ivan I. Kravchenko, Deliang Bao, Sokrates T. Pantelides, Martin Wolf, Lukas Eng, Pablo Alonso-Gonzalez, Susanne Kehr, Thomas G. Folland, •Alexander Paarmann, Joshua D. Caldwell
HL 18.5	Tue	11:45–12:15	H17	**Programmable polariton nanophotonics using phase-change materials** — •Thomas Taubner
HL 30.1	Wed	9:30–10:00	H13	**Exploring semiconducting epigraphene grown by polymer-assisted sublimation growth** — •Teresa Tschirner, Julia Guse, Stefan Wundrack, Frank Hohls, Klaus Pierz, Hans Werner Schumacher
HL 30.2	Wed	10:00–10:30	H13	**Huge Enhancement of the Giant Negative Magnetoresistance with Decreasing Electron Density** — •Lina Bockhorn, Christian Reichl, Werner Wegscheider, Rolf J. Haug
HL 30.3	Wed	10:30–11:00	H13	**Ultrafast quantum optics with single-photon emitters in 2D materials** — •Steffen Michaelis de Vasconcellos
HL 30.4	Wed	11:15–11:45	H13	**Realistic simulation of quantum emitter dynamics made easy** — •Moritz Cygorek
HL 30.5	Wed	11:45–12:15	H13	**Data-driven Design of Next Generation 2D Materials and Their Heterostructures** — •Rico Friedrich
HL 34.1	Wed	9:30–10:00	H17	**From complex internal dynamics to emission characteristics control in quantum billiards** — •Martina Hentschel
HL 34.2	Wed	10:00–10:30	H17	**Positioning of microcavities around single emitters** — •Tobias Huber-Loyola
HL 34.3	Wed	10:30–11:00	H17	**Exploring Wave Chaos and Non-Hermitian Physics: Future Prospects for Quantum Emission from Chaotic Microcavities** — •Jan Wiersig

HL 34.4	Wed	11:15–11:45	H17	**Correlations and statistics in cavity embedded quantum dot sources of quantum light** — •Ana Predojevic
HL 34.5	Wed	11:45–12:15	H17	**Nonlinear Phenomena in Exciton-Polaritons from Bound States in the Continuum** — •Dario Ballarini
HL 42.1	Wed	16:45–17:15	H17	**Quantum key distribution with single photons from quantum dots** — Joscha Hanel, •Jingzhong Yang, Jipeng Wang, Vincent Rehlinger, Zenghui Jiang, Frederik Benthin, Tom Fandrich, Jialiang Wang, Fabian Klingmann, Raphael Joos, Stephanie Bauer, Sascha Kolatschek, Ali Hreibi, Eddy. Patrick Rugeramigabo, Michael Jetter, Simone. Luca Portalupi, Michael Zopf, Peter Michler, Stefan Kueck, Fei Ding
HL 46.1	Thu	9:30–10:00	H15	**Exploring Auto-Oscillations in Semiconductor Electron-Nuclear Spin System** — •Alex Greilich, Nataliia E. Kopteva, Vladimir L. Korenev, Manfred Bayer
HL 46.6	Thu	11:15–11:45	H15	**Development and Application of Computational Simulations to Optimize Organic Photovoltaic Modules** — •Annika Janssen
HL 47.1	Thu	9:30–10:00	H17	**Quantum-Dot Quantum Light Sources in Deployed Systems** — •Peter Michler
HL 47.2	Thu	10:00–10:30	H17	**Field test of semiconductor quantum light sources** — •Fei Ding
HL 47.3	Thu	10:30–11:00	H17	**Quantum dot based quantum communication in urban networks** — •Rinaldo Trotta
HL 47.4	Thu	11:15–11:45	H17	**Quantum communication protocols over a 14-km urban fiber link** — •Jürgen Eschner
HL 60.1	Fri	9:30–10:00	H17	**Constructing Artificial Matter in the Electron Microscope - Atomic Fabrication at Scale in CrSBr** — •Julian Klein
HL 60.2	Fri	10:00–10:30	H17	**Tuning the structure and magnetism in CrSBr via external pressure** — •Ece Uykur
HL 60.3	Fri	10:30–11:00	H17	**A theoretical perspective on exciton-magnon coupling and its implications** — •Akashdeep Kamra
HL 60.4	Fri	11:15–11:45	H17	**Exciton and valley properties of monolayer transition metal dichalcogenides on the van der Waals magnetic semiconductor CrSBr** — •Yara Galvao Gobato
HL 60.8	Fri	12:30–13:00	H17	**Electric field control of intra- and interlayer excitons in CrSBr** — •Nathan Wilson, Amine Ben Mhenni, Ferdinand Menzel, Alain Dijkstra, Zdenek Sofer, Jonathan Finley

Invited Talks of the joint SKM Dissertationspreis 2025 (SYSD)

See SYSD for the full program of the symposium.

SYSD 1.1	Mon	9:30–10:00	H2	**Nanoscale Chemical Analysis of Ferroic Materials and Phenomena** — •Kasper Aas Hunnestad
SYSD 1.2	Mon	10:00–10:30	H2	**Advanced Excitation Schemes for Semiconductor Quantum Dots** — •Yusuf Karli
SYSD 1.3	Mon	10:30–11:00	H2	**Aspects and Probes of Strongly Correlated Electrons in Two-Dimensional Semiconductors** — •Clemens Kuhlenkamp
SYSD 1.4	Mon	11:00–11:30	H2	**Mean back relaxation and mechanical fingerprints: simplifying the study of active intracellular mechanics** — •Till Münker
SYSD 1.5	Mon	11:30–12:00	H2	**Coherent Dynamics of Atomic Spins on a Surface** — •Lukas Veldman

Invited Talks of the joint Symposium AI-driven Materials Design: Recent Developments, Challenges and Perspectives (SYMD)

See SYMD for the full program of the symposium.

SYMD 1.1	Mon	15:00–15:30	H1	**Learning physically constrained microscopic interaction models of functional materials** — •Boris Kozinsky
SYMD 1.2	Mon	15:30–16:00	H1	**GRACE universal interatomic potential for materials discovery and design** — •Ralf Drautz
SYMD 1.3	Mon	16:00–16:30	H1	**Multiscale Modelling & Machine Learning Algorithms for Catalyst Materials: Insights from the Oxygen Evolution Reaction** — •Nong Artrith
SYMD 1.4	Mon	16:45–17:15	H1	**Inverse Design of Materials** — •Hongbin Zhang
SYMD 1.5	Mon	17:15–17:45	H1	**Data-Driven Materials Science** — •Miguel Marques

Invited Talks of the joint Symposium Progress and Challenges in Modelling Electron-Phonon Interaction in Solids (SYIS)

See SYIS for the full program of the symposium.

SYIS 1.1	Tue	9:30–10:00	H1	**Electron-phonon and exciton-phonon coupling in advanced materials** — •Claudia Draxl
SYIS 1.2	Tue	10:00–10:30	H1	**Exciton-phonon dynamics from first principles** — •Enrico Perfetto
SYIS 1.3	Tue	10:30–11:00	H1	**Polarons and exciton polarons from first principles** — •Feliciano Giustino
SYIS 1.4	Tue	11:15–11:45	H1	**Wannier-Function-Based First-principle Approach to Coupled Exciton-Phonon-Photon Dynamics in Two-Dimensional Semiconductors** — •Alexander Steinhoff, Matthias Florian, Frank Jahnke
SYIS 1.5	Tue	11:45–12:15	H1	**Phonon influence on (cooperative) photon emission from quantum dots** — •Erik Gauger, Julian Wiercinski, Moritz Cygorek

Invited Talks of the joint Symposium Electronic Structure Theory for Quantum Technology: From Complex Magnetism to Topological Superconductors and Spintronics (SYES)

See SYES for the full program of the symposium.

SYES 1.1	Fri	9:30–10:00	H1	**Ab-initio Design of superconductors** — •Lilia Boeri
SYES 1.2	Fri	10:00–10:30	H1	**Topological superconductivity from first principles** — Bendegúz Nyári, András Lászlóffy, Levente Rózsa, Gábor Csire, Balázs Újfalussy, •László Szunyogh
SYES 1.3	Fri	10:30–11:00	H1	**First-principles study and mesoscopic modeling of two-dimensional spin and orbital fluctuations in FeSe** — •Myrta Grüning, Abyay Ghosh, Piotr Chudzinski
SYES 1.4	Fri	11:15–11:45	H1	**Non-collinear magnetism in 2D materials from first principles: Multiferroic order and magnetoelectric effects.** — •Thomas Olsen
SYES 1.5	Fri	11:45–12:15	H1	**Spin-phonon and magnon-phonon interactions from first principles** — •Marco Bernardi

Sessions

HL 1.1–1.13	Mon	9:30–13:00	H13	**Perovskite and Photovoltaics I (joint session HL/KFM)**
HL 2.1–2.13	Mon	9:30–13:00	H15	**2D Semiconductors and van der Waals Heterostructures I**
HL 3.1–3.8	Mon	9:30–13:00	H17	**Focus Session: Machine Learning of semiconductor properties and spectra**
HL 4.1–4.10	Mon	15:00–17:45	H3	**2D Materials and their Heterostructures I (joint session DS/HL)**
HL 5.1–5.12	Mon	15:00–18:00	H11	**2D Materials Beyond Graphene: Growth, Structure and Substrate Interaction (joint session O/HL)**

HL 1: Perovskite and Photovoltaics I (joint session HL/KFM)

Time: Monday 9:30–13:00 Location: H13

HL 1.1 Mon 9:30 H13

Oxygen-Mediated (0D) Cs4PbX6 Formation during Open-Air Thermal Processing Improves Inorganic Perovskite Solar Cell Performance — Rafikul Ali Saha[1], •Wei-Hsun Chiu[2], Giedrius Degutis[1], Peng Chen[3], Matthias Filez[4], Eduardo Solano[5], Nikolai Orlov[6], Francesco De Angelis[7], Carlo Meneghini[7], Christophe Detavernier[4], Sawanta S. Mali[8], Minh Tam Hoang[2], Yang Yang[2], Erik C. Garnett[9], Lianzhou Wang[3], Hongxia Wang[2], Maarten B. J. Roeffaers[1], and Julian A. Steele[3] — [1]KU Leuven, Belgium — [2]Queensland University of Technology, Brisbane, Australia — [3]The University of Queensland, Brisbane, Australia — [4]Ghent University, Belgium — [5]ALBA synchrotron, Barcelona, Spain — [6]AMOLF, Amsterdam, The Netherlands — [7]Roma Tre University, Rome, Italy — [8]Chonnam National University, Gwangju, South Korea — [9]University of Amsterdam, The Netherlands

We highlight the beneficial role of ambient oxygen during the open-air thermal processing of metastable γ-CsPbI3-based perovskite thin films and devices. Physiochemical-sensitive probes elucidate oxygen intercalation and the formation of Pb-O bonds in the perovskite, entering via iodine vacancies at the surface, creating superoxide (O2-) through electron transfer reactions, which drives the formation of a zero-dimensional (0D) Cs4PbI6 protective capping layer during annealing (>330˚C). Applied to γ-CsPbI2Br perovskite solar cells, it boosts the operational stability and photo-conversion efficiency of champion devices from 12.7% to 15.4% when annealed in dry air.

HL 1.2 Mon 9:45 H13

Compositional Engineering of Mixed-Metal Chalcohalides for Photovoltaic Applications — •Pascal Henkel[1], Jingrui Li[2], and Patrick Rinke[1,3] — [1]Department of Applied Physics, Aalto University, P.O.Box 11100, 00076 AALTO, Finland — [2]School of Electronic Science and Engineering, Xi'an Jiaotong University, Xi'an 710049, China — [3]Technical University of Munich, 85748 Garching, Germany

Perovskite-inspired quaternary mixed-metal chalcohalides (MMCHs, $M(II)_2M(III)Ch_2X_3$) are an emerging materials class for photovoltaic's [1], that could overcome the stability and toxicity problems of halid perovskites [2], and still deliver high conversion efficiencies [3]. Compositional engineering enables the optimization of MMCH materials properties en route to commercialization.

We study the stability of MMCH alloys for three different compositional positions: the M(III), the Ch and the X site. We use a combination of density functional theory and machine learning to explore the compositional space of the alloys [4] and to compute their convex hulls. For x site alloying, for example $[Sn_2InS_2(Br_{1-c}I_c)_3]$, we obtained stable structures for $c = \frac{1}{3}$ and $c = \frac{2}{3}$ for the $Cmcm$ phase and for $c = \frac{1}{6}$ and $c = \frac{1}{3}$ for the $Cmc2_1$ phase, but not for $P2_1/c$. The energetically favored structures (at $c = \frac{1}{3}$) are highly symmetrical and exhibit a layered pattern. Every third halogen layer is fully occupied by iodine whereas the other two layers are filled with bromine.

Versatile Two-Step Process for Enhanced Stability and Efficiency in Perovskite Top Cells for Tandem Photovoltaics — •Ronja Pappenberger[1,2], Roja Singh[1,2], Alexander Diercks[2], and Ulrich W. Paetzold[1,2] — [1]Institute of Microstructure Technology, KIT, Germany — [2]Light Technology Institute, KIT, Germany

To achieve highly efficient 2T perovskite/silicon (Si) tandem solar cells (TSCs), textured-front Si bottom cells provide superior light-harvesting capabilities, making higher short-circuit current densities of TSC possible. A promising approach to fabricating uniform, high-quality perovskite films on these textured Si cells is the solution-based two-step method. One of the main challenges for perovskite solar cells (PSCs) remains their long-term stability. While methylammonium (MA)-based PSCs have demonstrated some of the highest efficiencies, their instability continues to pose a major obstacle. In this work, a versatile two-step process is employed – replacing MA with formamidinium – which maintains high efficiency, improves open-circuit voltage and enhances stability. A further performance boost is achieved by implementing a dual passivation strategy using $PDAI_2$ and BAI for bulk and surface passivation. This leads to a stable power output exceeding 20.8% for E_g = 1.67 eV due to reduced non-radiative recombination at the perovskite/ETL interface and improved film crystallization, enhancing charge carrier extraction. The long-term stability is also distinctly improved. When implemented on textured Si bottom cells, this process delivers efficiencies exceeding 24% for lab-scale monolithic perovskite/Si TSCs with a 1 cm^2 active area.

HL 1.4 Mon 10:15 H13

Recombination at grain boundaries in Cd(Te,Se) thin films in comparison with other photovoltaic absorber layers — •Luka Blazevic[1], Sebastian Weitz[1], Elisa Artegiani[2], Alessandro Romeo[2], and Daniel Abou-Ras[1] — [1]Helmholtz-Zentrum Berlin, Germany — [2]Universita di Verona, Italy

The role of grain boundaries on the device performance is of concern for all polycrystalline absorbers in photovoltaic solar cells. In the present work, recombination velocities s_{GB} at grain boundaries in Cd(Te,Se) thin-film absorbers were determined from cathodoluminescence (CL) intensity distributions, which were acquired together with electron backscatter diffraction (EBSD) and energy-dispersive X-ray spectroscopy (EDXS) maps. The resulting s_{GB} values exhibited ranges over several orders of magnitude (10^1–10^3 cm/s). These wide value ranges are in good agreement with those obtained on other photovoltaic absorber materials (multicrystalline Si, $Cu(In,Ga)Se_2$, $Cu_2ZnSn(S,Se)_4$). The present work suggests a model comprising the enhanced, nonradiative Shockley-Read-Hall recombination at grain boundaries as well as the upward/downward band bending (± several 10 meV) at these planar defects. This model can reproduce successfully the experimental s_{GB} values from various photovoltaic absorber materials and provides also ranges for the effective defect densities as well as their capture cross-sections at the grain boundaries. It will be shown that typical losses in the open-circuit voltage of the corresponding solar cells due to grain-boundary recombination in the absorbers are few 10 mV.

HL 1.5 Mon 10:30 H13

Microscopic origins of band-gap broadening and its relationship with Urbach tails in photovoltaic absorbers — •Daniel Abou-Ras — Helmholtz-Zentrum Berlin, Germany

The broadening of absorption edges is a general feature found in numerous semiconductors used as absorber layers for thin-film solar cells. Since this broadening gives rise to radiative losses of the open-circuit voltage, it is of importance to control the broadening by corresponding material design of the photovoltaic absorber materials. The present work provides an overview of the microscopic origins of band-gap broadening, addressing not only compositional aspects and microstrain, but also electrical and optoelectronic properties on the sub-μm scale. In addition, the Urbach energy extracted from absorptance or quantum efficiency spectra has been used broadly to quantify disorder in a material. However, up to date, it has not only not been clarified what the microscopic origins of Urbach tails are; the present contribution also shows that there is no direct correlation between the broadening of the absorption edge and the Urbach energy of a semiconductor, as verified for about 30 different photovoltaic absorbers.

HL 1.6 Mon 10:45 H13

Minimizing V_{OC} losses in high bandgap perovskite solar cells for the application in perovskite/perovskite/silicon triple-junction solar cells — •Athira Shaji[1,2], Minasadat Heydarian[1,3], Oliver Fischer[1,3], Michael Günthel[1], Orestis Karalis[4], Maryamsadat Heydarian[1], Alexander J. Bett[1], Hannes Hempel[4], Martin Bivour[1], Florian Schindler[1], Martin C. Schubert[1], Stefan W. Glunz[1,3], Andreas W. Bett[1,2], Juliane Borchert[1,3], and Patricia S. C. Schulze[1] — [1]Fraunhofer Institute for Solar Energy Systems ISE, Germany — [2]University Freiburg, Institute of Physics, Germany — [3]University of Freiburg, Department of Sustainable Systems Engineering, Germany — [4]Helmholtz-Zentrum Berlin, Solar Energy Division, Germany

The high bandgap (HBG) top cell is the main source of V_{OC} loss in perovskite/perovskite/silicon triple junction solar cells due to photoinduced phase segregation, non-radiative recombination at the perovskite bulk and interface with the charge transport layers (CTLs), as well as energetic misalignment between the perovskite layer and the CTLs. The starting point of this work was a triple-cation double-halide perovskite composition with a bandgap of 1.83 eV. By implementing a multi-faceted optimization approach, an average improvement in V_{OC} of 250 mV was achieved for HBG perovskite solar cells. Replacing the reference HBG perovskite with the optimised top cell in perovskite/perovskite/silicon triple-junction solar cells results in the improvement of V_{OC} by 124 mV, and the champion device achieves a voltage above 3 V.

HL 1.7 Mon 11:15 H13

The Effect of Overdamped Phonons on the Fundamental Band Gap of Perovskites — •Xiangzhou Zhu and David A. Egger — Physics Department, TUM School of Natural Sciences, Technical University of Munich, 85748 Garching, Germany

Different from conventional semiconductors, halide perovskites (HaPs) exhibit unique anharmonic fluctuations that strongly influence optoelectronic properties. Recent studies have shown that in specific temperature regimes, the strong phonon-phonon interactions in HaPs lead to overdamped phonons, where vibrational lifetimes drop below one oscillation period. However, the relationship between these overdamped phonons and atomic fluctuations, as well as their impact on optoelectronic properties, are not fully understood. Here, using molecular dynamics (MD) simulations and augmented stochastic Monte Carlo methods that account for phonon renormalization and imaginary modes, we contrast the band gap behavior of two anharmonic perovskite materials, $SrTiO_3$ and $CsPbBr_3$, of which only the latter exhibits overdamped phonons.[1] Our results show that the overdamped phonon dynamics in $CsPbBr_3$ drive slow atomic fluctuations that are not adequately captured by conventional phonon quasiparticle descriptions. Importantly, we show that these overdamped phonon lead to significant renormalization of the band gap. Our work disentangles the consequences of anharmonic effects on the optoelectronic properties and electron-phonon interactions in perovskites.

HL 1.8 Mon 11:30 H13

Polymorphism at surface in $CsPbI_3$ from first principles — •Jasurbek Gulomov[1], Guido Roma[1], Jacky Even[2], and Marios Zacharias[2] — [1]Université Paris-Saclay, CEA, Service de recherche en Corrosion et Comportement des Matériaux, SRMP, Gif sur Yvette, 91191, France — [2]Université Rennes, INSA Rennes, CNRS, Institut FOTON - UMR 6082, F-35000 Rennes, France

Halide perovskites show great potential for optoelectronics and photovoltaics, but challenges with ion migration and phase stability remain.Atomic-scale phenomena at surfaces and interfaces must be understood to block ion migration and enhance passivation. A peculiar property of these materials is the tendency to gain energy by disordered structural distortions, dubbed polymorphism, in contrast to the view of a perfectly symmetric monomorphous structure. Using first-principles calculations, we investigate the electronic and structural properties of polymorphous bulk $CsPbI_3$ and its 100 surface with two terminations. For the bulk, we generate a dynamically stable polymorphous structure for the cubic high-temperature phase using the method recently proposed by M. Zacharias et al. [1]. The energy gain and band gap opening are essentially linked to the increased average length of Pb-I bonds. Then we extend the concept of polymorphism to the surface, analyzing surface dipoles and work functions by comparing monomorphous and polymorphous slabs with experimental data. Our results tend to confirm the occurrence of polymorphism at surfaces in $CsPbI_3$.

HL 1.9 Mon 11:45 H13

Benchmarking approximations for the theoretical prediction of positron lifetimes in halide perovskites — Kajal Madaan[1], •Guido Roma[1], Jasurbek Gulomov[1], Pascal Pochet[2], Catherine Corbel[3], and Ilja Makkonen[4] — [1]Université Paris-Saclay, CEA, Service de recherches en Corrosion et Comportement des Matériaux, SRMP, 91191 Gif sur Yvette, France — [2]Department of Physics, IriG, Univ. Grenoble-Alpes and CEA, Grenoble, France — [3]LSI, CEA/DRF/IRAMIS, CNRS, Ecole Polytechnique, Institut Polytechnique de Paris, Palaiseau, 91120, France — [4]Department of Physics, University of Helsinki, P.O. Box 43, FI-00014 Helsinki, Finland

Positron annihilation spectroscopy is a well recognized tool for probing vacancies in materials. Recent applications of this technique to $APbX_3$ halide perovskites are sparse, and the rare theoretical predictions of positron lifetimes in these materials, published in association with experiments, do not fully agree with each other. These works suggest that vacancies on the A site are not detected. In our theoretical study we thoroughly revisit and compare several approximations for the electron-positron correlation functional, applied to methylammonium lead iodide ($MAPbI_3$) and $CsPbI_3$ and their vacancies. The discrepancies between the approaches make it difficult to unequivocally exclude the presence of methylammonium vacancies in $MAPbI_3$. Moreover, when using a truly nonlocal electron-positron correlation functional, the predicted positron density in a vacancy presents peculiar features and a much lower binding energy to the vacancy with respect to semilocal approximations.

HL 1.10 Mon 12:00 H13

Dynamics of electronic surface states in halide perovskites using machine-learning force fields — •Frederico Delgado[1], Frederico Simões[1], Waldemar Kaiser[1], Leeor Kronik[2], and David A. Egger[1] — [1]Physics Department, TUM School of Natural Sciences, Technical University of Munich, Germany — [2]Department of Molecular Chemistry and Materials Science, Weizmann Institute of Science, Israel

The photovoltaic performance exhibited by bulk halide perovskites (HaPs) hinges on their excellent optoelectronic properties, which have been extensively investigated. Nonetheless, extended defects like surfaces are ubiquitous, and as such, their impact on such properties requires further, careful investigation. Rigorous examination of dynamics in this context through ab-initio molecular dynamics implies large computational costs, which are here circumvented by the use of machine learning (ML) force fields. In this study, we demonstrate the transient and shallow nature of surface states in $CsPbBr_3$. We shed light on the mechanisms which underpin the behaviour of such states through the framework of local, internal dipoles. Our results aid in rationalizing the benign nature of surfaces in $CsPbBr_3$, and further the understanding of the correlation between structural dynamics and optoelectronic properties of HaP surfaces.

HL 1.11 Mon 12:15 H13

Comprehensive High-Throughput DFT Study of Intrinsic Defects and Dopability in p-type Zn3P2 for Photovoltaic Applications — •Nico Kawashima[1,2,3] and Silvana Botti[1,3] — [1]Ruhr-Universität, Bochum, Germany — [2]Friedrich-Schiller-Universität, Jena, Germany — [3]RC FEMS, Bochum, Germany

Zn_3P_2 has attracted significant interest as a thin-film absorber material for photovoltaic applications due to its intrinsic p-type conductivity and earth-abundant constituents. However, the nature of the dominant native defects – whether phosphorus interstitials (P_i) or zinc vacancies (V_{Zn}) – remains a subject of debate, with implications for the material's electronic structure and dopability through mechanisms such as Fermi-level pinning and defect compensation.

We perform a high-throughput density functional theory (DFT) analysis to systematically investigate both intrinsic point defects and potential extrinsic dopants. By resolving the ground-state configurations and formation energies of key native defects, we provide a clearer understanding of their impact on the electronic landscape. This insight is then applied to evaluate a range of extrinsic dopants, predicting their incorporation and activation potentials in the presence of native defects.

Our study offers a comprehensive framework that links intrinsic defect behavior with extrinsic doping strategies, providing critical guidance for tuning the electrical properties of Zn_3P_2. The findings present experimentally actionable insights that can drive the optimization of Zn_3P_2 for next-generation photovoltaic devices.

HL 1.12 Mon 12:30 H13

Density functional theory study of hydrogen passivation mechanisms in defective silicon — •Hania Azzam[1], Tobias Binninger[1], and Michael Eikerling[1,2] — [1]Theory and Computation of Energy Materials (IET-3), Institute of Energy Technologies, Forschungszentrum Jülich GmbH, 52425 Jülich, Germany — [2]Chair of Theory and Computation of Energy Materials, Faculty of Georesources and Materials Engineering, RWTH Aachen University, 52062 Aachen, Germany

Silicon heterojunction (SHJ) solar cells offer high-effeciency energy conversion, with reported efficiencies up to 27%. Their performance and durability depend on effective passivation of dangling bonds at the amorphous/crystalline silicon interface, where electron-hole recombination reduces efficiency. Hydrogen atoms play a crucial role in passivating those dangling bonds, minimizing recombination loses. Recent experimental studies by IMD-3 at Forschugnszentrum Jülich showed performance improvements after light soaking, a process where solar cells are exposed to intensive light at elevated temperatures. It is hypothesized that light soaking activates hydrogen migration toward defect sites. This theoretical study explores hydrogen passivation mechanisms in defective silicon for SHJ solar cells. Using Density Functional Theory (DFT), we analyze how silicon vacancies alter the electronic structure of Si-H systems, introducing localized defect states within the band gap and shifts in Fermi level, and subsequently investigate the changes induced by hydrogen passivation. These insights contribute to understanding the beneficial effects of light soaking on SHJ solar cells.

HL 1.13 Mon 12:45 H13

First principles theory of nonlinear long-range electron-phonon interaction — •Matthew Houtput[1,2], Luigi Ranalli[2], Jacques Tempere[1], and Cesare Franchini[2] — [1]University of Antwerp, Belgium — [2]University of Vienna, Austria

Electron-phonon interactions in a solid are crucial for understanding many interesting material properties, such as transport properties and the temperature dependence of the electronic band gap. For harmonic materials, the linear interaction process where one electron interacts with one phonon is sufficient to quantitatively describe these properties. However, this is no longer true in anharmonic materials with significant electron-phonon interaction, such as quantum paraelectrics and halide perovskites. Currently, the only available models for nonlinear electron-phonon interaction are model Hamiltonians, written in terms of phenomenological parameters. Here, we provide a microscopic semi-analytical expression for the long-range part of the 1-electron-2-phonon matrix element, which can be interfaced with first principles techniques. We show that

unlike for the long-range 1-electron-1-phonon interaction, the continuum approximation is not sufficient and that the entire phonon dispersion must be taken into account. We calculate an expression for the quasiparticle energies and show that they can be written in terms of a 1-electron-2-phonon spectral function. To demonstrate the method in practice, we calculate the 1-electron-2-phonon spectral function for $KTaO_3$ from first principles. The framework in this article bridges the gap between model Hamiltonians and first-principles calculations for the 1-electron-2-phonon interaction.

HL 2: 2D Semiconductors and van der Waals Heterostructures I

The session covers the photonic properties and corresponding devices made from 2D semiconductors and van der Waals heterostructures.

Time: Monday 9:30–13:00 Location: H15

HL 2.1 Mon 9:30 H15

Probing strong electron-phonon coupling in graphene by resonance Raman spectroscopy with infrared excitation energy — •Simone Sotgiu[1,2], Tommaso Venanzi[1], Lorenzo Graziotto[1], Francesco Macheda[1], Taoufiq Ouaj[2], Elena Stellino[1], Bernd Beschoten[2], Christoph Stampfer[2], Francesco Mauri[1], and Leonetta Baldassarre[1] — [1]Department of Physics, Sapienza University of Rome, Rome, Italy — [2]JARA-FIT and 2nd Institute of Physics, RWTH Aachen University, Aachen, Germany

Resonance Raman spectroscopy (RRS) has been a key asset to study the interplay between electronic and vibrational properties of graphene. We report on RRS measurements with an excitation photon energy down to 1.17 eV on mono (MLG) and bilayer (BLG) graphene, to study how low-energy carriers interact with lattice vibrations. Thanks to the excitation energy close to the Dirac point, we unveil in the MLG a giant increase of the intensity ratio between the double-resonant 2D and 2D* Raman peaks with respect to graphite [1]. In BLG, the low excitation energy hampers some of the resonant Raman processes giving rise to the 2D peak. Consequently, the sub-features composing the 2D mode are spectrally more separated with respect to visible excitations. We compare experimental measurements on BLG with ab initio theoretical calculations and we trace back such modifications on the joint effects of probing the electronic dispersion close to the band splitting and enhancement of electron-phonon matrix elements [2]. [1] T. Venanzi et al., Phys. Rev. Lett. 2023, 130, 256901 [2] L. Graziotto et al., Nano Lett. 2024, 24, 1867

HL 2.2 Mon 9:45 H15

Nonlinear Probing of Ultrafast Bandgap Modulations in Atomically Thin Semiconductors — •Sebastian Klimmer[1,2], Thomas Lettau[3], Jan Wilhelm[4,5], Dragomir Neshev[2], and Giancarlo Soavi[1] — [1]Institute of Solid State Physics, Friedrich Schiller University Jena, Jena, Germany — [2]ARC Centre of Excellence for Transformative Meta-Optical Systems, Department of Electronic Materials Engineering, Research School of Physics, The Australian National University, Canberra, Australia — [3]Institute of Condensed Matter Theory and Optics, Friedrich Schiller University Jena, Jena, Germany — [4]Regensburg Center for Ultrafast Nanoscopy (RUN), University of Regensburg, Regensburg, Germany — [5]Institute of Theoretical Physics, University of Regensburg, Regensburg, Germany

Bandgap modulations are pivotal for semiconductor based applications, typically achieved by permanent modifications of material composition or size. Recently, dynamic, ultrafast bandgap modulations have been demonstrated in transition metal dichalcogenides, exploiting the valley exclusive optical Stark (OS) and Bloch-Siegert (BS) shifts. However, their detection requires state of the art two-color pump-probe schemes. Here, we show a simplified method by measuring the second-harmonic (SH) power dependence in monolayer WSe_2. The fundamental beam (FB) blue-shifts the bandgap by OS/BS shifts, which scale linearly with intensity, resulting in a enhanced (reduced) SH signal, depending on the detuning $E_g - 2\hbar\omega_{FB}$. Our experimental data are fully explained by an analytical SBE model, which allows us to extract values for the transition dipole element and dephasing time.

HL 2.3 Mon 10:00 H15

Detecting out-of-plane polarized luminescence in TMDs with laser-written waveguide circuits — •Alina Schubert[1], Karo Becker[1], Rico Schwartz[1], Andreas Thies[2], Alexander Szameit[1], Matthias Heinrich[1], and Tobias Korn[1] — [1]Institut für Physik, Universität Rostock, Rostock, Germany — [2]2Ferdinand Braun Institut, Leibnitz Institut für Höchstfrequenztechnik, Berlin, Germany

Photoluminescence (PL) spectroscopy is used widely to investigate the outstanding excitonic properties of two-dimensional crystals. However, since these measurements are typically performed in vertical incidence, the sample is excited with light polarized in the plane of its layer. Despite, these detection schemes systematically neglect the out-of-plane polarized components of the emitted signal that propagate along the layer and therefore are only accessible by side-on detection.

Here, a side-on detection is achieved by using femtosecond laser direct written waveguides in fused silica glass as substrates [1]. By inscribing the waveguides directly under the surface of the glass, interactions of the waveguide's evanescent field and the sample are enabled in a controlled fashion. Therefore, the sample can be excited due to its proximity to the waveguide, while, in turn, the excitonic emission can be coupled into the waveguide and subsequently be detected.

In this work, the in-plane propagating luminescence in TMDs is analyzed with a particular focus on determining influences on the signal resulting from combining TMDs and surface waveguides.

[1] A. Szameit et al., J. Phys. B.: At. Mol. Opt. Phys., 43 (2010).

HL 2.4 Mon 10:15 H15

Current-induced second-harmonic generation in monolayer graphene-devices — •Nele Tornow[1], Friederike Renz-Wieland[1], Omid Ghaebi[1], and Giancarlo Soavi[1,2] — [1]Institute of Solid State Physics, Friedrich Schiller University Jena, Jena, Germany — [2]Abbe Center of Photonics, Friedrich Schiller University Jena, Jena, Germany

In pristine and isolated graphene, second-order nonlinear optical processes are, within the dipole approximation, forbidden due to the invariance under space inversion symmetry. Few studies have suggested that inversion symmetry can be broken by in-plane currents, leading to a measurable second-harmonic generation (SHG) [1,2]. In particular, investigations have shown that interfacial charge trapping between a monolayer graphene and silicon dioxide (SiO_2) on silicon substrate results in electrically tunable SHG when driving in-plane currents [2]. To further verify this hypothesis, we study current-tunable second-harmonic emission in two graphene based devices: one high-quality double-encapsulated hexagonal boron nitride/graphene field-effect transistor and one with a graphene-SiO_2 interface, finding SHG only in the latter one.

Our findings provide insights into the origin of current-tunable SHG and the mechanisms underlying space inversion symmetry breaking in graphene.

[1] Dean, J. et al., Appl. Phys. Lett. 26, 261910 (2009)

HL 2.5 Mon 10:30 H15

Electron-phonon coupling across the TMD/hBN van der Waals interface — •Gianmarco Gatti[1,2], Christophe Berthod[3], Julia Issing[2], Michael Straub[2], Salony Mandloi[2], Yann Alexaniann[2], Anna Tamai[2], and Felix Baumberger[2] — [1]Department of Physics and Astronomy, Aarhus University, Aarhus, Denmark — [2]Department of Quantum Matter Physics, University of Geneva, Geneva, Switzerland — [3]Department of Theoretical Physics, University of Geneva, Geneva, Switzerland

The lattice mismatch at van der Waals interfaces is widely used to engineer single particle band structures supporting complex quantum phases in two dimensions. Electronic states in van der Waals heterostructures may also couple to bosonic excitations in an adjacent substrate. These interfacial interactions are difficult to identify, and it is commonly assumed that they play a marginal role. Here, we reveal that quasiparticles in monolayer transition metal dichalcogenides (TMDs) are dressed by a remote cloud of phonons in the adjacent hexagonal boron nitride slab. Using angle resolved photoemission, we identify replica bands in the TMDs which are a clear fingerprint of a long-range electron-phonon interaction. We develop a modified Fröhlich model that shows quantitative agreement with the experimental spectral functions and discuss the properties of this model. Our analysis shows that remote electron-phonon coupling is a generic property of interfaces with hBN. This has implications for electron mobilities in 2D materials, for superconductivity and possibly for moiré correlated phases.

HL 2.6 Mon 10:45 H15

Polaron spectroscopy of many-body systems — •Ivan Amelio — Université Libre de Bruxelles, Brussels, Belgium

When an impurity is immersed in a many-body background, it is dressed by the excitations of the bath, and forms "a polaron".

As a result, the injection spectrum of the impurity carries the hallmarks of the correlations present in the bath. This physics is relevant for excitons optically injected in a few layer heterostructure, or for cold atomic mixtures.

In this talk, we will first review the basic theoretical framework and recent experimental progress.

Then, we will theoretically analyze a few cases of correlated many-body states: the impurity injection spectra are predicted to display peculiar features, that al-

low to distinguish whether the bath features BCS pairing, charge density waves, topological phases, the BKT transition, etc.

HL 2.7 Mon 11:15 H15

Ultrafast All-Optical Probe of Broken Time-Reversal Symmetry in Monolayer WSe_2 — •Paul Herrmann[1], Sebastian Klimmer[1], Thomas Lettau[1], Till Weickhardt[1], Anastasios Papavasileiou[2], Kseniia Mosina[2], Zdeněk Sofer[2], Jan Wilhelm[3], and Giancarlo Soavi[1] — [1]Friedrich Schiller University Jena, Germany — [2]University of Chemistry and Technology, Prague, Czech Republic — [3]University of Regensburg, Germany

The combination of broken space inversion and preserved time-reversal symmetry (TRS) underlies the spin-valley degree of freedom in monolayer transition metal dichalcogenides (TMDs). Introduction of an imbalance between the energy degenerate, but non-equivalent valleys (local extrema of the bandstructure) at the ±K points of the Brillouin zone breaks TRS. We probe broken TRS and a valley imbalance on ultrashort time scales by comparing the second harmonic (SH) intensity for a circularly *vs.* linearly polarized fundamental beam (FB). By numerically and analytically solving the semiconductor Bloch equations, we show that a two-photon resonant right/left circularly polarized FB interacts exclusively with the ±K valley. Thus, a circularly polarized FB probes the C_{3h} wave vector group of the ±K valleys, in contrast to a linearly polarized FB probing the D_{3h} group of the Γ point. This difference between wave vector groups at K and Γ fully captures and explains the experimentally measured deviation from the otherwise expected ratio of 2 in the circular *vs.* linear SH intensities.

HL 2.8 Mon 11:30 H15

Layer number sensitive Raman modes of atomically thin layered MoS_2 — •Henry Hübschmann[1], Gerhard Berth[1], Klaus Jöns[1], Katharina Burgholzer[2], and Alberta Bonanni[2] — [1]PhoQS Institute, CeOPP and Department of Physics, Paderborn University, Paderborn, Germany — [2]Johannes Kepler University Linz, Linz, Austria

The material group of TMDCs like molybdenum disulfide has gained great attention in the fields of quantum technologies over the last decade due to their particular electronic and optical properties [1]. 2D-MoS_2 has found many applications in optoelectronics and photonics, where the tunable electronic band gap exhibiting strong strutural dependency is an essential feature [2]. Here Raman spectroscopy represents the method of choice for the layer number identification of such 2D structures [3].

This work deals with layer structure sensitive phonon modes of mechanically exfoliated 2D-MoS_2 utilizing Raman analysis. Regarding the two main phonon modes occuring we successfully observed corresponding Raman shifts for monolayer to nine-layer configurations showing a specific dependency on the layer number, enabling the unambiguous determination of the layer number. Besides the two dominant vibrations many other phonon modes are identified, assigned to the symmetry and analyzed in the same manner. Within our comprehensive study we found other structure sensitive phonon modes, showing specific dependency on the layer number, expanding the set of Raman modes for the investigation of 2D-MoS_2 and its properties.

HL 2.9 Mon 11:45 H15

Universal and ultrafast probe of broken time-reversal symmetry — •Florentine Friedrich[1], Paul Herrmann[1], Sebastian Klimmer[1], Zdeněk Sofer[2], Shridhar Sanjay Shanbhag[3], Jan Wilhelm[3], and Giancarlo Soavi[1] — [1]Institute of Solid State Physics, University of Jena, Germany — [2]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Czech Republic — [3]Institute of Theoretical Physics and Regensburg Center for Ultrafast Nanoscopy, University of Regensburg, Germany

Time-reversal symmetry (TRS) defines some of the most fundamental properties of condensed matter, such as the relation between energy, spin and Berry curvature, therefore influencing features like topology or non-trivial spin textures. Two-dimensional transition metal dichalcogenides (TMDs) offer the possibility to engineer TRS and space-inversion symmetry independently, rendering them excellent model systems. TRS in TMDs can be lifted *via*, *e.g.* valley-selective bandgap opening. Nonlinear optics (NLO) as a probe of TRS is non-invasive and ultrafast; however, detection *via* second harmonic generation is limited to non-centrosymmetric systems. In this work, we make the nonlinear all-optical probe of broken TRS universal by utilizing polarization-resolved third harmonic generation (THG), which is always present also in centro-symmetric crystals. As a proof of principle, we probe broken TRS in a TMD monolayer, by using elliptically polarized light, leading to valley and spin asymmetric gap opening. We then test our method on a TMD bilayer, probing broken TRS in a centrosymmetric system with THG for the first time.

HL 2.10 Mon 12:00 H15

Ultrafast pump-probe spectroscopy of WSe_2 multilayer bubbles — •Jens-Christian Drawer, Henri Melchert, Marti Struve, Christian Schneider, and Martin Esmann — Carl von Ossietzky Universität Oldenburg, Oldenburg, Germany

Heterostructures of van der Waals materials have recently emerged as a versatile platform for the tailored generation and detection of coherent acoustic phonons in the GHz up to THz frequency range [1]. In this work, we investigate WSe_2 layers of different thicknesses by ultrafast pump-probe spectroscopy and observe thickness-dependent breathing-type acoustic phonon modes up to 850 GHz in frequency in the bilayer case. Under suitably chosen conditions for the dry-gel stamping preparation, 40 nm thick WSe_2 flakes form nanobubbles. For these bubbles, our pump-probe measurements reveal a significant improvement in the quality factor of their fundamental 29 GHz acoustic Fabry-Pérot mode from $Q = 13.9 \pm 0.7$ to $Q = 141 \pm 5$. We then tailor these high-Q modes by encapsulating the bubbles with hBN, introducing new spectral features attributed to coupled acoustic modes between WSe_2 and hBN. For example, our approach may enable the ultrafast modulation of strain-defined quantum emitters found in WSe_2.

HL 2.11 Mon 12:15 H15

Polarized optical contrast spectroscopy of in-plane anisotropic van-der-Waals heterostructures — Ernst Knöckl[1,2], •Alexandre Bernard[1,2], Alexander Holleitner[1,2], and Christoph Kastl[1,2] — [1]Walter Schottky Institute and Physics Department, TU Munich, Garching, Germany — [2]Munich Center for Quantum Science and Technology, München, Germany

To properly exploit interfacial symmetry breakings in van der Waals (vdW) heterostructures, giving rise to emergent behaviors, it is crucial to determine the symmetry axes of the individual layers.

I will discuss polarized optical contrast spectroscopy as a simple and non-destructive approach to characterize the crystalline anisotropy and orientation of 2D materials in vdW heterostructures. We developed a 3D-printed motorized polarization module compatible with typical microscope platforms, allowing broadband polarization-resolved reflectance spectroscopy. We investigated the in-plane birefringence of exfoliated MoO3 thin films (optically transparent) and few-layer WTe2 crystals (semi-metallic). We compared the measured spectra to a model based on a transfer matrix formalism.

Contrasting with other polarization-sensitive approaches, such as Raman or second harmonic generation spectroscopy, this method requires orders of magnitude less excitation power densities, avoiding degradation of delicate layers. Furthermore, it allows quick and simple polarization-sensitive absorbance measurements to resolve anisotropic excitonic properties in symmetry-breaking heterostructures or anisotropic semiconductors.

HL 2.12 Mon 12:30 H15

Microscopic comparison of TMD and QW laser capabilities — •Tommy Schulz, Daniel Erben, Alexander Steinhoff, and Frank Jahnke — Institut für theoretische Physik, Bremen, Germany

The lasing capabilities of monolayer transition metal dichalcogenides (TMDs) are compared to quantum wells (QWs). For material-realistic calculations of the optical gain we connect tight-binding bandstructures for TMDs and $\vec{k} \cdot \vec{p}$ band structures for QWs and the respective interaction matrix elements with state of the art many-body theory. The semiconductor Bloch equations are solved for highly excited materials, where Coulomb interaction is treated selfconsistently on a GW level together with carrier-phonon interaction. While TMDs provide larger material gain, they also exhibit large shifts of the peak gain with increasing high excitation densitiy, thereby limiting the lasing capabilities.

HL 2.13 Mon 12:45 H15

Strong coupling between light confined in a dielectric nanocavity and excitons in a monolayer TMDC — •Frederik Schröder[1,2], Paweł Wyborski[1], Meng Xiong[1,2], George Kountouris[1,2], Battulga Munkhbat[1], Martijn Wubs[1,2], Philip T. Kristensen[1,2], Jesper Mørk[1,2], and Nicolas Stenger[1,2] — [1]Department of Electrical and Photonics Engineering, Technical University of Denmark, 2800 Kgs. Lyngby, Denmark — [2]NanoPhoton - Center for Nanophotonics, Technical University of Denmark, Ørsteds Plads 345A, DK-2800 Kgs. Lyngby, Denmark

Enhancing light-matter interactions with optical nanocavities is essential for many applications, such as nanolasers and quantum technologies. Recently, advances in the design and fabrication of extreme dielectric confinement (EDC) cavities enabled the confinement of electromagnetic fields in InP on the tens of nanometer scale without being limited by absorption losses [1]. We demonstrate experimentally strong light-matter interactions between excitons in a single layer of $MoTe_2$ and light confined in an EDC nanocavity. The avoided crossing of the system is verified with both photoluminescence and reflection measurements. The observed Rabi-energy of 10.1 meV exceeds the averaged losses in the system [2]. These results pave the way for future studies on nonlinearities at the single-photon level [3].

HL 3: Focus Session: Machine Learning of semiconductor properties and spectra

The focus session highlights recent advances of machine learning concepts for the characterization of semiconductors. It particularly spotlights ML-driven advances in the prediction of key semiconductor properties, such as band gaps, dielectric constants and optical spectra, which are critical for the design of next-generation energy materials.

The focus session is organized by Erich Runge (TU Ilmenau).

Time: Monday 9:30–13:00 Location: H17

Invited Talk HL 3.1 Mon 9:30 H17

Alexandria Database - Improving machine-learning models in materials science through large datasets — •Jonathan Schmidt[1], Tiago Cerqueira[3], Aldo Romero[4], Silvana Botti[2], and Miguel Marques[2] — [1]Department of Materials, ETH Zürich, Zürich, CH-8093, Switzerland — [2]Research Center Future Energy Materials and Systems of the University Alliance Ruhr and ICAMS, Ruhr University Bochum, D-44801, Bochum, Germany — [3]CFisUC, Department of Physics, University of Coimbra, Coimbra, PortugalLarga, 3004- — [4]Department of Physics, West Virginia University, Morgantown, WV, 26506, USA

Accurate machine learning models hinge on the availability of large, high-quality datasets for both training and validation - a need that is particularly acute in materials science due to the scarcity of robust datasets. To address this gap, we present Alexandria, an open-access database generated through high-throughput studies using crystal-graph-attention networks to identify novel, stable crystal structures. The database includes over five million density-functional theory calculations for periodic compounds spanning one, two, and three dimensions.

Leveraging data generated with higher fidelity exchange-correlation functionals, we also explore the effectiveness of transfer learning strategies in detail. Finally, we assess to what extent incorporating experimental data can further enhance predictions of DFT band gaps.

Schmidt, Jonathan, et al. Materials Today Physics 48 (2024): 101560.

Invited Talk HL 3.2 Mon 10:00 H17

Generative Models on the Rise - Which one shall I pick for my Inverse Design Problem? — •Hanna Türk[1,2], Elisabetta Landini[2], Christian Kunkel[2], Patricia König[2], Christoph Scheurer[2], Karsten Reuter[2], and Johannes Margraf[2,3] — [1]EPFL, Lausanne, Switzerland — [2]Fritz-Haber-Institut der MPG, Berlin, Germany — [3]Universität Bayreuth, Bayreuth, Germany

The pursuit of novel materials through computational discovery appears endless due to the vast space of potential structures and compositions. For inorganic materials, this complexity is heightened by the combinatorial possibilities presented by the periodic table, where even a single-crystal structure can theoretically exhibit millions of compositions.

Recently, generative machine learning models have emerged as method for direct exploration of the material design space. Here, we evaluate the efficacy of various conditioned deep generative models, including reinforcement learning, variational autoencoders, and generative adversarial networks, in the prototypical task of designing Elpasolite compositions with low formation energies. Utilizing the fully enumerated space of 2 million main-group Elpasolites, we rigorously assess the precision, coverage, and diversity of the generated materials. Furthermore, we develop a hyperparameter selection scheme tailored for generative models in chemical composition space. Finally, we demonstrate the power of these machine learning models on a realistic application.

Invited Talk HL 3.3 Mon 10:30 H17

Machine-learning accelerated prediction of two-dimensional conventional superconductors — Thalis H. B. da Silva[2], Théo Cavignac[1], Tiago F. T. Cerqueira[2], •Haichen Wang[1], and Miguel A. L. Marques[1] — [1]Research Center Future Energy Materials and Systems of the University Alliance Ruhr and Interdisciplinary Centre for Advanced Materials Simulation, Ruhr University Bochum, Universitätsstraße 150, Bochum, Germany — [2]CFisUC, Department of Physics, University of Coimbra, Rua Larga, Coimbra, Portugal

We perform a large-scale search for two-dimensional (2D) superconductors, by using electron-phonon calculations with density-functional perturbation theory combined with machine learning models. In total, we screened over 140 000 2D compounds from the Alexandria database. Our high-throughput approach revealed a multitude of 2D superconductors with diverse chemistries and crystal structures. Moreover, we find that 2D materials generally exhibit stronger electron-phonon coupling than their 3D counterparts, although their average phonon frequencies are lower, leading to an overall lower T_c. In spite of this, we discovered several out-of-distribution materials with relatively high-T_c. In total, 105 2D systems were found with $T_c > 5$ K. Some interesting compounds, such as CuH_2, NbN, and V_2NS_2, demonstrate high T_c values and good thermodynamic stability, making them strong candidates for experimental synthesis and practical applications. Our findings highlight the critical role of computational databases and machine learning in accelerating the discovery of novel superconductors.

Invited Talk HL 3.4 Mon 11:15 H17

Machine Learning for Design, Understanding, and Discovery of (Semiconducting) Materials — •Pascal Friederich — Karlsruher Institut für Technologie

Machine learning can accelerate the screening, design and discovery of new molecules and materials in multiple ways, e.g. by virtually predicting properties of molecules and materials, by extracting hidden relations from large amounts of simulated or experimental data, or even by interfacing machine learning algorithms for autonomous decision-making directly with automated high-throughput experiments. In this talk, I will focus on our research activities on graph neural networks for property prediction [1] and understanding of structure-property relations [2], as well as on the use of machine learning for automated data analysis and autonomous decision-making in self-driving labs, especially in the area of semiconductor optimization for photovoltaics [3,4].

OptiMate: Artificial intelligence for optical spectra — •Malte Grunert and Max Grossmann — Theoretical Physics I, Institute of Physics, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Machine Learning (ML) is currently transforming computational materials science - many material properties can now be predicted to *ab initio* accuracy almost instantly using modern ML techniques. Until recently, optical properties such as absorption in the UV/VIS region were excluded from the ever-growing list of machine-learned properties, due to lack of high-quality training data for electronic excitations. To address this missed opportunity, we present OptiMate [1], a graph attention neural network trained on the largest high-quality, high-throughput dataset of optical properties available to date – a dataset that we have independently generated. OptiMate is capable of predicting the complex optical properties of a wide class of materials up to the XUV range with quantitative accuracy. In addition, OptiMate learns physical properties of spectra like continuity and causality directly from high-quality data, without such properties being enforced by constraints in the model architecture or with penalties during training. We detail the workings of OptiMate, show that it (and probably other complex models) learns a surprisingly meaningful representation of the material space, and preview current developments such as transfer learning to higher levels of theory.

HL 3.6 Mon 12:15 H17

Mechanical Properties of Hybrid Perovskites study using explainable Machine Learning — •Yuxuan Yao[1,2], Dan Han[3], and Harald Oberhofer[2] — [1]Chair for Theoretical Chemistry, Technical University of Munich — [2]Chair for Theoretical Physics VII, University of Bayreuth — [3]School of Materials Science and Engineering, Jilin University

Lead-based halide perovskite photovoltaics are of great interest for use in optoelectronic devices due to the high power conversion efficiency and low cost. 2D hybrid organic and inorganic perovskites (HOIPs) have been utilized as capping layers on top of 3D perovskites to increase the stability. On top of that, soft and stable HOIPs are an attractive material for use in flexible electronic devices. We utilize explainable machine learning (ML) techniques to accelerate the in silico prediction of elasticities of 2D perovskites, based on their Young's moduli. Our ML models allow us to distinguish between stiff and nonstiff HOIPs and to extract the materials' features most strongly influencing their elasticities. The Pb-halogen-Pb bond angle and the cations' steric effect indices (STEI) emerge as the dominant physical feature with an inverse correlation to the structural non-stiffness. The deformation of the octahedra strongly affects the material's mechanical properties, which allows us to perform the transferability test from single-layered to multi-layered 2D perovskites. Overall, our work thus points the way towards future design efforts of HOIPs with regards to their elasticity.

HL 3.7 Mon 12:30 H17

Exploring Strongly Anharmonic Thermal Insulators with Machine-Learned Interatomic Potential using an Active Learning Scheme — •Shuo Zhao, Kisung Kang, and Matthias Scheffler — The NOMAD Laboratory at the FHI of the Max Planck Society

Thermal insulating semiconductors often exhibit significant anharmonicity, particularly associated with rare events such as defect creation and phase-transition precursors [1]. These phenomena disrupt the conventional phonon picture and render perturbative methods ineffective or even incorrect for describing heat transport, leading to a substantial challenge for reliable prediction of thermal conductivity. This work presents a framework that combines the Green-Kubo formalism with machine-learned interatomic potentials, enhanced by a sequential active learning scheme [2]. Equivariant neural networks `NequIP` [3] and `So3krates` [4] are employed and systematically compared for this purpose. Based on this framework, we examine 15 materials that possibly have ultra-low thermal conductivity previously, predicted by a symbolic regression machine-learning model [5]. Our demonstrations and results not only provide precise thermal conductivity predictions for strongly anharmonic systems but also pave the way for accelerated exploration and design of novel thermal insulators.

Learning an effective Hamiltonian for large-scale electronic-structure calculations — •Martin Schwade and David A. Egger — TUM School of Natural Sciences, Technical University of Munich, 85748 Garching, Germany

Exploring the optoelectronic properties of large-scale systems across various temperatures using conventional density functional theory (DFT) often encounters significant computational challenges. Recent advancements in machine learning force fields (ML-FFs) have made it easier to generate atomic trajectories at different temperatures. However, determining the electronic structure with temperature dependence remains a difficult task. Building on our earlier work involving a temperature-transferable tight-binding (TB) model [1] to learn an effective Hamiltonian, we introduce an extension of this method that leverages machine learning techniques to increase the accuracy and transferability of this approach. By integrating ML with TB models, this strategy offers a promising pathway to evaluate temperature-dependent material properties with reduced computational demands. [1] M. Schwade, M.J. Schilcher C. First-Principles Investigation of NV Centers in Silicon Carbide Polytypes — •Timur Biktagirov, Uwe Gerstmann, and Wolf Gero Schmidt — Universität Paderborn, Paderborn, Germany

Optically addressable spin defects in semiconductors offer versatile platforms for quantum applications, including computing, communication, and sensing. Among these, nitrogen-vacancy (NV) centers in silicon carbide (SiC) polytypes have emerged as a promising class of quantum defects, analogous to the NV center in diamond. In contrast to diamond, SiC is a technologically mature material with large-scale production capabilities, advanced doping techniques, and compatibility with CMOS fabrication methods. Additionally, the emission wavelengths of NV centers in SiC lie in the near-infrared range, making them particularly suitable for applications in single-photon emission. In this work, we discuss recent advancements in the ab initio investigation of NV centers in the 4H, 6H, and 3C polytypes of SiC. Simulating the magneto-optical properties of these spin centers, which are crucial for quantum applications, requires a detailed and accurate description of both the host material and the embedded defect. Accordingly, we demonstrate how supercell density functional theory (DFT) and recent implementations based on DFT can be employed to model key properties, including intra-defect optical transition energies, electron-electron and electron-nuclear spin interactions, and electron-phonon coupling. These theoretical insights provide a foundation for optimizing NV centers in SiC for next-generation quantum technologies.

HL 6.2 Mon 15:15 H13

tunable superconductivity in Ga-doped SixGe1-x via ion implantation and flash lamp annealing — •yu cheng[1,2], yi li[1,2], oliver steuer[1], mao wang[3], artur erbe[1,2], manfred helm[1,2], shengqiang zhou[1], and slawomir prucnal[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Ion Beam Physics and Materials Research, Dresden, Germany — [2]TU Dresden, Dresden, Germany — [3]Laboratory of Micro-Nano Optics, College of Physics and Electronic Engineering, Sichuan Normal University, Chengdu, PR China

Group-IV superconducting semiconductors offer promising opportunities for scalable superconductor-semiconductor platforms in quantum computing. However, realizing a superconducting phase in semiconductors requires doping concentrations beyond the metal-insulator transition (MIT). Achieving such high doping levels in silicon (Si) and germanium (Ge) is challenging due to the limited solid solubility of acceptors in these materials. Various advanced techniques have been developed to overcome this problem, such as gas immersion laser doping or ns-pulsed laser melting [1]. Here, we explore tunable superconducting states in Ga-hyperdoped SixGe1-x alloys by applying ion implantation followed by ms-range flash lamp annealing. We observed that the critical temperature depends on the Ge-concentration. Samples with the highest Ge content demonstrate the transition temperature (Tc) of 1.2 K, attributed to increased Ga solubility, while samples with 70% of Si shows Tc around 100 mK. Notably, all samples achieved carrier concentrations over solid solubility, illustrating the effects of hyperdoping on superconductivity.

HL 6.3 Mon 15:30 H13

Direct printing of microlenses on hexagonal boron nitride to improve light outcoupling — •Daniel Klenkert[1,2], Paul Konrad[2], Andreas Sperlich[2], Vladimir Dyakonov[2], and Jens Ebbecke[1] — [1]1Technology Campus Teisnach Sensor Technology, Deggendorf Institute of Technology, 94244 Teisnach — [2]Experimental Physics 6, Julius-Maximilians-University Würzburg, 97074 Würzburg

Optically active defects in hexagonal boron nitride (hBN) have attracted wide research interest in the field of quantum technology. Solid immersion lenses can be employed in order to increase light outcoupling and thus the external quantum efficiency (EQE) of such defects. These lenses are, however usually created by etching them into the surface of the host material, which makes them rather unsuitable for 2D materials such as hBN.

Here we present an alternative approach: direct printing of polymer microlenses onto hBN using the two-photon polymerization technique. This strategy is not limited to bulk crystals, but can also be applied to thin films. Using a ceramic hybrid polymer with low fluorescence and high optical transparency, hemispherical lenses were directly printed on macroscopic hBN crystals and on thin flakes to demonstrate the feasibility and EQE enhancement of this approach.

HL 6.4 Mon 15:45 H13

Dynamical reorientation of spin multipoles in silicon carbide by transverse magnetic fields — •Alberto Hernández-Mínguez[1], Alexander V. Poshakinskiy[2], Michael Hollenbach[3], Paulo V. Santos[1], and Georgy V. Astakhov[3] — [1]Paul-Drude-Institut für Festkörperelektronik, Berlin, Germany — [2]ICFO-Institut de Ciències Fotòniques, Castelldefels, Spain — [3]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

The long-lived and optically addressable high-spin state of the negatively charged silicon vacancy (V_{Si}) in silicon carbide makes it a promising system for applications in quantum technologies. Most studies of its spin dynamics have been performed under external magnetic fields applied along the symmetry axis of the V_{Si} center. Here, we show that the application of a weak magnetic field perpendicular to the symmetry axis leads to a non-trivial behavior of the optically detected magnetic resonances (ODMRs) caused by the dynamical reorientation of the spin multipole under optical excitation. Particularly, we observe the inversion of the quadrupole-spin polarization in the excited state and the appearance of a dipole-spin polarization in the ground state. The latter is much higher than the thermal polarization and cannot be induced solely by optical excitation. Our theoretical model reproduces well all sharp features in the ODMR spectra and shine light on the complex dynamics of spin multipoles in these kinds of solid-state systems.

[1] A. Hernández-Mínguez *et al.*, Phys. Rev. Appl. **22**, 044021 (2024)

HL 6.5 Mon 16:00 H13

The hBN defects database for quantum applications — •Chanaprom Cholsuk[1,2], Asli Cakan[1,2], Sujin Suwanna[3], and Tobias Vogl[1,2,4] — [1]Department of Computer Engineering, School of Computation, Information and Technology, Technical University of Munich, 80333 Munich, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany — [3]Optical and Quantum Physics Laboratory, Department of Physics, Faculty of Science, Mahidol University, Bangkok 10400, Thailand — [4]Abbe Center of Photonics, Institute of Applied Physics, Friedrich Schiller University Jena, 07745 Jena, Germany

Hexagonal boron nitride (hBN) has emerged as a solid-state platform for hosting a variety of defects for quantum applications. Identifying optimal defects for specific quantum applications has been challenging as some defects exhibit similar properties while others encounter strain. Comprehensive properties are therefore required. This work addresses this gap by utilizing density functional theory and open quantum system approaches to thoroughly characterize the properties of 257 defects and evaluate their potential for quantum emitter and quantum memory applications. This enables matching defects with suitable quantum applications. Furthermore, all findings are compiled into an accessible online database at https://h-bn.info, allowing one to compare our calculated optical fingerprints with experiments and other simulations. Consequently, this work enriches hBN defect resources, supporting progress in quantum technologies and defect identification.

HL 6.6 Mon 16:15 H13

Scanning NV center thermometry — Elias Sfeir[1], Maxime Rollo[1], Yoann Baron[2], Felipe Favaro de Oliveira[3], Gediminas Seniutinas[3], Marcelo Gonzàlez[3], Mathieu Mathieu[3], Patrick Maletinsky[3,4], Jean-Baptiste Jager[5], Jean-Michel Gérard[5], Vincent Jacques[1], •Aurore Finco[1], and Isabelle Robert-Philip[1] — [1]Laboratoire Charles Coulomb, Université de Montpellier, CNRS, Montpellier, France — [2]Univ. Grenoble Alpes, CEA, LETI, Grenoble, France — [3]Qnami, Muttenz, Switzerland — [4]Department of Physics, University of Basel, Basel, Switzerland — [5]Univ. Grenoble Alpes, CEA, Grenoble INP, IRIG, PHELIQS, Grenoble, France

Scanning NV center microscopy relies on a single nitrogen-vacancy (NV) defect in diamond as a quantum sensor for scanning probe experiments. It is now routinely used as a powerful magnetometry technique, and its functionalities can be extended to temperature measurements by exploiting the temperature dependence of the NV electron spin resonance (ESR) frequency. In this work, we show how to simultaneously map the Joule heating and the Oersted field generated by an electrical current flowing through a semiconductor nanowire with a scanning NV center microscope. Our results highlight that the component of the magnetic field perpendicular to the NV center quantization axis competes with the effect of temperature on the NV ESR frequency, making quantitative temperature measurements challenging. Therefore, we finally propose solutions to improve the overall performances of the technique through the design of optimized diamond probes.

HL 6.7 Mon 16:45 H13

Luminescence of electron and ion beam irradiated hBN — •Jan Böhmer, Annkathrin Köhler, Christian T. Plass, and Carsten Ronning — Friedrich Schiller University, Jena, Germany

Defect centers in solid state materials have emerged as promising candidates for quantum emitters. Here, hexagonal boron nitride (hBN) has attracted much interest as an interesting material for the realization of room temperature single photon emitters (SPEs). Emitting defects can be specifically created by irradiation of hBN flakes and nanoparticles with (focused) electron and ion beams, which allows to modify the luminescence properties of the hBN samples and fabricate targeted localized SPEs. The effects of the irradiation on the luminescence spectrum were investigated using micro photoluminescence (μPL). The nature and applicability for SPEs were determined by $g_{(2)}$-autocorrelation measurements as a function of the irradiation parameters.

HL 6.8 Mon 17:00 H13

Strain-induced tuning of quantum emitters in hexagonal boron nitride — •Tjorben Matthes[1,2], Anand Kumar[1,2], Mohammad Nasimuzzaman Mishuk[1,2], and Tobias Vogl[1,2] — [1]Department of Computer Engineering, TUM School of Computation, Information and Technology, Technical University of Munich, 80333 Munich, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany

In this talk, we will show our recent progress in controlling the emission characteristics of our single photon emitters in hexagonal boron Nitride (hBN).

We have previously demonstrated our results on the polarisation characteristics of both the absorption and the emission characteristics of our single photon emitters. By conducting a statistical analysis of a large array of emitters, we found some unexpected results that indicate a shift of the emission axes in one direction compared to the crystal axes. We suspected a strain induced by the exfoliation process as the cause. We, therefore, conduct now further tests deliberately inducing strain into the hBN flakes in which the emitters are embedded.

HL 6.9 Mon 17:15 H13

Impact of a magnetic field on low-temperature photoluminescence of indium-doped silicon — •Kevin Lauer[1,2], Mario Bähr[1], Richard Grabs[1], Frank Long[1,3], Martin Kaleta[1], Andreas Frank[1], Thomas Ortlepp[1], Katharina Peh[2], Noah Stiehm[2], Rüdiger Schmidt-Grund[2], Dirk Schulze[2], and Stefan Krischok[2] — [1]CiS Forschungsinstitut für Mikrosensorik GmbH, Erfurt, Germany — [2]Technische Universität Ilmenau, Institut für Physik, Ilmenau, Germany — [3]Universität Göttingen, Göttingen, Germany

Acceptor-interstitial silicon (ASi-Sii)-defects [1] were proposed to be responsible for a gain loss in low-gain avalanche detectors (LGAD) and for an efficiency loss in silicon solar cells. Recently, it was speculated that this defect category could be relevant for silicon-based quantum technology, as well. To advance the understanding of these defects in silicon with respect to their potential use as qubits, low-temperature photoluminescence (PL) measurements are performed while subjecting the sample to magnetic fields. Silicon samples with and without indium doping were treated by a temperature quenching step to generate ASi-Sii-defects. The ASi-Sii-defect generation was done using a local laser quenching method as well as using a Bunsen burner with subsequent water quenching. As expected, the integrated PL intensity increased after this generation process. While the sample is subjected to magnetic fields, the integrated PL intensity changes significantly. Differences between samples with and without indium doping will be discussed. [1]K. Lauer et al., Phys. Status Solidi A, 219 (2022) 2200099

HL 6.10 Mon 17:30 H13

Fabrication, characterization and deformation of Si/SiGe membranes for spin qubit devices — •Lucas Marcogliese[1], Ouviyan Sabapathy[1], Rudolf Richter[2], Dominique Bougeard[2], and Lars R. Schreiber[1,3] — [1]JARA-FIT Institute for Quantum Information, Aachen, Germany — [2]University of Regensburg, Regensburg, Germany — [3]ARQUE Systems GmbH, Aachen, Germany

The energy separation between the two lowest lying energy states in silicon, known as valley splitting, has been shown to have a significant impact on dephasing times, readout and shuttling fidelities of spin qubits in Si/SiGe. Greater control over the strain tensor field may be decisive for deterministic valley splitting enhancement in the presence of alloy disorder. Here, we demonstrate the fabrication of SiGe/Si/SiGe quantum well membranes suspended by the handle wafer via wet etching. Relying on SiGe as an etch stop, the robust and reproducible process yields membranes down to micrometer thicknesses. Raman maps confirm that etching preserves epitaxial tensile strain in the quantum well. Remarkably, they reveal that the in-plane strain components generated by the cross-hatch pattern typical of Si/SiGe heterostructures on bulk substrates disappear on etched membranes. To probe their elastic properties, the membranes are stressed by loading with a profilometer stylus at room temperature. We envision the Si/SiGe membrane as a flexible scientific platform for investigating novel, advanced valley splitting enhancements techniques, required for scalable Si/SiGe quantum computing with electron spins.

HL 6.11 Mon 17:45 H13

Design and optimization of bimodal cavities coupled to multi-level quantum systems — •Oscar Camacho Ibarra, Jan Gabriel Hartel, Atzin Ruiz Perez, Sonja Barkhofen, and Klaus Jöns — PhoQS Institute, CeOPP, and Department of Physics, Paderborn University, Paderborn, Germany

Photonic integrated cavities are essential building blocks for qubit-controlled switches, routers, and gates in quantum networks and quantum information

processing. These devices rely on the integration of multi-level quantum systems coupled to multiple photonic modes inside a cavity. Thus, the present work introduces a systematic workflow for the design of bimodal cavities by employing one-dimensional crossed photonic crystal nanobeam cavities with non-zero cavity lengths. By optimizing three key parameters*the periodicity, a single feature size of the hole shape, and the central cavity length*we establish a robust methodology for designing crossed nanobeam cavities. This approach supports configurations with either matching or mismatched resonance frequencies, offering flexibility for diverse quantum applications. Solak, Daniel Z. Rossatto, and Celso J. Villas-Boas, Universal quantum computation using atoms in cross-cavity systems. Phys. Rev. A 109, 062620 (2024).

HL 6.12 Mon 18:00 H13

In Situ Defect Density Determination of Spin Defects in Hexagonal Boron Nitride — Atanu Patra[1], •Paul Konrad[2], Andreas Sperlich[2], Timur Biktagirov[3], Thinh Tran[4], Igor Aharonovich[4], Sven Höfling[1], and Vladimir Dyakonov[2] — [1]Technische Physik, Julius-Maximilians-University Würzburg, 97074 Würzburg — [2]Experimentelle Physik 6, Julius-Maximilians-University Würzburg, 97074 Würzburg — [3]Lehrstuhl für Theoretische Materialphysik, Universität Paderborn, 33095 Paderborn, Germany — [4]School of Mathematics and Physical Sciences, University of Technology Sydney, Ultimo, NSW 2007, Australia

In recent years, the negatively charged boron vacancy (V_B^-) spin defects in hexagonal boron nitride (hBN) caught attention for their sensitivity to environmental parameters such as magnetic field, temperature, and pressure, making them ideal for quantum sensing. The optical emission from these defects, crucial for applications, depends on their density, which could -so far- not be determined directly for thin flakes. Our study identifies distinct Raman modes alongside the E_{2g} peak in defect-enriched hBN. Polarization-dependent Raman measurements reveal that these modes arise from atomic vibrations associated with the V_B^- defects. Additionally, we corroborate this result by density functional theory. We investigate the interdependent relationship between the vibronic states and defect density and obtain a universally applicable method to directly determine the absolute spin-defect density in flakes by Raman spectroscopy alone.

HL 6.13 Mon 18:15 H13

Electric-circuit realization of the Floquet-SSH-Model — •Christine Barko[2], Alexander Stegmaier[1], Alexander Fritzsche[1], Riccardo Sorbello[1], Martin Greiter[1], Hauke Brand[2], Maximilian Hofer[2], Udo Schwingenschlögl[3], Roderich Moessner[4,5], Ching Hua Lee[6], Alexander Szameit[5,7], Andrea Alù[8,9], Tobias Kiessling[2,5], and Ronny Thomale[1,5] — [1]Physikalisches Inst. (TP1), Universität Würzburg, Würzburg, Germany — [2]Physikalisches Inst. (EP3), Universität Würzburg, Würzburg, Germany — [3]Physical Science and Engineering Division, King Abdullah University of Science and Technology (KAUST), Thuwal, Saudi Arabia — [4]Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Straße 38, Dresden, Germany — [5]Würzburg-Dresden Cluster of Excellence ct.qmat, Würzburg, Germany — [6]Department of Physics, National University of Singapore, Singapore — [7]Institute of Physics, University of Rostock, Rostock, Germany — [8]Photonics Initiative, Advanced Science Research Center, City University of New York, New York, USA — [9]Physics Program, Graduate Center, City University of New York, New York, USA

We build Floquet-driven capactive circuit networks to realize topological states of matter in the frequency domain. We find the Floquet circuit network equations of motion to reveal a potential barrier which effectively acts as a boundary in frequency space. By implementing a Su-Shrieffer-Heeger Floquet lattice model and measuring the associated circuit Laplacian and characteristic resonances, we demonstrate how topological edge modes can nucleate at such a frequency boundary.

HL 6.14 Mon 18:30 H13

Erbium dopants in nanophotonic resonators — •Andreas Gritsch, Alexander Ulanowski, Stephan Rinner, Johannes Früh, Jakob Pforr, and Andreas Reiserer — Technical University of Munich, TUM School of Natural Sciences and Munich Center for Quantum Science and Technology (MCQST), 85748 Garching, Germany

Optically addressable spin qubits are pristine candidates for large-scale quantum networks [1] and modular quantum computing architectures [2]. Erbium dopants are the only emitter with a coherent optical transition in the minimal-loss-band of optical fibers. In silicon, erbium integration is compatible with industrial-grade nanofabrication processes [4]. In nanophotonic resonators efficient spin-photon interfaces can be realized, in which about ten single dopants can be resolved with Purcell enhancement up to 177. Their spin state can be initialized and read out with a combined fidelity of 87%. This spin further exhibits a second-long lifetime and a Hahn-echo coherence time of 48 s [4]. We further investigate the optical coherence and the spectral multiplexing capabilities in our silicon devices, which allows a detailed comparison to our experiments with YSO membranes integrated into Fabry-Perot resonators [5].

HL 7: Semiconductor Lasers

Time: Monday 15:00–15:45 Location: H14

HL 7.1 Mon 15:00 H14

Development and Analysis of a VECSEL based on InGaAs Quantum Dots for Emissions in the Telecom O-Band — •Justus Unfried, Philipp Noack, Rebecca Rühle, Michael Jetter, and Peter Michler — Institut für Halbleiteroptik und funktionelle Grenzflächen (IHFG), Center for Integrated Quantum Science and Technology (IQST) and SCoPE, University of Stuttgart, Allmandring 3, 70569 Stuttgart, Germany

The advancement of sophisticated laser technologies for high-resolution spectroscopy and sensing applications has stimulated interest in versatile, high-performance light sources. Vertical External-Cavity Surface-Emitting Lasers (VECSELs) based on InGaAs quantum dots (QDs) are promising for emissions in the telecommunications O-band and offer broad wavelength tunability, high output power, and excellent beam quality. This study focuses on optimizing QD layers through metal-organic vapor-phase epitaxy (MOVPE), utilizing the Stranski-Krastanov growth mode, followed by laser performance characterization. To enhance QD density and emission characteristics, the gallium precursor was substituted with TEGa, exhibiting a higher decomposition rate at lower growth temperatures. The indium supply was modified, and the duration of the arsine interruption following QD deposition was examined to increase density and reduce large In-clusters. Subsequently, 12 of these high-density QD layers are deposited on a distributed Bragg reflector (DBR) structure, completing the VECSEL. This laser development is accompanied by structural and performance characterizations.

HL 7.2 Mon 15:15 H14

Comparison between a 675nm and 532nm pumped 4x3 InGaAsP QW VECSEL emitting at around 760nm in a V-Shaped resonator — •Rebecca Rühle[1], Maxim Leyzner[2], Marwan Abdou Ahmed[2], Thomas Graf[2], Michael Jetter[1], and Peter Michler[1] — [1]Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology (IQST) and SCoPE, Universität Stuttgart, Allmandring 3, 70569 Stuttgart, Germany — [2]Institut für Strahlwerkzeuge, Universität Stuttgart, Pfaffenwaldring 43, 70569 Stuttgart, Germany

The quantum defect between the emission and the pump wavelengths has a substantial impact on the performance of a vertical external-cavity surface-emitting lasers (VECSEL). An increase in the wavelength of the pump laser should result in an improvement in thermal behavior and the laser performance. One disadvantage is that the pump absorption is reduced, given that the pump energy is typically below the barrier bandgap. In our previous studies, the GaInP barrier of our InGaAsP VECSEL structure was modified to absorb pump light at a wavelength of 675nm. Power measurements were conducted with a 675nm pump laser and a 532nm pump laser, employing the aforementioned adapted structure. By varying the reflectivity of the outcoupling mirror in the V-shaped resonator, we gain further insight into the absorption characteristics within the active region of the VECSEL. Due to the specifications of the laser source, the pump spot size was approximately 310μmx230μm, resulting in a multimode emission from the VECSEL rather than single mode for both pumplasers.

HL 7.3 Mon 15:30 H14

Quantum optical validation of high-β lasing in monolayer-based self-assembled photonic-defect nanocavities — •Aris Koulas-Simos[1], Chirag Palekar[1], Kartik Gaur[1], Imad Limame[1], Bárbara Rosa[1], Cun-Zheng Ning[2], and Stephan Reitzenstein[1] — [1]Institut für Festkörperphysik, Teschnische Universität Berlin, 10623 Berlin, Germany — [2]College of Integrated Circuits and Optoelectronic Chips, Shenzhen Technology Univesity, Shenzhen 518118, China

Nanolasers based on transition metal dichalcogenides have garnered substantial research interest for innovative photonic applications. This study presents the

fabrication of multiple self-assembled photonic defect nanocavities within a single, fully encapsulated WSe_2 monolayer integrated into a dielectric distributed Bragg reflector (DBR) structure. Spontaneously formed bubbles during the encapsulation process lead to the generation of photonic-defect nanocavities in the DBR. These structures achieve strong optical lateral confinement and exhibit size-dependent optical characteristics, as confirmed by μPL-measurements in both the real and k-space and numerical cavity simulations. Optical power-dependent investigations conducted at cryogenic temperatures reveal lasing behavior, evidenced by a distinct kink in the input-output curve, accompanied by slight linewidth narrowing and a lineshape transition in two specific devices. Finally, photon-autocorrelation measurements performed on one of these devices provide unequivocal confirmation of a lasing transition [1].

HL 8: 2D Semiconductors and van der Waals Heterostructures II

The session covers the physics of emerging 2D materials.

Time: Monday 15:00–16:15 Location: H15

HL 8.1 Mon 15:00 H15

atomic and electronic structures of colloidal ultrathin PbSe nanoplatelets — •Huu Thoai Ngo[1,2], Leon Biesterfeld[3], Ahmed Addad[1], Bruno Grandidier[1], Christophe Deere[1], Jannika Lauth[3], and Louis Biadala[1] — [1]Université de Lille, CNRS, Centrale Lille, Université Polytechnique Hauts-de-France, Junia-ISEN, UMR 8520-IEMN, INRAE, UMR-8207, UMET- Unité Matériaux et Transformations, F-59000 Lille, France. — [2]Solid Surface Analysis, Institute of Physics, Chemnitz University of Technology, 09126 Chemnitz, Germany. — [3]Institute of Physical Chemistry and Electrochemistry, Leibniz University Hannover, Callinstr. 3A, D-30167 Hannover, Germany

Two-dimensional (2D) PbSe nanoplatelets (NPLs) are promising materials for lighting technologies due to their efficient and tunable photoluminescence (PL), such as narrow PL emission reaching telecom bands. However, the electronic properties of single NPLs remain underexplored, limiting insights into quantum confinement effects. Here, we investigate the structural and electronic properties of ultrathin PbSe NPLs using low-temperature scanning tunneling microscopy (LT-STM). STM images confirm flat 2D morphologies at various thicknesses while tunneling spectra reveal pronounced quantum confinement along the thickness, resulting in bandgap shifts. High-angle annular dark-field scanning transmission electron microscopy confirms the rock-salt crystal structure, providing atomic-level insights. Additionally, tight-binding calculations demonstrate lateral quantum confinement effects, showing that in-plane dimensions influence electronic properties.

HL 8.2 Mon 15:15 H15

Modifying properties of 2D transition metal dichalcogenides by confined-space annealing — •Christian Tessarek, Christian Petersen, Tim Grieb, Florian F. Krause, Alexander Karg, Christian Habben, Andreas Rosenauer, and Martin Eickhoff — Institute of Solid State Physics, University of Bremen, Otto-Hahn-Allee 1, 28359 Bremen, Germany

2D transition metal dichalcogenides (TMDs) can be grown by different methods, e.g. chemical vapor or atomic layer deposition (ALD) [1]. Subsequent annealing is often applied to improve the properties of the as-grown 2D layers. Decomposition of TMD layers due to desorption of chalcogenides usually limits the temperature range. Higher annealing temperatures are possible in a chalcogene containing atmosphere but require special safety requirements of the annealing equipment.

In this study, a confined-space annealing (CSA) approach is demonstrated and realized by a close contact face-to-face sample arrangement of TMD layers on SiO_2/Si or graphene substrates. CSA is performed in vacuum or in an inert gas atmosphere without using additional chalcogene containing precursors. Such sample arrangement strongly reduces chalcogene outdiffusion from the confined space and allows annealing at higher temperatures and longer durations. The influence of CSA parameters is investigated with respect to structural and optical properties of the TMDs and compared to a standard annealing process of uncovered layers. It will also be shown that CSA can be used for conversion of MoS_2 to ternary $Mo(S,Se)_2$ and binary $MoSe_2$.

HL 8.3 Mon 15:30 H15

Mapping the lateral homogeneity of semiconducting monolayer 2D polar Ag using spectroscopic imaging ellipsometry — •Ulrich Limberg[1], Jakob Henz[1], Siavash Rajabpour[2], Alexander Vera[2], Joshua Robinson[2], and Ursula Wurstbauer[1] — [1]Institute of Physics, University of Muenster, Germany — [2]MatSE; Center for 2DLM; Atomic; 2D Crystal Consort, PennState University, USA

2D polar metals are a novel family of atomically thin plasmonic quantum materials, which are synthesized by confinement heteroepitaxial growth (CHet)[1]. Hereby, metal atoms such as silver or gallium are intercalated between bilayer graphene and a silicon carbide substrate. In the case of 2D polar silver, a stable monolayer structure forms which has been shown to be an indirect bandgap semiconductor[2]. However, Raman imaging seems to indicate the existence of a second, possibly metallic, phase[3].

We investigated 2D polar silver samples of varying growth conditions via spectroscopic imaging ellipsometry, in order to access lateral inhomogeneities by modifications in the dielectric functions sensitive to different phases.

HL 8.4 Mon 15:45 H15

Biaxial Compressive Strain Tuning of Quantum Properties in 2D Materials — •Eudomar Rafael Henriquez Guerra[1,3], Lisa Almonte[1,3], Hao Li[4], Daniel Elvira[3], Reyes Calvo[1,2,3], and Andres Castellanos Gomez[4] — [1]BCMaterials, Basque Center for Materials, Applications and Nanostructures — [2]Ikerbasque, Basque Foundation for Science — [3]Depto. de Física Aplicada, Instituto Universitario de Materiales, Universidad de Alicante — [4]2D Foundry Group, Instituto de Ciencia de Materiales de Madrid, CSIC

This study investigates the impact of biaxial compressive strain on 2D materials at cryogenic temperatures, focusing on single-layer transition metal dichalcogenides (TMDs) and multilayered NbSe2. While tensile strain has been widely explored, compressive strain at low temperatures remains underexplored, despite its potential to significantly alter quantum properties such as magnetic and superconducting phase transitions. We show that biaxial compressive strain, induced by the thermal expansion mismatch between the polymer substrates and TMDs, leads to dramatic shifts in exciton energy and gauge factors, surpassing previous compressive strain effects. Moreover, we observe a consistent reduction in the superconducting critical temperature of NbSe2 flakes, with the most pronounced changes in thinner samples. Remarkably, this effect is still noticeable even for NbSe2 flakes as thick as 86 nm. These results highlight a powerful and cost-effective method for tuning phase transitions and other quantum phenomena in 2D materials at low temperatures.

HL 8.5 Mon 16:00 H15

Two-dimensional semiconductor with tunable bandgap close to the full visible spectrum: a MOCVD study — •Nils Langlotz, Robin Günkel, Tigmanshu Sundiyal, Oliver Massmeyer, Jürgen Belz, and Kerstin Volz — Department of Physics and Material Sciences Center, Philipps-University Marburg, Germany

Two-dimensional (2D) semiconductors have attracted considerable attention due to their extraordinary thickness-dependent properties. III-VI compounds such as GaSe or GaS exhibit a unique Mexican hat band structure with a van Hove singularity near the valence band maxima (VBM) at the Γ point. Furthermore, 2D GaSe and GaS as bulk material have a direct band gap of 2.0 eV and 2.5 eV, respectively, making a dilute $GaSe_xS_{1-x}$ system a tunable LED in the visible regime. Tuning the band gap in the few layer regime is also possible, but the indirect band gap has to be overcome, which is suggested by doping. Metal organic chemical vapour deposition (MOCVD) is used for the growth of bulk GaSe, GaS and $GaSe_xS_{1-x}$ on sapphire (0001). Growth for all materials was performed in an AIX200GFR at 50 mbar at 500°C in a flow modulated growth mode where the first pulse is 30 s of the gallium species and the second pulse is 30 s of selenium or sulphur, repeated for 150 cycles for the pure crystals. For the diluted crystal the second pulse is replaced by $(30-x)$ s of selenium followed by x seconds of sulphur. The organometallic precursors used were tri-tertiary-butyl-gallium (TTBGa), di-iso-propyl-selenide (DiPSe) and tertiary-butyl-sulphide (TBS). Raman spectroscopy is used to verify the selenium/sulphur incorporation.

HL 9: Oxide Semiconductors I

Time: Monday 15:00–16:30 Location: H17

HL 9.1 Mon 15:00 H17

Nitrogen Doping of Sputtered $BiVO_4$ Thin Films — •Hannah Sassenfeld[1,2], Tsedenia Zewdie[1,2], Ian D. Sharp[1,2], and Verena Streibel[1,2] — [1]Walter Schottky Institute, Technical University of Munich, D-85748 Garching, Germany — [2]Physics Department, TUM School of Natural Sciences, Technical University of Munich, D-85748 Garching, Germany

Bismuth vanadate ($BiVO_4$) is a promising photoanode material for photoelectrochemical (PEC) water splitting, given its suitable band gap (≈2.5 eV) and valence band maximum position relative to the water oxidation potential. Reducing the band gap of $BiVO_4$ can lead to a more effective utilization of the solar spectrum. One strategy towards band gap reduction is nitrogen incorporation, as previously reported by Irani et al. [1] and Kim et al. [2]. While both studies observe reduced band gaps, they do not agree on how nitrogen is incorporated into $BiVO_4$ and whether it improves or deteriorates PEC performance. To shed light onto the nature and effects of nitrogen incorporation, we use well-controlled reactive co-sputter deposition of $BiVO_4$ in nitrogen-containing environments (N:$BiVO_4$). Adjusting the amount of nitrogen in the reactive gas mixture and post-annealing treatments allow us to control the amount of incorporated nitrogen. Using this systematic sample library of N:$BiVO_4$, we interrogate the optical and structural properties of N:$BiVO_4$, its composition and electronic structure, and evaluate the impact of nitrogen incorporation on PEC performance.

HL 9.2 Mon 15:15 H17

Plasma Plume Deflection and Target Surface Roughness During Pulsed Laser Deposition of Functional Oxides — •Jonas Elz, Holger von Wenckstern, and Marius Grundmann — Leipzig University, Felix Bloch Institute for Solid State Physics, Semiconductor Physics Group, Leipzig, Germany

Pulsed laser deposition (PLD) is a highly flexible, fast and reproducible physical vapor deposition technique that uses a pulsed laser to evaporate a target material, producing an excited laser-induced plasma. Although simple in set-up, modeling the ablation process is difficult because of its non-equilibrium nature due to the high pulse energy incident on a short time scale (20 ns laser pulse width). Ablation of any target material requires optimization of the process parameters. Some targets used in PLD develop a rough surface structure upon longer use that causes the plasma plume to deflect toward the incoming laser beam during the ablation process. Typically, the plume deflection increases until a stable surface morphology is reached. In this work, we present a comparison of the plasma plume deflection with surface roughness and morphology of different PLD targets as measured by laser scanning microscopy. A Python script is used to evaluate plume images to determine the deflection angle.

HL 9.3 Mon 15:30 H17

Analysis of film thickness distributions for combinatorial pulsed laser deposition — •Clemens Petersen, Marius Grundmann, and Holger von Wenckstern — Universität Leipzig Felix-Bloch-Institut für Festkörperphysik, Leipzig, Deutschland

Recently combinatorial deposition methods have increasingly gained scientists* attention, due to the high experimental throughput and resource-wise efficiency they offer in materials discovery. They enable fast screening of material properties of multinary material systems using just a single sample. By employing pulsed laser deposition with our segmented target approach [1] we realized the deposition of α-$(Al_xGa_{1-x})_2O_3$ with continuous composition spread over the whole composition range on a single 2-inch sapphire wafer [2]. Accompanied by the usage of high-throughput measurements such as spectroscopic ellipsometry and X-ray diffraction, the characterization of physical properties with high chemical resolution and comparably low efforts becomes feasible.

Here we utilize a predictive numerical model, based on the corrected plasma expansion description of Anisimov *et al.* [3], for the calculation of binary growth rates of group-IIII and transition metal sesquioxides. Further the model can be applied to predict and model elemental composition and thickness distributions of ternary alloys for these materials. HL 9.4 Mon 15:45 H17

Influence of different gate metals on α-Ga_2O_3 MESFET device performance — •Sebastian Köpp, Clemens Petersen, Sofie Vogt, Holger von Wenckstern, and Marius Grundmann — Universität Leipzig, Felix Bloch Institute for Solid State Physics, Semiconductor Physics Group, Leipzig, Germany

We present metal-semiconductor field effect transistors (MESFET) on α-Ga_2O_3 grown by pulsed laser deposition in a two-step process on Al_2O_3 [5]. The MESFETs exhibit high on/off ratios above 9 orders of magnitude and subthreshold swings as low as 100 mV/dec. We evaluate different gate materials in an effort to optimize device switching and breakdown behaviour.

With its ultra-wide bandgap of 5.3 eV to 5.6 eV [1,2] and a high predicted breakdown field of 10 MV/cm [3], α-Ga_2O_3 is a promising material for high-power devices, as well as deep-UV photodetectors. α-Ga_2O_3, being isostructural to aluminium oxide, allows for heteroepitaxial growth on cost-efficient sapphire substrates, and also opens up the option of α-$(Al_xGa_{1-x})_2O_3$ alloys [4], potentially pushing device performance even further.

HL 9.5 Mon 16:00 H17

Adsorption-controlled growth of κ-Ga2O3 — •Alexander Karg[1], Niklas Krantz[1], Manuel Alonso-Orts[1,2], Marco Schowalter[1,2], Patrick Vogt[1,3], Andreas Rosenauer[1,2], and Martin Eickhoff[1,2] — [1]Institute of Solid State Physics, University of Bremen, Otto-Hahn-Allee 1, 28359 Bremen, Germany — [2]MAPEX Center for Materials and Processes, University of Bremen, Bibliotheksstraße 1, 28359 Bremen, Germany — [3]Max Planck Institute for solid state research, Heisenbergstraße 1, 70569 Stuttgart, Germany

The ultra-wide band gap semiconductor Ga2O3 can crystallize in at least 5 different polymorphs. For one of these, the metastable κ-Ga2O3, a spontaneous polarization along the c-axis is predicted [1]. Utilizing this property in heterostructure devices requires the formation of sharp, distinct interfaces between different alloyed layers to achieve high sheet carrier densities.

The recent development of suboxide MBE (S-MBE) has enabled the adsorption-controlled growth of Ga2O3 thin films [2]. In this contribution, S-MBE is specifically applied to the growth of metastable, orthorhombic κ-Ga2O3. The growth process, phase stabilization, and their impact on layer properties are analyzed in detail. This is combined with the use of indium as surfactant. Additionally, the study is complemented by the realization of κ-Ga2O3-based heterostructures using suboxide MBE [3].

HL 9.6 Mon 16:15 H17

Realization of highly rectifying pn-heterojunctions on pulsed laser deposited α-Ga_2O_3 thin films — •Paul Bokemeyer, Sofie Vogt, Clemens Petersen, Holger von Wenckstern, and Marius Grundmann — University Leipzig, Felix-Bloch-Institut für Festkörperphysik, Linnestr. 5, Leipzig, Germany

The wide band gap of about 5.3 eV[1], the possibility for adjusting the band gap energy by alloying with isostructural aluminum oxide or indium oxide[1] and a high expected breakdown field of up to 10 MV/cm[2], renders the corundum α-phase of Ga_2O_3 interesting for high power applications. We present lateral p^+n-heterojunction diodes on α-Ga_2O_3:Sn grown by pulsed laser deposition(PLD) using a two step approach[3]. Room temperature deposited ZnCoO(ZCO) (PLD), NiO (PLD) and CuI (PLD and sputtering) were used as p^+-type materials. We further investigated the influence of a remote oxygen plasma treatment prior to the deposition of the p-type layers on the device performance. High current rectification ratios of of 8.2 (ZCO), 7.8 (NiO), and 5.1 (CuI) orders of magnitude at ± 3V were achieved. Additionally, α-Ga_2O_3:Zr junction-field-effect-transistors(JFETs) with ZCO and NiO as gate materials were fabricated, yielding on/off ratios of more than 9 orders of magnitude and sub-threshold-swings down to 119 mV/dec.

HL 11: Ultra-fast Phenomena I

Time: Monday 16:00–18:45 Location: H14

HL 11.1 Mon 16:00 H14

Femtosecond Photocurrents in 2D materials — •Björn Sinz[1,2], Johannes Schmuck[1,2], Johannes Gröbmeyer[1,2], Nina Pettinger[1,2], Sergey Zherebtsov[1,2], and Alexander Holleitner[1,2] — [1]Walter Schottky Institute and Physics Department, TU Munich, Munich, Germany — [2]Munich Center of Quantum Science and Technology (MCQST), Munich, Germany

Light-field-driven currents have already been investigated in graphene by ultrashort laser pulses. In the strong-field regime, the electric field directly generates such photocurrents on a time scale of femtoseconds, whereas in the weak-field regime other photogeneration processes like the photo-thermoelectric effect dominate [1]. The different photocurrents are not limited to graphene but are also predicted for transition metal dichalcogenide (TMDC) monolayers. We report on femtosecond-pulse driven photocurrents in monolayer TMDC samples.

HL 11.2 Mon 16:15 H14

Hot-Electron-Induced Substrate Response in Transient Absorption Spectroscopy of Tantalum — •Erik Willem de Vos[1,2], Sergej Neb[1], Marko Hollm[1], Florence Burri[1], Lukas Gallmann[1], and Ursula Keller[1] — [1]Department of Physics, Institute for Quantum Electronics, ETH Zurich, Switzerland — [2]Department of Materials, ETH Zurich, Zurich, Switzerland

We show that for extreme ultraviolet transient absorption spectroscopy measurements on thin-film metals, the substrate can significantly contribute to the observed change in absorption even if the substrate is transparent to the excitation wavelengths of the pump pulse and does by itself not produce a transient signal. Irradiation of a thin-film tantalum layer deposited on a silicon nitride substrate by a near-infrared femtosecond pulse is found to excite a coherent acoustic phonon in both the tantalum as well as the substrate. The response in the substrate rises on sub-picosecond timescales and is the result of direct excitation by the hot-electron distribution in the metal layer.

HL 11.3 Mon 16:30 H14

Nonequilibrium electron-phonon dynamics: dynamical control of quantum matter — •Yaxian Wang — Institute of Physics, Chinese Academy of Sciences

Electron-phonon interaction is an old yet evergreen problem in condensed matter physics. It is closely related to many quantum states we are concerned with, such as superconductivity, charge density waves, and polarons. It also profoundly affects, or often accompanies, critical phenomena such as the formation of excitonic insulators and metal-insulator transitions. When the system is driven out of equilibrium, for example pumped by an ultrafast laser pulse, the potential energy surface and thus the coupling in the excited states can be greatly reshaped, and this may open up a new avenue of ultrafast coherent control of quantum phases and topological orders. However, theoretical approaches often fail to capture the coupled dynamics of the non-thermal excited carriers and the nonequilibrium lattice order. In this talk, I will introduce how light-induced coherent phonons can cause a quasi-static lattice distortion and result in a Lifshitz transition in a nodal-line semimetal. We also demonstrate how the laser energy can shift the quasi-equilibrium lattice structure towards opposite directions, thus engineering the electronic structure via different regimes. Moreover, I will discuss our recent discovery on how nonequilibrium electron-phonon interaction can interact with the spin degree of freedom, causing ultrafast demagnetization and excitation of chiral phonons in a monolayer ferromagnet.

HL 11.4 Mon 16:45 H14

Nonequilibrium control of the ultrafast electron dynamics in semiconductors via light-driven coherent phonons — •Chenyu Wang[1,2], Yaxian Wang[1], and Sheng Meng[1,2,3] — [1]Institute of physics, Chinese Academy of Sciences — [2]School of physical sciences, University of Chinese Academy of Sciences — [3]Songshan Lake Materials Laboratory

Driving lattice vibration with a high degree of spatial and temporal coherence via strong light-matter interactions has emerged as a unique knob to control the out-of-equilibrium quantum states and the exotic ultrafast phenomena.

In this talk, I will present our recent theoretical works on the exploration and understanding of how the coherent phonon excitation can be utilized to control the electronic behaviors on ultrafast timescales, for example to engineer the carrier transport in monolayer WSe2 and to manipulate the nonrelativistic spin splitting in the prototypical altermagnetic semiconductor MnTe.

In photoexcited monolayer WSe2, we observe an unconventional 'step-like' electron intervalley scattering dynamics and meanwhile a Rabi oscillation driven by the coherent phonons, as a direct manifestation of the nonadiabatic electron-phonon coupling beyond equilibrium; On the other side, we demonstrate the light-driven coherent phonon can also be utilized to break the crystal symmetry in the altermagnet MnTe. Such symmetry breaking phase holds an extra spin-splitting particularly in the zone center, and thus a strongly enhanced spontaneous anomalous Hall effect.

HL 11.5 Mon 17:00 H14

Semiconductor Bloch Equations and Ehrenfest Dynamics in a Wannier Function Framework: An Integrated Approach to Ultrafast Electron and Ion Dynamics — •Stefano Mocatti, Giovanni Marini, Giulio Volpato, Pierluigi Cudazzo, and Matteo Calandra — Department of Physics, University of Trento, Via Sommarive 14, 38123 Povo, Italy

Real-time simulations of photoexcited semiconductors offer valuable insights but are challenged by the complex interplay of interactions and high computational cost. Here, we present an efficient ab initio scheme within the EPIq code, combining semiconductor Bloch equations with Ehrenfest dynamics in the Wannier representation. Electron-phonon and electron-electron interactions follow a Fan-Migdal+GW approximation, while phonon-phonon interactions include non-perturbative quantum anharmonic effects. Through the real-time tracking of the dynamics, we find that electron-electron interaction dominates photocarrier thermalization, yielding a double chemical potential electronic Fermi distribution. Furthermore, atomic forces converge to those calculated within constrained density functional perturbation theory. This work connects out-of-equilibrium and quasi-equilibrium states, advancing the understanding of ultrafast light-driven phenomena.

The screening of core excitons is an inherent many-body process that can reveal insight into charge-transfer excitations and electronic correlations. Here we demonstrate the dynamic Coulomb screening induced by photoexcited carriers on core excitons employing X-ray transient absorption (XTA) spectroscopy with picosecond time resolution. Our interpretation is supported by state-of-the-art *ab initio* calculations including many-body perturbation theory. Using ZnO as an archetypal wide band-gap semiconductor, we show that the Coulomb screening modification at the Zn L_3- and K-edge leads to a decrease in the core-exciton binding energy. We also theoretically predict the effect of core-exciton screening on the femtosecond time scale for the case of ZnO, a major step towards hard X-ray excitonics. The results have implications for the interpretation of ultrafast X-ray spectra in general and their use in tracking charge carrier dynamics in complex materials on atomic length scales.

HL 11.7 Mon 17:45 H14

Ultrafast Coherent Dynamics of a Hybrid WS2/Plasmon Structure Probed by Two-Dimensional Electronic Spectroscopy — •Daniel Timmer[1], Moritz Gittinger[1], Daniel C. Lünemann[1], Thomas Quenzel[1], Sven Stephan[1,2], Martin Silies[1,2], Antonietta De Sio[1], and Christoph Lienau[1] — [1]IfP, Carl von Ossietzky Universität Oldenburg, Oldenburg, Germany — [2]ILO, Hochschule Emden/Leer, Emden, Germany

Transition metal dichalcogenide (TMD) monolayers (1L) have been established as important building blocks for quantum materials. Hybridization between

light and matter states, in particular in plasmonic nanostructures, offers great opportunities to tailor their optical and electronic properties [1]. Here, we investigate such a hybrid plasmonic structure in the intermediate coupling regime comprised of 1L-WS2 [2] placed on a periodic silver nano-slit array using ultrafast two-dimensional electronic spectroscopy (2DES). We observe a 20-fold increase of the optical nonlinearity and ultrafast coherent plexciton dynamics during the dephasing time (~50 fs). We rationalize our observations via a Tavis-Cummings model that gives rise to collective dark states and a Rabi contraction of the 2-quantum states. Using ultrafast 2DES, we obtain access to probe and disentangle the coherent and incoherent dynamics in TMD-based plasmonic systems. [1]: Timmer et al. "Plasmon mediated coherent population oscillations in molecular aggregates." Nat. Commun. 14.1 (2023): 8035. [2]: Timmer et al. "Ultrafast Coherent Exciton Couplings and Many-Body Interactions in Monolayer WS2" Nano Lett. 24.26 (2024): 8117-8125.

HL 11.8 Mon 18:00 H14

Excited-state symmetry breaking and antisymmetric mode brightening in quadrupolar dye — •Somayeh Souri[1], Katrin WInte[1], Daniel Lünemann[1], Fulu Zheng[2], Mohamed Madjet[2], Teresa Kraus[3], Elena Mena-Osteritz[3], Peter Bäuerle[3], Sergei Tretiak[4], Antonietta De Sio[1], and Christoph Lienau[1] — [1]Oldenburg University, Germany — [2]Bremen University, Germany — [3]Ulm University, Germany — [4]Los Alamos National Laboratory, USA

Quadrupolar acceptor-donor-acceptor (A-D-A) dyes are chemically tunable materials displaying a rapid photo-induced charge transfer of interest for applications in solution-processed photovoltaics. The origin of the ultrafast charge transfer is unknown. Using sub-10-fs ultrafast spectroscopy, we investigate the excited-state dynamics of a prototypical A-D-A with comparable electronic and vibronic coupling strengths. Our results reveal that vibronic couplings to high-frequency C-C-stretching vibrations on each arm of the quadrupolar dye induce a double-minimum potential energy surface (PES) in the excited-state S1 driving symmetry breaking along the antisymmetric vibrational coordinate (Q-). Upon excitation, this induces periodic splitting of the optically launched coherent wavepacket along Q- with 20-fs period, rapidly relaxing into local minima of the symmetry-broken PES within less than 100 fs. Our results demonstrate highly nonadiabatic vibronic quantum dynamics, theoretically predicted for this class of dyes [1], and unravel their role for the ultrafast charge transfer in this class of molecules. [1] J. Chem. Phys. 141, 164317 (2014).

HL 11.9 Mon 18:15 H14

Phonon-driven exciton population oscillations in Methylammonium Lead Bromide Perovskites. — •Mohsin Sayar[1], Katrin Winte[1], Daniel Timmer[1], Somayeh Souri[1], Davide Ceratti[2], David Cahen[2], Christoph Lienau[1], and Antonietta De Sio[1] — [1]Carl von Ossietzky Universität, Oldenburg, Germany. — [2]Weizmann Institute of Science, Rehovot, Israel

Halide perovskites exhibit unique optoelectronic properties significantly influenced by electron-phonon interactions. Recent work shows that the internal fields induced by coherent lattice motions can transiently control ultrafast excitonic optical response in bulk $CsPbBr_3$[1]. Here, we demonstrate this behaviour also in $CH_3NH_3PbBr_3$ across different crystal phases, using temperature-dependent ultrafast transient reflectivity with 10 fs time resolution. Following resonant exciton excitation reveals coherent low-frequency phonon oscillations at 40cm^{-1} and 67cm^{-1}, corresponding to Pb-Br-Pb bending and stretching modes[2] that most strongly couple to the exciton. Additionally, we observe faster oscillations with dominant period of 105 fs in all crystal phases, arising from coherent exciton population transfer between 1s and 2p excitonic states, off-resonantly driven by the low-frequency phonon fields. We rationalize these results by a phenomenological model accounting for the coupling of excitons to the low frequency phonon modes and coupling of 1s-2p vibronic manifolds via the phonon fields[1]. These results may have important implications for transiently modifying the optoelectronic properties of perovskites.

HL 11.10 Mon 18:30 H14

Coherent suppression of high-harmonic generation in Dirac materials — •Wolfgang Hogger[1], Alexander Riedel[1], Debadrito Roz[2], Angelika Knothe[1], Cosimo Gorini[3], Juan-Diego Urbina[1], and Klaus Richter[1] — [1]Institute for theoretical physics, University of Regensburg, Germany — [2]Indian Institute of Science, Bengaluru 560012, India — [3]Université Paris-Saclay, CEA, CNRS, SPEC, 91191, Gif-sur-Yvette, France

The study of high-harmonic generation in solids by intense laser pulses provides a fascinating platform for studying ultra-fast electron dynamics and material properties, where the coherent character of the electron dynamics is a central aspect. Starting with the semiconductor Bloch equations, we show the ubiquitous presence of a mechanism suppressing the high harmonic spectrum arising from the coherent superposition of intra- vs inter-band contributions to the total signal [1]. We provide evidence for the generality of this phenomenon by extensive numerical simulations exploring the parameter space of this coherent suppression of high harmonic generation in systems of massive Dirac Fermions (as a prototypical model for topologically non-trivial matter [2]), systems with a pseudo- relativistic dispersion. We supplement our numerical observations with analytical results for a simplified single-mode analysis.

kdotpy: A Python application for k·p band structure simulations of zincblende semiconductors — •Wouter Beugeling[1,2], Florian Bayer[1,2], Christian Berger[1,2], Jan Böttcher[3], Leonid Bovkun[1,2], Christopher Fuchs[1,2], Maximilian Hofer[1,2], Saquib Shamim[1,2], Moritz Siebert[1,2], Li-Xian Wang[1,2], Ewelina M. Hankiewicz[3], Tobias Kiessling[1,2], Hartmut Buhmann[1,2], and Laurens W. Molenkamp[1,2] — [1]Physikalisches Institut (EP3), Universität Würzburg, Am Hubland, 97074 Würzburg, Germany — [2]Institute for Topological Insulators, Am Hubland, 97074 Würzburg, Germany — [3]Institut für Theoretische Physik und Astrophysik (TP4), Universität Würzburg, Am Hubland, 97074 Würzburg, Germany

The software project kdotpy aims at simulations of electronic band structures of semiconductor devices with k·p theory. The application implements the widely used Kane model, capable of reliable predictions of transport and optical properties for a large variety of topological and non-topological materials with a zincblende crystal structure.

In this presentation, I present the core functionality and features of kdotpy. I will explain how we have implemented principles of modern software engineering and good scientific practice in this project.

HL 12.2 Mon 17:00 H15

End states in zigzag Haldane model nanoribbons — Simone Traverso, Maura Sassetti, and •Niccolò Traverso Ziani — Physics Department, University of Genova, Italy

As topological materials based on the graphene lattice become experimentally realizable in materials such as germanene, the physics of the bound states that characterize them at step edges and in quasi one-dimensional settings becomes relevant.

In this context, the appearance of topological bound states in zigzag Haldane nanoribbons will be addressed [1]. A reentrant topological phase diagram is found. Together with numerical results, a low energy theory extending the Jackiw-Rebbi paradigm will be presented.

HL 12.3 Mon 17:15 H15

Time-reversal invariant Chalker-Coddington model and the real-space renormalisation group — •Syl Shaw and Rudolf A. Römer — Department of Physics, University of Warwick, Coventry, CV4 7AL, UK

The Chalker-Coddington model has been utilised to great success in understanding the plateau transitions in the quantum Hall effect. Since the model's inception, it has been extended to a time-reversal invariant symmetry class to describe the quantum-spin Hall effect. Here we adapt a real-space renormalisation group method[1] to respect time-reversal symmetry and use it investigate the phase diagram of the quantum-spin Hall effect. We aim to find distinct phases as a function of both saddle-point height, z and spin-mixing angle ϕ. At the phase boundary between insulator and metal, we compute the value of the critical exponent of the localisation length, ν, with the same real-space renormalisation technique. [1] S. Shaw, R. A. Römer Physica E 165, 116073 (2025)

HL 12.4 Mon 17:30 H15

Utilizing Silicon Qubit Devices for Quantum Electrical Metrology — •Dustin Wittbrodt[1], Johannes Christian Bayer[1], Lars Schreiber[2,3], Janne Lehtinen[4], Marcelo Jaime[1], and Frank Hohls[1] — [1]Physikalisch-Technische Bundesanstalt, Braunschweig, Germany — [2]RWTH Aachen University, Aachen, Germany — [3]Forschungszentrum Juelich, Juelich, Germany — [4]SemiQon Technologies Oy, Espoo, Finland

The 2019 redefinition of the SI system established fixed values for fundamental constants such as the elementary charge (e) and the Planck constant (h), enabling the quantum realization of the units of Ampere, Volt, and Ohm. While the quantum realization of Volt and Ohm is well-established, the realization of the Ampere, whether directly through Single Electron Pumps (SEPs) or indirectly via the Volt and Ohm, has yet to achieve the same level of accuracy. Moreover, further device applications in practical circuits require paralelization approaches to achieve higher current outputs. The international project "Advanced Quantum Technology for Metrology of Electrical Currents" (AQuanTEC) aims to upscale SEPs beyond the 1 nA threshold. To achieve this, AQuanTEC explores several strategies, including the use of silicon devices first designed for spin qubit realization. These devices are highly promising due to their potential scalability, driven by ongoing advancements in integrating large numbers of qubits.

HL 12.5 Mon 17:45 H15

Surface state dominated transport in HgTe topological insulator devices — •Maximilian Hofer[1,2], Christopher Fuchs[1,2], Lena Fürst[1,2], Tobias Kiessling[1,2], Wouter Beugeling[1,2], Hartmut Buhmann[1,2], and Laurens W. Molenkamp[1,2] — [1]Physikalisches Institut, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany — [2]Institute for Topological Insulators, Am Hubland, 97074 Würzburg, Germany

Recently grown three dimensional topological insulators based on tensile strained HgTe exhibit an exceptionally high mobility and very low intrinsic carrier density. The high quality material has made it possible to study the Landau level dispersion at low magnetic fields and identify four distinct transport regimes. We demonstrate that while a contribution from the topological surface states to transport measurements is expected across the full experimentally accessible density range, there exists only a narrow density regime for which the electronic transport is exclusively carried by the topological surface states. We present the corresponding phase diagram for pure topological surface state transport depending on layer thickness and carrier concentration. For thick HgTe films grown pseudomorphically strained on CdTe, the total carrier density needs to be kept between 1.8×10^{11} cm^{-2} and 2.6×10^{11} cm^{-2} to remain in the pure surface state region and avoid contributions from bulk states. The experimental observations are supported by eight band $\boldsymbol{k} \cdot \boldsymbol{p}$ band structure calculations.

HL 12.6 Mon 18:00 H15

Designing a quantum sorter based on two-dimensional topological insulators — •Amanda Teodora Preda[1,2], Iulia Ghiu[2], Lucian Ion[2], Andrei Manolescu[3], and George Alexandru Nemnes[1,2] — [1]Horia Hulubei National Institute for Physics and Nuclear Engineering, Reactorului 30, Magurele- Ilfov, 077125, Romania — [2]University of Bucharest, Faculty of Physics, Atomistilor 405, Magurele-Ilfov, 077125, Romania — [3]Department of Engineering, Reykjavik University, Menntavegur 1, Reykjavik IS-102, Iceland

The idea of a quantum sorter emerged in quantum information, a field that aims to exploit quantum effects and manipulate qubits for information processing. In theory, it was proven that one can propose a universal quantum sorter for any arbitrary observable. To this point, suitable experimental schemes of implementation for this proposal were explored mainly in quantum optics. In our study, we introduce a solid-state version of a quantum sorter, based on a multi-terminal mesoscopic device with multiple output ports, that aims to separate the incoming states by both their spin and transversal mode. In order to maximize the state-separation efficiency of such a device, we chose to exploit the unique transport properties of topological insulators. Employing the tight-binding based simulation package Kwant, we modeled a device that meets the criteria of an irreversible quantum sorter, using the well-established BHZ Hamiltonian to simulate a multi-terminal quantum system made up of both trivial and topological materials.

reducing waste through substrate reuse: a pathway to cost-effective iii-v optoelectronics — •radouane ennadir — 3IT, Sherbrooke University, Sherbrooke, QC, Canada

III-V materials, such as Gallium Arsenide (GaAs), are widely used in optoelectronic devices due to their superior electronic and optical properties. However, the high cost of III-V substrates, primarily made from Ge or other expensive materials, represents a significant barrier to the widespread adoption of these technologies. Our research focuses on reducing waste in the production of III-V optoelectronics through the reuse of Germanium (Ge) substrates. In this study, we propose a novel approach to mitigate substrate waste by reusing Ge substrates in the fabrication of III-V optoelectronics. By carefully optimizing the recycling process, including substrate cleaning, surface treatment, and the integration of new III-V layers, we aim to significantly reduce material costs without compromising device performance. This approach not only enhances the sustainability of optoelectronic manufacturing but also provides a cost-effective pathway to large-scale production of III-V-based devices. The findings of this study contribute to both environmental sustainability and economic viability in the growing field of optoelectronics, opening up new opportunities for the development of advanced, cost-effective optoelectronic devices.

HL 13.2 Mon 17:00 H17

Understanding local charge transfer processes in nanostructured photosystems — •Nina Miller, Sven Doll, Sergej Levashov, Lukas Wolz, Matthias Kuhl, and Johanna Eichhorn — Physics Department, School of Natural Sciences, Technical University of Munich, Am Coulombwall 4, 85748 Garching, Germany

Photoelectrochemical energy conversion offers a promising approach for directly converting solar energy into storable chemical fuels. For scalability, photoelectrodes are often fabricated using thin film technologies yielding material architectures with complex micro- and nanoscale structures. One challenge in this context is that the characteristics of these nanostructured material architectures often deviate from the properties of idealized model systems. To understand energy conversion processes at surfaces and interfaces of nanostructured material systems, novel atomic force microscopy methods have emerged recently, such as AFM-based scanning electrochemical microscopy, to resolve local chemical transformations, charge transport, and material changes under operation conditions. By correlating nanoscale and macroscale properties, we will establish the link between nanoscale processes and macroscopic performance, advancing the design of efficient semiconductor/catalyst systems for PEC applications.

HL 13.3 Mon 17:15 H17

Simulation of charge and excitation dynamics across nanostructured organic-organic interfaces — •Giacomo Cotelli[1,2], Engin Torun[2], Stefano Gottardi[2], and Anna Köhler[1] — [1]Soft Matter Optoelectronics (EP II), University of Bayreuth, Bayreuth 95440, Germany — [2]Simbeyond B.V., Eindhoven, The Netherlands

The deposition of organic layers via solution processing may lead to rough interfaces or intermixed regions between layers. To investigate the impact of roughness at organic-organic interfaces on the performances of OLEDs, we performed 3D kinetic Monte Carlo simulations of symmetrical bi- and three-layer devices. Our results reveal that the macroscopic behaviour of a device can be significantly affected by the shape and size of roughness at the organic interfaces, influencing both charge and exciton dynamics.

Namely, we introduced interfaces with periodic corrugation and either triangular or rectangular cross-section. In presence of charge accumulation at an interface with triangular cross-section, bilayer devices exhibit strong inhomogeneity in the spatial distribution of charge carriers, excitons and excitonic losses. Comparison to a flat-interface device reveals an increment in current density by a factor from 2 to 10^3, depending on the height of the energy barrier at the interface. This current density boost was successfully applied to improve charge injection towards a central emissive layer (EML) in simulated three-layer devices; the size and configuration of the interfaces can also be leveraged to fine-tune the recombination zone inside the EML. Nevertheless, we raise our concerns in terms of increased local material degradation.

HL 13.4 Mon 17:30 H17

Strain gradients in bent GaAs nanowires as a new way of engineering electronic transitions — •Francisca Marín[1], Yiannis Hadjimichael[2], Christian Merdon[2], Patricio Farrell[2], Constanza Manganelli[3], Oliver Brandt[1], and Lutz Geelhaar[1] — [1]Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e. V. Berlin, Germany — [2]Weierstraß-Institut für angewandte Analysis und Stochastik. Berlin, Germany — [3]Institut für Halbleiterphysik, Leibniz-Institut für innovative Mikroelektronik. Frankfurt (Oder), Germany

Strain gradients open up a new degree of freedom in strain engineering, enabling polarization in all dielectric materials through the flexoelectric effect. However, flexoelectric coefficients remain unknown for many inorganic semiconductors, including GaAs, leaving this phenomenon unexplored in this material system.

Here, we exploit the pronounced strain gradient in bent GaAs nanowires grown by molecular beam epitaxy to study this effect using photoluminescence spectroscopy. Strain and strain gradients in these nanowires influence the bandgap and generate electric fields from piezoelectric and flexoelectric effects. By combining experiments with a simple one-dimensional model to calculate

the expected shift of the electronic transitions, and finite element simulations of piezoelectricity, we provide new insights into flexoelectricity in GaAs.

HL 13.5 Mon 17:45 H17

Understanding Local Charge Transport Using Advanced Kelvin Probe Force Microscopy — •Sven Erik Doll, Sergej Levashov, Nina Miller, and Johanna Eichhorn — Department of Physics, TUM School of Natural Sciences, Technical University of Munich, Am Coulombwall 4, 85748 Garching, Germany

Efficient photosystems for solar-to-chemical energy conversion are often based on nanostructured semiconductor architectures. In these material systems, the nanoscale properties frequently dominate the performance at the macroscale. Therefore, local understanding of their charge transfer and transport properties is decisive for optimizing their efficiency and stability.

To this end, we use Kelvin probe force microscopy (KPFM) in a controlled atmosphere to spatially resolve band bending, charge accumulation, and local variations of the generated surface photovoltage. However, analyzing nanostructured materials with complex morphologies is not trivial since topographic crosstalk can dominate the results. To overcome these limitations, we combine a commercial AFM with an external Lock-In amplifier to enable dual-frequency and heterodyne KPFM measurements with improved resolution and sensitivity compared to conventionally frequency-modulated and amplitude-modulated KPFM modes. Here, we compare different KPFM modes and highlight the importance of careful imaging and data analysis to reveal insights into local semiconductor material properties at grain boundaries or different facets.

HL 13.6 Mon 18:00 H17

Topological Phase Diagram of Mercury Cadmium Telluride Quantum Wells — •Leonid Bovkun[1,2], Lena Fürst[1,2], Christopher Fuchs[1,2], Vladimir Marković[1,2], Maximilian Hofer[1,2], Moritz Siebert[1,2], Christian Berger[1,2], Florian Bayer[1,2], Wouter Beugeling[1,2], Steffen Schreyeck[1,2], Hartmut Buhmann[1,2], Laurens W. Molenkamp[1,2], and Tobias Kiessling[1,2] — [1]Physikalisches Institut (EP3), Universität Würzburg, Am Hubland, 97074 Würzburg, Germany — [2]Institute for Topological Insulators, Am Hubland, 97074 Würzburg, Germany

The key ingredient for the formation of a topological insulator phase in Mercury Cadmium Telluride is the inversion of the energetic positions of the electronic Γ_6 and Γ_8 bulk bands, that can be controlled by alloying with Cd to get within reach of electronic tunability.

We present a systematic experimental study of the topological phase transition in a series of ~ 10 nm thick $Hg_{1-x}Cd_xTe$ quantum wells by tuning the Cd content x. We provide detailed structural and magneto-optical spectroscopic characterization measurements and establish a comprehensive picture of the alloy structural and energetic properties.

Using these as input, we employ $\mathbf{k} \cdot \mathbf{p}$ modeling to establish the topological phase diagram of $Hg_{1-x}Cd_xTe$ in dependence of the Cd content and quantum well thickness for thin films which are pseudomorphically strained to the lattice constant of pure CdTe.

HL 13.7 Mon 18:15 H17

Electrostatic control of the band structure in HgTe heterostructures — •Moritz Siebert[1,2], Maximilian Hofer[1,2], Leonid Bovkun[1,2], Vladimir Marković[1,2], Christian Berger[1,2], Florian Bayer[1,2], Julian Kuther[1,2], Daniel Michel[1,2], Lena Fürst[1,2], Christopher Fuchs[1,2], Wouter Beugeling[1,2], Steffen Schreyeck[1,2], Hartmut Buhmann[1,2], Laurens W. Molenkamp[1,2], and Tobias Kiessling[1,2] — [1]Physikalisches Institut (EP3), Universität Würzburg, Am Hubland, 97074 Würzburg, Germany — [2]Institute for Topological Insulators, Am Hubland, 97074 Würzburg, Germany

We investigate the band structure of topologically inverted thick HgTe quantum wells employing magneto-optical THz- and IR-spectroscopy. The lithographic fabrication of a semi-transparent gate enables control of the charge carrier density in the quantum well. Our magnetic field dependent self-consistent $\mathbf{k} \cdot \mathbf{p}$ band structure calculations give insights into the physical origin of the observed spectral signatures. In this talk, I present how the electrostatic gating not only sets the number of free charge carriers in the HgTe quantum well - but also modifies the electronic dispersion - and explain the observed features.

HL 15.1 Tue 9:30 H13

Predictive theory of multi-particle states of GaAs quantum dots — •Petr Klenovsky — Masaryk University, Brno, Czech Republic — Czech Metrology Institute, Brno, Czech Republic

The correlated multi-particle electronic structure of GaAs quantum dots (QDs) in AlGaAs matrix is studied. GaAs QDs have unique physical properties, like an absence of built in strain as well as exhibiting the effects of the weak confinement, leading to the superradiance. GaAs QDs are an almost ideal candidate as a source of single and entangled photons for usage in quantum cryptography and computing. Unfortunately, so far current physics models of their electronic structure were not successful to *quantitatively* reproduce observed experimental results like, e.g., binding energies of trions (X+ and X-) and biexciton (XX) with respect to exciton (X) as well as the radiative emission of those complexes. We endeavored to change that and show in this contribution the results of our improved theory model based on $\mathbf{k} \cdot \mathbf{p}$ approximation and configuration interaction (CI) schemes. Using that we demonstrate computed binding energies of X+, X-, and XX in agreement with experiment which are also *converged* with respect to the size of CI basis, i.e., they include the effects of the Coulomb correlation. While the latter is found to be of a paramount role, surprisingly, we also find that the binding energies strongly depend on the way the electron-electron and hole-hole *exchange* integrals are calculated. Our results show very good agreement with photoluminescence and nuclear spin relaxation experiments on GaAs/AlGaAs QDs.

HL 15.2 Tue 9:45 H13

Electron capture and emission dynamics of self-assembled quantum dots far from equilibrium — •Maximilian Erdmann[1], Jan Lange[1], Lukas Berg[1], Laurin Schnorr[1], Thomas Heinzel[1], Severin Krüger[2], Arne Ludwig[2], and Andreas Wieck[2] — [1]Condensed Matter Physics Laboratory, Heinrich Heine University, Düsseldorf, Germany — [2]Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität, Bochum, Germany

The subject of the experiment were the electron capture and emission dynamics of Self-Assembled Quantum Dots (SAQD) far away from equilibrium conditions, at a temperature of 77 K. The SAQDs are located in a semiconductor structure that can be regarded as a Schottky diode. For analysing the capture and emission dynamics, the capacitance transients of this sample were investigated using the methods of Deep Level Transient Spectroscopy (DLTS).

HL 15.3 Tue 10:00 H13

Spatial Statistics of InAs Quantum Dots on GaAs(100) — •Normen Auler[1], Viktoryia Zolatanosha[2], and Dirk Reuter[1,2,3] — [1]Department Physik, Universität Paderborn, DE — [2]Institute for Photonic Quantum Systems (PhoQS), Universität Paderborn, DE — [3]Center for Optoelectronics and Photonics Paderborn (CeOPP), Universität Paderborn, DE

Self-assembled InAs quantum dots (QDs) on GaAs are potential building blocks for quantum technology applications. One interesting aspect is the spatial arrangement of the QDs.

In this contribution, we investigated the spatial distribution of QDs for samples with different QD densities by analyzing atomic force microscopy images. We evaluated Voronoi cell areas and nearest neighbor configurations. Contrary to the expected random distribution for Stranski-Krastanow-grown QDs, we observe deviations indicating an influence of strain fields and a corresponding effect on inter-island adatom diffusion on the final QD arrangement. We discuss the behavior for different densities in detail.

HL 15.4 Tue 10:15 H13

Epitaxial growth and in-situ integration of high-quality single InGaAs quantum dots on a silicon substrate — •Imad Limame[1], Peter Ludewig[2], Aris Koulas-Simos[1], Chirag C. Palekar[1], Wolfgang Stolz[2], and Stephan Reitzenstein[1] — [1]Technische Universität Berlin — [2]NAsP III/V GmbH, Marburg, Deutschland

For over two decades, the integration of light sources onto the silicon (Si) platform has garnered significant interest in both scientific and industrial commu-

nities. Despite the cost-effectiveness of Si and its extensive use in semiconductor technology, its indirect bandgap limits its potential for optoelectronic applications. The direct growth of III-V materials, which offer excellent optical properties, on Si is appealing but challenging due to factors such as lattice mismatch, differences in thermal expansion coefficients, Si surface reactivity, and dislocation formation. We report on the direct epitaxial growth of InGaAs QDs in both the 940 and 1300 nm ranges with excellent quantum optical properties on a Si substrate. The heteroepitaxy of GaAs heterostructures on Si is achieved using a GaP buffer layer. The resulting QDs exhibit outstanding optical properties, showcasing the significant potential of this approach. Furthermore, using a strain-reducing layer (SRL), we grow single QDs in the telecom O-band, which are then integrated via in-situ electron beam lithography (EBL) into circular Bragg gratings (CBG) to enhance extraction efficiency for quantum communication applications.

Our results represent a significant step toward scalable, cost-effective, and Si-compatible quantum photonics devices.

HL 15.5 Tue 10:30 H13

Electrostatic Inter-Layer Coupling between Self-Assembled Quantum Dots — •Jan Lange[1], Lukas Berg[1], Laurin Schnorr[1], Thomas Heinzel[1], Charlotte Rothfuchs-Engels[2], Nikolai Bart[2], Arne Ludwig[2], and Andreas Wieck[2] — [1]Condensed Matter Physics Laboratory, Heinrich Heine University, Düsseldorf, Germany — [2]Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität, Bochum, Germany

Electrostatic coupling between Self-Assembled Quantum Dots (SAQDs) in spatially separated layers is studied using transient capacitance spectroscopy. The coupling effect is analysed as a function of temperature, applied bias voltage, and the occupancy of the quantum dot layers. The observed interaction is attributed to the electric field modulation induced by charge redistribution in one layer, influencing the capture and emission dynamics in the other. A rate equation model was developed, incorporating self-consistent band bending calculations, to describe the impact of the inter-layer coupling on the charge transfer processes. The findings indicate that the coupling arises from the electrostatic field generated by the charged quantum dots in the adjacent layer, providing a quantitative explanation for the altered capacitance transients.

HL 15.6 Tue 10:45 H13

Photoluminescence from SiGe and Ge quantum dots on Si nanotips: role of composition and capping — •Diana Ryzhak[1], Johannes Aberl[2], Enrique Prado-Navarrete[2], Lada Vukušić[2], Agnieszka Anna Corley-Wiciak[1], Oliver Skibitzki[1], Marvin Hartwig Zoellner[1], Markus Andreas Schubert[1], Michele Virgilio[3], Moritz Brehm[2], Giovanni Capellini[1,4], and Davide Spirito[1] — [1]IHP Leibniz-Institut für innovative Mikroelektronik, Im Technologiepark 25, 15236 Frankfurt (Oder), Germany — [2]Institute of Semiconductor and Solid State Physics, Johannes Kepler University Linz, Altenberger Strasse 69, 4040, Linz, Austria — [3]Dipartimento di Fisica E. Fermi, Università di Pisa, Largo Pontecorvo 3, 56127, Pisa, Italy — [4]Dipartimento di Scienze, Università Roma Tre, V.le G. Marconi 446, 00146 Roma, Italy

Quantum dots (QDs) have been studied for their unique optical properties, which are essential for LEDs and lasers. The main challenge remains to control the fabrication processes of QDs. Therefore, we have used a nanoheteroepitaxy (NHE) approach and fabricated nearly strain-free SiGe and Ge QDs on Si(001) nanotip (NT) patterned substrates. The QDs were deposited by molecular beam epitaxy at 850°C, yielding defect-free structures selectively on the NTs as observed by transmission electron microscopy. Upon tuning the Si content, the photoluminescence (PL) peak emission shifted from 0.78 to 0.9 eV. The PL emission can be remarkably enhanced by capping the QDs with Al2O3 or Si3N4 for reduction of the surface recombination processes.

HL 16.1 Tue 9:30 H14

Modeling charge transport in organic semiconductors: why and when the conventional Miller-Abrahams rate is inappropriate — •Magdalena Dörfler, Heinz Bässler, Andrey Kadashchuk, Harald Oberhofer, and Anna Köhler — Universität Bayreuth, 95447 Bayreuth

A widely applied expression to model charge transport in organic semiconductors is the Miller-Abrahams rate, which describes the probability for charge transfer from one site, e.g. a molecule, to a neighboring site. However, the expression that is conventionally referred to as Miller-Abrahams rate is an approximation of a more general term. This approximation is only valid when energy differences between neighboring sites are large compared to the thermal energy. Here, we show the differences that result when charge transport is modelled by kinetic Monte Carlo simulations (KMC) using either of the two expressions. The widely used, approximate, rate can lead to serious errors in the magnitude and, more importantly, in the trends obtained for the temperature and field dependence of charge transport. The implications for modelling work and the interpretation of experimental data are discussed.

HL 16.2 Tue 9:45 H14

Accurate ab-initio parametrization of electron-phonon coupling models with Gaussian and plane-wave basis sets — •Konrad Merkel[1], Maximilian Dorfner[1], Manuel Engel[2], and Frank Ortmann[1] — [1]TUM School of Natural Sciences, TU Munich, Germany — [2]VASP Software GmbH, Vienna, Austria

For the simultaneous treatment of electronic and vibrational degrees of freedom, the Holstein-Peierls model has become a cornerstone in various scientific communities due to its versatility and remarkable success in the accurate description of materials. To use it, one needs to calculate all model parameters for the electronic structure, phonons and electron-phonon coupling constants. In particular, the calculation of the electron-phonon coupling constants is a challenge as they involve both degrees of freedom. Although various approaches exist, comprehensive benchmarks comparing different methods and basis sets are still rare. In our study, we investigate two different methods to calculate the electron-phonon couplings. The first approach was developed by Engel et al. [1] and is based on the projector-argumented-wave formulation and maximally localized Wannier functions and is implemented in the VASP code. The second approach is based on a real-space description in terms of Gaussian basis functions and is implemented using cp2k. Both approaches use a finite-displacement and finite-difference scheme to calculate the coupling constants. We compare both methods using different molecules and discuss critical points for accurate calculations.

HL 16.3 Tue 10:00 H14

Excitons in organic donor-acceptor cocrystals — •Sebastian Anhäuser[1], Ana Maria Valencia[2], Caterina Cocchi[2], and Gregor Witte[1] — [1]Philipps-Universität Marburg, FB Physik — [2]Carl von Ossietzky Universität Oldenburg, Institut für Physik

Organic donor-acceptor heterostructures have gained significant attention due to their unique properties, such as low-bandgap semiconductivity and ambipolar transport, making them promising candidates for optoelectronic applications like organic photovoltaics. There, the formation of charge-transfer excitons is typically regarded as the precursor state for charge separation. However, the microscopic nature of these excitons is not yet well understood. In the presented study, we perform detailed polarization-resolved optical spectroscopy on high quality acene-perfluoroacene donor-acceptor single crystals in the optical and UV range. This approach allows us to investigate both the excitation energies and the transition dipole moments of various (charge-transfer-)excitons. Using complementary state-of-the-art first principles calculations based on density functional and many-body pertubation theory, we analyse the nature of different classes of excitons within the cocrystalline structure. Our findings provide a refined understanding of charge-transfer excitons in organic materials, paving the way for improved design strategies in organic optoelectronics.

HL 16.4 Tue 10:15 H14

Detecting charge patterns on a novel type of rubrene crystals by time-of-flight photoemission electron microscopy — •Moha Naeimi[1,2], Ingo Barke[1,2], and Sylvia Speller[1,2] — [1]University of Rostock, Institute of physics, Rostock, Germany — [2]University of Rostock, Department of life, light and matter, Rostock, Germany

Organic molecules are increasingly drawing attention due to their broad applications, not only in organic field effect transistors and organic light emitting diodes [1], but also with respect to the exciton dynamics and charge transfer [2]. To this end, single crystalline domains with compact and stable molecular packing are beneficial. In this work, we focus on charge patterns and its dynamics for a recently discovered type of rubrene single crystals consisting of two distinct types of domains [3]. We show that both domains exhibit different charging properties, and that one of them can be controlled by photon exposure. This charge pattern can be *reset* by a second light source with lower photon energy, essentially neutralizing the charged sections. We tentatively attribute the behavior to the selective photo-injection of mobile excitons, resulting in spatially dependent conductivities.

HL 16.5 Tue 10:30 H14

Toward High Efficiency and Stable Blue OLEDs/Organic Light-Emitting Diodes with Lanthanide-Based Complexes: Host Material Impact — •Mahmoud Soleimani[1,2], Paulius Imbrasas[2], Sebastian Schellhammer[1], Carsten Rothe[2], and Sebastian Reineke[1] — [1]Institute for Applied Physics (IAP), Technische Universität Dresden, Germany — [2]beeOLED GmbH, Dresden, Germany

Lanthanides offer a new approach for achieving blue emission in organic light-emitting diodes (OLEDs). Cerium (III) and Europium (II) complexes emit in the blue range via the 5d-4f transition, potentially enhancing the stability and efficiency of OLEDs, outperforming current emitters. However, precise ligand design around the lanthanide is required for a stable, blue-emissive complex. With the right ligands, emitters with near-unity photoluminescence quantum yield in solution have been demonstrated. In the transition to OLED-compatible thin-films, we found that the host material plays a key role in maintaining this luminescence efficiency and that it can also impair emission through quenching mechanisms caused by unfavorable energy level alignment and coordination of the metal-organic complex by the host. This study investigates the photoluminescence of Cerium (III) tris(pyrazolyl)borate complex blended with four common OLED emission layer hosts. These insights guide the development of efficient blue OLEDs with lanthanide complexes.

HL 16.6 Tue 10:45 H14

Modifying the density of states in dipolar organic semiconductors — •Andrei Stankevich[1], Prakhar Sahay[3], Heinz Bässler[1], Wolfgang Brütting[3], Fabian Eller[2], Eva M. Herzig[2], Andrey Kadashchuk[1], and Anna Köhler[1] — [1]Soft Matter Optoelectronics, University of Bayreuth — [2]Dynamics and Structure Formation, University of Bayreuth — [3]Institute of Physics, University of Augsburg,

Charge transport properties of amorphous organic semiconductors are controlled by energetic disorder. Certain device properties, such as the energies of charge transfer states in organic light-emitting diodes, can be improved by using dipolar molecules as host. Such molecules, however, also introduce interactions between charge carriers and randomly aligned dipoles. A key consequence of this is that increases the energetic disorder, hence causing a broad distribution of localized states, which hinders charge transport. We combined thermally stimulated luminescence studies with grazing incidence wide angle X-ray scattering, to demonstrate how the density of states in dipolar materials can be tailored. We demonstrate that the DOS is highly sensitive to the deposition technique and, consequently, the resulting film morphology. Furthermore, we show that the energetic disorder is not only determined by the static dipole moment, but also by the polarizability of charged molecules. Through this insight we derive design rules for common OLED materials that exhibit a with high dipole moments while maintaining charge transport properties comparable to those of non-polar counterparts.

HL 16.7 Tue 11:15 H14

Electrical and Optical Processes in Blue TADF OLEDs Studied by Temperature-Dependent Spectroscopy — •Ahmed Mohamed, Felix Kübert, Klara-Maria Bögle, Tolga Durmus, Vladimir Dyakonov, and Andreas Sperlich — Experimental Physics 6, University of Würzburg, 97074 Würzburg, German

This study explores the electrical and photophysical processes in Thermally-Activated Delayed Fluorescence (TADF) Organic Light- Emitting Diodes (OLEDs) using temperature-dependent spectroscopic techniques. Key aspects such as charge carrier transport, current loss mechanisms and recombination dynamics are examined to pro- vide a comprehensive understanding of device performance. We analyze current density-voltage-luminance (JVL) with respect to leak- age current, efficiency roll-off, and current density at 90% external quantum efficiency *90. Electroluminescence (EL)/photoluminescence (PL) microscopy is employed to analyze the photophysical processes in OLEDs. EL spectra of blue OLEDs with the multi-resonance emitter *-DABNA exhibit remarkable spectral stability at temperatures be- tween 200-300 K. Analysis of transient EL with rate equations yields activation energy and the rates of triplet-singlet transitions in OLEDs, including reverse intersystem crossing (rISC), triplet-triplet annihilation (TTA), and triplet-polaron annihilation (TPA). Understanding the mechanisms of current loss and (non-)radiative transitions is the prerequisite for enhancing the efficiency and stability of blue OLEDs.

HL 16.8 Tue 11:30 H14

Low Invasive Deposition of Metal Films on Carbon Nanotubes — •Martin Ernst[1,2], Martin Hartmann[1,2,3], and Sascha Hermann[1,2,3,4] — [1]Center for Micro and Nano Technologies, Chemnitz University of Technology, Germany — [2]Center for Materials, Architecture and Integration of Nanomembranes, Chemnitz University of Technology, Germany — [3]Fraunhofer Institute for Electronic Nano Systems ENAS, Chemnitz, Germany — [4]Center for Advancing Electronics Dresden, Dresden University of Technology, Germany

Carbon nanotubes (CNTs) are one of the most promising materials for the next generation of electronics. Their unique one-dimensional electronic structure and their remarkable optical, thermal and mechanical properties makes them ideal candidates for different application scenarios. These range from the integration in transistors for analog and digital applications, as well as their usage in CNT-based gas, bio and stress sensors. One of the key challenges is the realization of a proper CNT-metal contact, in order to effectively transport charge carriers trough an electronic device, such as the carbon nanotube field-effect transistor (CNTFET). In this study we investigated the effects of different deposition parameters on the amount of lattice defects in single-walled semiconducting CNTs by Raman spectroscopy. There, a clear dependency between the amount of introduced defects and the deposition parameters, like the kinetic energy of the incident target atoms, was observed. Moreover, these finding were correlated to electrical results of CNTFETs, that were fabricated with the same deposition parameters.

HL 16.9 Tue 11:45 H14

High-Frequency CNT-based FETs for Radio Frequency Communication — •Martin Hartmann[1,2,3], Simon Böttger[1,2,3], Martin Ernst[1,2], and Sascha Hermann[1,2,3,4] — [1]Center for Micro and Nanotechnologies, Chemnitz University of Technology, Germany — [2]Center for Materials Architecture and Integration of Nanomembranes, Chemnitz University of Technology, Germany — [3]Fraunhofer Institute for Electronic Nanosystems ENAS, Chemnitz, Germany — [4]Center for Advancing Electronics Dresden, Dresden University of Technology, Germany

High frequency carbon nanotube-based (CNT) field effect transistors (FETs) are a highly promising candidate for future communication electronics due to their high charge carrier mobility and low intrinsic capacitance. It has already been shown in 2019 that this technology surpassed comparable silicon-based radio frequency FETs e.g. in terms of their extrinsic current gain cut-off frequencies as well as maximum frequencies of oscillation [1]. Moreover, in recent years their performance was further enhanced approaching the THz region [2]. We report on the impact of the device geometry as well as the CNT layer properties of high frequency CNTFETs onto their operating speed, linearity and contact resistance. Therefore, the spacers between the gate and the source electrode and gate to drain electrode were varied resulting in extrinsic current gain cut-off frequencies up to 14 GHz. By manipulating the spacer region, the device electrostatics in the CNT-metal contact area are balanced. This impacts the charge carrier injection and reflection at the Schottky-like barriers.

HL 17: 2D Semiconductors and van der Waals Heterostructures III

The session covers electronic and optoelectronic phenomena in two-dimensional semiconductors and van der Waals heterostructures.

Time: Tuesday 9:30–13:00 Location: H15

HL 17.1 Tue 9:30 H15

Size-Dependent Electrical Transport in Quasi-1D $ZrSe_3$-Stripes — •Davin Höllmann[1], Lars Thole[1], Sonja Locmelis[2], and Rolf J. Haug[1,3] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, 30167 Hannover, Germany — [2]Institut für Anorganische Chemie, Leibniz Universität Hannover, 30167 Hannover, Germany — [3]Laboratorium für Nano- und Quantenengineering, Leibniz Universität Hannover, 30167 Hannover, Germany

The anisotropy in form of quasi one-dimensional (1D) chains in transition metal trichalcogenides (TMTCs) makes them stand out compared to other more conventional two-dimensional (2D) materials [1]. Building on previous work [2], we investigated the electrical properties of thin stripes of the TMTC $ZrSe_3$ particularly regarding their width and thickness. The bulk material used was fabricated by a chemical vapor transport method and then exfoliated to achieve thin stripes.

We determined band gap energies for samples with varying heights. Those are

shown to increase linearly from 0.37 eV to 0.63 eV as the thickness of the material decreases from 35 nm to 14 nm. Furthermore, we compared narrow samples with wider samples where both have comparably similar length and thickness and found that the conductivity happens dominantly in the outer selenium atoms i.e. across the chains.

HL 17.2 Tue 9:45 H15

MOCVD Growth of two-dimensional, high-mobility InSe — •Robin Günkel[1], Milan Solanki[1], Daniel Anders[2], Markus Stein[2], Badrosadat Ojaghi Dogahe[1], Oliver Massmeyer[1], Max Bergmann[1], Nils Langlotz[1], Jürgen Belz[1], Sangam Chatterjee[2], and Kerstin Volz[1] — [1]Department of Physics and Material Sciences Center, Philipps-University Marburg, Germany — [2]Institute of Experimental Physics I and Center for Materials Research (ZfM/LaMa), Justus-Liebig-University Giessen, Germany

To advance Moore's Law, transistors must shrink while maintaining performance, but 3D semiconductor-based gates face limitations as their thickness approaches the nanometer scale due to surface scattering effects. 2D materials, such as graphene, offer a promising alternative that combines miniaturization with high field effect mobility. Among these, layered indium selenide (InSe) is a focus for logic devices due to its high mobility. However, the complex phase diagram of InSe poses challenges, often resulting in undesired phases. This study uses metal-organic chemical vapor deposition (MOCVD) to grow homogeneous, single-phase InSe on 2" sapphire by tuning the precursor ratio of DiPSe and TMIn. Growth starts with small nuclei forming a continuous layer, with subsequent layers growing as InSe triangles. Atomic force microscopy, Raman spectroscopy, STEM, and XRD provide insight into the growth behavior and the role of surface chemistry. Terahertz spectroscopy confirms carrier mobilities in the order of 1000 cm^2/(Vs). Ongoing efforts focus on heterostructures with other van der Waals materials to further tailor properties.

HL 17.3 Tue 10:00 H15

Transparent and reproducible contacts to MoS_2 nanotube quantum dots — •Robin T. K. Schock[1], Stefan B. Obloh[1], Korbinian Fink[1], Matthias Kronseder[1], Matjaž Malok[2], Maja Remškar[2], and Andreas K. Hüttel[1] — [1]Institute for Experimental and Applied Physics, University of Regensburg, 93040 Regensburg, Germany — [2]Solid State Physics Department, Jožef Stefan Institute, 1000 Ljubljana, Slovenia

MoS_2, a leading material among transition metal dichalcogenides, exhibits remarkable optical and electronic properties. However, its high effective electron mass necessitates narrow confinement potentials to achieve single quantum level transport.

Nanotubes offer a compelling solution by naturally confining electrons in two dimensions. Our previous work demonstrated single level transport in nanotube QDs confined to the active device area, using the classical Scotch tape method.[1] Despite this, a major challenge remains in fabricating reliable electrical contacts, as devices still exhibit large resistance variations. We attribute this to the curved geometry of the nanotube surface, leading e.g. to nanogaps between the contact material on the tube and the chip surface.[2]

Here we introduce a contact deposition technique that addresses these challenges, achieving highly improved contact yield and reproducibility. This advancement enables the fabrication of more complex device architectures, as e.g., nanotube QDs on top of 2D material heterostacks. - [1] R. T. K. Schock et al., Adv. Mat. 35, 2209333 (2023); [2] R. T. K. Schock et al., PSSb, 2400366 (2024)

HL 17.4 Tue 10:15 H15

Defect engineering in two-dimensional materials for resistive switching — •Manoj Dey, Matthias Scheffler, and Wahib Aggoune — The NOMAD Laboratory at the FHI of the Max-Planck-Gesellschaft, Berlin, Germany

Non-volatile resistive switching (RS) in memristors has attracted significant attention for advancing in-memory technologies. Recently, exceptional RS has been observed in defected two-dimensional (2D) materials, called atomristors. Adsorption/desorption of metal atoms from the electrodes onto vacancy sites is experimentally observed and proposed as its origin [1,2]. Here, we explore the characteristics of defects and demonstrate their relationship with the observed RS. Using hybrid density functional theory with many body van der Waals corrections, we reveal that the defective monolayers are semiconducting (*i.e.*, high resistivity), whereas adsorption of metal atoms leads to a metallic character (*i.e.*, low resistivity). Interestingly, the adsorption energy of metal is found to be exothermic, with magnitude varying depending on the host materials. This indicates the feasible adsorption and switching in experiments. To bridge with experiments we also consider both the effects of the electrode (*e.g.* Au(111)) and finite-temperature vibrations. While vibrational effects are negligible, electrode screening induces band gap renormalization and slightly stabilizes metal adsorption compared to free-standing monolayers. These insights will guide the exploration of novel 2D materials for RS applications.

HL 17.5 Tue 10:30 H15

Anisotropic supercurrent suppression and revivals in a graphene-based Josephson junction under in-plane magnetic fields — •Katarina Stanojević[1,5], Philipp Schmidt[1,2], Kenji Watanabe[3], Takashi Taniguchi[4], Bernd Beschoten[1], Vincent Mourik[5], and Christoph Stampfer[1,2] — [1]JARA-FIT and 2nd Institute of Physics, RWTH Aachen University, Germany — [2]Peter Grünberg Institute (PGI-9), Forschungszentrum Jülich, Germany — [3]Research Center for Electronic and Optical Materials, National Institute for Materials Science, Japan — [4]International Center for Materials Nanoarchitectonics, National Institute for Materials Science, Japan — [5]JARA Institute for Quantum Information (PGI-11), Forschungszentrum Jülich, Germany

Graphene-based Josephson junctions represent a promising platform for hybrid quantum devices due to their unique electronic properties. The absence of Schottky barriers enables highly transparent interfaces, while graphene's ability to host proximity-induced superconductivity make it an interesting candidate for realizing tunable weak links. A key step towards harnessing graphene Josephson junctions for topological quantum applications is understanding the influence of in-plane magnetic fields, which tune the Zeeman energy and might enable the formation of topologically protected states. Here, we report on a tunable bilayer graphene Josephson junction encapsulated in WSe_2. We investigate the behavior of the supercurrent under applied in-plane magnetic fields, revealing a pronounced anisotropy in the magnetic field induced decay and revival of the supercurrent for varying in-plane field angles.

HL 17.6 Tue 10:45 H15

Electric field control of the proximity-induced spin-orbit gap in bilayer graphene/WSe2 quantum dots — •Hubert Dulisch[1,2], David Emmerich[1,2], Eike Icking[1,2], Katrin Hecker[1,2], Samuel Möller[1,2], Leonie Müller[1,2], Kenji Watanabe[3], Takashi Taniguchi[4], Christian Volk[1,2], and Christoph Stampfer[1,2] — [1]2nd Institute of Physics, RWTH Aachen — [2]PGI-9, Forschungszentrum Jülich — [3]Research Center for Functional Materials, NIMS, — [4]International Center for Materials Nanoarchitectonics, NIMS

We investigated induced spin-orbit coupling (SOC) in a bilayer graphene (BLG) quantum dot (QD), which is in proximity to tungsten diselenide (WSe_2). Magneto-transport measurements were performed on the Coulomb-resonance of the first charge carrier to extract the spin-orbit gap Δ_{SO}. In-plane magnetic field measurements indicate an increased SOC-induced energy splitting. Out-of-plane field measurements demonstrate a reduced valley g-factor at larger displacement fields, consistent with weaker lateral confinement of the QD wavefunction. Our measurements reveal an enhanced SOC effect that decreases with the applied displacement field, distinguishing it from the behavior observed in pure BLG. We interpret this as a reduced influence of the WSe_2, which we attribute to the increased displacement field. This causes the QD to become more localized in the lower layer of the bilayer graphene. Being farther from the WSe_2, this layer experiences reduced induced SOC, leading to a diminished spin-orbit gap in the BLG QD.

HL 17.7 Tue 11:00 H15

High-Performance and Energy-Efficient Sub-5nm 2D Double-Gate MOSFETs Based on SiAs Monolayers — •Dogukan Hazar Ozbey and Engin Durgun — UNAM - National Nanotechnology Research Center and Institute of Materials Science and Nanotechnology, Bilkent University, Ankara 06800, Turkey

As the demand for high-performance, energy-efficient transistors grows, traditional silicon-based MOSFETs face significant scaling limitations. To overcome these challenges and sustain advancements in semiconductor technology, new materials and device architectures are being explored. In this study, sub-5nm double-gate metal-oxide-semiconductor field-effect transistors (MOSFETs) based on 2D SiAs are investigated using first-principles calculations and the Non-equilibrium Green's function (NEGF) formalism to assess their potential as a high-performance alternative. SiAs monolayers exhibit an indirect bandgap of 1.58 eV and demonstrate promising electronic properties. Key performance metrics such as the on/off current ratio, subthreshold swing (SS), gate capacitance (C_g), intrinsic delay time (τ), and power-delay product (PDP) are evaluated. Devices with 1 nm and 2 nm underlap (UL) structures show enhanced performance, achieving on-state current (I_{on}) values up to 1206 $\mu A/\mu m^{-1}$, meeting ITRS-2028 high-performance (HP) standards. The SS ranges from 112 to 142 mV/dec, and minimized delay and power-delay products indicate the suitability of SiAs transistors for ultra-scaled, energy-efficient applications. Results suggest that 2D SiAs transistors offer a promising solution to the scaling challenges of MOSFET technologies.

HL 17.8 Tue 11:30 H15

Resistance standards from artifact wire coils to graphene quantum Hall resistance — •Yefei Yin[1], Mattias Kruskopf[1], Stephan Bauer[1], Teresa Tschirner[1], Klaus Pierz[1], Frank Hohls[1], Rolf J. Haug[2], and Hans W. Schumacher[1] — [1]Physikalisch-Technische Bundesanstalt, Bundesallee 100, 38116 Braunschweig, Germany — [2]Institut für Festkörperphysik, Leibniz Universität Hannover, 30167 Hannover, Germany

Historically, resistance standards were made by physical artifact wire coils before 1990 and quantum resistors based on GaAs heterostructures after 1990. However, conventional GaAs quantum Hall resistance (QHR) standards with the quantized resistance $R_H = h/2e^2$ are operating under high magnetic flux densities B > 10 T, limited currents I < 50 μA, and low temperatures T < 1.5 K, which significantly hinder the dissemination of primary resistance standards. In this work, we developed practical primary QHR standards based on n- and p-type epitaxial graphene. This study first systematically demonstrated that p-type epitaxial graphene can also be used for primary resistance standards, as accurate (10^{-9} accuracy) as GaAs and n-type graphene counterparts for realizing the SI unit ohm in quantum metrology. [1] The n-type graphene QHR standards achieved the world best performance so far with a 10^{-9} accuracy under relaxed conditions (B = 4.5 T, I = 232.5 μA, T = 4.2 K) simultaneously. [2-3] Our graphene QHR standards have been utilized in the national metrology institutes in European countries. [1] Appl. Phys. Lett., 125, 064001 (2024). [2] Adv. Phys. Res. 1, 2200015 (2022). [3] Phys. Rev. Applied, 2024

HL 17.9 Tue 11:45 H15

1D graphene superlattices and the influence of the potential shape — •Julia Amann[1], Alina Mreńca-Kolasińska[2], Angelika Knothe[1], Ming-Hao Liu[3], Takashi Taniguchi[4], Kenji Watanabe[4], Dieter Weiss[1], and Jonathan Eroms[1] — [1]University of Regensburg, Germany — [2]AGH University, Krakow, Poland — [3]National Cheng Kung University, Tainan, Taiwan — [4]National Institute for Materials Science, Tsukuba, Japan

One-dimensional superlattices (1DSLs) in graphene have been predicted to exhibit intriguing effects such as transport anisotropy, additional Dirac points and hence higher degeneracy, leading to a different quantum Hall plateau sequence compared to pristine graphene. We use a patterned few-layer graphene gate under an encapsulated monolayer graphene to fabricate a 1DSL device. With the combined effect of a global gate and a patterned bottom gate, we are able to control the superlattice potential strength and carrier density independently. We show low-temperature transport measurements on a gate-tunable 1DSL in monolayer graphene with a period of 50 nm in directions parallel and perpendicular to the modulation using an L-shaped Hall bar. We observe anisotropic transport and the appearance of multiple Dirac points and additional Landau fans in the modulation direction. We also see Weiss oscillations, confirming the 1DSL modulation. However, the predicted anomalous quantum Hall sequence was not observed and we looked more closely at the 1DSL potential we were applying. We found an asymmetric potential shape, which strongly influences the change in the band structure and degeneracy.

HL 17.10 Tue 12:00 H15

Ultrafast mid-infrared interferometric photocurrents in graphene-based two-terminal devices for femtosecond autocorrelation — •Sebastian Loy[1,2], Nina Pettinger[1,2], Johannes Schmuck[1,2], Xiaoyi Zhou[1,2], Sergey Zherebtsov[1,2], Christoph Kastl[1,2], and Alexander Holleitner[1,2] — [1]Walter Schottky Institute and Physics Department, Technical University of Munich, Am Coulombwall 4a, 85748 Garching, Germany — [2]Munich Center of Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 Munich, Germany

We present the autocorrelation of femtosecond mid-IR pulses with wavelengths ranging from 5.5 μm to 14 μm and pulse durations of approximately 100 fs on graphene-based two-terminal devices. The results indicate that the interaction between the electric field and optoelectronic dynamics at the metal-graphene interface underlies the principle of ultrafast detection. Our approach stands out due to the ease of nanofabricating graphene two-terminal optoelectronic devices and their inherent robustness [1].

[1] Nina Pettinger et al., accepted (2024).

HL 17.11 Tue 12:15 H15

Enhancement of optoelectronic properties of layered 2D semiconductors — •Borna Radatović[1,2], Onur Çakiroğlu[2], Hao Li[2], Fedor Lipilin[1], Aljoscha Soll[1], Andres Castellanos-Gomez[2], and Zdenek Sofer[1] — [1]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Technicka 5, Prague 6, 166 28 Czech Republic — [2]2D Foundry group. Instituto de Ciencia de Materiales de Madrid (ICMM-CSIC), E-28049 Madrid, Spain

Standard semiconductor methods for the enhancement of electronic devices' properties, such as doping via ion implantation and similar approaches, do not apply to 2D materials due to their atomical thickness. However, various alternative methods for customization of optoelectronic properties of 2D devices have been investigated, from electric or magnetic fields to substitutional doping, that were demonstrated for many devices, such as light sources, optical modulators and photodetectors. In our work, we focus on photodetectors based on different 2D semiconductors (i.e. MoS2, ZrSe3, Sb2S2O and CuInP2Se6) in monolayer and few-layer forms. We investigated how external strain can modulate the intrinsic optical and electronic properties of 2D materials and enhance photodetectors' performances. Furthermore, we have demonstrated how 2D heterostructures can offer a practical approach to specific custom optoelectronic properties of 2D devices.

HL 17.12 Tue 12:30 H15

Surface acoustic wave-controlled photocurrent in few-layer TMDCs — •Benjamin Mayer, Felix Ehring, Matthias Weiss, Hubert Krenner, Ursula Wurstbauer, and Emeline Nysten — Institute of Physics, University of Münster, Germany

Surface acoustic waves (SAWs) provide a versatile platform for integrating GHz-frequency control and sensing schemes at micron-scale wavelengths on a chip. Combining the SAWs dynamic electric field, high-resolution optical spectroscopy, and electrical transport allows a deep insight in the optical properties and carrier transport processes in nanoscale materials, paving the way for innovative acousto-optoelectronic devices [1].

Here, we study the SAW-driven acousto-electric current (AEC) and the underlying charge carrier dynamics in mechanically exfoliated transition metal dichalcogenide (TMDC) 2D materials. To this aim, few-layered TMDCs are placed on top of two gold electrodes integrated in hybrid lithium niobate-based SAW-devices with design frequencies of 150-250MHz. The power and directional dependence of the induced AEC offer an initial understanding of the contact barriers forming at the Au-TMDC interface. By locally photodoping our samples, we establish a qualitative model for the formed Schottky and tunneling barriers, enabling the investigation of their influence on the wavelength-dependent SAW-driven charge carrier dynamics [2].

HL 17.13 Tue 12:45 H15

Accelerated electron-hole separation at the organic-inorganic anthracene/Janus MoSSe interface — •Hamid Mehdipour[1], Peter Kratzer[2], and Oleg Prezhdo[3] — [1]University of Duisburg-Essen, Duisburg, Germany — [2]University of Duisburg-Essen, Duisburg, Germany — [3]University of Southern California, Los Angeles, United States;

Organic light-absorbing materials with two-dimensional semiconductor layers as contact electrodes are promising for efficient and low-cost energy-harvesting applications. Considering anthracene as an absorber and a MoSSe Janus monolayer, and basing our work on a set of preliminary DFT calculations, we employ non-adiabatic molecular dynamics to show that electron transfer from anthracene to MoSSe is faster on the Se than on the S side. The transfer from anthracene to MoS_2 and $MoSe_2$ monolayers takes intermediate times. As a rule, we find that a shorter adsorption distance produces a stronger donor-acceptor coupling. The smaller distance on the Se side is rationalized by the attractive dipolar interaction between the intrinsic dipole moment of the Janus structure and the dipole induced upon molecule adsorption. Quantum coherence adjusted by the out-of-plane vibrations also has a significant impact on the transfer time. Our study provides detailed insights into adsorption of molecules on Janus structures and the resulting electronic and electron-vibrational interactions. The results suggest that the dipole interaction plays an important role in thermodynamic stability, alignment of electronic levels, and electron-vibrational dynamics.

HL 18: Focus Session: Nanoscale Light-matter Interaction I

The focus session highlights recent breakthroughs in resolving the optoelectronic properties of individual nanostructures down to the atomic scale. Moreover, the session introduces the rich field of surface polaritons, confined electromagnetic modes through which light can be guided on subwavelength scales.

The focus session is organized by Markus Huber (U Regensburg) and Fabian Mooshammer (U. Regensburg).

Time: Tuesday 9:30–13:00 Location: H17

Invited Talk HL 18.1 Tue 9:30 H17

Ultrafast Nano-Spectroscopy of Photo-Induced Dynamics in Low-Dimensional Materials — •Takashi Kumagai — Institute for Molecular Science, Okazaki, Japan

Low-dimensional semiconductors have been extensively studied as platforms for fascinating physics and as potential components for quantum nano-devices. Their low dimensionality leads to unique physical properties, driven by strong quantum confinement and reduced dielectric screening. However, this also renders low-dimensional materials highly sensitive to local structures and interactions with their surroundings. To fully understand their superior properties, it is essential to investigate their local structures and how they correlate with photo-induced dynamics. Recently, ultrafast infrared nano-spectroscopy based on scanning near-field optical microscopy (IR-SNOM) has emerged as a powerful tool to directly visualize local structures and dynamics in real time and space at the nanoscale. I will present our latest research to apply ultrafast IR-SNOM to explore nanoscale photo-induced dynamics in low-dimensional materials [1]. In single-layer transition metal dichalcogenides, we have visualized the local many-body dynamics of high-density electron-hole plasma, uncovering the significance of dynamic heterogeneity linked to the non-uniform optoelectronic properties. Furthermore, we have extended ultrafast IR-SNOM to study local exciton dynamics in single-walled carbon nanotubes (SWCNTs). Within individual, isolated SWCNTs, the non-uniform formation of electron-hole pairs is correlated with local strain. [1] Y. Wang, J. Nishida et al. ACS Photonics, accepted.

Invited Talk HL 18.2 Tue 10:00 H17

Landau level Nanoscopy of charge and heat transport in low-dimensional heterostructures — •Mengkun Liu — Stony Brook University

In contemporary condensed matter physics and photonics, four key length scales play an essential role in shaping the behavior of quantum materials: (1) the polaritonic wavelength, which governs light confinement and light-matter interactions; 2) the magnetic lengths, determined by the magnetic field B, which constrains electron motion; 3) the diffusion length of the hot carriers at interfaces and the edges, which dictates energy relaxation, and 4) the periodicities of superlattices induced by moiré engineering, which defines the energy scale of emerging quantum phases. For instance, the commensurability of the magnetic lengths (~10 nm for graphene at 7T) and superlattice constant (~10 nm for twisted bilayer graphene at "magic" angle) would give rise to exotic fractal quantum states. In this talk, I will present: 1) A cutting-edge optical spectroscopy technique, Landau-level nanoscopy, capable of simultaneously probing all four critical length scales in a single experiment; 2) the discovery of classes of infrared polaritons that can be tuned by magnetic fields, enhancing our ability to manipulate light-matter interactions and probe many-body physics at the nanoscale; 3) nanoscale mapping of thermoelectric properties in the quantum Hall bulk, revealing strong violations of the Wiedemann-Franz law. Our approach establishes Landau-level nanoscopy as a versatile platform for investigating magneto-optical effects and many-body interactions at the nanoscale.

Invited Talk HL 18.3 Tue 10:30 H17

Real space mapping of electrically tunable anisotropic THz plasmon polaritons in hBN encapsulated black phosphorus — •Eva Pogna — Institute of Photonics and Nanotechnology, CNR-IFN, Milan, Italy

Polaritons in two-dimensional layered crystals offer effective means to confine and manipulate terahertz (THz) electromagnetic waves at the nanoscale, a crucial step in advancing photonic technologies.

In this study, we investigate anisotropic plasmon polaritons in black phosphorus nanoflakes at THz frequencies, utilizing near-field photocurrent nanoscopy combined with THz hyperspectral near-field scattering techniques.

Encapsulation with hexagonal boron nitride protects black phosphorus from air-induced degradation, while field-effect transistor (FET) devices enable photo-thermoelectric detection of plasmon polaritons.

Our findings reveal highly confined, gate-tunable plasmon polaritons with subwavelength dispersion ($\sim \lambda/76$ at 2.01 THz).

The dielectric anisotropy of black phosphorus leads to polaritons with elliptic wavefronts at THz frequencies, enabling enhanced confinement and control over THz field propagation. Moreover, electrostatic control of carrier density allows precise tuning of polariton wavelength, highlighting the versatility of this platform for nanoscale THz light manipulation and reconfigurable infrared nanophotonics.

Notably, the four-gate FET architecture introduced here to examine in-plane propagation anisotropy can be readily adapted for the study of other anisotropic conductive materials.

15 min. break

Invited Talk HL 18.4 Tue 11:15 H17

Ultra-confined THz hyperbolic phonon polaritons in a transition metal dichalcogenide — Ryan A. Kowalski[1], Niclas S. Mueller[2], Gonzalo Alvarez-Perez[3], Maximilian Obst[4], Katja D. Granados[1], Giulia Carini[2], Aditha Senarath[1], Saurabh Dixit[1], Richarda Niemann[1,2], Ragu B. Iyer[5], Felix Kaps[4], Jakob Wetzel[4], J. Michael Klopf[6], Ivan I. Kravchenko[7], Deliang Bao[1], Sokrates T. Pantelides[1], Martin Wolf[2], Lukas Eng[4], Pablo Alonso-Gonzalez[3], Susanne Kehr[4], Thomas G. Folland[5], •Alexander Paarmann[2], and Joshua D. Caldwell[1] — [1]Vanderbilt University, Nashville, TS, USA — [2]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [3]University of Oviedo, Oviedo, Spain — [4]TUD Dresden University of Technology, Dresden, Germany — [5]The University of Iowa, Iowa City, IA, USA — [6]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [7]Oak Ridge National Laboratory, TN, USA

Phonon polaritons are hybrid light-matter quasiparticles in polar crystals that enable waveguiding of light on length scales much smaller than the photon wavelength. Here, we introduce $HfSe_2$ as a new van der Waals material that supports phonon polaritons in the terahertz (THz) spectral range. Using THz near-field optical microscopy, we demonstrate extreme confinement of light from 61 μm free-space wavelength to 245 nm. We show that the origin of this record-high confinement is an exceptionally large light-matter coupling of hyperbolic $HfSe_2$.

Invited Talk HL 18.5 Tue 11:45 H17

Programmable polariton nanophotonics using phase-change materials — •Thomas Taubner — I. Institute of Physics (IA), RWTH Aachen University, Aachen, Germany

Tailoring light-matter interaction is essential to realize nanophotonic components and can be achieved with polaritons, an excitation of photons coupled to charges in metals and semiconductors. Adding a thin layer of Phase-change material (PCM) leads to stronger polariton confinement and enables optical writing of resonator structures based on a change in the refractive index [1]. The recently introduced plasmonic PCM In_3SbTe_2 (IST) can be reversibly switched from an amorphous dielectric to a crystalline metallic state, enabling optically re-writable IR nanoantennas and metasurfaces [2].

Here, we show direct optical writing of resonators for surface phonon polariton (SPhP) by crystallizing IST on top of a SiC crystal and investigate the strongly confined resonance modes with s-SNOM. Reconfiguring the size and shape of the resonators leads to mode confinements of $\lambda/35$ [3]. We also demonstrate the real-space imaging of IR surface plasmon polaritons on bulk doped semiconductors, enabled by the strong polariton confinement induced by the added thin dielectric PCM layer [4]. Our concept allows for the rapid prototyping of reconfigurable structures for polaritonics, especially useful with anisotropic 2d materials.

HL 18.6 Tue 12:15 H17

Heralding non-classical light by tailored free-electron interactions with photonic modes — •Armin Feist[1,2], Guanhao Huang[3,4], Germaine Arend[1,2], Yujia Yang[3,4], Jan-Wilke Henke[1,2], Zheru Qiu[3,4], Hao Jeng[1,2], Arslan Sajid Raja[3,4], Rudolf Haindl[1,2], Rui Ning Wang[3,4], Tobias J. Kippenberg[3,4], and Claus Ropers[1,2] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, DE — [2]4th Physical Institute, University of Göttingen, DE — [3]Institute of Physics, EPFL, Lausanne, CH — [4]Center for Quantum Science and Engineering, EPFL, Lausanne, CH

Integrated photonics facilitates control over fundamental light-matter interactions in manifold quantum systems. Extending these capabilities to electron beams [1] fosters free-electron quantum optics.

Here, we show the coupling of single electrons and photons at an integrated photonics waveguide [2,3]. Spontaneous scattering of the nanoscale-focused electron beam at empty optical modes creates multi-photon superposition states. Energy-selective and event-based electron detection enables herald-

ing non-classical light, which we characterize by intensity correlations in a Hanbury Brown and Twiss (HBT) setup, showing high-fidelity single-photon generation [3].

This provides a pathway toward novel hybrid quantum technology with entangled electrons and photons, as well as the capability for quantum-enhanced electron imaging and Fock-state photon sources.

HL 18.7 Tue 12:30 H17

Attosecond electron microscopy using free-electron homodyne detection — •John H. Gaida[1,2], Sergey V. Yalunin[1,2], Hugo Lourenço-Martins[1,2], Murat Sivis[1,2], Thomas Rittmann[1,2], Armin Feist[1,2], F. Javier García de Abajo[3,4], and Claus Ropers[1,2] — [1]MPI for Multidisciplinary Sciences, Göttingen, Germany — [2]4th Physical Institute, University of Göttingen, Germany — [3]ICFO-Institut de Ciencies Fotoniques, Castelldefels (Barcelona), Spain — [4]ICREA-Institució Catalana de Recerca i Estudis Avançats, Barcelona, Spain

Advancements in condensed matter science aim to map material structures and dynamics at levels of ångströms and attoseconds. Although X-ray and electron methods offer structural detail, attosecond temporal resolution is progressing through optical spectroscopy techniques. Techniques like PINEM allow nanometric resolution imaging of near-field intensities [1], but to examine the evolution of nanoscale fields and structures within the light cycle, optical phase sensitivity is needed, as provided by phase-contrast Lorentz PINEM [2], interferometric detection [3], or electron pulse bunching [4]. This contribution introduces Free-Electron Homodyne Detection (FREHD), a universally applicable approach for high spatiotemporal resolution imaging of phase-resolved optical responses [3].

HL 18.8 Tue 12:45 H17

Light-matter interaction on subcycle time and atomic length scales — •Tom Siday[1,2], Johannes Hayes[1], Felix Schiegl[1], Fabian Sandner[1], Peter Menden[1], Valentin Bergbauer[1], Martin Zizlsperger[1], Svenja Nerreter[1], Sonja Lingl[1], Jascha Repp[1], Jan Wilhelm[1], Markus A. Huber[1], Yaroslav A. Gerasimenko[1], and Rupert Huber[1] — [1]Department of Physics and Regensburg Center for Ultrafast Nanoscopy (RUN), University of Regensburg, Regensburg, Germany — [2]School of Physics and Astronomy, University of Birmingham, Birmingham, UK

Near-field microscopy has revolutionized the study of nanoscale light-matter interaction, achieving subcycle temporal and ~10 nm spatial resolution. However, the geometry of the tip apex has so far restricted access to atomic resolution. By harnessing extreme nonlinearities within tip-confined evanescent light fields, we introduce a novel contrast mechanism, advancing all-optical microscopy to the atomic scale while preserving subcycle temporal resolution. This Near-field Optical Tunnelling Emission (NOTE) microscope can resolve nanometer-scale packing defects on a gold surface and trace the subcycle quantum flow of electrons between the scanning tip and a semiconducting van der Waals trilayer in real time. Moreover, NOTE microscopy is compatible with insulating samples, where rectified currents cannot flow, and enables the integration of all-optical subcycle spectroscopy with atomic-scale resolution. Thus, NOTE provides direct access to atomic-scale quantum light-matter interactions and dynamics on their natural spatial and temporal scales.

HL 19: Focus Session: Strongly Correlated Quantum States in Moire Heterostructures (joint session TT/HL/MA)

In recent years, significant progress has been made in realizing and exploring correlated quantum states in multilayer moiré heterostructures of graphene or transition metal dichalcogenides. These achievements have been made possible by the high level of control and tunability of these systems. Striking phenomena have been demonstrated experimentally, including unconventional superconductivity, fractional quantum anomalous Hall states, Mott-Wigner states and density waves, as well as kinetic ferromagnetism. Moreover, recently novel spectroscopic experimental techniques have been developed which allow for new ways to explore the dynamical response of these exotic states. This focus session will discuss recent experimental advancements as well as theoretical developments in the field of strongly correlated moiré heterostructures.

Organizers: Dmitri K. Efetov (LMU München), Michael Knap (TU München)

Time: Tuesday 9:30–13:15 Location: H36

See TT 18 for details of this session.

HL 20: Poster I

The first poster session covers the physics of semiconductor heterostructures, interfaces and surfaces. Moreover, most recent results on oxide semiconductors, as well as perovskite and photovoltaics are presented.

Time: Tuesday 10:00–12:30 Location: P3

HL 20.1 Tue 10:00 P3

Accuracy Requirements for Polarizabilities in MD-based Raman Spectra — •Markus Amaseder[1], Manuel Grumet[1], Tomáš Bučko[2,3], and David A. Egger[1] — [1]TUM School of Natural Sciences, Technical University of Munich — [2]Faculty of Natural Sciences, Comenius University Bratislava — [3]Institute of Inorganic Chemistry, Slovak Academy of Sciences

Raman spectroscopy provides a versatile and accessible method for characterizing atom dynamics in materials. While frozen phonon approaches have proven well for the prediction of Raman spectra in many cases, they do not inherently include anharmonic and temperature-dependent effects. Raman spectra calculated from molecular dynamics (MD) offer an alternative [1] and have received considerable interest. However, they remain computationally challenging as they require many single-point polarizabilities. We have shown previously that machine learning (ML) can aid in the speed-up using a delta learning approach [2]. However, it is still to be fully understood how accurate single-point polarizabilities need to be in order to provide sufficiently correct spectra. We present an evaluation of polarizabilities from density functional theory and ML for MD Raman spectra, investigating the effects of the functional and further parameters. This is relevant both in terms of training data and ML predictions. Since many single-point calculations are needed, the trade-off between accuracy and computational cost is crucial for the practical application of MD-based Raman spectra. [1] Thomas, et al. Phys. Chem. Chem. Phys. 15, 6608-6622 (2013) [2] Grumet, et al. J. Phys. Chem. C 128, 6464-6470 (2024)

HL 20.2 Tue 10:00 P3

low-temperature buffer layer-assisted heteroepitaxial growth of γ-CuI thin films by pulsed laser deposition: tailoring electrical properties — •Yang Chen[1], Michael S. Bar[1], Susanne Selle[2], Daniel Splith[1], Michael Lorenz[1], Marius Grundmann[1], and Holger v. Wenckstern[1] — [1]Felix Bloch Institute for Solid State Physics, Faculty of Physics and Earth Sciences, Universität Leipzig, 04103 Leipzig, Germany — [2]Fraunhofer Institute for Microstructure of Materials and Systems IMWS, 06120 Halle, Germany

As the first discovered p-type transparent conductive material, copper(I) iodide (CuI) is considered to be among the most competitive p-type candidate in the field of transparent electronics. Herein, we introduced a low-temperature buffer-layer-assisted strategy to grow γ-CuI on c-plane sapphire by pulsed laser deposition with unprecedented structural quality and electrical transport properties. By adjusting the growth temperature, we can manipulate the rotation domain

structure, control the hole concentration in the range from 10^{14} cm^{-3} to 10^{19} cm^{-3} and achieve mobility $\mu_h = 25$ $cm^2V^{-1}s^{-1}$ being similar to that of bulk CuI. Based on the temperature dependent Hall-effect measurement, the ionization energy of shallow acceptors $E_{I,S}$ = 137 ± 8 meV and deeper acceptors $E_{I,D}$ = 262 ± 23 meV were determined. This strategy not only enables high-quality CuI film preparation, but also to tailor their electrical properties for integration with n-type semiconductors in transparent electronic circuits.

HL 20.3 Tue 10:00 P3

Semiconductor membrane transfer for deterministic Circular Bragg Gratings fabrication — •Juan Nicolas Claro Rodriguez, Dennis Deutsch, Leonie Schubert, Dirk Reuter, and Klaus Joens — PhoQS Institute, CeOPP, and Department of Physics, Paderborn University, Paderborn

Highly indistinguishable single photons and strongly entangled photon-pairs are fundamental for photonic quantum communication [1]. InGaAs quantum dots (QDs) grown on InP substrates using MBE deposition [2] emit in the telecom C-band, making them ideal for long-distance communication, though their brightness is limited. Embedding these QDs in hybrid Circular Bragg Gratings (CBGs) enhances photon collection efficiency and the Purcell factor, supported by a backside mirror and transparent medium configuration [3]. We present a membrane transfer method involving backside mirror growth, press-bonding, and InP substrate removal via HCl etching, enabling emitter localization and CBG integration. PL spectra are used to assess sample quality.

[1] Applied Physics Letters, 118(10), 100502. [2] AIP Advances, 13(5). [3] Journal of the Korean Physical Society, 73(10), 1502*1505.

HL 20.4 Tue 10:00 P3

Comparative Investigations of GaN/p-GaInP and p-GaInP Photocathodes: Stability and Performance in Acidic Electrolytes — •Sahar Shekarabi[1], Mohammad Amin Zare Pour[1], David Osteimer[1], Haoqing Su[2], Wentao Zhang[2], Agnieszka Paszuk[1], Wolfram Jaegermann[3], Shu Hu[2], and Thomas Hannappel[1] — [1]Technische Universität Ilmenau, Institut für Physik, Ilmenau, Germany — [2]Yale University, Department of Chemical and Environmental EngineeringNew Haven, USA — [3]Technische Universität Darmstadt, Department of Materials and Earth Sciences, Darmstadt, Germany

GaInP(100) is a widely used photoabsorber in tandem solar cells and photoelectrochemical (PEC) devices. To enhance stability against photo-induced corrosion, GaN passivation layers have been employed. This study evaluates the stability of p-GaInP/GaN and p-GaInP electrodes for solar-driven hydrogen evolution reactions (HER) in 1.0 M HClO4. Faradaic efficiency was monitored via gas chromatography during PEC, while X-ray photoelectron spectroscopy and atomic absorption spectroscopy were used to investigate surface and dissolution process conditions. The large valence band offset of around 2.0 eV at the GaN/p-GaInP interface acts as a hole barrier, reducing recombination, while conduction band alignment facilitates electron transport. The GaN passivation layer enhances stability and achieves a low onset potential of -0.5 V for HER. Surface and electronic structural changes were analyzed to understand corrosion mechanisms.

HL 20.5 Tue 10:00 P3

Characterization of surfaces of mixed semiconductor crystals — •Marsel Karmo[1] and Martin Brehm[2] — [1]Warburger Str. 100 33098 Paderborn — [2]Warburger Str. 100, 33098 Paderborn

Compositionally disordered crystals, also known as mixed-crystals, play a crucial role in semiconductor engineering. They enable the manipulation of material properties such as the band gap, which is important for opto-electronic devices like solar cells. Additionally, these crystals are used as buffer layers to mitigate strain from lattice constant mismatches between different material layers. However, accurately describing mixed crystals theoretically presents significant challenges. Due to the random occupation of atomic sites it is not possible to introduce a unit cell in other words the crystal as a whole is the unit cell. This prohibits also the use of boundary conditions. A commonly used approach to approximate mixed crystals is the Supercell Method (SCM), which employs a large, unit cell with random atomic site occupations. While this method approximates a mixed crystal, it is limited by computational resources. Another approach is the Virtual Crystal Approximation (VCA), which replaces the mixed crystal with an analytically averaged system. This method reduces the computational effort by using a smaller unit cell but may overlook local atomic environments, potentially limiting its ability to capture certain physical properties. In this work, we compare these two methods, VCA and SCM within the Vienna Ab Initio Simulation Package (VASP) to evaluate their performance in calculating the electronic structure and surface formation energy.

HL 20.6 Tue 10:00 P3

Photoelectrochemical characterisation of InGaN/GaN nanowire arrays — •Genrietta Steingelb[1], Hannah Nell[1], Rudolfo Hötzel[1], Ruben Neelissen[1], Stephan Figge[1], Tim Grieb[1], Florian Krause[1], and Martin Eickhoff[1,2] — [1]Institute of Solid State Physics, University of Bremen, Otto-Hahn-Allee 1, 28359 Bremen, Germany — [2]MAPEX Center for Materials and Processes, University of Bremen, Bibliotheksstraße 1, 28359 Bremen, Germany

Group III-nitride materials are known for their stability under physiological conditions, making them ideal candidates for use as electrochemical biosensors [1]. In this work, we present a detection mechanism that combines simultaneous photoluminescence (PL) and photocurrent measurements of InGaN/GaN nanowire (NW) arrays, allowing sensitive and selective detection of redox-active biomolecules. However, the performance of the NW photoelectrode is limited by non-radiative surface recombination of photogenerated carriers at the semiconductor-electrolyte interface, leading to irreversible photooxidation of the NW surface, mainly caused by unpassivated surface states. The deposition of ultrathin metal oxide films is a possibility to suppress such effects. The influence of surface coatings on sensor properties was analysed through photoelectrochemical characterisation, with and without metal oxide coatings. This analysis highlights how surface modifications affect sensor performance for the detection of redox-active molecules in complex biochemical environments. [1] G. Steinhoff, et al., Appl. Phys. Lett. 83, 177 (2003).

HL 20.7 Tue 10:00 P3

Impact of Surface States on the Performance and Stability of AlGaAs/GaAs HEMT Structures — •Vincent Leon Spreter[1,2], Selma Delic[1,2], Xuelin Jin[1,2], Nils von den Driesch[1], Christoph Krause[1], Detlev Grützmacher[1,2], and Beata Kardynal[1,2] — [1]Peter Grünberg Institut 9, Forschungszentrum Jülich, 52428 Jülich, Germany — [2]Department of Physics, RWTH, 52074 Aachen, Germany

Electrostatic gating is commonly used to define single-electron quantum dots (QDs) in two-dimensional electron gases, such as those in GaAs/AlGaAs heterostructures. It can also be used to tune the electronic states of epitaxial quantum dots. For the use for quantum information processing applications, gated devices must maintain a stable working point over long time.

In our contribution, we investigate the effect of surface preparation of GaAs/AlGaAs heterostructure on the long-term stability of gates on the example of split-gate devices. In addition, we explore the use of passivation layers to mitigate the effects of dangling bonds associated with surface states. We discuss the processing of devices with AlOx passivation and action of electrostatic gates on device performance, offering insights into its potential for optimizing GaAs-based optoelectronic devices.

HL 20.8 Tue 10:00 P3

Low-temperature RAS of MOVPE-prepared Si(100) surfaces — •Kai Daniel Hanke[1], Max Grossmann[2], Chris Y. Bohlemann[1], Mohammad Amin Zare Pour[1], Paszuk Agnieszka[1], Runge Erich[2], and Hannappel Thomas[1] — [1]1Technische Universität Ilmenau, Fundamentals of Energy Materials, Ilmenau, Germany — [2]2Technische Universität Ilmenau, Theoretical Physics I, Ilmenau, Germany

Recent studies have shown that As-modified Si(100)-(2 x 1) surfaces prepared in a MOCVD environment exhibit asymmetric hydrogen-passivated Si-As dimers as dominating surface motif, in contrast to the previously assumed symmetric As dimers. Due to the importance of this surface for subsequent nucleation of III-V materials, such as GaP, for high-efficiency solar cell structures, we have performed low-temperature reflection anisotropy spectroscopy measurements, which are extremely surface sensitive, in combination with density functional theory and many-body perturbation theory calculations. We also performed X-ray photoelectron spectroscopy and low-energy electron diffraction measurements for a detailed understanding of the structure and electronic properties of this surface. Our method seeks to improve knowledge of the spectral properties of semiconductor surfaces by combining theoretical understanding with experimental data to understand the complex variables that influence RAS spectra.

HL 20.9 Tue 10:00 P3

Optimization of GaSb(100) Substrate Preparation for MBE Growth of GaSb Layers — •Peter Zajac[1], Sascha R. Valentin[2], Timo A. Kurschat[2], Rainer Krage[2], Arne Ludwig[1], and Andreas D. Wieck[1] — [1]Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum, 44801 Bochum, Germany — [2]Gesellschaft für Gerätebau mbH, Klönnestr. 99, 44143 Dortmund, Germany

The preparation of epi-ready substrates for MBE growth typically involves degassing and oxide removal. The latter is often done by thermal processes, resulting in rough interfaces that are associated with pyramidal defects (PDs) in GaSb layers grown on GaSb(100) substrates [1].

This study aims to optimize GaSb substrate preparation and buffer layer growth to reduce PD formation.

We compare standard thermal oxide desorption to methods proposed in the literature, such as Ga-assisted oxide removal [2] and the insertion of an AlAsSb layer into the buffer layer [1].

Using photoluminescence spectroscopy (PL) mapping, we assess quantum well and buffer layer luminescence as indicators of material quality. Additionally, we analyze the surface morphology with atomic force microscopy (AFM), focusing on the properties of pyramidal defects.

[1] Murray, Lee M., et al. *J. Vac. Sci. Technol. B* **31.3** (2013).
[2] Mathews, Sen, et al. *J. Vac. Sci. Technol. B* **35.2** (2017).

HL 20.10 Tue 10:00 P3

Passivation Protection Layers for Highly efficient Multi-Absorber Devices for Photoelectrochemical Solar Fuel Production — •Negin Mogharehabed[1], Mohammad Amin Zare Pour[1,2], Jennifer Velázquez Rojas[3], Christian Höhn[3], Roel van de Krol[3], Thomas Hannappel[2], and Agnieszka Paszuk[1] — [1]Paszuk Group, Technische Universität Ilmenau, Germany — [2]Fundamentals of Energy Materials, Technische Universität Ilmenau, Germany — [3]Institute for Solar Fuels, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Germany

In photoelectrochemical cells with the highest solar-to-hydrogen conversion efficiencies, the heterointerface between a III-V top layer and a metal oxide protection layer should be optimized to minimize charge carrier losses. Using photoemission spectroscopy, we study the TiO_2/InP(100) heterointerface as a function of InP surface preparation and Ti precursor.

InP(100) substrates were prepared with either a well-ordered, phosphorus-terminated surface in a metal-organic chemical vapor deposition (MOCVD) reactor or with a thin oxide layer. TiO_2 was deposited via atomic layer deposition (ALD) using either titanium tetrachloride ($TiCl_4$) or titanium isopropoxide (TTIP) as the Ti precursor, along with water as the co-reactant.

Depending on the Ti precursor and the InP surface preparation, we observed either a nucleation delay or acceleration and differences in the band alignment. Layers grown with the TTIP precursor showed the presence of Ti^{3+} states, which may act as trap centers.

HL 20.11 Tue 10:00 P3

Characterization of Arsenic- and Antimony Containing Heterostructures Grown by Molecular Beam Epitaxy — •Max H. W. Ziehfreund[1], Peter F. Zajac[1], Sascha R. Valentin[2], Timo A. Kurschat[1,2], Rainer Krage[2], Arne Ludwig[1], and Andreas D. Wieck[1] — [1]Lehrstuhl für Angewandte Festkörperphysik der Ruhr-Universität Bochum, 44801 Bochum, NRW, Germany — [2]Gesellschaft für Gerätebau mbH, Klönnestr. 99, 44143 Dortmund, NRW, Germany

This study focuses on the investigation of the surface morphology of various arsenic- and antimony-containing semiconductor heterostructures grown by molecular beam epitaxy. The objective is to optimize the growth parameters used in fabrication and to gain a better understanding of the underlying growth process. The characterization methods developed and approved for GaAs-based heterostructures are applied to GaSb-heterostructures. The primary methods employed are photoluminescence spectroscopy and atomic force microscopy. It was possible to examine the influence of various parameters, such as the antimony flux used during growth on the epitaxial quality of the grown layers and collect valuable experience for defect-free growth of arsenic- and antimony-containing heterostructures.

HL 20.12 Tue 10:00 P3

High Resolution Temperature Mapping of GaSb Wafers during MBE Growth — •Timo A. Kurschat[1], Sascha R. Valentin[1], Peter Zajac[2], Rainer Krage[1], and Andreas D. Wieck[2] — [1]Gesellschaft für Gerätebau mbH, Klönnestr. 99, D-44143 Dortmund — [2]Lehrstuhl für angewandte Festkörperphysik, Ruhr-Universität Bochum, D-44801 Bochum

The substrate temperature is one of the most important parameters during MBE growth. Thermocouples and pyrometers, as well as more advanced techniques, measure only a single spot on the wafer at a time. Knowing the temperature distribution allows to optimize the growth parameters from just a single grown sample.

To obtain high-resolution thermal maps we use a commercial SLR camera with its infrared filter removed. The sensor is sensitive up to a wavelength of about 1000 nm and can therefore be used as a high resolution pyrometer. Without substrate rotation and 10 s exposure time, measurements can be made down to T_S = 400 °C. With rotation enabled and a reduced exposure time of 0.25 s, it is still possible to obtain images at the growth temperature of T_S = 680 °C.

Images of quarter 2-inch GaSb wafers show differences of more than 20 K between the center and the corners. The effect of a washer was investigated with this method, which is a ring placed at the backside of the wafer to improve its temperature uniformity. The temperature differences also effect the photoluminescence intensity of a quantum well grown on the wafer.

HL 20.13 Tue 10:00 P3

Raman spectroscopy on MBE grown III-V semiconductors heterostructures — •Arijit Chakraborty[1], Yiteng Zhang[1], Tom Fandrich[1], Doaa Abdelbarey[1], Tom Rakow[1], Krupali Dobariya[1], Sulabh Shrestha[1], Eddy P. Rugeramigabo[1], Michael Zopf[1,2], and Fei Ding[1,2] — [1]Leibniz Universität Hannover, Institute for Solid State Physics, Hannover, Germany — [2]Leibniz Universität Hannover, Laboratorium for Nano- und Quantum Engineering, Hannover, Germany

We present micro-Raman spectroscopic measurements on molecular beam epitaxy (MBE) grown semiconductors heterostructures, and quantum dots. This technique offers unique insights into the vibrational modes, crystal structure, strain, alloying effects and defects of grown semiconductor structures, making it invaluable for the optimization of MBE processes. The Raman results for the relaxed material have been interpreted in the framework of the modified random element isodisplacement theory considering different vibrational modes of the lattice with changing compositional range. Optical-phonon deformation potentials have been successfully used to fit the different vibrational phonon frequencies in strained layers of semiconductors. Using comparable theoretical models, a substantial compositional dependency with phononic vibrations is found and established. Disordered activated vibrational modes are investigated for layers produced on various substrates. An analogous conclusion with the peak shift in photoluminescence spectra is reached by analyzing the Raman spectra of herostructures grown on InP-based substrates.

HL 20.14 Tue 10:00 P3

Copper tin oxide: an amorphous, bipolar, ternary oxide system with tunable electrical and optical properties — •Arne Jörns, Holger von Wenckstern, and Marius Grundmann — Leipzig University, Felix Bloch Institute for Solid State Physics

Copper oxide (CuO) is one of the most studied p-type semiconducting metal oxides [1]. Tin oxide (SnO_2) features high transparency in the visible range, high n-type electrical conductivity and non-toxicity [2]. Due to mismatching crystal structures of CuO and SnO_2 (and their other oxidation states) an amorphous alloy, copper tin oxide (CTO), can form when combining these materials. Depending on growth pressure and cation composition the material can be p-type [1] or n-type making it a promising candidate for complementary amorphous devices. In this work, we investigated physical properties of CTO thin films, deposited by combinatorial pulsed laser deposition of segmented CuO and SnO_2 targets at room temperature and in oxygen atmosphere, as a function of cation composition and growth pressure. The resulting samples are X-ray amorphous and n-type semiconducting with mobilities up to 11 cm^2/Vs for Cu/(Cu + Sn) < 0.8. Optical and electrical properties can be tuned by varying composition ratio and oxygen pressure. A temperature-dependent Hall effect analysis has led to the conclusion that the percolation model provides the most accurate description. For Cu/(Cu + Sn) > 0.8, the samples become p-type conducting and feature low mobilities.

HL 20.15 Tue 10:00 P3

low-temperature buffer layer-assisted heteroepitaxial growth of γ-CuI thin films by pulsed laser deposition: tailoring electrical properties — •Yang Chen[1], Michael S. Bar[1], Susanne Selle[2], Daniel Splith[1], Michael Lorenz[1], Marius Grundmann[1], and Holger v. Wenckstern[1] — [1]Felix Bloch Institute for Solid State Physics, Faculty of Physics and Earth Sciences, Universität Leipzig, 04103 Leipzig, Germany — [2]Fraunhofer Institute for Microstructure of Materials and Systems IMWS, 06120 Halle, Germany

As the first discovered p-type transparent conductive material, copper(I) iodide (CuI) is considered to be among the most competitive p-type candidate in the field of transparent electronics. Herein, we introduced a low-temperature buffer-layer-assisted strategy to grow γ-CuI on c-plane sapphire by pulsed laser deposition with unprecedented structural quality and electrical transport properties. By adjusting the growth temperature, we can manipulate the rotation domain structure, control the hole concentration in the range from 10^{14} cm^{-3} to 10^{19} cm^{-3} and achieve mobility μ_h = 25 $cm^2V^{-1}s^{-1}$ being similar to that of bulk CuI. Based on the temperature dependent Hall-effect measurement, the ionization energy of shallow acceptors $E_{I,S}$ = 137 ± 8 meV and deeper acceptors $E_{I,D}$ = 262 ± 23 meV were determined. This strategy not only enables high-quality CuI film preparation, but also to tailor their electrical properties for integration with n-type semiconductors in transparent electronic circuits.

HL 20.16 Tue 10:00 P3

Mechanical, electronic and optical properties of $LiNbO_2$ and $NaNbO_2$ from first-principles calculations — •Frederik Schmidt and Arno Schindlmayr — Universität Paderborn, Department Physik, 33095 Paderborn, Germany

The layered compound $LiNbO_2$ is of interest as a superconductor and possible battery material, but its electronic and optical properties have not yet been extensively analyzed, especially in theoretical simulations. There are even fewer studies of the closely related $NaNbO_2$. In this work, we perform first-principles calculations to investigate the properties of $LiNbO_2$ and $NaNbO_2$. The elastic constants and related parameters, such as elastic moduli, are determined using density-functional theory. We show that even small biaxial strain up to ±5%, which corresponds to common substrates like $MgAl_2O_4$ or SiC, may lead to significant changes in the electronic band structure and to a qualitative transition from a direct to an indirect band gap. Accurate results for the electronic band structure and the optical absorption spectrum are obtained from the *GW* approximation and the Bethe-Salpeter equation. We find that both the quasiparticle corrections and excitonic effects have a significant influence on the dielectric function. Good quantitative agreement with the experimentally measured absorbance and the absorption edge at 2 eV for $LiNbO_2$ is achieved only by a proper inclusion of both factors.

HL 20.17 Tue 10:00 P3

Bismuth oxyselenide (Bi2O2Se): Insights into chemical bonding and structural properties — •Sumayya Sumayya[1], Yuan Yu[1], Carl Friedrich Schon[1], Kim Dasol[1], Yueyang Yang[2], and Matthias Wuttig[1] — [1]RWTH, Aachen, Germany — [2]Tsinghua University, China

The Bismuth Oxychalcogenides (Bi2O2X, X=S, Se, Te) are potential candidates in various fields such as Thermoelectrics, Ferroelectrics, Piezoelectrics, and photodetectors due to their unique 2D layered structure containing a bismuth oxide layer and a chalcogen layer. In this family, Bi2O2Se is considered the 2D rising star for the semiconductor industry because of its high crystallographic symmetry, tunable band gap, ultra-high electron mobility, strong Shubnikov-des Haas quantum oscillations, unique defects, and excellent stability. The relationship between bonding and material properties offers a versatile platform for tailoring electronic and vibrational properties, potentially leading to improved functional characteristics. Recently, many theoretical and experimental bonding descriptors such as electron transferred and shared values, Born effective charge, electrical conductivity, optical dielectric constant, Grüneisen parameter, and Probability of Multiple events in atom probe tomography have been devised. Our study employs a combination of advanced characterization techniques and theoretical calculations to probe the nature of bonding at different length scales, from local atomic level to extended structural motifs. In the future, this model can be used for other layered materials to understand the structure-property relationship via chemical bonding.

HL 20.18 Tue 10:00 P3

Reactive Sputter Deposition and Nitrogen Modification of $CuBi_2O_4$ as Photocathode — •Dominic Rapf[1,2], Tsedenia A. Zewdie[1,2], Ian D. Sharp[1,2], and Verena Streibel[1,2] — [1]Walter Schottky Institute, Technical University of Munich, D-85748 Garching, Germany — [2]Physics Department, TUM School of Natural Sciences, Technical University of Munich, D-85748 Garching, Germany

Copper bismuthate ($CuBi_2O_4$) is a ternary oxide that is of special interest for photoelectrochemical (PEC) water splitting. Unlike most transition metal oxides, which predominantly exhibit n-type conductivity, copper bismuthate is a native p-type semiconductor. [1] In addition, it has a suitable bandgap for the absorption of visible light, as well as a high photocurrent onset potential > 1 V vs. RHE. [2] These properties make $CuBi_2O_4$ highly desirable as a photocathode. This project focuses on the development of reactive co-sputter recipes to deposit copper bismuthate thin films and their structural, optical, morphological and opto-electronic analysis. In addition, we explore nitrogen incorporation to narrow the band gap of $CuBi_2O_4$ for more efficient light absorption (N:$CuBi_2O_4$). By modifying the nitrogen content in the reactive gas mixture and applying post-annealing treatments, we can tailor the level of nitrogen incorporation. On a library of N:$CuBi_2O_4$ thin films, we investigate the impact of nitrogen incorporation on optical and structural properties and assess their PEC performance.

HL 20.19 Tue 10:00 P3

The impact of Bi and Na non-stoichiometry on the electrocaloric effect in (Na0.5Bi0.5)TiO3-BaTiO3 ceramics — •Sobhan M. Fathabad, Mohammadamin H. Kashani, Eva Kröll, Vladimir V. Shvartsman, and Doru C. Lupascu — Institute for Materials Science and Center for Nanointegration Duisubrg-Essen (CENIDE), University of Duisburg Essen, Essen, Germany

The electrocaloric effect (ECE) is the phenomenon where polar crystals experience a change in isothermal entropy or adiabatic temperature in response to the application or removal of an electric field. In this work, we investigate the influence of Bi and Na non-stoichiometry on the depolarization mechanism and electrocaloric effect in BaTiO3 - (Na0.5Bi0.5)TiO3 compounds at the morphotropic phase boundary. Ceramic samples were prepared using the solid-state synthesis method. The polarization hysteresis loops were measured in the temperature range from -20 °C to 200 °C and subsequently the ECE was indirectly estimated in the framework of the thermodynamic approach based on the Maxwell relation. The depolarization temperature was studied using dielectric permittivity, X-ray diffraction, and pyrocurrent analysis. Direct measurements of the ECE were conducted using a quasi-adiabatic calorimeter. It was shown that the introduced defects reduce the depolarization temperature, consequently shifting the maximum ECE towards room temperature.

HL 20.20 Tue 10:00 P3

Structure and lattice distortions of KTaO3(001) studied by LEED I-V and nc-AFM — Dominik Wrana[1,2], Marek Kuzmiak[1], Michele Reticcioli[3], Tomas Dolak[1], Florian Kraushofer[4], Michele Riva[5], Aji Alexander[1], Llorenc Albons[1], Jesus Redondo[1], Cesare Franchini[3], and •Martin Setvin[1] — [1]Charles University, Prague, Czech Republic — [2]Jagiellonian University, Krakow, Poland — [3]University of Vienna, Vienna, Austria — [4]TU Munich, Germany — [5]TU Wien, Vienna, Austria

Perovskites attract attention in many fields, yet understanding their surface structure represents a challenge. Special emphasis is focused on little lattice distortions associated with ferroelectric properties, often present in this broad class of materials. Hydroxylated KTaO3(001)-(2x1) is used here as a test case to extract the precise positions of lattice atoms by means of low energy electron diffraction (LEED) I-V, obtaining a final Pendry R-factor below 0.17. The main challenge lies in the extreme sensitivity of this surface to damage induced by the electron beam; the progressing damage is visualized at the atomic scale by noncontact atomic force microscopy (nc-AFM). Positions of lattice atoms obtained from LEED I-V analysis are used as a benchmark for a comparison with theoretical calculations performed within 30 different setups. The overall trend is that the closest match with the experiment is obtained for setups without the Hubbard U-term and with the SCAN functional

Work supported by GACR 20-21727X and MSMT LL2324.

HL 20.21 Tue 10:00 P3

Photoluminescence and photophysical properties of halide perovskite MAPbBr3 single crystal — •Liangling Wang[1,2], Francesco Vitale[2], Edwin Eobaldt[2], Thomas Alexander Zaunick[2], and Carsten Ronning[2] — [1]School of Physics and Technology, University of Jinan, Jinan 250022, P. R. China — [2]Institute of Solid State Physics, Friedrich-Schiller University Jena, Max-Wien-Platz 1, 07743 Jena, Germany

The remarkable optoelectronic properties of halide perovskite MAPbBr3 (MA=methylammonium), including near-unity photoluminescence quantum yield (PL QY), small full width at half-maximum (FWHM), tunable bandgap by mixing halide and defect tolerance, make it a compelling candidate material in solar cell, light emitting diodes (LED), photodetectors, X-ray imaging, and so on. The PL spectrum of MAPbBr3 at room temperature can be deconvoluted into two emission peaks. The major peak at 545 nm arises from band-to-band transition, while the lower energy peak at 560 nm is associated with recombination in trap states (Br vacancies) below the optical gap. Interestingly, PL enhancement of MAPbBr3 is found under certain laser irradiation, indicating that the surface defects are benefit charge carrier trapping and recombination. In order to verify the origin of the emission centers, power dependent PL, including both power increase and decrease processes, will be analyzed. Furthermore, thermal activation and excitonic effects of PL under different temperature from cryogenic temperature of liquid Helium to room temperature will be investigated.

HL 20.22 Tue 10:00 P3

Resolving temporal signatures of optical excitations in semiconductor nanostructures — •Lion Krüger, Fabian Brütting, Moritz B. Heindl, and Georg Herink — Experimental Physics VIII, University of Bayreuth, Germany

Characteristic ultrafast signatures in the photo-induced response of nanostructured materials encode the class of optical excitations and characterize the performance for opto-electronic applications. Time-resolved visible transient absorption (TA) spectroscopy and optical pump THz probe (OPTP) spectroscopy are well-established methods for contact-free probing of ultrafast dynamics. Here, we present correlated TA-OPTP measurements performed in a setup that combines multiple probing modalities under identical excitation conditions. In particular, we present different strategies to enhance detection speed and sensitivity, enabling the disentanglement of free carrier and excitonic signatures in semiconductor nanostructures of varying dimensionality and quantum-confinement [1].

HL 20.23 Tue 10:00 P3

Characterization of the electrical properties of Bismuth doped Methylbenzylamine Lead Iodide 2D Perovskites using impedance spectroscopy — •Keito Mizukami[1,2,3], Hannes Hergert[1,3], Tim Schneider[3,4], Jan Heinrich Littmann[1,3], Satoko Fukumori[2], Philip Klement[1,3], Derck Schlettwein[3,4], Hirokazu Tada[2], Sangam Chatterjee[1,3], and Matthias T. Elm[1,3] — [1]Institute of Experimental Physics I, JLU Giessen, Giessen, Germany — [2]Graduate School of Engineering Science, Osaka University, Japan — [3]Center for Materials Research, JLU Giessen, Giessen, Germany — [4]Institute of Applied Physics, JLU Giessen, Giessen, Germany

Low-dimensional organic-inorganic perovskites offer largely tunable materials properties such as the crystal structure or the electronic band gap due to the flexibility of the incorporated building blocks. Perovskites with incorporated chiral organic molecules as the cation attract a lot of attention as they exhibit chiral properties such as chirality-induced spin selectivity or spin-polarized electron current. However, the typically low electrical conductivity hinders applications and requires appropriate doping schemes to improve the device performance. In this study, we investigate the impact of Bi substitution for Pb in methylbenzylamine bismuth lead iodide single crystals and thin films on the electric properties using impedance spectroscopy. Our objective is to get a fundamental understanding of the charge transportation and relaxation mechanism in these mixed conductors.

HL 20.24 Tue 10:00 P3

Hysteretic Piezochromism in a two-dimensional perovskite — •Paul Steeger[1], Mohammad Adnan[1], Thorsten Deilmann[2], Xiang Li[3,4], Susanne Müller[4], Katarzyna Skrzynska[5], Michael Hanfland[4], Efim Kolesnikov[3], Jutta Kösters[6], Theresa Block[6], Robert Schmidt[1], Ilya Kupenko[3,4], Carmen Sanchez-Valle[3], Vijaya Prakash[7], Steffen Michaelis de Vasconcellos[1], and Rudolf Bratschitsch[1] — [1]Physikalisches Institut Universität Münster — [2]Institut für Festkörpertheorie Universität Münster — [3]Institute für Mineralogie Universität Münster — [4]Europäischer Synchrotron ESRF Grenoble — [5]Institute of Earth Sciences University of Silesia — [6]Institut für Anorganische und Analytische Chemie Universität Münster — [7]Department of Physics IIT Dehli

Two-dimensional inorganic-organic hybrid perovskites hold potential for application in the field of optoelectronics. One representative of this class of materials is cyclohexenyl-eythylammonium lead-iodide (CHPI). Here, we present pressure-dependent optical absorption and emission spectra of CHPI. We find a strong change of the band gap when exerting pressure on the crystal using a diamond anvil cell. In contrast to other 2D perovskites the bandgap of CHPI undergoes a full hysteresis loop under pressure. To reveal the origin of the observed phenomena, we combine our optical experiments with DFT calculations as well as X-ray diffraction measurements under high pressure. HL 20.25 Tue 10:00 P3

Electron and Hole polaron Formation in lead-free CsGeX3 (X=Cl,Br,I) perovskites — •Mehmet Baskurt — Chalmers University of Technology

The unique electronic properties of CsGeX3 (X = Cl, Br, I) perovskites make them promising candidates for nonlinear optical applications. The nature of charge localization must be understood to explain their physical and electronic behaviors. Here, we carry out a theoretical investigation on electron and hole polaron formation in CsGeX3. We carry out density functional theory calculations in the hybrid function level. Our results show that there is a trend in the polaron formation energies, CsGeCl3 > CsGeBr3 > CsGeI3. In particular, single electron polarons form highly favorably in all three materials, whereas single hole polarons can only be formed in CsGeCl3. Moreover, double electron polarons form energetically favorably across the series. These findings constitute a basis for understanding polaronic effects on the electronic properties of CsGeX3 perovskites and open up access to their optimization in nonlinear optical applications.

Transport properties of quantum dots for single-electron pumps — •Johannes C. Bayer, Thomas Gerster, Dario Maradan, Frank Hohls, and Hans W. Schumacher — Physikalisch-Technische Bundesanstalt, 31668 Braunschweig, Germany

A single-electron pump (SEP) is a device emitting a well-defined number of n electrons per cycle of an external drive. With driving frequency f and elementary charge e, this results in a current of $I = nef$. Since the revision of the SI system, the elementary charge e hereby is an exact value, so that SEPs provide a suitable basis for a quantum current standard. The accuracy of this current is directly related to erroneous cycles, where the emitted number of electrons deviates from n. Our SEP devices are based on electrostatically defined quantum dots in GaAs/AlGaAs two-dimensional electron gases. In such devices, the tunnel barriers as well as the energy levels are controllable via gate voltages. Based on multiple quantum dot devices we here investigate relations between transport properties and SEP operation characteristics.

HL 23.2 Tue 11:30 H13

Non-Markovian higher-order electron pump: improvement of efficiency — •Lukas Litzba, Jürgen König, and Nikodem Szpak — Fakultät für Physik, Universität Duisburg-Essen, Lotharstraße 1, Duisburg 47057, Germany

We consider an electron pump that consists of a non–interacting quantum dot and electron baths. Our pumping setup utilizes only higher–order tunneling processes, which are purely quantum mechanical and have no classical analog. In order to study higher order tunneling–mechanism and non–Markovian effects, we extend the exact Heisenberg equation and the Laplace transform technique to time–dependent Hamiltonians and apply this technique to our model. Thereby, we identify parameter ranges which lead to a significant increase of the current flowing through the quantum dot and an improvement of the energetic efficiency of these processes.

HL 23.3 Tue 11:45 H13

Fast Machine-Learning assisted characterisation of current quantisation — •Wang Ngai Wong[1], Yannic Rath[1], Nikolaos Schoinas[1], Shota Norimoto[1], Masaya Kataoka[1], Alessandro Rossi[1,2], and Ivan Runnger[1,3] — [1]National Physical Laboratory, Teddington, TW11 0LW, UK — [2]Department of Physics, SUPA, University of Strathclyde, Glasgow G4 0NG, UK — [3]Department of Computer Science, Royal Holloway, University of London, Egham, TW20 0EX, UK

Characterisation of single-electron pumps (SEPs) has long been bottlenecked by the process of fine-tuning measurement parameters to study their novel properties. This limits potential experimental parameters to those that can remain static throughout the fine-tuning process. We demonstrate a novel method assisted by machine learning which has led to an eightfold speedup in the measurement process (see Appl. Phys. Lett. 125, 124001 (2024)), and in so doing opens the door to further characterisation experiments which are impossible using conventional methods. Our method is based around an active learning cycle to navigate the information landscape of the gate voltage parameter space, while also significantly reducing the number of measurement points required. This is paired with a post-processing approach which allows us to accurately predict and characterise the small operational regimes significantly more efficiently than conventional sweeps across the parameter space. We exploit the framework to characterise the behaviour of multiplexed GaAs multi-pump devices across a range of magnetic fields.

HL 23.4 Tue 12:00 H13

Novel Mixed-Dimensional Reconfigurable Field Effect Transistors — •Sayantan Ghosh[1,2], Muhammad Bilal Khan[1], Phanish Chava[1], Kenji Watanabe[3], Takashi Taniguchi[3], Slawomir Prucnal[1], René Hübner[1], Thomas Mikolajick[2], Artur Erbe[1,2], and Yordan M Georgiev[1,4] — [1]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]Technische Universität Dresden, Dresden, Germany — [3]National institute for Material Science, Tsukuba, Japan — [4]Institute of Electronics, Bulgarian Academy of Sciences, Sofia, Bulgaria

The limitations of CMOS downscaling drive the exploration of alternative device concepts like reconfigurable FETs (RFETs), which can dynamically switch between n- and p-polarity through electrostatic gating. This work introduces a novel mixed-dimensional RFET utilizing 1D silicon (Si) nanowires combined with 2D hexagonal boron nitride (hBN) as a dielectric and encapsulating layer. hBN*s insulating properties, chemical stability, and absence of dangling bonds make it ideal for its use as a dielectric in 1D electronics. The RFET fabrication employs electron beam lithography, reactive ion etching, and flash lamp annealing for precise silicide formation. Mechanically exfoliated hBN flakes (5-10 nm) were integrated using dry stamping transfer, with thickness characterized by

microscopy techniques. Device characterization reveals improved subthreshold swing, on-current, and ION/IOFF ratio due to hBN*s 2D passivation, highlighting its potential for advanced nanowire-based RFET architectures.

HL 23.5 Tue 12:15 H13

Kondo effect for half-filling of the third shell of a quantum dot — •Olfa Dani[1], Johannes C. Bayer[1], Timo Wagner[1], Gertrud Zwicknagl[2], and Rolf J. Haug[1] — [1]1Institut für Festkörperphysik, Leibniz Universität Hannover, Hannover, Germany — [2]2Institut für Mathematische Physik, Technische Universität Braunschweig, Braunschweig, Germany

In this work, we investigate the electrical transport in the third shell [1] of a gate-defined GaAs quantum dot. The exact number of electrons in the quantum dot (N_e) is determined using a quantum point contact as a sensitive charge detector, detecting single-electrons tunneling through the system [2]. N_e is varied by changing the applied gate voltage.

The addition energy E_c for N_e = 7 - 11 shows a triangular behavior with a maximum at half-filling of the shell. This observed behavior is described analytically with Hund's rule exchange interaction. Besides, for successive numbers of electrons occupying the quantum dot N_e = 7 to 11, a Zero-bias anomaly (ZBA) characteristic for the Kondo effect is observed [3]. The width of the ZBA exhibits a triangular behavior, with a maximum at N_e = 9, similar to E_c. The broadening of the ZBA is attributed to the contribution of the Kondo resonance as well as Hund's satellite peaks, originating from the degenerate orbitals observed in the spectral function.

Beyond full counting statistics and Langevin theory: The quantum polyspectra approach to multi-detector measurements — •Armin Ghorbanietemad, Markus Sifft, and Daniel Hägele — Ruhr University Bochum, Faculty of Physics and Astronomy, Experimental Physics VI, Germany

The quantum polyspectra approach to quantum measurements has recently been shown to cover the full range between weak and strong quantum measurements [1 - 3]. It provides thus a more general approach to quantum measurements than the full counting statistics used in nano-electronics or the Langevin-approach used in spin noise spectroscopy. This approach draws its strength from comparing higher order spectra of the measurement record with model spectra calculated from quantum expressions that are calculated on the level of a Lindblad master equation. Here, we generalize the polyspectra approach to include the case of the simultaneous measurements of more than one quantity of a quantum system. The approach regards measurement induced damping, measurement backaction, and the quantum Zeno effect. We give a few examples of multi-detector polyspectra that were calculated by a multi-detector extension of our SignalSnap and QuantumCatch library [4, 5].

HL 23.7 Tue 12:45 H13

Revealing Hidden States in Quantum Dot Array Dynamics: Quantum Polyspectra Versus Waiting Time Analysis — •Markus Sifft[1], Johannes C. Bayer[2], Daniel Hägele[1], and Rolf J. Haug[2] — [1]Faculty of Physics and Astronomy, Ruhr University Bochum, GER — [2]Institute of Solid State Physics, Leibniz Universität Hannover, GER

We show how by virtue of the recently introduced quantum polyspectral analysis of transport measurements [1,2], the complex transport measurements of multi-electron QD systems can be analyzed. This method directly relates higher-order temporal correlations of a raw quantum point contact (QPC) current measurement to the Liouvillian of the measured quantum system. By applying this method to a two-electron double QD system, we uncover dynamics between singlet and triplet states, indistinguishable in the QPC current, without requiring the identification of quantum jumps or prior assumptions about the number of quantum states involved. Our findings demonstrate that system models in such cases of hidden dynamics are inherently non-unique. Furthermore, we compare our method to a traditional analysis via the waiting-time distribution. Our method achieves parameter estimates with up to 50% lower errors, while also being applicable in scenarios with low signal-to-noise, where traditional counting methods falter. Our approach challenges previous assumptions and models, offering a more nuanced understanding of QD dynamics and paving the way for the optimization of quantum devices.

HL 24: Thermal Properties

Time: Tuesday 12:15–13:00 Location: H14

HL 24.1 Tue 12:15 H14

Combined optical and thermal characterization of III-nitride membranes by microphotoluminescence and Raman thermometry — •Gordon Callsen[1], Mahmoud Elhajhasan[1], Julian Themann[1], Katharina Dudde[1], Guillaume Würsch[1], Jean-François Carlin[2], Raphaël Butté[2], Nicolas Grandjean[2], Nakib Haider Protik[3], and Giuseppe Romano[4] — [1]Universität Bremen, Germany — [2]EPFL, Lausanne, Switzerland — [3]HU Berlin, Germany — [4]MIT-IBM Watson AI Lab, Cambridge, USA

We present the optical and thermal analysis of photonic III-nitride membranes, which provides novel insights into the physics of thermal transport on the micrometer scale [1]. By combining Raman thermometry (RT) with μPL spectroscopy, we demonstrate a non-invasive approach to extract the thermal conductivity κ. This analysis shows that even at 295 K one can still observe quasi-ballistic phonon transport in GaN, which challenges commonly applied models building on purely diffusive transport. Our membranes are made from c-plane GaN and comprise $In_xGa_{1-x}N$ (e.g., x = 0.15) quantum wells that already served as an active medium in various nanolasers [2]. The material is either grown on silicon or sapphire and is subsequently underetched, yielding freestanding structures. On such samples we perform μ-RT, either based on one-laser RT or spatially resolved two-laser RT. The latter is key to our thermal imaging, representing a significant step towards non-invasive and quantitative thermometry on photonic membranes.

HL 24.2 Tue 12:30 H14

Impact of AlGaAs interlayers on the thermal conductivity of GaAs micropillars — •Guillaume Würsch[1], Ching-Wen Shih[2], Mahmoud Elhajhasan[1], Katharina Dudde[1], Imad Limame[2], Stefan Reitzenstein[2], and Gordon Callsen[1] — [1]Institut für Festkörperphysik, Universität Bremen, Germany — [2]Institut für Festkörperphysik, Technische Universität Berlin, Germany

First measurements of coherent heat conduction in semiconductor superlattices (SL) were reported over a decade ago. Interestingly, such an effect that is based on phonon interference can already be observed at room temperature, which sparks interest in measuring and controlling most fundamental phonon parameters like their mean free path l_{mfp} and wavelength λ_{therm}.Observing the effects of phonon interference in SLs can be challenging, because material stacks with superb crystalline quality and interfaces is required. In this work, we follow a step-by-step approach, meaning that we analyse GaAs micropillars (diameter: 0.5 - 2 μm) with a rising number (0 - 7) of $Al_{0.8}Ga_{0.2}As$ interlayers. A thin layer of gold on top of these structures enables the measurement of the thermal conductivity κ via the frequency-domain thermal reflection (FDTR) technique, which is complementary to the Raman thermometry that we apply.Our study on first samples with a small numbers of interlayers provides not only insight into the thermal impact of each individual interface, but highlights the impact of the micropillar diameter. Building on such knowledge will allow us in future studies on larger SLs to disentangle phonon interference effects and phonon scattering phenomena.

HL 24.3 Tue 12:45 H14

Signature of thermal phonon mean free paths monitored by Raman thermometry — •Katharina Dudde[1], Mahmoud Elhajhasan[1], Guillaume Würsch[1], Julian Themann[1], Nakib Protik[2], Dwaipayan Paul[2], Giuseppe Romano[3], and Gordon Callsen[1] — [1]Institut für Festkörperphysik, Universität Bremen, Germany — [2]Institut für Physik und IRIS Adlershof, Humboldt-Universität zu Berlin, Germany — [3]MIT-IMB Watson AI Lab, IBM Research, Cambridge, MA, USA

For an understanding of thermal phonon interference effects, one requires knowledge about the related phonon mean free paths l_{mfp}. In the recent past, spectroscopy methods were developed to determine l_{mfp} based on this idea: One performs thermal transport measurements under the variation of a characteristic experimental length scale L aiming to extract effective thermal properties such as the effective thermal conductivity $\kappa_{eff}(L)$. In this contribution, we analyze how non-invasive one-laser Raman thermometry (1LRT) can pose a novel option to perform thermal phonon l_{mfp} spectroscopy. Therefore, we first analyze bulk silicon at 293 K, while varying the laser focus spot radius (w_e). Here, we find a strong dependence of κ_{eff} on w_e. This dependence is more pronounced at 200 K, because l_{mfp} is increased. The second variable length scale for 1LRT

is the light penetration depth (h_α), which is varied in a set of measurements for silicon membranes at 293 K. Again, a dependence of κ_{eff} on h_α is observed. Finally, our variation of w_e or h_α during 1LRT provides first insight into the impact of different thermal phonon l_{mfp} ranges on κ_{eff}.

HL 29: Poster II

The second poster session on the physics of semiconductors covers topics from 2D semiconductors and van der Waals heterostructures, the physics of the van der Waals magnetic semiconductor CrSBr, materials and devices for quantum technology, quantum dots and wires, transport properties, to ultra-fast phenomena in semiconductors.

Time: Tuesday 18:00–20:00 Location: P1

HL 29.1 Tue 18:00 P1

Electrical Field Effect and Schottky Barriers in $FePSe_3$ Thin Films — •Paul Perl[1], Lars Thole[1], Sonja Locmelis[2], and Rolf J. Haug[1] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, 30167 Hannover, Germany — [2]Institut für Anorganische Chemie, Leibniz Universität Hannover, 30167 Hannover, Germany

Transition metal selenophosphates (MTPs) are a group of promising 2D materials for applications like transistors and photodetectors [1,2]. Among MTPs, iron selenophosphate ($FePSe_3$) has one of the lowest band gap energies at 1.3 eV [2]. The goal of this work is to examine the influence of the electric field effect on electrical transport and to study the Schottky barriers formed at metal contacts. Moreover, the temperature dependence of the investigated effects is analyzed.

In order to investigate the electrical properties of $FePSe_3$ in thin films below 30 nm, layers are mechanically exfoliated onto a Si/SiO_2 substrate. Electrical contacts for the exfoliated flakes are fabricated via electron beam lithography and physical vapor deposition. $FePSe_3$ exhibits a hysteresis in its transport characteristics when the applied backgate voltage is altered, indicating favorable characteristics for memory devices. Furthermore, differences in Schottky barriers for various contact material compositions become apparent, showing their influence on electric transport properties.

HL 29.2 Tue 18:00 P1

Fabricating MoS_2 nanotube quantum dots on 2D heterostructures — •Korbinian Fink[1], Robin T. K. Schock[1], Stefan B. Obloh[1], Matthias Kronseder[1], Matjaž Malok[2], Maja Remškar[2], and Andreas K. Hüttel[1] — [1]Institute for Experimental and Applied Physics, Universität Regensburg, Regensburg — [2]Solid State Physics Department, Jožef Stefan Institute, Ljubljana, Slovenia

MoS_2, a transitional metal dichalcogenide (TMDC) with interesting optical and electronic properties, e.g., broken inversion symmetry and strong spin-orbit coupling leading to spin split bands, is at the center of manifold research efforts. Building a MoS_2 based QD remains challenging: the spatial quantization depends on the effective electron mass, which is high in MoS_2, and minuscule devices sizes are required.

In order to reduce the lithographic constraints we utilize nanotubes, as these confine charges in an additional dimension. However, these QDs are still limited by the disorder from the SiO_2 surface. This can be resolved by fabricating the devices on top of 2D heterostacks consisting of hBN and few layer graphite.[1]

The major challenge for creating such devices is reproducible contacts to the nanotubes, as nanogaps between the contact on the chip and the metal on top of the tube lead to high resistance variations. This can be solved by variation of the incident angle and heating during metalisation as well as fixing the tubes on the chip by cross linked resist. - [1] R. T. K. Schock et al., PSSb, 2400366 (2024)

HL 29.3 Tue 18:00 P1

Preparation of folded graphene heterostructures via dry transfer — •Hannes Kakuschke[1], Dustin Wittbrodt[2], Lina Bockhorn[1], and Rolf Haug[1] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, 30167 Hannover, Germany — [2]Physikalisch-Technische Bundesanstalt, 38116 Braunschweig, Germany

Mono- and bilayer systems of graphene have been extensively researched due to their unique magnetic and electronic transport properties. In more recent work, folded graphene [1, 2] heterostructures exhibit fascinating phenomena. This is due to the topology of the folded region, causing effects such as snake states and zero line modes. However, in transport measurements of self-assembled, folded graphene [3], multiple effects occur simultaneously. This drastically complicates the analysis of individual contributions. To solve this problem, we use the dry transfer method to fold graphene around hBN, decoupling the overlapping graphene regions.

To simulate the behaviour of such samples, Tight-Binding model calculations [4], considering strain effects [5] at the folded edge have been carried out.

HL 29.4 Tue 18:00 P1

Ferroelectric Potential Investigations of 3R MoS_2 through fast Optical Measurements — •Jan-Niklas Heidkamp[1], Swarup Deb[1,2], Takashi Taniguchi[3], Kenji Watanabe[3], Rico Schwartz[1], and Tobias Korn[1] — [1]Institute of Physics, University of Rostock, Rostock, Germany — [2]Saha Institute of Nuclear Physics, Kolkata, India — [3]National Institute for Material Science, Tsukuba, Japan

In recent years, sliding ferroelectricity has emerged as a topic of significant interest due to its possible application in nonvolatile random-access memory. This phenomenon is unique to two-dimensional van der Waals materials, where vertical polarization switching is induced by in-plane sliding of the constituent layers. The resulting polarization is influenced by the intrinsic stacking order, creating distinct polarization regions separated by domain walls. These regions, along with the domain walls, can be manipulated using an external vertical electric field, enabling a switchable system that retains the environmental robustness of van der Waals materials under ambient conditions.

In this study, we investigate 3R-MoS_2 using various optical measurement techniques at room temperature. The spatially resolved measurements reveal clear signal changes corresponding to different ferroelectric stacking orders and variations in layer count. Our findings demonstrate that fast optical mapping at room temperature is a reliable method for probing ferroelectric potential steps in 3R-stacked samples. This approach does not require a conductive substrate or backing, making it more versatile than traditional Kelvin Probe Force Microscopy (KPFM) techniques.

HL 29.5 Tue 18:00 P1

Probing TMD-nanowire hybrid structures with second harmonic generation. — •Benedikt Mathes, Maximilian Tomoscheit, Edwin Eobaldt, Alexander Zaunick, Carsten Ronning, and Giancarlo Soavi — Institut of Solid State Physics, University of Jena

Hybrid nanostructures have been drawing attention in fundamental science, since they allow to control and engineer the electronic and optical properties of samples. Transition metal dichalcogenide(TMD)-nanowire(NW) hybrid structures could have interesting applications beyond fundamental science, since they allow to tune the lasing properties of NW lasers. To understand the photophysical response of the hybrid system, it is helpful to measure the optical and electronic response of each of its individual constituent. However, this is in general difficult to achieve. In this work, we solve this problem by showing that polarization-dependent second harmonic generation(SHG) can selectively probe each constituent of a WSe_2-ZnO NW hybrid, provided that the subsystems are properly and deterministically aligned. TMDs exhibit a threefold symmetry with two main axes, armchair(AC) and zigzag(ZZ). When excited along the ZZ axis, the SH is emitted along the AC axis, whereas the SH of the NW is always emitted parallel to its long axis. Hence, by aligning the NW along the ZZ axis one can differentiate the emission from NW and TMD with a polarizer in detection aligned along the ZZ or AC axis, respectively. This way, the subsystems of the hybrid structure can be investigated individually, offering new insights into their contribution to the hybrid system.

HL 29.6 Tue 18:00 P1

Raman and photoluminescence spectroscopy on differently synthesised $MoSe_2$ — •Lara Blinov[1], Hendrik Lambers[1], Zdeněk Sofer[2], and Ursula Wurstbauer[1] — [1]Institute of Physics, University of Münster, Münster, Germany — [2]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Prague, Czech Republic

There are various synthesis methods for the widely researched transition metal dichalcogenides (TMDCs). We examine optical responses of $MoSe_2$ synthesised by chemical vapor transport (CVT) with different halogen contributions in the transport gas. Therefore, mono- and bilayers of those differently grown parental crystals are mechanically exfoliated and investigated by Raman and photoluminescence (PL) spectroscopy at room temperature as well as in temperature-dependent PL measurements.

We analyse and compare the energies and intensities corresponding to the neutral A and B excitons as well as a prominent A^- trion in the PL spectra and the frequency of the first order Raman modes. We conclude that the CVT synthesised crystals seem to have an inhomogeneous distribution of charge carrier densities or defects and that the defect density seems to be larger than in conventionally synthesised $MoSe_2$.

HL 29.7 Tue 18:00 P1

Optical Properties of Janus Transition Metal Dichalcogenides — •Sai Shradha[1], Julian Picker[2], Nicole Engel[1], Lukas Krelle[1], Daria Markina[1], Roberto Rosati[3], Ermin Malic[3], Andrey Turchanin[2], and Bernhard Urbaszek[1] — [1]Institute for Condensed Matter Physics, TU Darmstadt, Darmstadt, Germany — [2]Institute for Physical Chemistry, Friedrich Schiller University, Jena, Germany — [3]Department of Physics, Philipps-Universität Marburg, Marburg, Germany

Janus transition metal dichalcogenides (JTMDs) have a crystal structure of X-M-Y where X and Y are chalcogens and M is a transition metal. Their asymmetric structure, with chalcogen atoms of different electronegativity above and below the transition metal, leads to an intrinsic out-of-plane electric dipole. This out-of-plane symmetry breaking in JTMDs causes Rashba splitting, vertical piezoelectricity and enhanced exciton-phonon coupling. Due to a reduced overlap of the electron and hole wave functions, excitons in JTMDs are predicted to have lower binding energies and longer lifetimes. This makes them promising candidates for photovoltaic devices. Via chemical vapour deposition (CVD), high-quality Janus monolayers have been synthesised [1]. This work investigates the optical properties of CVD-grown monolayer Janus MoSSe and WSSe. Photoluminescence, Raman and differential reflectivity spectroscopy performed at room temperature and 4K are used as the key techniques to identify and further analyse excitons and exciton-phonon coupling in such systems.

HL 29.8 Tue 18:00 P1

Microscopic, Optical, and Electrical Characterization of Spray-Coated Graphene Dispersions on Sapphire Substrates — •Yasaman Jarrahi Zadeh[1], Lars Grebener[2], Muhammad Ali[3], Felix Schaumburg[1], Mohaned Hammad[2], Günther Prinz[1], Martin Geller[1], Hartmut Wiggers[3], Doris Segets[2], and Axel Lorke[1] — [1]Faculty of Physics, and CENIDE, University of Duisburg-Essen, Germany — [2]Institute for Energy and Materials Processes, and CENIDE, University of Duisburg-Essen, Germany — [3]Institute for Combustion and Gas Dynamics, and CENIDE, University of Duisburg-Essen, Germany

Processing graphene into thin films is crucial for its potential in cutting-edge applications. Here, we report on different characterization techniques to analyze the dispersion and coating performance of spray-coated graphene films on sapphire substrates. The deposited films were characterized using optical and scanning electron microscopy to evaluate coating morphology. Raman Spectroscopy and electrical characterization were used to assess the structural integrity and functional performance of the constituent graphene sheets. The deposited films fabricated from graphene sheets dispersed in water with carboxymethyl cellulose (CMC) exhibited uniform surface morphology compared to deposition with ethanol dispersion. Raman spectroscopy and electrical characterization confirmed the quality and structural integrity of the water-CMC dispersion. This study highlights key process-structure relationships for optimizing dry-synthesized graphene films for advanced technologies.

HL 29.9 Tue 18:00 P1

Vibrational fingerprint of 2D transition-metal dichalcogenide WSe_2 — •Kanivar Türk, Bastian Thomssen, Gerhard Berth, and Klaus Jöns — PhoQS Institute, CeOPP and Department of Physics, Paderborn University, Paderborn, Germany

Thin-layered transition-metal dichalcogenides (TMDC) are on high demand in the material science community [1]. The advantages of monolayer configurations of these TMDCs include the transition from indirect to direct band gap, which leads to way superior properties when compared to bulk, like optical, electrical, magnetic, thermal and mechanical improvements [2].

In this work, exfoliated 2D flakes of WSe_2 have been produced and analysed in terms of their vibrational properties via Raman spectroscopy. Beside a comprehensive phonon mode assignment, a layer number specific analysis has been performed and compared to results from photoluminescence measurements.

HL 29.10 Tue 18:00 P1

Tuning of excitonic emission of 2D-TMDs by hybridization with phase change materials — •Jakob Cornelius Wurschi, Martin Hafermann, Edwin Eobaldt, and Carsten Ronning — Institut für Festkörperphysik FSU Jena

Transition metal dichalcogenides (TMDs) are a subject of growing interest, given their wide range of potential applications, such as transistors or biosensors. Especially in the context of optoelectronic devices a precise tuning of the emission behaviour can be a powerful tool for the realisation of advanced technologies. To gain insight into potential tuning mechanisms of the excitonic emission of TMD monolayers, we investigate the hybridization of 2D MoS_2 and WS_2 flakes with germanium-antimony-telluride (GST). This compound system is capable of undergoing a phase transition between an amorphous and two crystalline states accompanied with drastic changes in the electrical and optical properties. Thermal heating triggers the phase transitions of GST, which we monitor by measuring the reflectivity of the GST thin films on silicon. After 2D-TMD flake exfoliation, in-situ measurements of the TMD photoluminescence spectra were obtained during or after the phase transitions of the GST substrate. With our approach, we observe a significant spectral shift of the excitonic emission of MoS_2 on GST/Si by precisely tuning the phase of the underlying GST. Further, for WS_2

flakes on gold substrates we observed a GST layer thickness dependent spectral shift for the excitonic emission of WS_2.

HL 29.11 Tue 18:00 P1

Gate defined exciton confinement in $MoSe^2$. — •Moritz Scharfstädt[1], Abdul R. Kanikode[1], Lasse Ebeling[2], Max Wegerhoff[1], Michael Köhl[1], Stefan Linden[1], Bernd Beschoten[2], Christoph Stampfer[2], Lutz Waldecker[2], and Andrea Bergschneider[1] — [1]Physikalisches Institut, Universität Bonn, 53115 Bonn, Germany — [2]II. Physikalisches Institut, RWTH Aachen University, 52074 Aachen, Germany

Excitons in transition metal dichalcogenides (TMDs) are ideal candidates for strong light-matter interactions due to their high oscillator strength. This has been demonstrated in numerous experiments where 2D semiconductors were embedded in photonic cavities. However, these systems lack strong nonlinearity, necessitating further efforts to realize applications such as single-photon sources. One possible approach could be the spacial confinement of excitons using an in-plane inhomogeneous electric field, as first demonstrated by [1].

We present measurements on a similar system that achieves 1D confinement of excitons along the edge of a few-layer graphene gate. While the excitons are polarized perpendicular to the edge, we observe two orthogonal linear polarization axes of the confined states. This raises questions about the selection rules in such a system.

Furthermore, we show our approach to shape the confinement into a 0D configuration to enhance exciton-exciton interactions and, presumably, the system's nonlinearity.

HL 29.12 Tue 18:00 P1

PROBING INTERLAYER EXCITONS IN PARALLEL STACKED FERROELECTRIC MOS2 — •Johannes Krause[1], Jan-Niklas Heidkamp[1], Swarup Deb[3], Kenji Watanabe[2], Takashi Taniguchi[2], Rico Schwartz[1], and Tobias Korn[1] — [1]University of Rostock, Insitute of Physics, Germany — [2]International Center for Materials Nanoarchitectonics, National Institute for MAterials Science, Tsukuba — [3]Saha Institute of Nuclear Physics, Kolkata, India

2D Transtion Metal Dichalcogenides (TMDCs) garnered significant scientific interest, due to their unique optical properties. Interestingly, 3R-stacked TMDCs exhibit sliding ferroelectricity, which opens up new platforms for nanoelectronic and memory devices. Here, we investigate the photoluminescene (PL) associated with a 3R-stacked molybdenum disulfide homobilayer, particularly the signals attributed to the interlayer exciton. Additionally, electric fields are applied to control the characteristic properties of the stack. We employ mechanical exfoliation of bulk 3R-grown MoS2-crystals and the deterministic transfer technique to fabricate and transfer the homobilayers onto SiO2 wafers with pre-patterned electrical contacts. We utilize PL measurements to characterize the relevant optical signals. By applying gate voltages across the homobilayer, we explore the optical behavior of the homobilayer stack, enabling precise modulation of exciton properties by controlling charge carrier density and Stark effect.

HL 29.13 Tue 18:00 P1

Moiré superlattice effects in $MoSe_2$-WS_2 heterobilayers — •P. Parzefall[1], N. Paulik[1], M. Lorenz[1], C. Serati de Brito[1,2], J. Göser[3], J. Trapp[3], T. Taniguchi[4], K. Watanabe[4], A. Högele[3], Y. Galvão Gobato[2], and C. Schüller[1] — [1]Institut für Exp. und Angewandte Physik, Uni Regensburg (UR), Germany — [2]Physics Department, Federal University of São Carlos, Brazil — [3]Faculty of Physics, Munich Quantum Center and Center for NanoScience, LMU Munich, Germany — [4]NIMS, Tsukuba Ibaraki, Japan

We report about optical studies on type-I $MoSe_2$-WS_2 heterostructures at cryogenic temperatures. We confirm the influence of the moiré superlattice on excitonic features of angle aligned R- and H-type structures in photoluminescence spectroscopy. The moiré-exciton and moiré-trion features are further studied by resonant low-frequency Raman spectroscopy. Here, we tune a Ti:Sapphire laser into close resonance to the $MoSe_2$ intralayer excitonic transitions. We detect an efficient pumping of the moiré trion when exciting resonantly to the moiré exciton, as the binding energy is equivalent to a phonon energy.

In time-resolved measurements using a Streak camera, we measure the lifetimes of both H-type and R-type moiré-excitonic species. The detected short excitonic lifetimes in the R-type sample is indicative of a type-I band alignment and the longer moiré-exciton lifetimes in the H-type samples might be due to a hybridization in the conduction bands [1, 2]. [1] B. Polovnikov et al., Phys. Rev. Lett. 132, 076902 (2024), [2] Y. Galãvo Gobato et al., Nano Lett. 22, 8641 (2022)

HL 29.14 Tue 18:00 P1

Acousto-optic characterization of van der Waals systems — •Felix Ehring, Benjamin Mayer, Hubert Krenner, Ursula Wurstbauer, and Emeline Nysten — Institute of Physics, University of Münster, Germany

With wavelengths in the micrometer range at GHz frequencies, surface acoustic waves (SAWs) are a versatile tool for radio frequency control and probing of charge carrier dynamics in novel semiconductor nanostructures. They are generated on a piezoelectric chip and routed over long distances to couple either mechanically or electrically with almost any nanosystem [1]. In our experiments, we fabricated hybrid lithium niobate SAW-devices including SAW delay lines with design frequencies of 150-250MHz, on which different mechanically exfoliated transition metal dichalcogenide (TMDC) 2D materials can be placed. The dynamic strain and electric field of the SAW induce a band modulation in the TMDC structure. The focus of the experiments was the investigation of MoSe2-WSe2 heterostructures and their interlayer excitons. For the characterization, the influence of the SAW fields on the recombination time and energy was investigated. Since interlayer excitons provide a much longer lifetime than intralayer excitons, transport along the propagation direction of the wave should be possible and will be part of future experiments. [1] J. Phys. D:Appl. Phys. 52(35):353001 (2019)

HL 29.15 Tue 18:00 P1

Influence of interface dielectric disorder on interlayer excitons in mixed binary/ternary TMD heterostructures — •Mohammed Adel Aly[1,2], Emmanuel Oghenevo Enakerakpor[2], Hilary Masenda[2], and Martin Koch[2] — [1]Institute of Physics and Center for Nanotechnology, University of Münster, 48149 Münster, Germany — [2]Faculty of Physics and Materials Sciences Center, Philipps-Universität Marburg, 35032 Marburg, Germany

The unique properties of transition metal dichalcogenide (TMD) monolayers and their heterostructures offer exceptional tunability. In these heterostructures, interlayer excitonic emission can be tailored based on the selection of the monolayer materials. In this study, we fabricated heterostructures based on binary-ternary monolayers, which offer enhanced tunability of the interlayer exciton emission. To understand the physics behind the interlayer excitons and their photoluminescence linewidths, we measured the photoluminescence of excitons in two TMD heterostructures, MoSe2/Mo0.5W0.5Se2 and WSe2/Mo0.5W0.5Se2, at different temperatures ranging from 10 K - 300 K. Besides neutral excitons and trions, we found that the linewidths of interlayer excitons are significantly broadened due to dielectric disorder caused by the spatial inhomogeneity at the interfaces of the heterostructures. These are important for our understanding of the nature of the interlayer excitons and their tunability for future optoelectronic devices.

HL 29.16 Tue 18:00 P1

High-Pressure Optical Spectroscopy of Intralayer and Interlayer Excitons in 2H-MoS_2 Bilayers — •Vedhanth Senthiappan Vellaiappan Uthayasurian, Paul Steeger, Robert Schmidt, Steffen Michaelis de Vasconcellos, and Rudolf Bratschitsch — Institute of Physics and Center for Nanotechnology, University of Münster, 48149 Münster, Germany

Molybdenum disulfide (MoS_2) is a van der Waals material from the class of Transition Metal Dichalcogenides (TMDCs). In 2H-MoS_2 homo-bilayers, interlayer excitons, where the electron and hole are located in different layers, are observed with a large oscillator strength and distinct energy separation from intralayer excitons. We investigate these inter- and intralayer excitons in 2H-MoS_2 homobilayers under applied pressure using a diamond anvil cell [1]. Optical transmission spectra reveal that increasing pressure reduces the energy splitting between the A exciton and the interlayer exciton. Ab initio calculations, combined with our experimental observations, indicate that this behavior cannot be attributed to conventional hydrostatic compression. Instead, it results from the MoS_2 bilayer adhering to the diamond surface, which limits in-plane compression. Furthermore, we show that the unique real-space distributions and the associated contributions from the valence band are responsible for the differing pressure responses of the inter- and intralayer excitons in compressed MoS_2 bilayers. HL 29.17 Tue 18:00 P1

Magneto-Optical Spectroscopy of van der Waals CrSBr — •Lukas Krelle[1], Ryan Tan Qai Shen[1], Daria Markina[1], Priyanka Mondal[1], Kseniia Mosina[2], Kevin Hagmann[1], Regine von Klitzing[1], Zdenek Sofer[2], and Bernhard Urbaszek[1] — [1]Institute for Condensed Matter Physics, TU Darmstadt, Hochschulstraße 6-8, D-64289 Darmstadt, Germany — [2]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Technicka 5, 166 28 Prague 6, Czech Republic

The layered antiferromagnet CrSBr is a promising Van der Waals material due to its quasi 1D nature and the strong coupling between excitons, phonons and magnons. In particular, the strong coupling of excitons to the magnetic order of the crystal opens new avenues for the study of correlated magnetic phases in optical spectroscopy. In this work, we perform magneto-optical spectroscopy on multilayer CrSBr. We use Photoluminescence and Reflectivity measurements to identify the different magnetic phases present in the sample. We report drastic changes of the emission and absorption depending on the magnetic phase of the material, which we control through the application of magnetic fields along specific directions.

HL 29.18 Tue 18:00 P1

Raman investigation of the 2D magnetic semiconductor $MnPS_3$ — •Thomas Kliewer[1], Pierre-Maurice Piel[1], Zdeněk Sofer[2], and Ursula Wurstbauer[1] — [1]Institute of Physics, University of Münster, Germany — [2]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Czech Republic

The van-der-Waals (vdW) material $MnPS_3$ is a member of the group of metal phosphorus trichalcogenides (MPX_3; X=S, Se) which experiences rising interest due to its rich physical, chemical and structural properties. $MnPS_3$ is a 2D magnetic semiconductor with an electronic bandgap of 2,79 eV[1]. Below the Néel-Temperature of 78 K, it exhibits an antiferromagnetic order within the layers and a ferromagnetic coupling between adjacent layers[2]. These properties are interesting for fundamental studies on magnetism in the 2D limit, the investigation of coupling between spin, lattice and charge degrees of freedom and for possible applications in spintronics. $MnPS_3$ flakes of various thicknesses have been studied by temperature dependent Raman spectroscopy to uncover the coupling of lattice and spin degree of freedom. The Raman-spectra of $MnPS_3$ show several phonon modes in accordance with the crystal structure. The intensity of the modes varies with the thickness of the crystal. Besides the expected hardening of the modes, the temperature-dependent measurements imply possible influence of the magnetic ordering on the observed modes. [1] Grasso et al. Physical Review B 44.20 (1991), p. 11060 [2] Wildes et al. Journal of Physics: Condensed Matter 6.24 (1994), p. L335

HL 29.19 Tue 18:00 P1

Polarisation dependant reflectance measurements of CrSBr — •Manuel Terbeck, Aleksandra Lopion, Pierre-Maurice Piel, and Ursula Wurstbauer — Institute of Physics, University of Muenster, Germany

The van der Waals layered material CrSBr has multiple interesting characteristics. It is an air-stable, optically active magnetic semiconductor. Magnetically, CrSBr exhibits ferromagnetic ordering in-plane and antiferromagnetic ordering between adjacent layers, with the easy axis being in-plane [1]. In this material the coupling between magnetic and optical properties is strong allowing us to study magnetic properties by measuring interband emissions and absorption spectra. The electronic structure is often described as quasi-1D due to the highly anisotropic properties [1]. Thus the polarisation of light is important when measuring CrSBr optically. With Raman scattering, we checked the symmetry of the crystal. Considering those axes, we measured reflectance from thin CrSBr flakes using different polarisation of light to get information about the excitonic states in this material. Unlike emission, reflectance measurements enables additional access to higher electronic states. [1] J. Klein, et al. ACS Nano, 17, 5316-5328 (2023)

HL 29.20 Tue 18:00 P1

Semiconductor-Metal Interfaces in 2D TMDCs for High-Efficiency Optoelectronic Devices — •Linus Schneider[1], Ariane Ufer[1], Elena Vinnemeier[1], Rebecca Saive[2], and Ursula Wurstbauer[1] — [1]Institute of Physics, University of Münster, Münster, Germany — [2]MESA+ Institute for Nanotechnology University of Twente, Enschede, Netherlands

Efficient solar energy conversion requires new materials and technologies that enhance solar cell performance while minimizing material usage. Two-dimensional (2D) materials, specifically transition metal dichalcogenides (TMDCs) like molybdenum disulfide (MoS_2), exhibit strong exciton-mediated light-matter interactions, making them ideal for optoelectronic devices and solar energy conversion. A critical challenge for implementation is effective charge carrier extraction at the metal-semiconductor interface. We prepare TMDC flakes using mechanical exfoliation and fabricate semiconductor-metal junctions by transferring these layers onto metallic contacts using a dry viscoelastic stamping technique. The structural and optical properties of these samples are characterized using photoluminescence (PL) and Raman spectroscopy. The charge transfer behavior at the 2D semiconductor-metal interface is probed by localized laser beam-induced current measurements and the local potential change across the junction regions by kelvin probe force microscopy (KPFM).

HL 29.21 Tue 18:00 P1

Advancing 2D Materials for Optoelectronic and Photonic Devices: Insights from WSe_2 — •Bastian Thomssen, Ioannis Caltzidis, and Klaus D. Jöns — PhoQS Institute, CeOPP and Department of Physics, Paderborn University, Paderborn, Germany

Two-dimensional (2D) materials have garnered significant attention due to their unique structural, electronic, and optical properties, which make them ideal candidates for next-generation optoelectronic and photonic devices. [1] Transition metal dichalcogenides (TMDs), such as tungsten diselenide (WSe_2), exhibit remarkable characteristics: in monolayer form, WSe_2 transitions from an indirect to a direct bandgap semiconductor, enhancing light-matter interactions. This property positions WSe_2 as a promising material for applications in light-emitting diodes, lasers, and quantum emitters. [1] The layer-dependent properties of WSe_2, including the transition from an indirect to a direct bandgap, can be effectively characterized using photoluminescence measurements. These allow for precise determination of the layer number, providing valuable insights into the electronic and optical behavior of the material. Such measurements are essential for tailoring the material's properties for specific optoelectronic and photonic applications.

HL 29.22 Tue 18:00 P1

Having a Good Vibe: Electron-Phonon Coupling in 1L-TMDCs Measured by Transient Absorption Spectroscopy — Tim Völzer[1,2], •Julian Schröer[1,2], Marvin Krupp[1,2], Annika Bergmann[1,2], Tobias Korn[1,2], and Stefan Lochbrunner[1,2] — [1]University of Rostock, Institute of Physics — [2]Department "Life, Light & Matter, University of Rostock

The optoelectronic properties of monolayer transition metal dichalcogenides (1L-TMDCs) are strongly determined by their electronic dynamics after light excitation. In this work, we present insights on the ultrafast dynamics of three different 1L-TMDCs by employing transient absorption (TA) spectroscopy. Our findings show that the basic processes after optical excitation can be divided into cooling of the electronic and phononic system and the subsequent recombination of the excited species. We reveal the importance of the differing coupling strengths to high- versus low-energy phonons. Due to the ultrashort pump pulse excitation, we are also able to trigger the displacive excitation of coherent phonons, which we assign to the A'_1 Raman mode of the system. Our results demonstrate the strong coupling between the electronic and phononic systems and lead to better understanding of excited state carrier dynamics in 1L-TMDC materials.

HL 29.23 Tue 18:00 P1

Probing time-reversal symmetry breaking in graphene — •Konrad Krieghoff[1], Nele Tornow[1], Omid Ghaebi[1], and Giancarlo Soavi[1,2] — [1]Institute of Solid State Physics, Friedrich Schiller University Jena, Jena, Germany — [2]Abbe Center of Photonics, Friedrich Schiller University Jena, Jena, Germany

In graphene, space inversion symmetry (SIS) and time-reversal symmetry (TRS) combined with a hexagonal lattice give rise to a linear band dispersion at the +/−K points of the Brillouin zone. Breaking TRS can result in exotic phenomena, such as the realization of the Haldane model and the photoinduced anomalous quantum Hall effect. Thanks to its high sensitivity to changes in the crystal symmetry, nonlinear optical spectroscopy provides an excellent tool to study these effects.

In our work, we use an elliptically polarized laser beam to excite monolayer graphene, where the circular polarization component breaks TRS. This symmetry breaking induces new nonzero elements in the third-order nonlinear susceptibility tensor, which are then probed by the linear component of the excitation beam. The combination of the already existing and the light induced tensor elements results in a rotation of the emitted third harmonic signal. Preliminary experimental results further indicate an impact of both excitation power and doping of the sample. Since SIS is still intact, our approach offers a new method for exploring broken TRS and topology in centrosymmetric materials.

HL 29.24 Tue 18:00 P1

Optical Probing of the K-Point Band Structure in Monolayer TMDs *via* SHG — •Jonas Margraf[1], Paul Herrmann[1], Sebastian Klimmer[1,2], Shridhar Sanjay Shanbhag[3], Jan Wilhelm[3], and Giancarlo Soavi[1,4] — [1]Institute of Solid State Physics, University of Jena, Germany — [2]ARC Centre of Excellence for Transformative Meta-Optical Systems, Department of Electronic Materials Engineering, Research School of Physics, The Australian National University, Canberra, Australia — [3]Institute of Theoretical Physics and Regensburg Center for Ultrafast Nanoscopy (RUN), University of Regensburg, Germany — [4]Abbe Center of Photonics, Institute of Applied Physics, University of Jena, Germany.

Crystal properties are ultimately defined by their band structure and dispersion relation, which are typically measured *via* angle-resolved photoemission spectroscopy. Recently, all-optical approaches based on non-perturbative nonlinear optics (NLO) have been proposed as a promising alternative. While optical probing of the band structure requires non-perturbative measurements of the entire Brillouin zone, it is often sufficient to probe the dispersion relation in the vicinity of optical resonances. In this work, we aim to measure the dispersion relation of a transition metal dichalcogenide monolayer at the ±K valleys using perturbative NLO. We investigate a modulation of the total second harmonic (SH) intensity as a function of the fundamental polarization angle upon two-photon resonant SHG. We assign this modulation of the SH intensity to the specific dispersion relation of the ±K valleys induced by trigonal warping.

HL 29.25 Tue 18:00 P1

Optical properties of transition metal dichalcogenides under high pressure — •Paul Luca Grosserhode, Paul Steeger, Robert Schmidt, Steffen Michaelis de Vasconcellos, and Rudolf Bratschitsch — Institute of Physics, University of Münster, Germany

Transition metal dichalcogenides (TMDCs), such as MoS_2 or WS_2, have received growing attention during the last years. Using micromechanical exfoliation, sin-

gle semiconducting layers can be readily prepared. Furthermore, multi-layered artificial crystals can be fabricated with single layer precision. In this study, we use a diamond anvil cell to apply pressures in the gigapascal range on such samples and observe how their optical properties change due to the induced deformation.

HL 29.26 Tue 18:00 P1

Analytical Theory Of Third Harmonic Generation In Two-Dimensional Materials — •Shridhar Sanjay Shanbhag[1], Florentine Friedrich[2], Paul Herrmann[2], Giancarlo Soavi[2,3], and Jan Wilhelm[1] — [1]Institute of Theoretical Physics and Regensburg Center for Ultrafast Nanoscopy (RUN), University of Regensburg, 93053 Regensburg, Germany — [2]Institute of Solid State Physics, Friedrich Schiller University Jena, 07743 Jena, Germany — [3]Abbe Center of Photonics, Friedrich Schiller University Jena, 07745 Jena, Germany

Valleytronics explores the valley degree of freedom in materials like transition metal dichalcogenides, using electrons in *K valleys as binary states for information encoding. In valleytronics, efficient valley readout is crucial, and third harmonic generation (THG) could provide an ultrafast solution to valley readout for any material, regardless of inversion symmetry.

We derived an analytical expression for THG by solving the semiconductor Bloch equations perturbatively to obtain an expression for the polarization state of the outgoing third harmonic. Our compact expression reveals how material parameters influence the polarization and attributes polarization rotation to valley-dependent optical Stark and Bloch-Siegert shifts. Our theoretical predictions closely align with experiments, providing the microscopic mechanism and thus helping to advancing valleytronic readout mechanisms.

HL 29.27 Tue 18:00 P1

Plasma-Induced Defect Emission in Hexagonal Boron Nitride — •Felix Schaumburg, •David Plitt, Timo Wagner, Nicolas Wöhrl, Martin Geller, Günther Prinz, and Axel Lorke — Faculty of Physics, University of Duisburg-Essen and CENIDE, Germany

Hexagonal boron nitride (hBN) has been the subject of numerous research efforts in the last decade. Of particular interest is the creation of single emitters in hBN because of their easy integration, e.g. in van-der-Waals heterostructures, and their room temperature photon emission. Many methods to create single emitters in hBN are still under investigation. We present our approach to create single quantum emitters in hBN using a remote plasma with different plasma species. We have used argon, nitrogen, and oxygen plasmas and present statistics on the emitters, produced by the different gas species, and their optical properties. In particular, we examine the emission of the exfoliated flakes before the plasma processes *without* an annealing step to avoid creating emitters that are not caused by the plasma exposure. Our findings suggest that the purely physical argon plasma treatment is the most promising route for creating optically active single emitters in hBN by plasma exposure.

HL 29.28 Tue 18:00 P1

Single-photon emission in the van der Waals material hBN — •Akhilesh Dubey, Janne Becker, Robert Schmidt, Steffen Michaelis de Vasconcellos, and Rudolf Bratschitsch — Institute of Physics and Center for Nanotechnology, University of Münster, 48149 Münster, Germany

Single-photon sources are crucial components for quantum networks and communications. Recently, single-photon sources in 2D materials have emerged as robust solid-state light emitters. Promising materials include transition metal dichalcogenides, such as WSe_2, transition metal monochalcogenides (e.g. GaSe), and also hexagonal boron nitride (hBN). Here, we investigate the light emission from single-photon emitters in hBN. We measure photoluminescence spectra of individual centers in hBN nanocrystals and analyze their prominent phonon sidebands. Time-resolved photoluminescence measurements reveal typical lifetimes. Our results are important for devising novel nanoscale devices based on these robust quantum light emitters.

HL 29.29 Tue 18:00 P1

Spectroscopic investigation of defects in strained WSe_2 van-der-Waals heterostructures — •F. Stechemesser[1], F. Schaumburg[1], J. König[2], C. Dietrich[2], C. Steiner[3], P. Pesch[3], G. Prinz[1], M. Geller[1], and A. Kurzmann[2] — [1]Faculty of Physics and CENIDE, University Duisburg-Essen, Germany — [2]University of Cologne, Physics Institute II, Germany — [3]2nd Institute of Physics, RWTH Aachen University, Germany

Van-der-Waals heterostructures offer a versatile platform for tailoring material properties through diverse layer compositions, making them suitable for a wide range of applications. We investigated the single photon emitting behavior of the Van-der-Waals heterostructure, that is composed of stacked layers containing graphene as a front and back gate, hexagonal boron nitride as dielectric layers and the transition metal dichalcogenide tungsten diselenide (WSe_2) as the host of optical emitters. The WSe_2 heterostructure was biaxially strained by nanopillars on the silicon wafer, which was used as substrate. By irradiating the points of large strain with an electron beam, point defects in the lattice structure of WSe_2 were created. The point defects, in the strained area, act as artificial atoms in the structure and can show single photon emission. We studied the samples using spacially resolved photoluminescence spectroscopy using a He-Ne laser. Applying this method, it is possible to localize an emitter and perform temperature, time and power dependent measurements. Finally, to prove the single photon characteristic of the emitter sites, we conducted second order correlation ($g^2(0) = 0.323$) measurements.

HL 29.30 Tue 18:00 P1

Tailoring Quantum Emission in Bilayer WSe2 via Strain Engineering — •Jasleen Kaur Jagde[1], Palwinder Singh[1], Grant Wilbur[1], Megha Jain[1], Edith Yeung[2], David Northeast[2], Seid Mohammad[2], Jean Lapointe[2], Dan Dalacu[2], and Kimberley Hall[1] — [1]Department of Physics and Atmospheric Science, Dalhousie University, Halifax, Nova Scotia B3H 4R2, Canada — [2]National Research Council Canada, Ottawa, Ontario K1A 0R6, Canada

Two-dimensional semiconductors subjected to strain have shown exceptional promise as single-photon emitters, due to their direct bandgap and an ease of integration with photonic structures. Emitters have been observed in a host of monolayer (ML) materials including MoS2, WSe2, WS2, MoTe2 and hBN. Quantum emitters have also recently been discovered in bilayers of TMDs, however their optical properties are less well understood. In this study, we demonstrate site-selective quantum emission in bilayer (BL) WSe2 using strain localized by engineered dielectric nanopillars of varying diameters. Through a systematic investigation of the dependence of quantum emitter properties on strain, we determine the optimum conditions for the observation of bright and narrow photoluminescence emission peaks. We observe a strain-driven blue shift in the emission wavelength that is controllable by the characteristics of the nanopillar. A strong antibunching (g (2)(0) = 0.139) is observed, confirming single photon emission behavior. These results highlight strain engineering of 2D materials as a scalable strategy for on-demand quantum light sources.

HL 29.31 Tue 18:00 P1

Electrical impact of He ion broad beam irradiation on multi-layer WSe2 — •Madhuri Chennur[1,2], Zahra Fekri[1,2], Ulrich Kentsch[1], Gregor Hlawacek[1], Jens Zscharschuch[1,2], and Artur Erbe[1,2] — [1]Helmholtz-Zentrum Dresden Rossendorf, Institute of Ion Beam Physics and Materials Research, 01328Dresden, Germany — [2]TUD Dresden University of Technology, 01062 Dresden, Germany

Nanoelectronics enables the development of innovative, cost-effective, miniaturized, and versatile materials. Among these, 2D materials hold immense potential for tailoring nanoscale functionalities. Structural defects in such materials play a significant role. By analyzing defect types, densities, and distributions, it is possible to unlock insights and exploit them for various applications, such as doping, tuning band gaps, or enhancing catalytic activity.

In this work, the impact of defects in multi-layer WSe2 is explored under the influence of Si/SiO2 and hBN substrates, introduced via a single broad-beam Helium ion irradiation at 7.5 keV. Electrical contacts are patterned using electron beam lithography (EBL), and all measurements are conducted under ambient conditions to assess changes in defect states post-irradiation.

The evolution of defects is monitored over time, with observations made one and two weeks following irradiation. Initially, the devices demonstrate degraded performance but later, their current exceeds pre-irradiation levels. Raman spectroscopy before and after irradiation provides deeper insights into the material's behavior. Additionally, the findings reveal the role of defects in influencing gas-sensing capabilities.

HL 29.32 Tue 18:00 P1

Probing the Band Splitting near the Γ Point in the van der Waals Magnetic Semiconductor CrSBr — •Kaiman Lin[1,2], Yi Li[1,3], Mahdi Ghorbani-Asl[1], Zdenek Sofer[4], Stephan Winnerl[1], Artur Erbe[1,3], Arkady V. Krasheninnikov[1], Manfred Helm[1,3], Shengqiang Zhou[1], Yaping Dan[2], and Slawomir Prucnal[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]Shanghai Jiaotong University, Shanghai, China — [3]TU- Dresden, Germany — [4]University of Chemistry and Technology Prague, Czech Republic

As a van der Waals magnetic semiconductor, CrSBr has a direct bandgap of approximately 1.5 eV and undergoes an antiferromagnetic transition around 131 K [1]. In this study, the electronic band structure of CrSBr is investigated through comprehensive photoluminescence (PL) characterization [2]. We distinctly identify low-temperature optical transitions between two closely adjacent conduction-band states and two different valence-band states. The analysis of the PL data robustly reveals energy splittings, bandgaps, and excitonic transitions across different CrSBr thicknesses, ranging from monolayer to bulk. Temperature-dependent PL measurements shed light on the stability of band splitting below the Néel temperature, suggesting that magnons coupled with excitons are responsible for the symmetry breaking and the brightening of transitions from the secondary conduction band minimum (CBM2) to the global valence band maximum (VBM1). [1] N. P. Wilson, K. Lee, J. Cenker et al., Nat. Mater. 20, 1657 (2021). [2] K. Lin, et al. J. Phys. Chem. Lett. 15, 6010-6016 (2024).

HL 29.33 Tue 18:00 P1

Tuning of non-radiative decay channels in CrSBr by a magnetic phase transition — •Fabian Glatz[1], Minjiang Dan[1,2], Till Weickhardt[1], Zdeněk Sofer[3], Marie-Christin Heissenbüttel[4], Julian Klein[5], and Giancarlo Soavi[1,6] — [1]Friedrich Schiller University Jena, Germany — [2]Southwest University of Science and Technology, Mianyang, China — [3]University of Chemistry and Technology Prague, Czech Republic — [4]Westfälische Wilhelms-Universität Münster, Germany — [5]Massachusetts Institute of Technology, USA — [6]Abbe Center of Photonics, Jena, Germany

CrSBr is a layered magnetic semiconductor with a direct bandgap [1]. Magnetic measurements have shown that below the Néel temperature (132 K) the spins within a single layer arrange ferromagnetically, while multiple layers couple antiferromagnetically (AFM) [2]. Here, we investigate the evolution of CrSBr under a magnetic phase transition by using nonlinear optics. In agreement with existing literature, second harmonic generation (SHG) becomes allowed due to the symmetry-breaking by AFM ordering at low temperatures [3]. Additionally, this phase change from paramagnetic (PM) to AFM leads to a change in the band structure that enhances third harmonic generation (THG) at the lowest energy optical resonance while quenching the photoluminescence quantum yield. This indicates the opening of a phonon mediated non-radiative decay channel upon transition from PM to AFM phase.

HL 29.34 Tue 18:00 P1

Defect induced magnetic phase transition in CrSBr — •Fangchao Long[1,2], Mahdi Ghorbani-Asl[1], Kseniia Mosina[3], Joachim Thomsen[4], René Hübner[1], Zdenek Sofer[3], Florian Dirnberger[5], Arkady V. Krasheninnikov[1], Slawomir Prucnal[1], Manfred Helm[1,2], and Shengqiang Zhou[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Germany — [2]Technische Universität Dresden, Germany — [3]University of Chemistry and Technology Prague, Czech Republic — [4]Forschungszentrum Jülich, Germany — [5]Institute of Applied Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, Germany

As an air-stable van der Waals magnetic semiconductor, CrSBr is receiving great research attention due to its exceptional properties. Below the Néel temperature of 132 K, CrSBr exhibits a typical A-type antiferromagnetic order comprised of antiferromagnetically coupled ferromagnetic monolayers. This special structure makes it susceptible to external stimuli, such as ion irradiation. In this work, we present the magnetic phase transition from antiferromagnetic to ferromagnetic in CrSBr crystals irradiated by non-magnetic ions. We observe the rise and fall of the ferromagnetic phase in antiferromagnetic CrSBr with increasing the irradiation fluence. Raman spectroscopy reveals phonon softening, suggesting the formation of defects. Structure analysis of the irradiated crystals in conjunction with density functional theory calculations suggest that the displacement of constituent atoms due to collisions with ions and the formation of interstitials favor a ferromagnetic order between the layers.

HL 29.35 Tue 18:00 P1

Self-Driven Photodetectors Based on Intercalated CrSBr — •Aljoscha Söll[1], Kseniia Mosina[1], Martin Vesely[1], Jiří Šturala[1], Florian Dirnberger[2], and Zdeněk Sofer[1] — [1]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, 166 28 Prague 6, Czech Republic. — [2]Department of Physics, Technical University of Munich, 85748 Munich, Germany.

The intercalation of lithium ions into layered materials has been an important field of research, leading not only to the development of lithium-ion batteries but also to countless insights in solid-state physics. Recently, it was shown that the intercalation of the quasi-1D semiconductor CrSBr can drastically alter its electronic structure, enhancing conductivity and potentially causing a transition from semiconductor to metal. Since the location and degree of intercalation can be precisely controlled, it allows us to fabricate devices using partially or fully intercalated CrSBr, harnessing properties of both the pristine and intercalated phases. Here we present a self-driven photodetector based on intercalated CrSBr, demonstrating high photoresponsivity across the entire NUV to NIR range with a response time in the millisecond range. Our findings not only deepen the understanding of intercalation effects in low-dimensional materials but also pave the way for the development of advanced optoelectronic devices using intercalated CrSBr.

HL 29.36 Tue 18:00 P1

Strong coupling of metal nanoparticles and 2d semiconductors: Physics behind a minimal model — •Lara Greten and Andreas Knorr — Institut für Theoretische Physik, Technische Universität Berlin, Germany

Transition metal dichalcogenide monolayers (TMDCs) feature strong light-matter interaction, governd by tightly bound, 2d-delocalized excitons. Metal nanostructures exhibit localized plasmons allowing for extreme electric field enhancements on the nanoscale. Hybrids of TMDCs and metal nanoparticles combine excitons and plasmons and may reach strong coupling as shown in numerous experiments. These experimental results are typically quantified via the coupled oscillator model (COM) employing a phenomenological coupling constant as a fitting parameter. To provide physical background to this model, we develop an analytical theory based on a microscopic perspective of the material dynamics and Maxwell's equations [1]. The emergent minimal model [2] provides a clear physical interpretation that highlights the importance of the spatial dispersion of 2d excitons. Depending on geometry and material properties we derive analytic expressions for all coupling and dephasing constants in a COM combining three oscillators: plasmons, bright and momentum-dark excitons. Strong coupling, that manifests as a peak splitting in optical spectra, is observed between momentum-dark excitons and plasmons, while the weakly coupled bright exciton yields a distinct third peak.

HL 29.37 Tue 18:00 P1

Non-Local Effects in Landau Quantized Two-Dimensional Electron Gases — •Sabrina Meyer[1], Andreas Knorr[1], Stephen Hughes[2], and Lara Greten[1] — [1]Institut für Theoretische Physik, Technische Universität Berlin, Germany — [2]Department of Physics, Queen's University, Kingston, Canada

Landau levels are the quantum analogon of the cyclotron motion under a strong magnetic field in two-dimensional electron gases, as present in high quality GaAs films. Even though recent experimental work examines nanopatterning - introducing metal gaps to localize and amplify electric fields on the nanoscale - current theoretical descriptions still rely on a local susceptibility for excitation with large wavelengths. This study includes non-local effects in a microscopic theory for the electron dynamics: We find modified selection rules beyond the dipole approximation that allow for the direct excitation of ground state electrons to higher Landau levels, that are forbidden in a local description. These modifications become especially important when the electric field varies significantly within the spatial extend of the Landau level wave function ($\propto$ 100 nm). This applies for nanopatterned devices as well as for light scattering with wavelength on the order of the Landau level radius.

HL 29.38 Tue 18:00 P1

Visualizing Atomic-Scale Charge Fluctuations in Real-Space Dielectric Response — •Bernadette Christ and Claudia Rödl — Institut für Festkörpertheorie und -optik, Friedrich-Schiller-Universität Jena, Max-Wien-Platz 1, 07743 Jena, Germany

The wave-vector and frequency-dependent dielectric function contains a plethora of information on the response of a given material to external perturbing electromagnetic fields that is rarely fully exploited. Its off-diagonal elements are known as local-field effects and encode the atomic-scale charge fluctuations that occur due to light-matter interaction or screening within the material.

We aim for developing a tool to visualize the impact of such an external perturbation on the electron density in the material in real space. In a first step, we calculate the independent-particle dielectric response function from first principles using density-functional theory. In this mean-field approach, we expect to see how interband transitions excite individual orbitals and how collective excitations such as plasmon waves propagate in the material. Later on, we will also consider inclusion of many-body effects in the evaluation of the response function to visualize the formation of excitons. This will help us to better understand the intricate interplay between the numerous electronic degrees of freedom and contribute to the analysis of spectroscopic experiments. As first benchmarks, we will study bulk semiconductors heading for more complex, technologically relevant materials systems afterwards.

HL 29.39 Tue 18:00 P1

Assessing Wafer Growth Success in Quantum Dot Photonic Device Fabrication — •Severin Krüger[1,2], Elias Kersting[1], and Arne Ludwig[1] — [1]Ruhr-Universität Bochum, Bochum, Germany — [2]Sparrow Quantum Aps, Copenhagen, Denmark

Molecular beam epitaxy (MBE) is crucial for fabricating photonic devices, including commercially viable single photon sources (SPS) based on quantum dots (QDs) [1]. Precise control of QD properties and surrounding layer design is essential for optimal device performance. We employ bandstructure and photonic simulations to design heterostructures, followed by comprehensive optical characterization of reference samples using photoluminescence (PL) mapping, Hall measurements, and surface analysis. This efficient characterization cycle allows rapid optimization of growth parameters on full 3" wafers, significantly reducing development time compared to direct SPS fabrication and testing. However, distributed Bragg reflectors in SPS wafers introduce PL signal artifacts due to reflectivity oscillations and stop bands, which significantly modulate the collectable photon yield across different wavelengths, alternately enhancing and suppressing the signal. We present our reference sample approach, characterization methods, and techniques to correct for optical stack-induced PL artifacts, enabling accurate assessment of MBE-grown structures for SPS applications.

HL 29.40 Tue 18:00 P1

Effect of TiO_2 thin films on the charge state of shallow NV centers in diamond. — •Arthur Witte, Tobias Lühmann, Peter Schlupp, Dominic Reinhardt, Holger von Wenckstern, and Marius Grundmann — Universität Leipzig, Felix-Bloch Institute for Solid State Physics, Germany

The nitrogen vacancy (NV) center is a color center in diamond. In its negative charge state, it has a relatively long spin coherence time at room temperature and a spin-dependent photoluminescence that enables optical spin polarization. Because of these properties, the NV center was proposed as a platform for room-temperature quantum computing. For this application the NV centers must be located close to the diamond surface. This can present new challenges due to surface effects resulting in, e.g. charge state instabilities of the shallow NV centers. Various surface treatments can be used to mitigate these effects, such as thermal oxidation, plasma surface treatments or the deposition of a thin passivation layer on the diamond surface.

We present a titanium dioxide thin film as the passivation layer. Titanium dioxide is a wide-bandgap semiconductor with a high refractive index of 2.5. In a first step, we investigate the growth of titanium dioxide layers by pulsed laser deposition and long-throw sputtering under different conditions. We then study the effect of optimized titanium dioxide layers on the luminescence properties of NV centers at implantation depths between 7 nm and 67 nm. Through spectroscopic analysis, we observe a significant increase in charge stabilization of shallow NV centers.

HL 29.41 Tue 18:00 P1

Secondary electron spectrometer for deterministic single ion implantation — •Priyal Dadhich, Nico Klingner, and Gregor Hlawacek — Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf(HZDR), Dresden, Germany

The deterministic placement of single ions is essential for programmable quantum computers based on the nuclear spin of the donor atom to serve as a spin qubit.

Spatially revolved single ion implantation requires the reliable detection of implantation events. Our approach utilizes SEs generated during ion impact. To optimize the detection we use a windowless silicon drift detector (SDD) biased up to +10 kV. The SDD measures the electron energy through electron-hole pair generation, enabling quantifying the number of electrons by counting pile-up pulses [1]. Given the low average SE yield per single-ion impact, optimizing the extraction geometry is crucial for achieving the maximum possible success rate.

We use the open-source three-dimensional ion optical C++ library, IBSIMU[2], to simulate a realistic extraction design for efficient SE collection on the detector's active area. For the highest detection efficiency, we must also consider the unlikely event of backscattering of the electrons from the SDD. The extraction geometry is designed to recapture these electrons and re-accelerate them into the detector's active area.

Emission properties of electron irradiated hBN — •Annkathrin Köhler, Jan Böhmer, Christian T. Plass, and Carsten Ronning — Friedrich Schiller Universität, Jena, Deutschland

Defect centers in solid state materials have emerged as promising candidates for quantum emitters. In particular, hexagonal boron nitride (hBN) has attracted significant attention due to its ability to host single-photon emitters (SPEs) at room temperature. Here, we systematically examined the luminescence properties of exfoliated hBN flakes as well as hBN nano-powders dispersed in various solutions and drop-casted onto a substrate. The effects of local electron irradiation and thermal annealing on the hBN samples were analyzed, providing insights into the conditions necessary for tuning their emission characteristics. Photoluminescence (PL) spectra were recorded using a micro-PL setup to compare the spectral distribution of the emission under different treatments. To further understand the quantum nature of the emitters, we conducted second-order correlation measurements as a function of the preparation parameters.

HL 29.43 Tue 18:00 P1

Germanium MOSFETs for Quantum Computation — •Thembelihle Dlamini and Mónica Benito — Institute of Physics, University of Augsburg

The project focuses on studying hole dynamics and spin properties in Germanium (Ge) metal-oxide-semiconductor (MOS) nanostructures to achieve high-fidelity single-qubit operations. Leveraging MOSFETs superior compatibility with industrial manufacturing techniques, holes' unique properties such as strong spin-orbit coupling, and Ge advantages over Si, GeMOS hole-spin qubits addresses some of the limitations of state-of-the-art spin quantum processors. The device-design phases will be assisted by three-dimensional structural simulations of the device. Moreover we will develop custom analytical models for holes in low-dimensional GeMOS geometries and the Ge/oxide interface by using symmetry analysis and $k \cdot p$ theory. Finally, we will investigate the effect of the multiband character of holes and their spin-orbit coupling in the effective spin representation of systems with a few holes in realistic quantum-dot potentials.

HL 29.44 Tue 18:00 P1

Crystal Growth and Influence of Fe^{3+} Doping on the Structural, Optical, and Magnetic Properties of Lead-Free Double Perovskites — •Volodymyr Vasylkovskyi[1,2], Anastasiia Kultaeva[1], Olga Trukhina[1], Patrick Dörflinger[1], Daniele Ludwig[1], Mykola Slipchenko[1,2], and Vladimir Dyakonov[1] — [1]Experimental Physics 6, University of Würzburg, 97074 Würzburg, Germany — [2]Institute for Scintillation Materials, NAS of Ukraine, 61072 Kharkiv, Ukraine

Semiconducting perovskite materials have attracted significant attention for their photovoltaic and light-emitting applications, yet their magnetic properties are largely unexplored. Doping perovskites with transition metal ions, such as Fe^{3+}, introduces novel properties, broadening their potential for spintronic and quantum applications.

In this study, Fe-doped $Cs_2AgBiBr_6$ and $Cs_2AgBiCl_6$ single crystals were synthesized using a controlled cooling crystallization technique with varying Fe^{3+} doping concentrations. Despite low Fe^{3+} incorporation (<0.01%), doping significantly affected defect density, optical properties, and magnetic behavior. Electron paramagnetic resonance revealed complex spin properties of the intrinsic spin centers and their interactions, which depend on both temperature and the orientation of single crystals with respect to the magnetic field.

Our findings highlight Fe-doped lead-free perovskites as promising materials for spintronic applications, emphasizing the importance of precise doping and defect manipulation to optimize their performance.

HL 29.45 Tue 18:00 P1

Multi-Frequency ODMR applied to Boron Vacancy Spin Defects of hBN — •Lucas Schreiber, Selin Steinicke, Paul Konrad, Andreas Sperlich, and Vladimir Dyakonov — Experimental Physics 6, University of Würzburg, 97074 Würzburg, Germany

Spin defects in hexagonal boron nitride (hBN) present a multitude of potential applications in the fields of quantum sensing and quantum information technology. Especially, the negatively charged boron vacancy defect can interact with the nuclear spins of its surrounding nitrogen atoms, thereby giving rise to hyperfine interactions. In this study, the spin defect was analyzed using optically detected magnetic resonance (ODMR) spectroscopy, wherein the spin sublevels are controlled by microwave pulses. In contrast to previous studies, the coherent microwave pulses employed in this work simultaneously utilize the multiple resonance frequencies of the hyperfine splitting. We therefore implement a multi-resonance technique for enhanced contrast and exploitation of the spin system. For an accurate and quantitative comparison with conventional ODMR, we derived a value for the contrast, allowing for a direct comparison of the hyperfine interaction on the spin defect. This approach aims at enhancing the optical detection of resonant excitation of the spin defect and facilitating coherent control experiments in future studies.

HL 29.46 Tue 18:00 P1

Temperature-dependent Studies of Boron-Vacancy Spin Defects in hexagonal Boron Nitride — •Selin Steinicke, Paul Konrad, Andreas Sperlich, and Vladimir Dyakonov — Experimental Physics 6, University of Würzburg, 97074 Würzburg, Germany

Optically addressable spin-carrying defects in solid-state materials are promising candidates in the field of quantum information technology and sensing applications. The recently discovered negatively charged Boron vacancies (V_B^-) in hexagonal Boron Nitride (hBN) raised the prospect of quantum sensing in a two-dimensional material. Although numerous studies on hBN emerged in the last years, the optical pump cycle has not yet been fully researched. Temperature-dependent spectroscopy on V_B^- ensembles shows broad photoluminescence around 850 nm and an increase in intensity at cryogenic temperatures. Using temperature-dependent transient photoluminescence measurements, we investigate the non-radiative relaxation path from the triplet excited state into the triplet ground state via the metastable intermediate state. The dependence of the intermediate state's lifetime on temperature is examined. These results shed light into the dark processes of V_B^- and can be used to optimize coherent control of V_B^-, which leads to a higher sensitivity in quantum sensing.

HL 29.47 Tue 18:00 P1

Investigating the optical pumping of silicon vacancies in 4H-SiC to increase the maser output — •Emilian Eisermann, Vladimir Dyakonov, and Andreas Sperlich — Experimental Physics 6, University of Würzburg, 97074 Würzburg, Germany

A major breakthrough in the realization of a continuous-wave maser at room temperature was achieved with the utilization of nitrogen vacancies in diamond. However, diamond is a comparatively expensive material. For this reason, silicon carbide (SiC), a material used commercially in electrical systems, has received attention in recent years. Only recently, our group has demonstrated the first room temperature continuous-wave SiC maser. Despite innovative microwave feedback loop engineering, only a low output could be achieved. In an effort to boost the maser output, we investigate the fundamental pumping behavior of

silicon vacancy defects in SiC in dependence of the optical pump wavelength, the temperature and their density. Using electron paramagnetic resonance spectroscopy, we resolve microwave absorption and emission signals due to the optical polarisation of Zeeman-split states. By analyzing these features, we calculate the population inversion in the gain material. This crucial parameter allows us to quantitatively evaluate the pump efficiency. It turns out that an excitation with an energy of the zero-phonon line of the silicon vacancy is particularly efficient. Furthermore, we examine to what extent excitation with an energy lower than that of the zero-phonon line is possible if thermally driven phonons are used to compensate the missing energy. First results are presented on the poster, which we are discussing here.

HL 29.48 Tue 18:00 P1

UV Photolithographic Fabrication of Photonic Structures on Diamond — •Nidhin Varghese, Oleg Peter, and Wolfgang Harneit — Institute of Physics,University of Osnabrück,Germany

The NV center in diamond is a point defect with promising quantum applications at room temperature, combining long spin relaxation times with optical excitation and state readout. Photonic structures such as micron-sized pillars help to increase the photon collection efficiency, improving the SNR ratio and enhancing sensitivity. NV centers in photonic structures can also be used to read out and control other spins, e.g., molecular qubits The top-down approach to fabricating photonic structures is straightforward and based on reactive ion etching of diamond. The process first requires a patterned etching mask, which is usually defined using electron beam lithography (EBL). Although EBL allows to make very small patterns, it is quite expensive and time-consuming. Using photolithographic processes could enhance industry adoption and increase accessibility to diamond quantum technology for research labs that do not have access to EBL. Here, we present a novel approach to nano-pillar fabrication based on direct (UV) laser writing lithography. An easy-to-use epoxy stage was developed for spin coating of photoresists on very small substrates, which largely supresses the formation of edge beads. The photonic pillar structures were fabricated by lithography and ion etching, and characterized. Confocal fluorescence scans demonstrated the increased photon output performance. CW-ODMR measurements confirmed the presence and accessibility of NV centers.

HL 29.49 Tue 18:00 P1

Birefringence effects in crystalline AlGaAs/GaAs mirror coatings from 4 K to room temperature — •Mona Kempkes, Chun Yu Ma, Thomas Legero, Uwe Sterr, and Daniele Nicolodi — Physikalisch-Technische Bundesanstalt, Braunschweig

Coating thermal noise limits the performance of high precision interferometry experiments, including ultra-stable optical oscillators used for interrogating atomic clocks and gravitational wave detectors. Due to their low mechanical losses, Bragg-reflectors from crystalline $Al_{0.92}Ga_{0.08}As$/GaAs heterostructures emerged as a lower thermal noise alternative to traditional dielectric mirror coatings. Mirrors realized with this material exhibit still poorly understood birefringence that can be modified by temperature and incident optical power. Furthermore, experiments at 4 K, 16 K and 124 K revealed spontaneous fluctuations of the birefringence, as well as an additional and yet unidentified noise source that limits the performance well above the expected thermal noise floor [J. Yu et al., Phys. Rev. X 13, 041002 (2023)]. Reconciling these observations from different samples is challenging and hinders a common interpretation. Thus we have set up one system where the temperature can be swept continuously across a wide range. We will present our setup based on a low-vibration closed-cycle cryostat, and measurements of the birefringence of crystalline AlGaAs/GaAs mirror coatings from 4 K to room temperature and as function of optical power.

HL 29.50 Tue 18:00 P1

Stark Effect of color centers studied from a- and m-face 4H-SiC — •Fabio Candolfi, Johannes A. F. Lehmeyer, Michael Krieger, and Heiko B. Weber — Friedrich-Alexander Universität Erlangen-Nürnberg, Lehrstuhl für Angewandte Physik, Staudtstr. 7 91058 Erlangen, Germany

Color centers in silicon carbide (SiC) can operate as single photon sources and are well suited for photonic quantum technology. As compared to the intensively studied diamond platform, SiC provides both mature semiconductor functionality and process technology.

We investigated the Stark effect response of two different color centers in 4H-SiC; the established silicon vacancy defect and the less known TS defect. Both were studied from the c-face, but the photon emission occurs predominantly in the basal plane. This is why in this work low-temperature photoluminescence across the a- and m-faces were studied with Stark effect along three principal crystallographic axes. From the emission polarization of shifted and split photoluminescence lines we obtain the orientation of the dipole moment.

HL 29.51 Tue 18:00 P1

InGaAs quantum dots grown by local droplet etching — •Selma Delić[1,2], Xuelin Jin[1,2], Nils von den Driesch[1], Elias Kersting[3], Arne Ludwig[3], Alexander Pawlis[1], Detlev Grützmacher[1,2], and Beata Kardynał[1,2] — [1]Peter Grünberg Institut, Forschungszentrum Jülich, 52428 Jülich, Germany — [2]Department of Physics, RWTH, 52074 Aachen, Germany — [3]Lehrstuhl für angewandte Festkörperphysik, Ruhr-Universität Bochum, 44780 Bochum, Germany

Gallium arsenide quantum dots (QDs) grown using local droplet etching epitaxy (LDE) have been shown to be excellent single photon emitters. Integrated into GaAs heterostructures with two-dimensional electron gases (2DEG), the LDE QDs could facilitate spin-photon interface to spin-qubits in gated QDs, provided that photon absorption in the 2DEG in eliminated.

In this contribution, we demonstrate that the wavelength of LDE quantum dots can be effectively tuned by filling the holes edged in Al0.33Ga0.67As with InxGa1-xAs with x=10-20%. At such compositions, two-dimensional growth is expected and quantum dot formation should follow the same mechanism as that of GaAs QDs. We characterise the QDs using atomic force microscopy, low-temperature photoluminescence (PL), and microPL and analyse the effects of the growth temperature, etching step parameters, and filling material on the wavelength of QD emission. Furthermore, we show how the wetting layer emission wavelength can be used to evaluate the thickness and composition of the deposited InxGa1-xAs.

HL 29.52 Tue 18:00 P1

Tuning InGaAs quantum dots for quantum interface for heterogeneous quantum network — •Xuelin Jin[1,2], Selma Delic[1,2], Zheng Zeng[1,2], Nils von den Driesch[1,3], Alexander Pawlis[1,3], Detlev Grützmacher[1,2,3], and Beata Kardynal[1,2] — [1]Peter Grünberg Institute 9, Forschungszentrum Jülich, 52425 Jülich, Germany — [2]Department of Physics, RWTH Aachen, 52074 Aachen, Germany — [3]Peter Grünberg Institute 10, Forschungszentrum Jülich, 52425 Jülich, Germany

Abstract. Connecting different spin qubits using photonic qubits could facilitate building networks that would benefit from the inherent advantage of the individual subsystems. An efficient transfer of a qubit from a photon to the spin qubit requires matching of the energies and the bandwidths of the photon wave packet and the spin qubit optical transitions.

We discuss the design of an epitaxial quantum dot device that aim to use electrostatic gates to manipulate the bandwidth of the photons emitted from InAs QDs to improve the match to the spin qubits realized in trapped ions. We show that application of electrostatic fields can change the overlap of the e-h wavefunctions. We will discuss the conditions that the heterostructure has to fulfill for the device operation and will show the status of fabrication, which has centered on optimizing the epitaxial growth of the material. Finally, we will show the results of its characterisation aiming to show how the electronic states in these quantum dots evolve with voltages applied to the surface gates.

HL 29.53 Tue 18:00 P1

Spin-Dependent Processes Involving Defects Caused by Lithography — •Henry Stock[1,3], Michael Göldl[1,3], Niklas Bruckmoser[2,3], Leon Koch[2,3], Stefan Filipp[2,3], and Martin S. Brandt[1,3] — [1]Walter Schottky Institut, Technische Universität München, Am Coulombwall 4, 85748 Garching, Germany — [2]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Walther-Meißner-Straße 8, 85748 Garching, Germany — [3]School of Natural Sciences, Technische Universität München, James-Franck-Straße 1, 85748 Garching, Germany

A precise knowledge of the paramagnetic defects present in quantum devices and their contribution to magnetic noise can be crucial for the optimization of such devices. However, conventional electron spin resonance experiments are often not sensitive enough to observe the defects. Using spin selection rules governing, e.g., recombination, the sensitivity of magnetic resonance experiments can be improved significantly. In its pulsed form, this so-called electrically detected magnetic resonance (EDMR) even enables the time-resolved study of the spin dynamics of the defects, allowing for measurements of the formation and recombination of spin pairs, as well as of the spin relaxation times T_1 and spin decoherence times T_2. Here, we present a study where we investigate paramagnetic P_{b0} defects and lithographically induced fluorine defects in Si substrates used for the manufacturing of superconducting transmon qubits. Our results are important to illuminate the role these defects play in flux noise and their influence on qubit coherence.

HL 29.54 Tue 18:00 P1

Progress on fully gate-defined optical interfaces to spin qubits — •Maxim Reznikov[1], Sebastian Kindel[1], Kui Wu[2], Nikolai Spitzer[3], Andreas D. Wieck[3], Arne Ludwig[3], Jeremy Witzens[2], and Hendrik Bluhm[1] — [1]JARA-FIT Institute for Quantum Information, Forschungszentrum Jülich GmbH and RWTH Aachen University, Germany — [2]Institute of Integrated Photonics, RWTH Aachen University, Germany — [3]Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum, Germany

Advancing quantum networks beyond proof-of-concept applications requires an approach for fabricating quantum repeater nodes with multiple qubits and optical interfaces in a controlled manner. Semiconductor spin qubits in gate-defined quantum dots address these needs in terms of established high-fidelity qubit operations and compatibility with industrial semiconductor technology. By employing electrostatic gating on either side of a submicron-thick heterostructure, excitons can be precisely localized at deterministic positions, thus also realizing an optical interface. These exciton trapping devices overcome the fabrication randomness associated with self-assembled quantum dots and enabling fine-tuning of operational wavelengths.

In this work, we demonstrate the successful integration of exciton trapping devices based on GaAs quantum wells into photonic crystal cavities. Additionally, we show the same confinement mechanism can be transferred to the Ge/SiGe platform, which is more compatible with industrial processing and telecom wavelength.

HL 29.55 Tue 18:00 P1

RPCVD growth of nuclear spin-free 70Ge/28Si70Ge heterostructures on industrial SiGe wafers — •Patrick Daoust, Simone Assali, Anis Attiaoui, Gérard Daligou, Patrick Del Vecchio, Sebastian Koelling, Lu Luo, Nicolas Rotaru, Oussama Moutanabbir, and Éloise Rahier — Department of Engineering Physics, École Polytechnique de Montréal, C.P. 6079, Succ. Centre-Ville, Montréal, Québec, Canada H3C 3A7

The coherence and operation of hole spin qubits in planar Ge heterostructures are both very sensitive to the nuclear spin bath. Therefore, developing nuclear spin-depleted materials is critical to control the performance of these quits. To this end, it is important to eliminate the nuclear spin-full 29Si and 73Ge in the epitaxial Ge/SiGe heterostructures. Our group has recently demonstrated highly crystalline, defect free, isotopically purified (>99.9 at.% 70Ge) nuclear spin-depleted 70Ge quantum well (QW) heterostructures grown in a reduced pressure CVD using purified precursors (>99.9 at.% 70GeH4 and >99.99 at.% 28SiH4) on in situ grown reversed graded SiGe buffers [1]. However, this growth protocol is not efficient and consumes significantly these purified precursors. Herein, we show that the growth of 70Ge QW can be achieved on industrial SiGe wafers thus optimizing the usage of precursors, preventing any background contamination from natural precursors, and yielding highly purified 70Ge/28Si70Ge heterostructures.

HL 29.56 Tue 18:00 P1

Time resolved electron imaging of a high-Q nonlinear nanomechanical oscillator — •Kai Nettersheim[1], Alexander Schröder[1], and Sascha Schäfer[1,2] — [1]Department of Physics, University of Regensburg, Regensburg, Germany — [2]Regensburg Center for Ultrafast Nanoscopy (RUN), Regensburg, Germany

While micro-electromechanical systems are well adapted for probing nonlinear dynamics in nanomechanical systems, they are often limited in their spatial resolution. Recent advances in ultrafast electron microscopy (UTEM) [1] enable the highly localized probing of nanoscale oscillator dynamics as well as their atomic structure and material defects.

Here, we present the characterization of non-linear free-standing silicon membranes by UTEM imaging techniques using an event-based electron detector with nanosecond temporal resolution. By exiting the sample with a modulated continuous wave laser the sample is driven into the nonlinear regime, resulting in Duffing resonances with high quality factors of up to 10^5. We experimentally characterized the temperature and fluence dependencies of the resonance as well as the mode shapes involved and compare these to finite-element simulations.

[1] A. Schröder et al., arXiv:2410.23961v1 (2024)

HL 29.57 Tue 18:00 P1

Quantum Particles on Strongly Bent Curves — •Tim Bergmann, Benjamin Schwager, and Jamal Berakdar — Martin-Luther-Universität Halle-Wittenberg

Quantum systems under geometrical restrictions appear both in research and applied fields such as materials design, for example in the context of quantum wires. In the case of a curve these lead to a one-dimensional Schrödinger equation with its curvature appearing as a potential like term. Up to this point, there existed no ansatz for the treatment of singulary bent curves because the curvature diverges. We provide a solution to this problem for a subclass of such curves, employing a useful mathematical tool for the convergence of eigenvalue equations. This desingularization renders the approximation of the eigenspectrum and corresponding wave functions of systems with singular Hamilton operators possible.

HL 29.58 Tue 18:00 P1

Shutter synchronized deposition in molecular epitaxy for wafer scale homogeneous quantum emitter growth — •Elias Kersting, Hans Georg Babin, Nikolai Spitzer, Andreas Wieck, and Arne Ludwig — Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum, Deutschland

Most quantum dot (QD) based single photon emitters today are based on random position nucleated QDs with spectrally broad emission properties. Deterministic QD growth in position and emitter wavelength would be highly appreciated for large-scale and good turnabout chip manufacturing. Local droplet etching during molecular beam epitaxy is an all-in-situ method to predetermine the nucleation site of quantum dots. As recently demonstrated, this method can produce strain-free GaAs QDs with excellent photonic and spin properties. We use random position droplet nucleation and hole filling demonstrating enhanced emitter wavelength homogeneity on a wafer scale. By shutter synchronized rotation and ideal growth parameters, we grow QDs with a peak emission wavelength spread of no more than 2 nm on a full 2" diameter area with a narrow inhomogeneous ensemble broadening. While the emission wavelength of these QDs is < 800 nm, we can use this random local droplet nucleation, nanohole drilling and InAs infilling to produce QDs emitting in the telecom optical fibre transparency window around 1.3 μm, the so-called O-band. For this approach, we demonstrate 2" wafer scale control of the emission wavelength and excellent uniformity. We discuss our methodology, structural and optical properties.

HL 29.59 Tue 18:00 P1

Integration of quantum dot-based single-photon sources onto silicon photonic platform using micro-transfer printing — •Simon Oberle, Ponraj Vijayan, Simone Luca Portalupi, Michael Jetter, and Peter Michler — Institut für Halbleiteroptik und Funktionelle Grenzflächen, Universität Stuttgart, Germany

Silicon photonics for telecommunications applications has garnered much attention recently. The optical transparency and the large refractive index contrast of silicon in the telecommunication wavelengths allow the implementation of high-density photonic integrated circuits. One disadvantage of silicon photonics is the lack of a native light source due to the indirect band-gap nature of silicon. One potential solution is the integration of III-V material, which offers outstanding optical emission properties, on a silicon platform. The direct growth of III-V materials on silicon is economically favourable and therefore the most desired approach. However, it is challenging because of the large lattice mismatch between the III-V materials and silicon. An alternate approach for large-scale integration is through hybrid integration of III-V structures using micro-transfer printing. Our group has previously developed In(Ga)As quantum dots on GaAs emitting in the telecom C-band. Here, we report our approach to designing and fabricating structures for the hybrid integration of these QDs onto a silicon platform using micro-transfer printing.

HL 29.62 Tue 18:00 P1

Towards Efficient Entangled Photon Pair Sources by Semiconductor Quantum Dots in Planar Cavities — •Aditi Javali[1], Raphael Joos[1], Ponraj Vijayan[1], Lena Engel[1], Tobias Huber-Loyola[2], Sven Höfling[2], Michael Jetter[1], Simone Luca Portalupi[1], and Peter Michler[1] — [1]Institut für Halbleiteroptik und Funktionelle Grenzflächen (IHFG), Center for Integrated Quantum Science and Technology (IQST) and SCoPE, Universität Stuttgart, Allmandring 3, 70569 Stuttgart, Germany — [2]Lehrstuhl für Technische Physik, Physikalisches Institut, Julius-Maximilians-Universität Würzburg, 97074 Würzburg, Germany

Since the EPR violation, entangled photons have become key protagonists in quantum technology, serving as communication carriers via polarization qubits. Photon pairs entangled in telecom C-band are particularly advantageous, as this wavelength range minimizes dispersion and loss in standard optical fibers, enabling long-distance communication with reduced signal degradation. In this work, we demonstrate the generation of entangled photon pairs in the telecom C-band using InAs quantum dots integrated with a planar photonic cavity. The cavity enhances photon emission rates and collection efficiency with high entanglement fidelity. The biexciton state, emitting the entangled pair, is prepared using a two-photon excitation scheme. The entanglement is verified through state tomography, confirming the strong quantum correlations between the photons. This work highlights telecom C-band quantum dots' potential as efficient entangled-photon sources for high-performance quantum communication.

HL 29.63 Tue 18:00 P1

Influence of Short-Wavelength Irradiation on Self-Assembled Quantum Dots — •Julia Avdeev[1], Jan Lange[1], Lukas Berg[1], Laurin Schnorr[1], Thomas Heinzel[1], Charlotte Rothfuchs-Engels[2], Sven Scholz[2], Arne Ludwig[2], and Andreas Wieck[2] — [1]Condensed Matter Physics Laboratory, Heinrich Heine University, Düsseldorf, Germany — [2]Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität, Bochum, Germany

Using Deep Level Transient Spectroscopy (DLTS) the charge transfer to and from Self-Assembled Quantum Dots (SAQDs) at large distance from the reservoir can be observed. Measurements are performed at a temperature of 77 K studying the influence of short-wavelength infrared irradiation. With wavelengths larger than 1.5 μm photons are not capable to induce charge emission from neutral Quantum Dots in ground state but can cause free charge carriers from electronic states in SAQDs.

HL 29.64 Tue 18:00 P1

Quantum Mechanics on Periodically Deformed Manifolds — •Theresa Appel, Benjamin Schwager, and Jamal Berakdar — Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Deutschland

Quantum systems confined to low-dimensional geometries exhibit unique physical behavior due to curvature-induced potentials. The poster presents results on the dynamics of particles confined to periodically curved manifolds, which we term "deformation crystals". The periodic spatial deformations directly influence the particle dynamics resulting in a band structure similar to other crystalline systems. We examine the transition from a free electron gas to a one-dimensional deformation crystal while analyzing the energy dispersion relation and symmetry-breaking effects. Furthermore, the behavior of different deformations is compared. The results reveal that the specific geometric deformations significantly influence the effective potential landscape and the band structure, thus opening up new opportunities for applications via deformation modulation of the underlying space.

HL 29.65 Tue 18:00 P1

Single-electron charging events on quantum dots in InSb nanowires — •Marcus Liebmann[1], Kanji Furuta[1], Sasa Gazibegovic[2], Diana Car[2], Erik Bakkers[2], and Markus Morgenstern[1] — [1]II. Phys. Inst. B, RWTH Aachen Univ., Germany — [2]Dept. of Appl. Phys., Eindhoven Univ., The Netherlands

As a first step to realize a single-electron counting tip for a scanning tunneling microscope, we investigate the charge state of a quantum dot (QD) by recording the current through a floating-gate-coupled sensor dot. InSb nanowires are placed mechanically onto bottom gates with hexagonal boron nitride (h-BN) as a dielectric to define two quantum dots capacitively coupled via a floating gate. At zero source-drain voltage and high barriers, charge stability diagrams are acquired, and time series of the QD charge state reveal single-electron charging events. These are analyzed with respect to full counting statistics. The Fano factor and factorial cumulants [1] are extracted to search for correlation effects.

[1] P. Stegmann *et al.*, Phys. Rev. B **92**, 155413 (2015).

HL 29.66 Tue 18:00 P1

Spin relaxation dynamics of the excited triplet state in self-assembeld quantum dots — •Carl Nelson Creutzburg[1], Jens Kerski[1], Arne Ludwig[2], Andreas D. Wieck[2], Martin Geller[1], and Axel Lorke[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen, Germany — [2]Chair of Applied Solid State Physics, Ruhr-University Bochum, Germany

The two-electron triplet state in a self-assembled quantum dot (QD) can pair with the singlet ground state to form a spin qubit. This state is electrically addressable, making it a promising candidate for quantum information processing. Achieving this requires a long coherence time (T_2), which is limited by the spin relaxation time (T_1). While T_1 has been previously studied using optical techniques, we employ an all-electrical measurement approach. The dots are embedded in an inverted high electron mobility transistor (HEMT) to selectively charge and discharge their many-particle states with electrons from a tunnel-coupled electron reservoir (2DEG). The 2DEG also acts as a sensitive detector for the charge in the QD layer. By employing time-resolved transconductance spectroscopy [1] and varying the charging intervals, we observe the relaxation process from the excited triplet state to the singlet ground state. Using a rate equation model, we extract the spin relaxation time T_1. While there are already first results for T_1 [2], an improved temporal resolution provides new insights that could help to refine assumptions in previous studies.

Multiphoton Emission of Quantum Dots with Different Excitation Schemes — •Patricia Kallert, Nicolás Claro-Rodríguez, Francesco Salusti, Sonja Barkhofen, Santiago Bermúdez Feijóo, Lukas Hanschke, Normen Auler, Dirk Reuter, and Klaus D. Jöns — PhoQS Institute, CeOPP, and Department of Physics, Paderborn University, Paderborn, Germany

High efficiency, single-photon purity, high indistinguishability, and good qualities as entangled-photon pair emitters are key properties of ideal sources for photon-based quantum technologies. Accordingly, semiconductor quantum dots (QDs) are promising candidates. If a multi-level system is excited coherently with optical pulses of different pulse areas, such as 1π, 2π and higher, the system experiences Rabi rotations of the according rotation and the respective population inversions. For each pulse area, the probability of emitting different photon numbers for different pulse areas varies, which is recognizable in the second correlation function. [1] Since various excitation schemes are interesting for different qualities of QDs, we analyze the multiphoton emission characteristics with different excitation schemes. We anticipate that this gives a deeper insight into the structure of the emitted states and possible applications to generate customised quantum light states and required modifications to generate them.

HL 29.68 Tue 18:00 P1

Investigating Photo-Physical Properties of Ag-In-S Core and Core-shell Quantum Dots — •Johannes Kunze, Julian Mann, Sushant Ghimire, and Jochen Feldmann — Chair for Photonics and Optoelectronics, Nano-Institute Munich and Department of Physics, Ludwig-Maximilians-Universität (LMU), Königinstr. 10, 80539 Munich, Germany

Non-toxic I-III-VI quantum dots (QDs) are promising candidates for next-generation light-emitting and energy-harvesting devices. However, the optical properties in these QDs are governed by subgap defects which limit their applications. Here, we synthesize AgInS2 QDs, and study them using various steady-state and time-resolved spectroscopy. Photoluminescence spectroscopy reveals that these QDs exhibit a narrow free-exciton emission and a more dominant, broad, red-shifted emission. The observed dominance arises from defects in the QDs, which introduce donor and acceptor states within the bandgap, effectively trapping electrons and holes from the band edge. A femtosecond differential transmission spectroscopy reveals an ultrafast carrier trapping time in these QDs. Additionally, a broad absorption onset with a defect-related Urbach tail is observed. We coated AgInS2 QDs with gallium sulfide, forming core/shell QDs, which significantly enhanced the intensity of the narrow free-exciton emission, reduced defect emissions, and sharpened the absorption onset by lowering the Urbach energy. These results show that the defects in these QDs are located on their surface, and Ga-S coating effectively passivates them, improving the excitonic characteristics.

HL 29.69 Tue 18:00 P1

Effects of vacancies in a bilayer graphene quantum dot — •Ivan Verstraeten, Robin Smeyers, François Peeters, and Lucian Covaci — University of Antwerp, Antwerp, Belgium

Confining the motion of an electron to the nanoscale in all three dimensions, i.e. a quantum dot (QD), sees the emergence of interesting physics and useful applications, such as single electron control or qubits. Bilayer graphene in particular, is a suitable and promising material for quantum dots owing to the many exotic properties of graphene, as well as the possibility to create and tune electronic

confinement simply by applying a (position dependent) perpendicular electric field. In this work, the electronic spectrum of an electrostatically defined QD in a finite bilayer graphene flake is numerically calculated using the tight-binding model, which is compared to existing results in the literature where a low-energy continuum theory was used. The tight-binding approach allows for a straightforward implementation of vacancies in the lattice, of which the effects on the spectrum and its valley character are studied. The results show a generally good agreement between the continuum and tight-binding theory, with some interesting discrepancies. We find that vacancies enhance the inter-valley scattering, as in the magnetic field dependence of the spectrum we observe a widening of the avoided crossings between energy levels of a different valley character. Furthermore, vacancies are found to be able to significantly shift energy levels, alter the shape of the wavefunction density and make a state retain its valley mixed character even in the presence of perpendicular magnetic field

HL 29.70 Tue 18:00 P1

Towards scalable quantum circuits based on microlaser-pumped quantum emitters — •Maximilian Klonz, Aris Koulas-Simos, Léo Roche, Imad Limame, Sven Rodt, and Stephan Reitzenstein — Institut für Festkörperphysik, Technische Universität Berlin, Hardenbergstraße 36, 10623 Berlin, Germany

We report on activities towards the development of a scalable technology platform for integrated quantum photonic circuits (IQPCs) based on semiconductor quantum dots, which are deterministically integrated into photonic waveguides by in-situ electron beam lithography [1], acting as single-photon emitters. Photons, generated by these on-demand quantum emitters, serve as flying qubits in quantum communication systems and as input states for photonic quantum computing [2, 3]. Here, we present innovative technological approaches for a two-step epitaxial growth method to achieve areas with low and high density of quantum dots to further fabricate lasers and single-photon sources monolithically integrated on the same wafer. We show simulations towards a scheme for optical on-chip pumping of these single-photon emitters and first experimental results.

Duration of scattering processes on curved quantum wires — •Adrian Henrik Starke, Benjamin Schwager, and Jamal Berakdar — Martin-Luther-Universität Halle-Wittenberg, Institut für Physik

Over the last decade, the duration of quantum processes has become experimentally accessible via measurement of e.g. the Wigner time delay [1]. However, these measurements have so far only been performed in flat space. This study extends the concept of scattering time to curved, one-dimensional quantum wires. Wigner time delay and other parameters are examined for plane waves as well as wave packets constraint to propagate through these structures. The results demonstrate that the geometry-induced potentials significantly affect the scattering time, particularly at low energies, with the classical behavior emerging at higher energies. These findings offer insights into the interplay between curvature and quantum dynamics, paving the way for further analysis of scattering phenomena in complex geometries.

HL 29.72 Tue 18:00 P1

Towards a Quantitative Framework for Capacitance-Voltage Spectroscopy in Quantum Dot Ensembles — •Phil Julien Badura[1], Nico Frédéric Brosda[1], Ismail Bölükbaşı[1], Ibrahim Engin[1], Patrick Lindner[1], Sascha René Valentin[1], Andreas Dirk Wieck[1], Björn Sothmann[2], and Arne Ludwig[1] — [1]Lehrstuhl für angewandte Festkörperphysik, Ruhr-Universität Bochum, D-44780 Bochum, Germany — [2]Fakultät für Physik and CENIDE, Universität Duisburg-Essen, Lotharstraße 1, D-47048 Duisburg, Germany

This study investigates an inhomogeneous ensemble of quantum dots coupled to a charge reservoir using capacitance-voltage spectroscopy. Experimental measurements reveal shifts in capacitance peak positions influenced by AC frequency and temperature, with frequency-dependent shifts remaining unexplained by existing models. To address this, we develop a master equation-based theoretical model incorporating energy-dependent tunneling effects, which successfully reproduces the experimental data. Our findings emphasize the role of energy-dependent tunneling in distinct regimes: at low temperatures, energy level dispersion dominates, while at high temperatures and frequencies, shifts arise from optimized sequences of in- and out-tunneling events.

HL 29.73 Tue 18:00 P1

Experimental time-bin encoding quantum key distribution with telecom semiconductor quantum dot — •Jipeng Wang[1], Jingzhong Yang[1], Joscha Hanel[1], Zenghui Jiang[1], Vincent Rehlinger[1], Raphael Joos[2], Stephanie Bauer[2], Sascha Kolatschek[2], Eddy Rugeramigabo[1], Michael Jetter[2], Simone Portalupi[2], Michael Zopf[1,3], Peter Michler[2], and Fei Ding[1,3] — [1]Leibniz Universität Hannover, Institut für Festkörperphysik, Appelstraße 2, 30167 Hannover — [2]Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology (IQST) and SCoPE, University of Stuttgart, Stuttgart, Germany. — [3]Laboratorium für Nano-und Quantenengineering, Leibniz Universität Hannover, Schneiderberg 39, 30167 Hannover, Germany

Quantum Key Distribution (QKD) enables secure data transmission via quantum-generated secret keys. Semiconductor quantum dots (QDs) are promising light sources for high-speed quantum networks due to their deterministic single-photon emission. However, polarisation stability in fibre networks is often disrupted by environmental factors. Here, we demonstrate a stable QKD scheme using time-bin qubits derived from polarised photons emitted by a QD in the telecommunication C-band. A 16-bit pseudo-random sequence is encoded via a Sagnac-loop interferometer and decoded using an unbalanced Mach-Zehnder interferometer after transmission through 80 km of fibre. This study highlights QDs' potential for scalable, robust quantum networks.

HL 29.74 Tue 18:00 P1

HL 29.75 Tue 18:00 P1

Cyclic Growth of InAs Quantum Dots: Exploring Structure- Property Relations for Telecom O-Band Applications — •Lennart Anderson[1,2], Danial Kohminaei[1], Severin Krüger[1,3], Marcel Schmidt[1], Nikolai Spitzer[1], Peter Zajac[1,4], Andreas Wieck[1], and Arne Ludwig[1] — [1]Angewandte Festkörperphysik, Ruhr-Universität Bochum — [2]ICAMS, Ruhr-Universität Bochum — [3]Sparrow Quantum ApS, Copenhagen — [4]Gesellschaft für Gerätebau mbH, Dortmund

Quantum dots (QDs) are promising single-photon emitters that could transform long-range quantum communication within telecom optical fiber transparency windows. In this study, we grow self-assembled InAs QDs using the Stranski-Krastanov growth mode, enhanced by a strain reduction layer to achieve emission at 1.3 μm in the telecom O-band. By employing cyclic sub-monolayer deposition, we observe periodic modulations in QD density, emission wavelength, and geometric properties, driven by nucleation waves, i.e. a new generation of QDs is formed each time a critical material amount for nucleation is reached. We explore the correlations between the structural characteristics and opto-electronic properties by atomic force microscopy and photoluminescence as well as capacitance-voltage spectroscopy. Our results identify optimal regions for QD density and emission wavelength across 3-inch wafers and propose a modified deposition scheme to enhance the usable area of the wafers.

HL 29.76 Tue 18:00 P1

Statistical spectroscopy of perovskite quantum dots — •Christopher Borchers[1], Frederik Benthin[1], Tom Rakow[1], Pengji Li[1], Maximilian Heller[1], Chenglian Zhu[2,3], Ihor Cherniukh[2,3], Gabriele Rainò[2,3], Maksym Kovalenko[2,3], Michael Zopf[1,4], and Fei Ding[1,4] — [1]Leibniz Universität Hannover, Institut für Festkörperphysik, Appelstraße 2, 30167 Hannover — [2]Institute of Inorganic Chemistry, Department of Chemistry and Applied Biosciences, ETH Zürich, CH-8093 Zürich, Switzerland — [3]Laboratory for Thin Films and Photovoltaics, Empa - Swiss Federal Laboratories for Materials Science and Technology, CH-8600 Dübendorf, Switzerland — [4]Laboratory of Nano and Quantum Engineering, Leibniz University Hannover, Schneiderberg 39, D-30167 Hannover, Germany

The ability to perform fast and automated photoluminescence (PL) spectroscopy measurements greatly improves the efficient development of quantum light emitters and their optimization in quantum technologies.

We adopt and semi-automate standard low temperature optical characterization measurements for lead halide perovskite colloidal quantum dots. Here, PL spectroscopy on CsPbBr3 samples is used to characterize the emission spectrum, polarization properties, and fine structure, and to perform corresponding automated statistical analyses of these measurements. For these analyses, we have developed a program that processes PL spectral data, automatically detecting and fitting emission peaks for subsequent evaluation.

HL 29.77 Tue 18:00 P1

SUPER drived quantum dot at telecom wavelength — •Zenghui Jiang[1], Vikas Remesh[2], Frederik Benthin[1], Michael Zopf[1], and Fei Ding[1] — [1]Leibniz Universität Hannover, Institut für Festkörperphysik, Appelstraße 2, 30167 Hannover — [2]Department of Experimental Physics University of Innsbruck Technikerstr. 25d, Office 01/503 6020 Innsbruck, Austria

To obtain the best photon properties from quantum dots (QDs),a direct drive between the S-shell and ground state (resonance excitation) is required. However, since the excitation laser and the emitted wavelength are very close to each other, filtering out the laser becomes highly challenging. A theoretical study conducted in 2021 by Prof. Doris Reiter's group predicted that with two relatively detuned laser pulses, full population inversion can still be achieved without interacting with other energy levels. Consequently, photon properties comparable to those achieved through resonance excitation can be expected.

To efficiently drive QDs, two temporally overlapping laser pulses with different frequencies are needed. Compared to using two separate lasers for "SUPER" excitation, employing a single laser with a pulse shaper eliminates the need for synchronization between two lasers. However, until now, no experiment using a single laser with a pulse shaper has been performed on telecom-wavelength QDs. In our work, we constructed a pulse shaper using a spatial light modulator to generate two sharply defined laser pulses from a single broadband laser pulse,and successfully *SUPER* excited QD at telecom wavelength.

HL 29.78 Tue 18:00 P1

Fabrication of Ohmic contact for Electrical tuning of GaAs quantum dots — •Krupali Dobariya[1], Tom Fandrich[1], Yiteng Zhang[1], Johann Dzeik[1], Arijit Chakraborty[1], Tom Rakow[1], Sulabh Shrestha[1], Doaa Abdelbarey[1], Eddy P. Rugeramigabo[1], Michael Zopf[1,2], and Fei Ding[1,2] — [1]Leibniz Universität Hannover, Institut for Solid State Physics, Hannover, Germany — [2]Leibniz Universität Hannover, Laboratorium for Nano and Quantum Engineering, Hannover, Germany

Semiconductor quantum dots have shown unique properties as deterministic single photon and entangled photon pair sources. Their outstanding optical properties have the potential for use in quantum applications like quantum communication, quantum key distribution and quantum computing. Nevertheless, due to the stochastic nature of the self-assembly growth process, quantum dots typically emit photons with a broad wavelength distribution across the entire chip, posing challenges for applications requiring specific wavelengths. To address this issue, various tuning techniques have been developed. Electrical tuning, in particular, has emerged as an effective method for adjusting the wavelength and mitigating charge noise in semiconductor quantum dots. Our research focuses on the impact of contact fabrication on the emission properties of GaAs quantum dots. We aim to optimize the process of forming ohmic contacts to n- and p-doped GaAs, placing special emphasis on the selection of materials and the reduction of contact resistance. The quality and performance of the electrical contacts are evaluated through the photoluminescence characterization.

HL 29.79 Tue 18:00 P1

Marker-based deterministic EBL integration of GaAs quantum dots (QDs) into electrically tunable Circular Bragg Gratings (eCBGs) at a wavelength of 780 nm — •Dinara Basharova[1], Mudi Priyabrata[1], Avijit Barua[1], Setthanat Wijitpatima[1], Andreas D. Wieck[2], Sven Rodt[1], Arne Ludwig[2], Richard Warburton[3], and Stephan Reitzenstein[1] — [1]Institute of Solid State Physics, Technische Universität Berlin, D-10623 Berlin, Germany — [2]Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum, DE-44780 Bochum, Germany — [3]Department of Physics, University of Basel, Klingelbergstrasse 82, CH-4056 Basel, Switzerland

Integration of high-quality quantum emitters with photonic structures is essential for advancing quantum information technologies. We present a marker-based deterministic electron beam lithography (EBL) technique to integrate Gallium Arsenide (GaAs) quantum dots (QDs) into electrically contacted Circular Bragg Gratings (eCBGs) at an emission wavelength of 780 nm, combined with a PIN-diode structure. eCBG devices not only enhance the photon extraction efficiency through a circularly symmetric cavity design but also provide precise electrical control over the QD emission. This enables fine-tuning of the wavelength, addressing spectral mismatches, and stabilizing the charge environment around the QD, critical for high-performance quantum light sources. Therefore, combining the eCBG design with deterministic fabrication techniques ensures that the QDs are precisely positioned at the cavity center, maximizing light-matter interaction.

HL 29.80 Tue 18:00 P1

Laboratory management software: Plexy : Python Library for EXperimental Physics — •Frederik Benthin, Christopher Borchers, Nico Eggeling, Tom Fandrich, Dolores García de Viedma, Joscha Hanel, Maximilian Heller, Martin Hesse, Kai Hühn, Johannes Knollmann, Marcel Pölking, Tom Rakow, Eduard Sauter, Pavel Sterin, Fei Ding, Jens Hübner, and Michael Zopf — Leibniz Universität Hannover, Institute of Solid-State Physics, Appelstraße 2, 30167 Hannover

Measurements often involve complex protocols requiring the coordination of many different devices. Laboratory management or measurement software such as Qudi and NOMAD-CAMELS assist in performing these tasks. It provides a framework for easier collaboration and sharing of resources. It often includes a standalone graphical user interface (GUI). This GUI controls new compound instruments consisting of several devices and can be used to coordinate the measurement. Different projects often improve an additional aspect, such as NOMAD-CAMELS with metadata collection or MAHOS with messaging between distributed devices. Here we present Python Library for EXperimental Physics (Plexy), which is a highly modular repository of Python modules. Among the main design goals are automatic metadata recording, distributed device coordination, modular and flexible but standardized code organization as well as independent and common GUIs. An analyzer GUI performs common analyses specific to photoluminescence spectroscopy and time-correlated single-photon counting of quantum dot single-photon sources.

HL 29.81 Tue 18:00 P1

Signatures of the quantum skyrmion Hall effect in the Bernevig-Hughes-Zhang model — •Reyhan Ay, Adipta Pal, and Ashley M. Cook — Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Strasse 38, 01187 Dresden, Germany

Given the recent discovery of the quantum skyrmion Hall effect (QSkHE) revealing that the 2+1 D SU(2) gauge theory should be generalized to include terms from an underlying 4+1 D SU(2) gauge theory subjected to generalized fuzzification, we re-examine the canonical Bernevig-Hughes-Zhang (BHZ) model for the quantum spin Hall insulator (QSHI). Considering that the isospin degrees of freedom in the tight-binding model Hamiltonian effectively encode two additional spatial dimensions, we identify signatures of topological states within the QSkHE framework related to intrinsically 4+1 D topological phases revealed by breaking time-reversal symmetry through a weak Zeeman field. We identify distinctive real-space boundary orbital angular momentum textures due to the QSkHE, as well as gapless boundary modes that are robust against magnetic disorder, which is unexpected for a QSHI but predictable for compactified boundary 3D Weyl nodes in a topological skyrmion phase. Revisiting experimental work on robust edge conduction in HgTe quantum wells under Zeeman and orbital magnetic fields, we find these results consistent with theoretical predictions of compactified boundary 3D Weyl nodes to such external fields. These experiments are thus potentially the first-known experimental observation of the quantum skyrmion Hall effect.

HL 29.82 Tue 18:00 P1

Side-contacted narrow superconducting finger on quantum anomalous Hall insulator — •Bibek Bhujel, Anjana Uday, Gertjan Lippertz, Alexey A. Taskin, and Yoichi Ando — Physics Institute II, University of Cologne, Zülpicher Str. 77, 50937 Köln, Germany

Recently, the evidence for superconducting pair correlation is obtained in the chiral edge states of a vanadium-doped $(Bi_xSb_{1-x})_2Te_3$ thin film, tuned to the quantum anomalous Hall insulator phase by observing the negative nonlocal resistance downstream from a narrow superconducting (grounded) Nb finger electrode fabricated on the top [1]. This negative downstream resistance is due to the crossed Andreev reflection (CAR) process, which creates superconducting correlations in the chiral edge. To investigate this observation further, we are currently fabricating side-contacted Al and Nb finger electrodes on the etched QAHI. One of the main advantages of fabricating the side-contacted electrodes is their low contact resistance, which has high reproducibility. We will report on our progress on this project so far.

[1] Uday, A., Lippertz, G., Moors, K. et al. Induced superconducting correlations in a quantum anomalous Hall insulator. Nat. Phys. 20, 1589*1595 (2024). https://doi.org/10.1038/s41567-024-02574-1

HL 29.83 Tue 18:00 P1

Anomalous Hall effect in a two-dimensional disordered Lorentz gas — •Frederik Bartels[1], Zakaria Harroud[1], Beate Horn-Cosfeld[1], Mihai Cerchez[1], Jürgen Horbach[2], and Thomas Heinzel[1] — [1]Condensed Matter Physics Laboratory, Heinrich Heine University, Düsseldorf, Germany — [2]Theoretical Physics II: Soft Matter, Heinrich Heine University, Düsseldorf, Germany

Using a combination of experiment and simulation, it was studied the magnetotransport in a two-dimensional disordered Lorentz gas with cross-shaped ob-

stacles. Our focus is on the investigation of the Hall effect for obstacle densities beyond the low-density limit. From previous studies, we know that for lower obstacle densities, the magnetotransport properties, as obtained from the simulation and the experiment of a pristine sample, can be well described in terms of the Drude-Boltzmann model. At higher obstacle densities, deviations from the normal Hall effect are observed, depending on both obstacle density and magnetic field. These results extend previous studies on circular obstacles, where similar deviations were observed and the Hall coefficient does not accurately reflect the electron density because of the presence of memory effects. [1]

HL 29.84 Tue 18:00 P1

Accelerated Electrical Transport Predictions of the Non-Perturbative ab initio Kubo-Greenwood Method via a Deep-learned Hamiltonian technique: Strongly Anharmonic Material Cases — •Juan Zhang, Jingkai Quan, Matthias Scheffler, and Kisung Kang — The NOMAD Laboratory at the FHI of the Max Planck Society, Berlin, Germany

High-performance thermoelectric materials are characterized by low thermal and high electrical conductivities. Thermal insulators with ultra-low thermal conductivity feature strong anharmonicity, also significantly affecting electronic transport [1]. Strong anharmonicity impedes the application of perturbative methods due to the breakdown of the quasi-particle picture. This challenge can be overcome by the non- perturbative ab initio Kubo-Greenwood approach (aiKG)[1]. However, the aiKG method requires substantial computational cost due to its extensive supercell electronic structure evaluations at each step during ab initio Molecular Dynamics (aiMD). A recent deep neural network technique to train and predict the Kohn-Sham Hamiltonian, implemented by DeepH[2], can provide an efficient bypass to extract the electronic structure of each MD step with nearing ab initio accuracy. This work introduces an AI-assisted aiKG formalism with accelerated carrier mobility evaluations, exemplified by its application to strongly anharmonic materials. We thoroughly examine DeepH's capability for electronic property predictions with its spatial scalability.

HL 29.85 Tue 18:00 P1

Magnetotransport in the correlated metal $CaVO_3$ — •Olivio Chiatti[1], Mahni Müller[1], Maria Espinosa[1], Tatiana Kuznetsova[2], Roman Engel-Herbert[2,3], and Saskia F. Fischer[1,4] — [1]Novel Materials Group, Humboldt-Universität zu Berlin, 10099 Berlin, Germany — [2]Department of Materials Science and Engineering, The Pennsylvania State University, University Park, PA 16802, USA — [3]Paul-Drude-Institut für Festkörperelektronik, 10117 Berlin, Germany — [4]Center for the Science of Materials Berlin, Humboldt-Universität zu Berlin, 12489 Berlin, Germany

Transparent conductive materials are in great demand in the optoelectronic industry for their high-performance and cost-effectiveness. Enhancing the carrier effective mass through strong electron-electron interactions in correlated metals is a promising approach to achieve both high-optical transparency and high-electrical conductivity [1].

Here, we study the electric transport properties of thin $CaVO_3$ films grown on $LaAlO_3$ substrates by hybrid molecular beam epitaxy, with residual resistivity ratio (RRR) up to 98 [2]. Magnetoresistance and Hall measurements were performed between 50 mK and 300 K. Films with high RRR show nonlinear Hall resistivities and linear magnetoresistance below 40 K. Shubnikov-de Haas oscillations are also observed for magnetic fields above 6 T. The application of a multi-carrier model and the complex Fermi surface of $CaVO_3$ are discussed.

HL 29.86 Tue 18:00 P1

Selenium, Silicon and SiC power diodes as temperature sensors, operated in different voltage regimes and under extreme conditions — •Heinz-Christoph Neitzert, Arpana Singh, and Vincenzo Carrano — Dept. of Industrial Engineering (DIIn), Salerno University, Via Giovanni Paolo II 132, 84084 Fisciano (SA), Italy

Commercial semiconductor temperature sensors are nowadays mostly based on silicon diodes and transistors, operated under constant forward current conditions. We compared the temperature sensing capabilities of a series of different power diodes from different materials not only in the forward, but also in the reverse bias and in one example also in the breakdown voltage regime. All investigated devices, including the historical Se rectifiers, showed stable temperature sensing capabilities in the forward bias regime under moderate temperature changes. Some of them have been tested under extreme conditions like extreme temperatures and particle irradiation. In particular it is shown in the case of the SiC Schottky diodes, that the excellent temperature sensing properties are also maintained after irradiation with high energy ions. In the case of Silicon pn diodes the sensitivity as sensor in the forward voltage and avalanche breakdown regime has been determined. In both regimes the sensors showed very good linear characteristics, when biased under constant current conditions. For Silicon diodes, also the temperature limit, where no irreversible device changes are observed has been determined and the defect creation for higher temperatures has been monitored.

HL 29.87 Tue 18:00 P1

Structural Dynamics of Excimer Formation in single crystalline α-Perylene — •Helena Hollstein[1], Simon Versmissen[2], Bram Spijkerman[2], Heinrich Schwoerer[2], and Sebastian Hammer[1] — [1]University of Würzburg, 97074 Würzburg, Germany — [2]Max-Planck-Institut für Struktur und Dynamik der Materie, 22761 Hamburg, Germany

In the field of organic semiconductors an exact understanding of the formation of multi-molecular excited states, such as excimers, and geometric intermolecular changes caused thereby, is crucial but challenging. Quantum chemical methods are in principle able to capture all structural changes during excimer formation but are hardly feasible due to the complexity of organic crystals. Experimentally on the other hand, the molecular motion can be detected by ultra-fast electron diffraction (UED) on a femtosecond timescale [1], and by using structural modeling the molecular movement can be reconstructed from changes in the diffraction pattern [2].

In this contribution we examine the structural reorganization during the formation of the low lying excimer state in single crystalline perylene in its crystallographic α-phase by means of UED. We are able to reveal the pathways of the geometric relaxation during the excimer formation on a fs timescale and find that the formation happens on a 5 ps timescale.

HL 29.88 Tue 18:00 P1

All-optical spin injection in silicon investigated by element-specific time-resolved Kerr effect — Simone Laterza[1,2], Antonio Caretta[1], •Richa Bhardwaj[1,3], Roberto Flammini[4], Paolo Moras[5], Matteo Jugovac[5], Piu Rajak[6], Mahabul Islam[6], Regina Ciancio[6], Valentina Bonanni[1], Barbara Casarin[2], Alberto Simoncig[1], Marco Zangrando[1,6], Primož R. Ribič[1], Giuseppe Penco[1], Giovanni De Ninno[1], Luca Giannessi[1], Alexander Demidovich[1], Miltcho Danailov[1], Fulvio Parmigiani[1], and Marco Malvestuto[1,6] — [1]Elettra Sincrotrone Trieste, Italy — [2]University of Trieste, Italy — [3]Institute of Physics and Center for Nanotechnology (CeNTech), University of Münster, 48149 Münster, Germany — [4]Istituto di Struttura della Materia-CNR (ISM-CNR), Roma, Italy — [5]Istituto di Struttura della Materia-CNR (ISM-CNR), Trieste, Italy — [6]Istituto Officina dei Materiali (CNR-IOM), Trieste, Italy

Understanding how a spin current flows across metal-semiconductor interfaces at pico- and femtosecond time scales is of paramount importance for ultrafast spintronics, storage applications etc. However, the possibility to directly access the propagation of spin currents, within such time scales, has been hampered by the simultaneous lack of both ultrafast element-specific magnetic sensitive probes and tailored well-built and characterized metal-semiconductor interfaces. Here, by means of a novel free-electron laser-based element-sensitive ultrafast time-resolved Kerr spectroscopy, we reveal different magnetodynamics for the Ni $M_{2,3}$ and Si $L_{2,3}$ absorption edges.

HL 29.89 Tue 18:00 P1

Implementation and operation of a fiber-coupled CMOS detector for time-resolved photoemission electron microscopy — •Philipp Kessler[1], Johanna Kinder[1], Victor Lisinetskii[1], Torsten Franz[2], Florian Schütz[2], Matthias Hensen[1], and Tobias Brixner[1] — [1]Institut für Physikalische und Theoretische Chemie, Universität Würzburg, Am Hubland, 97074 Würzburg — [2]ELMITEC Elektronenmikroskopie GmbH, 38678 Clausthal-Zellerfeld

Since their invention, low-energy electron microscopy (LEEM) and photoemission electron microscopy (PEEM) have predominantly relied on microchannel plates for electron detection and image generation. Recent developments in detector technology allow the LEEM-PEEM community to use pixel- [1] and fiber-based [2] detectors that have a small detection pixel size, avoid blooming effects, and have an extended dynamic range. These advancements are particularly beneficial for ultrafast time-resolved experiments with weak signals. Here, we present the integration of the fiber-coupled CMOS detector XF416 (TVIPS GmbH, Germany) into an Elmitec AC-LEEM III system. This includes a structural solution to address the detector's inability to undergo bake-out, a critical step for achieving ultrahigh vacuum conditions. The first-time operation of the new detector unit is demonstrated through time- and energy-resolved PEEM measurements on terrylene bisimide-based molecular thin films, enabling the study of exciton dynamics at the nanoscale.

HL 29.90 Tue 18:00 P1

Experimental scheme for high-order fluorescence-detected pump–probe micro-spectroscopy on monolayer MoS_2 — •Ruidan Zhu, Patrick Grenzer, Simon Büttner, Matthias Hensen, Tobias Hertel, and Tobias Brixner — Institut für Physikalische und Theoretische Chemie, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany

Monolayers of transition metal dichalcogenides (TMDCs) are two-dimensional (2D) semiconductors with fascinating optoelectronic properties. However,

exciton–exciton interaction (EEI) sets a fundamental limit to optimizing the quantum efficiency of 2D materials under high exciton densities. In particular, EEI processes are frequently mixed with single-exciton dynamics, thereby complicating the elucidation of their underlying mechanisms. Here, we apply fluorescence-detected pump–probe spectroscopy [1] in a cryomicroscope to detect the exciton dynamics of monolayer MoS_2. By incorporating the high-order separation methods that we recently developed [2], we aim to isolate EEI dynamics from the single-exciton dynamics, other higher-order signal contributions, and non-resonant substrate responses. We present the fundamental concept, the experimental setup, and the first data.

HL 29.91 Tue 18:00 P1

Detection Strategies for Highspeed Impulsive Stimulated Raman Scattering — •Laura Hüllmandel, Julia Lang, and Georg Herink — Universität Bayreuth

Impulsive stimulated Raman scattering is an established method for resolving transient coherent superpositions of optical phonons in matter. Inside a laser cavity, however, this nonlinear interaction between multiple ultrashort temporal solitons can accumulate and determine their trajectories [1]. In this contribution, we study different regimes of the coupling between solitons via optical phonons. Based on extra-cavity spectroscopic experiments on crystalline media, we compare interferometric and spectrally-resolved sampling modes and, in particular, we discuss practical aspects in enhancing Raman signal quality. These new insights contribute to the understanding of phonon-driven soliton coupling and the development of time-domain intra-cavity Raman spectroscopy.

HL 29.92 Tue 18:00 P1

Two-dimensional spectroscopy setup for the investigation of excitons and polaritons in 2D materials — •Trideep Kawde, Pavel Trofimov, Matteo Russo, Anton Trenczek, David Koch, and Hélène Seiler — Freie Universität Berlin, 14195, Berlin, Germany

Coherent two-dimensional (2D) electronic spectroscopy is a powerful tool for probing interactions between electronically excited states and map their evolution in both energy and time domains. Here we introduce a coherent two-dimensional spectrometer tunable over the 460-950 nm spectral range to investigate the exciton and polariton dynamics in 2D materials. We employ a hollow-core fiber setup for broadband visible continuum generation. Pulse shapers are used to produce phase-locked sequences of pulses. A custom sample area has been designed specifically for 2D materials, typically featuring high degrees of spatial inhomogeneity and small sizes (few tens of micrometers). Linear spectroscopies can be performed at the same position as the 2D spectroscopy experiments, including angle-resolved spectroscopy to investigate polariton dispersion. With our setup we will be able to reveal insights into excitonic and polaritonic properties in 2D materials.

HL 29.93 Tue 18:00 P1

Measurement of ultrashort electron pulse durations using a transient electric field — •Lukas Nöding, Arne Ungeheuer, Ahmed Hassanien, Mashood Tariq Mir, Thomas Baumert, and Arne Senftleben — University of Kassel, Institute of Physics, Kas- sel, Germany

Ultrafast electron diffraction is a well-known method for conducting time-resolved measurements on molecules and condensed matter. In this approach, electron diffraction is performed with an electron pulse at a variable time after optical excitation of the sample. The duration of the electron pulse directly determines the temporal resolution. A streaking setup utilizing free electrons is implemented to measure the duration of the electron pulse. Therefore, a transient electron deflector, was designed. Its main feature is a metal surface parallel to the path of the electron pulse. A femtosecond laser pulse is focused from the side onto this metal surface. As the beam incides, electrons are released from the metal. Due to their momentum, they separate from the surface, create an electric field perpendicular to the surface and then recombine. The build-up and the subsequent fading of this transient electric field is used to streak the electron pulse, because different electrons in the pulse experience different field strengths. By that, the duration of the pulse is mapped into a spatial broadening of the pulse. The broadening is captured by the detector as a streak. We will show results measured with different numbers of electrons per pulse and compare them with simulations. Moreover, the evaluation process and the fitting algorithms for the electron streak will be explained.

HL 29.94 Tue 18:00 P1

Ultrafast dynamics reveal proximity induced changes in Graphite — •Mashood Tariq Mir, Ahmed Hassanien, Arne Ungeheuer, Lukas Nöding, Arne Senftleben, and Thomas Baumert — University of Kassel, Institute of Physics, D-34132 Kassel, Germany

Layered transition metal dichalcogenides (TMDs) are at the forefront of materials research due to their diverse electronic and structural properties. Among these materials, 1T-TaS2 exhibits a complex temperature-dependent phase diagram characterized by charge density waves (CDWs) of varying commensurabilities. When integrated into heterostructures, novel interfacial phenomena emerge, enabling the study of proximity effects in atomically thin materials. This work investigates the light-induced dynamics of a van der Waals heterostructure composed of 1T-TaS2 and graphene using ultrafast electron diffraction (UED). Femtosecond laser pulses induce rapid structural changes, revealing a proximity-induced CDW in graphene. This observation demonstrates how interfacial coupling can imprint the characteristic periodic lattice modulation of CDWs onto an otherwise non-CDW material. By controlling lattice heating, we probe the reversible phase transition of 1T-TaS2 from the nearly commensurate to the incommensurate phase and its influence on the interfacial properties of the heterostructure.

HL 29.95 Tue 18:00 P1

Determination of Arrival Time in Ultrafast Electron Diffraction in Specimen Close Proximity with High Accuracy — •Ahmed Hassanien, Mashood Tariq Mir, Arne Ungeheuer, Lukas Nöding, Arne Senftleben, and Thomas Baumert — University of Kassel, Institute of Physics, 34132 Kassel, Germany

The ability to determine time zero in a pump-probe experiment qualitatively indicates its ability to capture dynamics and quantitatively serves as a measure of its temporal resolution. There are only a few methods for determining the time zero in ultrafast electron diffraction (UED) [1,2]. Here, we propose a robust and easy-to-implement method to determine time zero in the immediate vicinity of the sample with sub-picosecond accuracy using Fourier-transformed electron micrography (FT-EM). In the same analogy as the Debye-Weller effect in crystalline solids, the attenuation of the peak amplitude in FT-EM patterns for a metal grid blurred by femtosecond optically-induced transient electrostatic lensing (TEL) allowed us to determine time zero to better than 500 fs. To demonstrate our method, we measured the time zero in the vicinity of a graphite flake, for which we also performed a routine UED measurement by exciting with the same optical pump fluence, well below the damage threshold for either material. Using the accurately determined time zero, we were able to identify the earlier onset of the out-of-plane coherent optical phonon mode in graphite. References: [1] Olshin, Pavel K., et al. APL 120.10 (2022). [2] Dwyer, Jason R., et al. Philos. Trans. of the Royal Society A: Math., Phys. and Eng. Sci. 364.1840 (2006): 741-778.

HL 29.96 Tue 18:00 P1

Investigation of dynamics and character of excitons in WSe_2 multilayers — •Anna Weindl[1], Matthias Brem[1], Jennifer Lehner[1], Kenji Watanabe[2], Takashi Taniguchi[3], and Christian Schüller[1] — [1]Institut für Experimentelle und Angewandte Physik, Universität Regensburg, 93053 Regensburg — [2]Research Center for Functional Materials, National Institute for Materials Science, Tsukuba Ibaraki 305-0044, Japan — [3]International Center for Materials Nanoarchitectonics, National Institute for Materials Science, Tsukuba Ibaraki 305-0044, Japan

We report about our time-resolved Faraday ellipticity (TRFE) experiments on multilayers of the transition metal dichalcogenide WSe_2. In a continuation of our recent work by Raiber et al. [1], we aim to investigate the nature of the temporal dynamics in WSe2 multilayers. These previous results have shown that pseudospin oscillations appear in the TRFE signal when we apply an in-plane magnetic field to our multilayer samples. Current results show that the oscillations have two different frequencies, a shorter one earlier in time and a longer one later in time. In differential transmission measurements, the lifetimes show a fast and slow decay on the same time scales. This suggests two different exciton dynamics or species. Now we try to characterize and manipulate these oscillations by playing with different experimental parameters. Varying the angle of the magnetic field, adding an electric field or investigating the layer dependence are examples for our toolbox of parameters to gain further insights in the dynamics of the multilayers.

HL 30: Focus Session: Young Semiconductor Forum

The young semiconductor forum gives a platform for post-docs at all career stages to present themselves and their scientific ideas. It consists of an oral session with invited talks and immediately afterwards, a poster session, where further participants present a poster about their work and/or scientific vita. With this format, we hope to attract both postdocs and senior researchers and decision makers to join this forum: for postdocs, to give them a platform to present themselves, and for professors, to meet the next generation of scientists.

Organized by Alexander Holleitner and the AGyouLeaP (Susanne Liese, Alexander Schlaich, and Christoph Kastl)

Time: Wednesday 9:30–12:15 Location: H13

Invited Talk HL 30.1 Wed 9:30 H13

Exploring semiconducting epigraphene grown by polymer-assisted sublimation growth — •Teresa Tschirner, Julia Guse, Stefan Wundrack, Frank Hohls, Klaus Pierz, and Hans Werner Schumacher — Physikalisch-Technische Bundesanstalt, Bundesallee 100, 38116 Braunschweig, Germany

Epitaxial graphene on SiC is a potential candidate in a variety of applications, such as the fabrication of 2D heterostructures and the intercalation of graphene layers with other materials for engineering new electronic material systems. Important for the quality of the graphene is the 0th layer, or buffer layer, which is covalently bonded to the SiC substrate. The buffer layer itself can be functionalized by intercalation. In a recent study it was shown that an electronic bandgap can be opened in the otherwise gapless buffer layer. The semiconducting epigraphene (SEG) on SiC has a bandgap of 0.6 eV and high room temperature mobilities (5000 cm^2/Vs), much larger than silicon and other 2D-semiconductors [1]. In this study we grow high-quality buffer layers not only across single terraces as in the aforementioned study but on millimeter scale, due to an advanced growth technique preventing step bunching and large terrace step heights. We use a polymer-assisted sublimation growth (PASG) method, where pretreatment of the SiC substrate supplies additional carbon and stabilizes the SiC surface by rapid buffer layer-formation preventing step-bunching. We investigate the growth parameters for homogeneous buffer layer formation with our PASG method and systematically study its structural properties and characteristics. [1] J. Zhao et al., Nature 625, 60 (2024).

Invited Talk HL 30.2 Wed 10:00 H13

Huge Enhancement of the Giant Negative Magnetoresistance with Decreasing Electron Density — •Lina Bockhorn[1], Christian Reichl[2], Werner Wegscheider[2], and Rolf J. Haug[1] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, Germany — [2]Laboratorium für Festkörperphysik, ETH Zürich, Switzerland

Ultra-high mobility two-dimensional electron gases often show a remarkably robust negative magnetoresistance at zero magnetic field. Below 800 mK, this phenomenon divides into two distinct parts [1-4]: a temperature-independent narrow peak around $B = 0$ T, arising from the interplay of smooth disorder and elastic scattering at macroscopic defects [2, 3], and a temperature-dependent giant negative magnetoresistance (GNMR) at higher magnetic fields. The theoretical understanding of the GNMR remains an open question, as it involves several independent parameters in addition to electron-electron interaction possibly leading to hydrodynamic transport effects. To gain insights into the nature of the GNMR, we investigate this effect as a function of electron density at various temperatures and currents. Our results show a significant dependence of GNMR on electron density [4], indicating that variations in scattering potentials [5] are not considered appropriately in theoretical models. [1] L. Bockhorn et al., Phys. Rev. B 83, 113301 (2011). [2] L. Bockhorn et al., Phys. Rev. B 90, 165434 (2014). [3] L. Bockhorn et al., Appl. Phys. Lett. 108, 092103 (2016). [4] L. Bockhorn et al., Phys. Rev. B 109, 205416 (2024). [5] Y. Huang et al., Phys. Rev. Materials 6, L061001 (2022).

Invited Talk HL 30.3 Wed 10:30 H13

Ultrafast quantum optics with single-photon emitters in 2D materials — •Steffen Michaelis de Vasconcellos — Physikalisches Intitut, Universität Münster, Germany

Single-photon sources are essential components for building quantum networks, though achieving optimal control remains a significant challenge in advancing quantum technologies. Recently, 2D van der Waals materials, such as transition metal dichalcogenides (TMDs) and hexagonal boron nitride (hBN), have emerged as promising platforms for solid-state quantum light emitters, enabling new possibilities for creating, tuning, and integrating quantum emitters into photonic devices [1].

In my talk, I will review the development of single-photon emitters in 2D materials, focussing particularly on the robust emitters in hBN, which efficiently emit single photons even at room temperature. We demonstrate the efficient collection of single-photons by 3D-printed microlenses [2] and explore ultrafast coherent control of individual hBN quantum emitters [3]. Understanding the underlying dephasing mechanisms is key to designing devices that meet the requirements for future quantum technologies. Our work paves the way towards controlled hybrid quantum systems integrating electronic and phononic excitations.

Invited Talk HL 30.4 Wed 11:15 H13

Realistic simulation of quantum emitter dynamics made easy — •Moritz Cygorek — TU Dortmund, Germany

Few-level quantum emitters such as quantum dots are a main workhorse for cutting edge research in quantum science, e.g., for nonclassical light generation. A practical challenge is the strong interaction with the physical environment such as phonons, which gives rise to a plethora of effects such as decoherence, phonon-assisted transitions, and renormalization. The intricacy of environment effects and computational challenges have in the past rendered the theoretical analysis an expert topic requiring an in-depth understanding of various theoretical methods.

Here, I demonstrate how the concept of process tensor matrix product operators (PT-MPOs) enables quick-and-easy, yet numerically exact simulations of very general open quantum systems. A computational framework is presented that can be used as a black box by the practitioner, which (i) requires no expert knowledge, (ii) leverages path integrals and tensor networks for exceptional speed and accuracy, (iii) is based on C++ for computational and memory efficiency, (iv) yet can be controlled by parameter files and requires no explicit programming, (iv) while also providing Python bindings for easy postprocessing.

Moreover, I demonstrate applications to solid-state cavity-QED relating to concrete experiments: single- and entangled photon generation, multitime correlation functions and dynamically dressed Mollow spectra, as well as phonon effects on cooperative emission and superradiance.

Invited Talk HL 30.5 Wed 11:45 H13

Data-driven Design of Next Generation 2D Materials and Their Heterostructures — •Rico Friedrich — TU Dresden — Helmholtz-Zentrum Dresden-Rossendorf — Duke University, USA

Two-dimensional (2D) materials and their heterostructures provide an extensive platform for realizing advanced electronic and magnetic functionalities at the nanoscale. While individual 2D systems are traditionally obtained from bulk layered compounds bonded by weak van der Waals (vdW) forces, the recent surprising experimental realization of semiconducting non-vdW 2D materials derived from non-layered crystals [1] opens up a new direction.

As outlined by our recent data-driven investigations employing autonomous *ab initio* calculations [2, 3], several dozens of new candidates showcase a wide range of appealing electronic, optical, and in particular magnetic properties owing to the (magnetic) cations at the active surfaces of the sheets. Further generalizing the data-driven modelling approach to all inorganic compounds provides fundamental insights into the exfoliation and cleavage of crystals. At the same time, chemical tuning by surface passivation provides a valuable handle to further control the electronic and magnetic properties of these next generation 2D compounds [4]. These features thus make non-vdW 2D materials an attractive platform for fundamental as well as applied nanoscience.

HL 31.1 Wed 12:15 H13

Exploring Auto-Oscillations in Semiconductor Electron-Nuclear Spin System — •Alex Greilich, Nataliia E. Kopteva, Vladimir L. Korenev, and Manfred Bayer — Experimentelle Physik 2a, TU Dortmund University, Dortmund, Germany

We demonstrate self-sustained auto-oscillations in a dissipative electron-nuclear spin system (ENSS) in semiconductors, where spontaneous breaking of translational symmetry in time produces robust limit-cycle dynamics across a broad range of parameters, including laser power, temperature, and magnetic field. These periodic oscillations exhibit coherence times extending to hours, reflecting ideal "time atom" ordering within the auto-oscillatory system.

Additionally, we uncover synchronization within excited subsystems without additional modulation, identifying its microscopic origins. Under periodic driving, modulation of parameters such as excitation power and pump polarization yields parametric resonances, signaling a transition to discrete auto-oscillatory behavior. Key phenomena include frequency entrainment, Arnold tongues, bifurcation jets, and a devil's staircase, showcasing the ENSS's versatility in exploring nonlinear dynamics, with broad implications for both fundamental physics and semiconductor applications.

HL 31.2 Wed 12:15 H13

Reducing waste through substrate reuse: a pathway to cost-effective iii-v optoelectronics — •radouane ennadir — 3IT, Sherbrooke University, Sherbrooke, QC, Canada

III-V materials, such as Gallium Arsenide (GaAs), are widely used in optoelectronic devices due to their superior electronic and optical properties. However, the high cost of III-V substrates, primarily made from Ge or other expensive materials, represents a significant barrier to the widespread adoption of these technologies.

Our research focuses on reducing waste in the production of III-V optoelectronics through the reuse of Germanium (Ge) substrates. In this study, we propose a novel approach to mitigate substrate waste by reusing Ge substrates in the fabrication of III-V optoelectronics. By carefully optimizing the recycling process, including substrate cleaning, surface treatment, and the integration of new III-V layers, we aim to significantly reduce material costs without compromising device performance. This approach not only enhances the sustainability of optoelectronic manufacturing but also provides a cost-effective pathway to large-scale production of III-V-based devices. The findings of this study contribute to both environmental sustainability and economic viability in the growing field of optoelectronics, opening up new opportunities for the development of advanced, cost-effective optoelectronic devices.

HL 31.3 Wed 12:15 H13

1D exciton confinement in monolayer $MoSe_2$ near ferroelectric domain walls in periodically poled $LiNBo_3$ — •Pedro Soubelet, Yao Tong, Asier Astaburuaga Hernandez, Andreas V. Stier, and Jonathan J. Finley — Walter Schottky Institut and TUM School of Natural Sciences, Technische Universität München, Am Coulombwall 4, 85748 Garching, Germany

Monolayer transition metal dichalcogenides are an emergent platform for exploring and engineering quantum phenomena in condensed matter. Due to their atomic thickness, the excitonic response is highly influenced by the dielectric environment. In this work, we explore the optical properties and exciton kinetics of monolayer thick $MoSe_2$ straddling domain wall boundaries in ferroelectric periodically poled $LiNbO_3$ (PPLN). Spatially resolved photoluminescence (PL) experiments reveal sorting of neutral and charged excitons across the boundary. Our results reveal evidence for extremely large in-plane electric fields (≃4000 kV/cm) at the domain wall (DW), whose effect is manifested in the routing of free charges and trions towards oppositely poled domains, resulting in a nonintuitive spatial PL intensity pattern. In a second step, we engineer the PPLN substrate and the 2D heterostructure to exploit the non-uniform in-plane electric field exerted by the DW to confine neutral excitons in a 1D dipolar gas. Reducing the dimensionality holds an excellent potential for unlocking strong exciton-exciton interaction regimes, enabling exploration of exotic quantum phases of matter and designing advanced optoelectronic devices.

HL 31.4 Wed 12:15 H13

Probing strong electron-phonon coupling in graphene by resonance Raman spectroscopy with infrared excitation energy — •Simone Sotgiu[1,2], Tommaso Venanzi[1], Lorenzo Graziotto[1], Francesco Macheda[1], Taoufiq Quaj[2], Elena Stellino[1], Bernd Beschoten[2], Christoph Stampfer[2], Francesco Mauri[1], and Leonetta Baldassarre[1] — [1]Department of Physics, Sapienza University of Rome, Rome, Italy — [2]JARA-FIT and 2nd Institute of Physics, RWTH Aachen University, Aachen, Germany

Resonance Raman spectroscopy (RRS) has been a key asset to study the interplay between electronic and vibrational properties of graphene. We report on RRS measurements with an excitation photon energy down to 1.17 eV on mono (MLG) and bilayer (BLG) graphene, to study how low-energy carriers interact with lattice vibrations. Thanks to the excitation energy close to the Dirac point, we unveil in the MLG a giant increase of the intensity ratio between the double-resonant 2D and 2D* Raman peaks with respect to graphite [1]. In BLG, the low excitation energy hampers some of the resonant Raman processes giving rise to the 2D peak. Consequently, the sub-features composing the 2D mode are spectrally more separated with respect to visible excitations. We compare experimental measurements on BLG with ab initio theoretical calculations and we trace back such modifications on the joint effects of probing the electronic dispersion close to the band splitting and enhancement of electron-phonon matrix elements [2]. [1] T. Venanzi et al., Phys. Rev. Lett. 2023, 130, 256901 [2] L. Graziotto et al., Nano Lett. 2024, 24, 1867

HL 31.5 Wed 12:15 H13

Effects of atomistic fluctuations on the excitonic fine-structure in alloyed colloidal quantum Dots — •Anne Nadine Tewonoue Djota, Surender Kumar, and Gabriel Bester — Institute of physical chemistry and physics, University of Hamburg

The electron-hole exchange interaction in the presence of spin-orbit coupling leads for an atomistic calculation to a small energy splitting of the excitonic state known in this context as the fine structure splitting (FSS). Although this splitting is typically small, it has large consequences for the optical properties. For instance, the photoluminescence originates from these few states and is governed by the splitting (giving rise to temperature dependence) and polarization of these low energy excitonic states. So far most of the theoretical modeling has assumed that high symmetry structures lead to a simple dark-bright splitting with a large degeneracy of the excitonic states. In this work, we show based on atomistic calculations, that even globally perfectly symmetric structures (i.e., as far as an atomistic construction permits a "spherical" quantum dot) show a qualitatively different FSS as soon as alloying is introduced. The alloying effect is significantly stronger than any global shape anisotropy where the symmetry is broken for instance by geometrical elongation of the quantum dot. On the other hand, alloying a quantum dot through processes such as cation exchange is inherently random. As a result, different random alloy configurations with the same size and composition can exhibit significantly different FSS.

HL 31.6 Wed 12:15 H13

Resistance standards from artifact wire coils to graphene quantum Hall resistance — •Yefei Yin[1], Mattias Kruskopf[1], Stephan Bauer[1], Teresa Tschirner[1], Klaus Pierz[1], Frank Hohls[1], Rolf J. Haug[2], and Hans W. Schumacher[1] — [1]Physikalisch-Technische Bundesanstalt, Bundesallee 100, 38116 Braunschweig, Germany — [2]Institut für Festkörperphysik, Leibniz Universität Hannover, 30167 Hannover, Germany

Historically, resistance standards were made by physical artifact wire coils before 1990 and quantum resistors based on GaAs heterostructures after 1990. However, conventional GaAs quantum Hall resistance (QHR) standards with the quantized resistance $R_H = h/2e^2$ are operating under high magnetic flux densities B > 10 T, limited currents I < 50 μA, and low temperatures T < 1.5 K, which significantly hinder the dissemination of primary resistance standards. In this work, we developed practical primary QHR standards based on n- and p-type epitaxial graphene. This study first systematically demonstrated that p-type epitaxial graphene can also be used for primary resistance standards, as accurate (10^{-9} accuracy) as GaAs and n-type graphene counterparts for realizing

the SI unit ohm in quantum metrology. [1] The n-type graphene QHR standards achieved the world best performance so far with a 10^{-9} accuracy under relaxed conditions (B = 4.5 T, I = 232.5 μA, T = 4.2 K) simultaneously. [2-3] Our graphene QHR standards have been utilized in the national metrology institutes in European countries. [1] Appl. Phys. Lett., 125, 064001 (2024). [2] Adv. Phys. Res. 1, 2200015 (2022). [3] Phys. Rev. Applied, 2024

HL 31.7 Wed 12:15 H13

Hybridized excitons in 2D van der Waals materials — •Andreas Stier — Walter Schottky Institut und TUM School of Natural Sciences, TU München, Garching, Deutschland

I will review our recent progress on magneto optical spectroscopy of atomically thin materials in magnetic fields up to 91 T with an emphasis on the spin-valley physics of neutral and charged excitons.

In monolayer (ML) semiconductors, magneto-absorption spectroscopy revealed the diamagnetic shifts of the exciton Rydberg states, which allowed the first direct experimental measure of the reduced mass and binding energy. Surprisingly, investigating the photoluminescence, we observe the emergence of a new excitonic peak, which we discuss in the framework of the theoretically predicted linear dispersing exciton branch originating from intervalley exchange interactions.

For heterostructures (HS) of a 2D semiconductor with graphene, we find a new multi-step proximity effect due to band folding in the HS, where we show that the spin-valley physics can be used to quantify interlayer hybridization. In HS from ML MoSe2 and the layered antiferromagnetic (AFM) semiconductor CrSBr, we show the formation of new exciton states depending on the twist angle. These excitons exhibit clear signatures of proximity coupling to the magnetic state of the AFM layer, such as hysteretic response to in- and out of plane B fields. We discuss these results in the framework of Ising-type spin-orbit proximity coupling.

HL 31.8 Wed 12:15 H13

Shaped pulses enable robust coherent control of quantum dots: perspectives for quantum technologies — •Vikas Remesh — Institute für Experimentalphysik, Universität Innsbruck, Innsbruck, Austria

Shaped laser pulses have been remarkably effective in investigating and controlling various light-matter interactions in a broad area of research. In quantum technologies, the techniques to shape complex spatiotemporal waveforms have found renewed interest, for instance in coherent control of quantum dots [1]. In this talk, I will navigate through the impact of pulse shaping techniques in nanospectroscopy and how it enabled efficient preparation schemes in quantum dots, based on our recent works [2], including the pioneering off-resonant coherent control of quantum dots, compact plug-and-play method of exciting multiple quantum dots and accessing dark excitons in quantum dots for advanced entanglement generation. Afterwards, I will conclude with my vision on the future scope of nanophotonics-assisted-quantum technology roadmap. [1] Photonic Quantum Technologies: Science and Applications 1, 53 (2023) [2] Nano Letters 22, 6567 (2022), Materials for Quantum Technology 3, 025006 (2023), APL Photonics 8, 101301 (2023), npj Quantum Information 10, 17 (2024), Advanced Quantum Technologies, 2300352 (2024), arXiv:2409.13981, arXiv:2406.07097, arXiv:2404.10708

HL 31.9 Wed 12:15 H13

First-Principles Investigation of NV Centers in Silicon Carbide Polytypes — •Timur Biktagirov, Uwe Gerstmann, and Wolf Gero Schmidt — Universität Paderborn, Paderborn, Germany

Optically addressable spin defects in semiconductors offer versatile platforms for quantum applications, including computing, communication, and sensing. Among these, nitrogen-vacancy (NV) centers in silicon carbide (SiC) polytypes have emerged as a promising class of quantum defects, analogous to the NV center in diamond. In contrast to diamond, SiC is a technologically mature material with large-scale production capabilities, advanced doping techniques, and compatibility with CMOS fabrication methods. Additionally, the emission wavelengths of NV centers in SiC lie in the near-infrared range, making them particularly suitable for applications in single-photon emission. In this work, we discuss recent advancements in the ab initio investigation of NV centers in the 4H, 6H, and 3C polytypes of SiC. Simulating the magneto-optical properties of these spin centers, which are crucial for quantum applications, requires a detailed and accurate description of both the host material and the embedded defect. Accordingly, we demonstrate how supercell density functional theory (DFT) and recent implementations based on DFT can be employed to model key properties, including intra-defect optical transition energies, electron-electron and electron-nuclear spin interactions, and electron-phonon coupling. These theoretical insights provide a foundation for optimizing NV centers in SiC for next-generation quantum technologies.

HL 31.10 Wed 12:15 H13

Transport properties of quantum dots for single-electron pumps — •Johannes C. Bayer, Thomas Gerster, Dario Maradan, Frank Hohls, and Hans W. Schumacher — Physikalisch-Technische Bundesanstalt, 31668 Braunschweig, Germany

A single-electron pump (SEP) is a device emitting a well-defined number of n electrons per cycle of an external drive. With driving frequency f and elementary charge e, this results in a current of $I = nef$. Since the revision of the SI system, the elementary charge e hereby is an exact value, so that SEPs provide a suitable basis for a quantum current standard. The accuracy of this current is directly related to erroneous cycles, where the emitted number of electrons deviates from n. Our SEP devices are based on electrostatically defined quantum dots in GaAs/AlGaAs two-dimensional electron gases. In such devices, the tunnel barriers as well as the energy levels are controllable via gate voltages. Based on multiple quantum dot devices we here investigate relations between transport properties and SEP operation characteristics.

HL 32: Nitrides: Preparation and Characterization I

Time: Wednesday 9:30–11:00 Location: H15

HL 32.1 Wed 9:30 H15

Optical properties of asymmetric cubic AlGaN/GaN quantum wells — •Erik Graper[1], Elias Baron[1], Martin Feneberg[1], Tobias Wecker[2], Donat J. As[2], and Rüdiger Goldhahn[1] — [1]Institut für Physik, Otto-von-Guericke-Universität Magdeburg, Germany — [2]Department Physik, Universität Paderborn, Germany

Group III-nitrides, particularly AlGaN and GaN, are essential materials for high-performance electronic and optoelectronic devices. While conventional hexagonal AlGaN/GaN high-electron-mobility transistors (HEMTs) operate in normally-on mode, cubic AlGaN/GaN structures enable normally-off operation - a crucial advantage for energy-efficient power electronics. These cubic AlGaN/GaN heterostructures offer additional benefits such as the absence of internal polarization fields in (001) orientation.

In this study, we investigate asymmetric cubic AlGaN/GaN double quantum wells (2.5 nm and 0.6 nm) with varying barrier thicknesses, grown by plasma-assisted molecular beam epitaxy on 3C-SiC/Si substrates in (001) orientation. We employed complementary spectroscopic techniques to analyze quantum well coupling, combining photoluminescence (PL) measurements using continuous-wave lasers (266 nm and 325 nm) with photoluminescence excitation (PLE) spectroscopy using a tunable pulsed laser (325 - 354 nm). The acquired spectra were analyzed to determine wavelength dependent luminescence of the 2.5 nm quantum well.

HL 32.2 Wed 9:45 H15

Nanoscale characterization of cascaded GaN/InGaN LEDs with tunnel junction — •Konstantin Wein, Gordon Schmidt, Frank Bertram, Holger Eisele, Peter Veit, Olga August, Christoph Berger, Armin Dadgar, André Strittmatter, and Jürgen Christen — Otto-von-Guericke-University Magdeburg, Germany

In this work, comprehensive cathodoluminescence (CL) and electron beam induced current (EBIC) characterization directly performed in a scanning transmission electron microscopy (STEM) were performed on an InGaN/GaN double cascaded LED using a GaN:Ge/GaN:Mg tunnel junction (TJ). Cascaded LEDs benefit from monolithic multi-wavelength emission, lower injection current density (lower droop), and smaller chip sizes compared with standard LEDs. In low temperature (T = 17 K) highly spatially resolved CL, each individual layer is identified by its characteristic emission. The GaN:Si layers exhibit NBE emission at 365 nm corresponding to donor-bound exciton recombination, in contrast to the GaN:Mg layers which exhibit donor-acceptor pair recombination emitting at 380 nm. The intensity profile across the InGaN MQWs of both active regions gives access to the transport and capture of the excess carriers and excitons. The direct comparison of the local CL emission with the EBIC signal exhibits not only the local quantum efficiency as well as transfer of carriers (diffusion/drift) but also the current spreading/injection distribution of the vertical device. The impact of functional layers like electron blocking layers or TJs on the transport of carriers is directly visualized on the nano-scale.

HL 32.3 Wed 10:00 H15

Understanding the Effect of Defects in Ta3N5 Thin Films on Charge Carrier Dynamics — •Jan Luca Blänsdorf[1], Lukas M. Wolz[1], Matthias Kuhl[1], Johannes Dittloff[1,2], Nina Miller[1], Gabriel Grötzner[1,2], Ian D. Sharp[1,2], and Johanna Eichhorn[1] — [1]Physics Department, TUM School of Natural Sciences, Technische Universität München, Germany — [2]Walter Schottky Institute, Technische Universität München, Germany

Transition-metal nitrides are a highly interesting material space for solar-energy conversion due to their suitable bandgap for visible light absorption and high theoretical solar-to-hydrogen efficiencies. An intensively studied example is Ta3N5, with a bandgap of 2.2 eV and favorable band alignment for solar water splitting. However, its photoelectrochemical performance is limited by oxygen impurities and nitrogen vacancies. Here, we used transient absorption spectroscopy on the microsecond timescale to reveal the impact of different defects on charge carrier dynamics in Ta3N5. Therefore, we synthesized Ta3N5 thin films with different concentrations of nitrogen vacancies and oxygen impurities. Their structure, defect and photoelectrochemical properties were correlated with charge carrier dynamics to identify current performance limitations.

HL 32.4 Wed 10:15 H15

Accessing and evaluating the full growth window of PAMBE grown AlGaN/GaN nanowires — •Rudolfo Hötzel[1], Marten Wilkens[1], Florian Krause[1], Andreas Rosenauer[1,2], Stephan Figge[1], and Martin Eickhoff[1,2] — [1]Institute of Solid State Physics, University of Bremen, 28359 Bremen, Germany — [2]MAPEX Center for Materials and Processes, 28359 Bremen, Germany

Typically group III/V nanowires synthesized by PAMBE are grown under a surplus of nitrogen. Under metal-rich conditions nanowire broadening is reported [1] leading to increased coalescence until self-stabilisation to stoichiometric conditions is reached. To establish stoichiometry single GaN nanowires consisting of multilayers of GaN grown with varying Ga fluxes were analyzed by STEM-EDX. The dependence of growth rates on temperature and fluxes could be consistently fitted with previously reported growth models [1] with the Ga desorption rate as the only free parameter. However a lateral broadening was not observed even for deep Ga-rich conditions. We attribute this to higher growth temperatures leading to an increased Ga desorption from the side facets. Based on these findings AlGaN/GaN nanowires were grown under deep metal-rich conditions. We observed that high Al/Ga fluxes lead to the formation of AlN regions due to the higher formation enthalpy of AlN with Ga accumulating on the c-face because of demixing. A homogenous incorporation of Al under deep metal-rich conditions was only possible for low Al/Ga flux ratios which are limited by the growth temperature. [1] S. Fernández-Garrido et al., Nano Lett. 13, 3274-3280 (2013)

HL 32.5 Wed 10:30 H15

Nanoscale multi-spectroscopic characterisation of InGaN pseudo-substrates grown on nanowire arrays — •Aidan Flynn Campbell, Jingxuan Kang, Huaide Zhang, Oliver Brandt, Lutz Geelhaar, and Jonas Lähnemann — Paul-Drude-Institut für Festkörperelektronik, Berlin, Deutschland

The efficiency of nitride light-emitting diodes (LEDs) in the amber and red spectral ranges is severely limited by the high strain in (In,Ga)N quantum wells with increasing In content when grown on GaN. Thus, reducing the lattice mismatch between the active region and adjacent layers is highly desirable. Our approach exploits the lateral elastic strain relaxation facilitated by nanowires fabricated top-down from a single-crystalline layer, epitaxial overgrowth of a subsequent layer achieves a strain free pseudo-substrate. In this study, we characterise the optical, chemical, and crystallographic properties of such overgrown layers, which are key in understanding and optimising our epitaxial overgrowth fabrication route.

We utilise experimental techniques such as continuous-wave and time-resolved cathodoluminescence (TRCL), energy-dispersive X-ray spectroscopy (EDX), and high-resolution electron backscatter diffraction (HR-EBSD). We demonstrate low dislocation densities, low compositional variations and low crystal misorientation across coalescence boundaries. Furthermore, the factors influencing defect formation and the relevance of dislocation propagation are investigated and correlated with the resulting luminescence efficiency of the overgrown layers.

HL 32.6 Wed 10:45 H15

Measuring solute concentrations in ammonothermal solutions via in situ X-ray absorption - estimating detection limits for novel nitrides — •Rajesh Chirala, Ege N. Civas, and Saskia Schimmel — Chair of Electron Devices (LEB), Dept. EEI, FAU Erlangen-Nürnberg, Cauerstr. 6, 91058 Erlangen, Germany

The ammonothermal method [1] is effective for producing high quality single crystals of binary and ternary nitrides [2], which are emerging semiconductor materials [3]. Despite the challenging process conditions (100 to 300 MPa, 400 to 800 °C), in situ measurement techniques such as X-ray imaging [4] allow to study reaction kinetics and solubilities, which are highly relevant to bulk crystal growth. In case of GaN, the quantitative determination of the concentration of Ga containing intermediates was already demonstrated [5].

By simulating the X-ray absorption of novel nitrides in an ammonothermal autoclave, we estimate element-specific detection limits for solute concentrations and derive strategies for detecting lighter elements or lower concentrations. Amongst the others, effectiveness of using a combination of lower X-ray energies and higher X-ray dose will be analyzed.

HL 33: Nitrides: Devices

Time: Wednesday 11:15–13:00 Location: H15

HL 33.1 Wed 11:15 H15

Influence of barrier height variations on the efficiency of AlGaN-based 225nm LEDs — •Markus A. Blonski[1], Jakob Höpfner[1], Tim Kolbe[2], Sylvia Hagedorn[2], Hyun Kyong Cho[2], Jens Rass[2], Paula Vierck[1], Tim Wernicke[1], Michael Kneissl[1,2], and Markus Weyers[2] — [1]Technische Universität Berlin, Institute of Solid State Physics, Berlin, Germany — [2]Ferdinand-Braun-Institut (FBH), Berlin, Germany

Deep ultraviolet (DUV) light emitting diodes (LEDs) with emission wavelengths shorter than 225 nm exhibit low external quantum efficiencies (EQEs). Since the AlGaN multi-quantum well (MQW) active region remains a significant limiting factor for EQE, the effects of the barrier height in the MQW region on the radiative recombination efficiency (RRE), carrier injection efficiency (CIE) and light extraction efficiency (LEE) are examined. For this, the barrier composition is varied from $Al_{0.82}Ga_{0.18}N$ over $Al_{0.86}Ga_{0.14}N$ to $Al_{0.89}Ga_{0.11}N$. The lowest barrier leads to the highest peak EQE at 0.05 % and the highest barrier to an EQE peak below 0.02 %. The RRE, CIE and LEE are determined using continuous wave and pulsed electroluminescence measurements, determination of optical polarization and Monte Carlo raytracing simulations. The analysis shows that an increase in barrier height leads to an increase in RRE and LEE and a significant decrease in CIE for an overall decrease in EQE. Drift diffusion simulations indicate a notable increase in electron spillover across the $Al_{0.98}Ga_{0.02}N$ electron blocking layer to the p-side, attributable to a reduced band offset between barrier and electron blocking layer, reducing the CIE.

HL 33.2 Wed 11:30 H15

Homoepitaxy on AlN-bulk substrates with different off-cut angles — •Sebastian Krüger[1], Sarina Graupeter[1], Massimo Grigoletto[1,2], Marcel Schilling[1], Sylvia Hagedorn[2], Carsten Hartmann[3], Thomas Straubinger[3], Tim Wernicke[1], and Michael Kneissl[1,2] — [1]Technische Universität Berlin, Institute of Solid State Physics, Berlin, Germany — [2]Ferdinand-Braun-Institut (FBH), Berlin, Germany — [3]Leibniz-Institut für Kristallzüchtung, Berlin, Germany

Laser diodes in the UVC spectral range require high-quality AlN and AlGaN layers with low threading dislocation densities (TDD) and smooth surfaces. AlN substrates with a TDD of $< 10^4$ cm^{-2} are the ideal choice. In this work we investigate the influence of substrate off-cut (0.1° to 0.5°) and growth parameters (e.g. TMAl flow, V/III-ratio) on the morphology of homoepitaxially grown AlN buffer layers. A transition from step flow growth for a 0.2° miscut AlN substrate to step bunching for miscuts of 0.39° and above is observed for a growth temperature of 1070°C, a TMAl flow of 35 μmol/min and a V/III-ratio of 15. For a miscut of 0.27° step flow growth is still present but the terrace width shows significant variation. The RMS roughness increases from 0.11 nm (on 0.2°) to 0.45 nm (on 0.39°). For 0.5° miscut, the substrate terrace width is even smaller, i.e. the diffusion length must be reduced to avoid step bunching e.g. by increasing the V/III-ratio. Between V/III ratios of 15 and 60 we found morphologies such as island growth and step meandering with the lowest RMS roughness of 0.11 nm for a TMAl flow of 35 μmol/min and a V/III-ratio of 15.

HL 33.3 Wed 11:45 H15

Stabilizing Ta_3N_5 Thin Films Photoelectrodes by Defect Engineering — •Lukas M. Wolz[1], Gabriel Grötzner[1,2], Tim Rieth[1,2], Laura I. Wagner[1,2], Matthias Kuhl[1], Johannes Dittloff[1,2], Guanda Zhou[1,2], Saswati Santra[1,2], Verena Streibel[1,2], Frans Munnik[3], Ian D. Sharp[1,2], and Johanna Eichhorn[1] — [1]Physics Department, TUM School of Natural Sciences, Technische Universität München, Germany — [2]Walter Schottky Institute, Technische Universität München, Germany — [3]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

Tantalum nitride (Ta_3N_5) is a highly investigated photoelectrode material due to its favorable optoelectronic properties for photoelectrochemical (PEC) energy conversion. However, intrinsic defects such as nitrogen vacancies and oxygen impurities play a crucial role in defining their optical, electronic, and photoelectrochemical properties. While the role of these defects in PEC activity is well investigated, their impact on material stability remains underexplored. We investigate the relationship between atomic-scale defects and macroscale PEC stability in Ta_3N_5 thin films. To reveal the impact of each defect type on the material properties, we introduced different defect concentrations in Ta_3N_5 by using three different precursors in the synthesis process. Low oxygen concentrations are found to increase long-range order but lead to high concentrations of deep-level defects, leading to increased charge recombination and decreased material stability. Conversely, higher oxygen contents result in reduced structural order but beneficially passivate deep-level defects, leading to improved stability.

HL 33.4 Wed 12:00 H15

Studying the carrier distribution of multicolor far-UVC LEDs by temperature dependent electroluminescence measurements — •Jakob Höpfner[1], Franz Biebler[1], Florian Kühl[1], Marcel Schilling[1], Anton Muhin[1], Massimo Grigoletto[1,2], Martin Guttmann[2], Gregor Hoffmann[3], Friedhard Römer[3], Tim Wernicke[1], Berndt Witzigmann[3], and Michael Kneissl[1,2] — [1]Technische Universität Berlin, Institute of Solid State Physics, Berlin, Germany — [2]Ferdinand-Braun-Institut (FBH), 12489 Berlin, Germany — [3]Lehrstuhl für Optoelektronik, Department EEI, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany

The low current injection efficiency (CIE) is one of the root causes for the poor external quantum efficiency of AlGaN based far-UVC LEDs. To improve the CIE it is necessary to gain insights into the carrier distribution and transport in the AlGaN multiple quantum well active region. Therefore, heterostructures were grown by metalorganic vapour phase epitaxy (MOVPE) with a varying number of QWs (2 –20) emitting at 233 nm and one single QW with an emission wavelength of 250 nm. This allows us to probe the carrier transport with the help of temperature dependent electroluminescence measurements (100 K - 340 K). The experimental findings were correlated with drift-diffusion simulations and Monte-Carlo ray-tracing simulations. Experiment and simulations show that the holes are weakly confined in the 233 nm emitting QWs and exhibit a long diffusion length over many QWs mainly due to thermal escape from the shallow barriers.

HL 33.5 Wed 12:15 H15

Influence of strain reduced HTA-AlN/sapphire templates with different offcuts on the performance of UVC LEDs — •Sarina Graupeter[1], Finn Kusch[1], Paula Vierck[1], Sylvia Hagedorn[2], Markus Weyers[2], Tim Wernicke[1], and Michael Kneissl[1,2] — [1]Technische Universität Berlin, Institute of Solid State Physics, Berlin, Germany — [2]Ferdinand-Braun-Institut (FBH), Berlin, Germany

High temperature annealing (HTA) of sputter dposited AlN layers on (0001) sapphire substrates allows for fabrication low threading dislocation densitiy templates (TDD of 4 x $10^8\,cm^2$) enabling UVC LEDs with improved external quantum efficiency and lifetime. However, due to the thermal expansion mismatch of the sapphire and the AlN, the AlN layers are under high compressive strain after cooling down from HTA at 1700°C. This can lead to strain relaxation and formation of dislocation half-loops during the subsequent growth of AlN and AlGaN layers, thus decreasing the radiative recombination efficiency (RRE). By growing a Si-doped AlN layer on HTA-AlN the in-plane compressive strain ϵ_{xx} is reduced by around 30% from -0.3 to -0.2. The impact of such an interlayer on the electro-optical properties of UVC-LEDs has been investigated with focus on the RRE. The RRE has been determined using cw and pulsed EL-measurements with the Titkov-Dai method. Using an AlN:Si interlayer shows an increase of the EQE value from 0.8% to 1%. Emission powers as high as 1.9 mW at 50 mA can be realized for UVC LEDs on strain reduced templates.

HL 33.6 Wed 12:30 H15

Characterisation of a Pt on-chip counter electrode on a GaN/AlGaN-ISFET Wheatstone bridge as pH-sensor — •Alexander Hinz[1], Niklas Krantz[1], Stephan Figge[1], and Martin Eickhoff[1,2] — [1]Institute of Solid State Physics, University of Bremen, Otto-Hahn-Allee 1, 28359 Bremen, Germany — [2]MAPEX Center for Materials and Processes, University of Bremen, Bibliotheksstraße 1, 28359 Bremen, Germany

The influence of a Pt on-chip counter electrode on field effect transistors as pH-sensors was investigated. The intention was to reduce the size of the complete sensor structure consisting of ISFET, counter and reference electrode. In addition, the function of the Pt on-chip electrode was be compared to setup using an external Pt counter electrode to discuss stability and leakage. Furthermore, a Wheatstone bridge design is used to compensate temperature drifts. A reduction of this drift to 0.02 mV/°C was achieved. The long-time behavior of the temperature drift and also of pH changes was also analysed.

HL 33.7 Wed 12:45 H15

Efficiency analysis of 233 nm far-UVC LEDs with varied DPD AlGaN layer thickness beyond 298 K — •Paula Vierck[1], Jakob Höpfner[1], Marcel Schilling[1], Massimo Grigoletto[1,2], Markus Blonski[1], Tim Wernicke[1,2], and Michael Kneissl[1,2] — [1]Technische Universität Berlin, Institute of Solid State Physics, Berlin, Germany — [2]Ferdinand Braun Institut (FBH), Berlin, Germany

Light emitting diodes (LEDs) emitting in the far ultraviolet-C (far-UVC) spectral range offer applications in skin safe disinfection and gas sensing. In this work we analyze far-UVC LEDs with a distributed-polarization doped (DPD) p-AlGaN layer as this offers a promising alternative to Mg-doping. By compositionally grading the Al content of the AlGaN layer, a 3D hole gas can be generated exceeding the free hole concentration of conventionally Mg doped samples. The theoretically calculated charge profile depends on the grading and can be controlled by changing the DPD layer thickness or the alloy composition. In this work, five samples with DPD layer thicknesses between 25 nm and 150 nm were investigated by electroluminescence spectroscopy and numerical simulations. With decreasing DPD layer thickness we find an increase in the peak external quantum efficiency (EQE) with a maximum EQE of 0.37 % for a DPD thickness of 25 nm due to an increased hole concentration. Further analysis at temperatures of up to 353 K revealed a notable decline in the devices EQE down to 0.15 % at 353 K for a 25 nm thick DPD. This work will provide an analysis of the different contributing factors to the EQE drop with insights provided by simulations.

HL 34: Focus Session: Quantum Emission from Chaotic Microcavities (joint session HL/DY)

In this joint focused session of the divisions DY, HL, and TT, we bring together two dynamic areas of research: semiconductor quantum emitters and chaotic cavities. While quantum emitters in cavities represent an established building block for quantum information technologies, chaotic microcavities may promise novel design routes towards optimized cavity performance parameters. Experts from both fields will provide an overview of the current state of research, exploring the potential of chaotic and unconventional microcavities to enhance the emission of quantum states.

Organized by Sonja Barkhofen (University of Paderborn) and Christian Schneider (University of Oldenburg).

Time: Wednesday 9:30–12:15 Location: H17

Invited Talk HL 34.1 Wed 9:30 H17

From complex internal dynamics to emission characteristics control in quantum billiards — •Martina Hentschel — 1 Institute of Physics, Technische Universität Chemnitz, D-09107 Chemnitz, Germany

The field of mesoscopic physics has given access to new classes of fascinating model systems ranging from ballistic quantum dots via microcavity lasers to graphene billiards over the past decades. Their rich internal dynamics, subject to quantum chaos and often successfully accessed employing wave-particle correspondence in real and phase space, is directly related to their emission properties. Here, we illustrate this close connection for various examples and system classes. For optical microcavities, we vary the internal dynamics by changing the geometric shape of the resonator and explain how the far-field emission characteristics is determined by the underlying steady probability distribution and a possibility to achieve directional emission required for microlasing devices with

the Limaçon geometry. Placing sources into the cavity will affect the internal dynamics of the cavity by, taking the particle point-of-view, effectively changing the set of initial conditions, as observed for optical cavities as well as for graphene billiards in the form of Dirac fermion optics. A further way to change the dynamics of a system is the existence of anisotropies that can either be intrinsically present such as in bilayer graphene in the form of trigonal warping [1], or can be induced to a given system by, for example, applying a mechanical strain. [1] L. Seemann, A. Knothe, and M. Hentschel, New J. Phys. 26, 103045 (2024).

Invited Talk HL 34.2 Wed 10:00 H17

Positioning of microcavities around single emitters — •Tobias Huber-Loyola — Technische Physik, Physikalisches Institut, Julius-Maximilians-Universität Würzburg, 97074 Würzburg, Germany

Single emitters in solids are great sources of single and entangled photons for usage in quantum information technologies. Many emitters possess high internal quantum efficiency, majority of the emission into the zero-phonon line and controllable single charge spins that can be used as quantum memories or as resource to generate chains of entangled photons. However, due to their solid-state host, which usually comes with a high refractive index, the outcoupling of photons requires the use of nanophotonic structures such as waveguides or microcavities. In this talk, I will show how we place microcavities around pre-registered quantum dots using hyperspectral imaging and e-beam lithography and I will give an overview of how placement accuracy has different effects on the emitted photons' properties based on the type of cavity.

Invited Talk HL 34.3 Wed 10:30 H17

Exploring Wave Chaos and Non-Hermitian Physics: Future Prospects for Quantum Emission from Chaotic Microcavities — •Jan Wiersig — Otto-von-Guericke-Universität Magdeburg, Germany

Optical microcavities play a fundamental role in many fields of basic and applied research in physics. A chaotic microcavity is a type of cavity where the light ray dynamics is (partially) chaotic [1]. This can occur in a microdisk cavity with a deformed boundary shape. Chaotic microcavities are ideal for studying ray-wave correspondence, or wave chaos, in open systems, allowing direct comparisons with experiments [2]. These cavities can also exhibit non-Hermitian phenomena such as reflectionless scattering modes [3] and exceptional points [4].

The light emission from chaotic microcavities has been studied exclusively within the classical domain. The effects of electromagnetic field quantization, including phenomena like entanglement, single-photon states, and squeezed light, remain unexplored in this context. In this talk, I will review my group's recent efforts to investigate classical emission from chaotic microcavities and quantum emission from semiconductor quantum dots embedded in conventional microcavities. Additionally, I will discuss the prospects for achieving genuine quantum emission from chaotic microcavities.

Correlations and statistics in cavity embedded quantum dot sources of quantum light — •Ana Predojevic — Stockholm University, Stockholm, Sweden

Single quantum dots coupled to photonic cavities are established emitters of single photons and entangled photon pairs. The cascaded generation of photon pairs intrinsically contains temporal correlations that negatively affect the ability of such sources to perform two-photon interference, hindering applications. I will show how such correlation interacts with decoherence and temporal postselection, and under what conditions temporal postselection could improve two-photon interference visibility. Our study identifies crucial parameters of the source and shows the way to achieve optimal performance. The single photons emitted by a quantum dot exhibit quantum statistics, which is usually verified in an autocorrelation measurement. Single photons can be subjected to more extensive tests of quantum nature, such as non-Gaussianity. However, there is little evidence that such a measurement can be made on pairs of photons. I will show that pairs of photons exhibit strongly non-classical properties that can be quantified. Our result is applicable to a wide range of quantum light sources and measurement methods.

Invited Talk HL 34.5 Wed 11:45 H17

Nonlinear Phenomena in Exciton-Polaritons from Bound States in the Continuum — •Dario Ballarini — CNR-NANOTEC, Lecce, Italy

Exciton-polaritons in semiconductor microcavities have demonstrated remarkable collective behaviors and nonlinear interactions. In this work, we introduce an alternative platform to study strong light-matter interactions within a waveguide configuration. Among other interesting phenomena and applications, such as dispersion engineering of waveguide exciton-polaritons or exciton tuning through the Stark effect [1,2], we highlight the demonstration of parametric nonlinearities, polariton lasing from bound-in-the-continuum (BIC) states, and the recent realization of polariton BICs operating at room temperature in 2D materials [3-5].

HL 36.1 Wed 15:00 H13

High aspect ratio wurtzite GaAs nanowires as a platform for hexagonal SiGe — •Marvin Marco Jansen[1], Wouter H.J. Peeters[1], Marcel A. Verheijen[1,2], and Erik P.A.M. Bakkers[1] — [1]Department of Applied Physics, Eindhoven University of Technology, Groene Loper 19, 5612AP Eindhoven, The Netherland — [2]Eurofins Materials Science BV, High Tech Campus 11, 5656 AE Eindhoven, The Netherlands

One of the most promising pathway to create a silicon based laser is the recently developed hexagonal silicon germanium (hex-SiGe) shells around wurtzite (WZ) gallium arsenide (GaAs) nanowires (NWs) for which efficient direct band gap emission was shown. However, studies have highlighted the limitations of the core/shell NW system. A main challenge is the recently discovered aspect ratio limitation in WZ GaAs NWs ascribed to a dynamic variation of the growth conditions. Here, we report on the crystal phase control of GaAs NWs down to the monolayer regime opening up new pathways for superlattices as well as high aspect ratios GaAs NWs. To achieve this, Ga pulses are executed by momentarily halting the As supply, leading to an accumulation of Ga atoms within the catalyst particle. This process leads to the increase of the contact angle of the catalyst particle enabling a controlled transition from the WZ phase to the zinc blende (ZB), and then back to the WZ phase. By using the ZB inclusion as a marker during the growth process, we successfully carried out a detailed investigation into the evolution of the NW growth, considering its diameter, length, and the pulse frequency.

HL 36.2 Wed 15:15 H13

Shaped pulses enable robust coherent control of quantum dots: perspectives for quantum technologies — •Vikas Remesh — Institute für Experimentalphysik, Universität Innsbruck, Innsbruck, Austria

Shaped laser pulses have been remarkably effective in investigating and controlling various light-matter interactions in a broad area of research. In quantum technologies, the techniques to shape complex spatiotemporal waveforms have found renewed interest, for instance in coherent control of quantum dots [1]. In this talk, I will navigate through the impact of pulse shaping techniques in nanospectroscopy and how it enabled efficient preparation schemes in quantum dots, based on our recent works [2], including the pioneering off-resonant coherent control of quantum dots, compact plug-and-play method of exciting multiple quantum dots and accessing dark excitons in quantum dots for advanced entanglement generation. Afterwards, I will conclude with my vision on the future scope of nanophotonics-assisted-quantum technology roadmap. [1] Photonic

HL 36.3 Wed 15:30 H13

Single-Electron Shuttling for Scalable Silicon Quantum Computers: Modeling, Simulation and Optimal Control — •Lasse Ermoneit[1], Burkhard Schmidt[1], Thomas Koprucki[1], Jürgen Fuhrmann[1], Tobias Breiten[2], Arnau Sala[3], Nils Ciroth[3], Ran Xue[3], Lars R. Schreiber[3,4], and Markus Kantner[1] — [1]Weierstrass Institute, Berlin, Germany — [2]Technical University Berlin, Germany — [3]JARA-FIT Institute for Quantum Information, Forschungszentrum Jülich GmbH and RWTH Aachen University, Germany — [4]ARQUE Systems GmbH, Aachen, Germany

While spin qubits in gate-defined Si/SiGe quantum dots provide excellent prospects for scalability, the lithographic processing, signal routing and wiring of large qubit arrays at a small footprint pose a significant challenge. A potential solution is to divide the qubit register into compact, dense qubit arrays linked by an interconnecting quantum bus shuttle, that allows for coherent transfer of quantum information by physically moving electrons along a channel. Limitations in qubit shuttling fidelity arise from the interaction of the electron with material defects within the channel that can cause non-adiabatic transitions to excited orbital states. Since those have an altered effective g-factor, this leads to a spin precession with an indeterministic phase. In this contribution, we theoretically explore the capabilities for bypassing defect centers using optimally engineered control signals that allow for a quasi-adiabatic passage of the electron through the channel without reducing the shuttling velocity. Our approach is based on quantum optimal control theory and Schrödinger wave packet propagation.

HL 36.4 Wed 15:45 H13

Spectral Hole linewidths and donor-acceptor dynamics in ultra-pure 28-Si:P — •Nico Eggeling[1], Finja Tadge[1], N.V. Abrosimov[2], Jens Hübner[1], and Michael Oestreich[1] — [1]Leibniz Universität Hannover, Germany — [2]IKZ Berlin, Germany

Donor-bound excitons in ultra-pure silicon show significant inhomogeneous broadening, which can be studied in detail using spectral hole burning[1]. Surprisingly, for decreasing pump intensities, the linewidth of these holes does not approach the natural transition linewidth, resulting from the dominating Auger effect at low temperatures[2]. Instead, time-dependent experiments show that the width and decay of the spectral holes change significantly with temperature and magnetic field, which an intricate model including donor-acceptor pair recombination can explain.

HL 36.5 Wed 16:00 H13

The Kitaev transmon qubit: design, readout and operation — •Tobias Kuhn and Monica Benito — Augsburg University, Augsburg, Germany

Fermionic-parity qubits are very stable but cannot be operated in isolation. Coupling two parity qubits allows us to construct parity-spin qubit states within one global parity [1]. Its degeneracy and non-locality should improve T_2 and T_1 times [2]. A parity qubit can be realized in a double quantum dot connected via a common superconducting lead, where elastic cotunneling t as well as crossed Andreev reflection Δ preserve parity. This minimal Kitaev chain possesses degenerate distinct-parity states at the sweetspot $\Delta = t$[1]. Weakly coupling two minimal Kitaev chains inside a transmon loop introduces an additional Josephson potential which is a consequence of the emerging parity-spin qubit [3]. This hybrid device combines the advantages of both quantum dots and transmons to promise a high-fidelity qubit device we call Kitmon (Kitaev transmon). We theoretically analyze even and odd global parity subspaces of the Kitaev junction and show that flux spectroscopy in a circuit QED implementation [4] determines global parity. Additionally, we derive an effective Hamiltonian depending on the transmon excitation state, which is useful for single qubit operations and qubit readout. [1] M. Leijnse and K. Flensberg, Phys. Rev. HL 36.6 Wed 16:15 H13

Towards the goal of reliably storing single-photons from a quantum dot — •Ioannis Caltzidis[1], Patricia A. Kallert[1], Chase Wallace[2], Sean Keenan[3], Nicolas Claro-Rodríguez[1], Santiago Bermúdez-Feijóo[1], Sonja Barkhofen[1], Margherita Mazzera[3], Eden Figueroa[2], and Klaus D. Jöns[1] — [1]Institute for Photonic Quantum Systems (PhoQS), Center for Optoelectronics and Photonics Paderborn (CeOPP) and Department of Physics, Paderborn University, Germany — [2]Quantum Memories Group, Heriot-Watt University, Edinburgh, Scotland, United Kingdom — [3]Department of Physics and Astronomy, Stony Brook University, Stony Brook, NY, USA and Brookhaven National Laboratory, Upton, NY, USA

In quantum networks, precise single-photon arrival times are crucial for effective entanglement swapping protocols. Therefore, quantum memories are curcial to store photons until read out simultaneously and synchronously routed to further processing, e.g. Bell measurements. To operate a varm vapor memory in our laboratories we present initial results demonstrating our ability to generate short optical pulses in the desired frequency domain optimized for the atomic transitions of rubidium. We further probe the interaction of short pulses with the atomic medium in the presence or absence of different supsidiary light-fields. This series of experiments aims to probe the parameter space of our system with the goal of storing single photons fom quantum dots in a rubidium based EIT Memory.

HL 36.7 Wed 16:45 H13

Stability of Majorana modes in disordered topological insulator nanowires — •Leonard Kaufhold — Institute for theoretical physics, Cologne, Germany

The possibility of Majorana bound states (MBS) in nanowire hybrid devices has sparked great interest over the past decade due to their potential application in quantum computing. In this talk, we evaluate theoretically the possibility to realize MBS in topological-insulator (TI) nanowires proximity-coupled to an s-wave superconductor with regards to one main obstacle: disorder, be it from charged impurities within the bulk of the TI or short ranged surface defects. Based on extensive numerical investigation of screening effects as well as the resulting surface states, we demonstrate, that Majorana modes can be achieved under realistic conditions.

HL 36.8 Wed 17:00 H13

Signature of topological transitions in Na-Sb-Bi alloys via Compton scattering — •Aki Pulkkinen[1], Veenavee Kothalawala[2], Kosuke Suzuki[3], Bernardo Barbiellini[2,4,5], Hiroshi Sakurai[3], Ján Minár[1], and Arun Bansil[4,5] — [1]New Technologies-Research Centre, Pilsen, Czech Republic — [2]School of Engineering Science, LUT University, Finland — [3]Graduate School of Science and Technology, Gunma University, Japan — [4]Department of Physics, Northeastern University, USA — [5]Quantum Materials and Sensing Institute, Northeastern University, USA

We investigate the topological transition in Na-Sb-Bi alloys using x-ray Compton scattering experiments, combined with first-principles modeling of the electronic structure. A robust signature of the semiconductor-to-Dirac semimetal transition is identified in the spherically averaged Compton profile. We demonstrate the evolution of the electronic structure across the topological transition as a function of Bi concentration using the coherent potential approximation (CPA) within the fully relativistic, full potential Korringa-Kohn-Rostoker (KKR) method implemented in the SPRKKR package. Spherically averaged Compton profiles are estimated by averaging over directional profiles over a set of special directions within the KKR method. We demonstrate how the number of electrons involved in the topological transition can be estimated, providing a new descriptor to quantify the strength of the spin-orbit coupling driving the transition. Our study also highlights the sensitivity of the Compton scattering technique in capturing the spillover of Bi 6p relativistic states onto Na sites.

HL 36.9 Wed 17:15 H13

Circular photonic crystal grating design for charge-tunable quantum light sources in the telecom C-band — •Chenxi Ma[1], Jingzhong Yang[1], Pengji Li[1], Eddy Rugeramigabo[1], Michael Zopf[1], and Fei Ding[1,2] — [1]Leibniz University Hannover, Institute of Solid State Physics, Hannover, Germany — [2]Leibniz University Hannover, Laboratory of Nano and Quantum Engineering, Hannover, Germany

Efficient generation of entangled photon pairs at telecom wavelengths is a key ingredient for long-range quantum networks. While embedding semiconductor quantum dots into hybrid circular Bragg gratings has proven effective, it conflicts with p-i-n diode heterostructures which offer superior coherence. We propose and analyze hybrid circular photonic crystal gratings, incorporating air holes to facilitate charge carrier transport without compromising optical properties. Through numerical simulations, a broad cavity mode with a Purcell factor of 23 enhancing both exciton and biexciton transitions, and exceptional collection efficiency of 92.4

HL 36.10 Wed 17:30 H13

Control of NV centre generation in pulsed plasma chemical vapor deposition (CVD) grown diamonds — •Ravi Teja Aditya[1], Felix Hoffmann[1], Patrik Stranak[1], Volker Cimalla[1], and Rüdiger Quay[1,2] — [1]Fraunhofer Institute for Applied Solid State Physics, Tullastraße 72, D-79108 Freiburg, Germany — [2]Department for Sustainable Systems Engineering INATECH, University of Freiburg, 79108 Freiburg, Germany

Nitrogen vacancy (NV) centres in diamond have emerged to be an integral part in many quantum computing and quantum sensing applications. High and precise NV density is required especially for quantum sensing applications. There is a need for control of nitrogen incorporation and NV yield without compromis-

ing crystal quality and growth rate. Although higher power levels ensure higher nitrogen incorporation, it is often limited by temperature. Investigating pulsed plasma chemical vapor deposition (CVD) for this purpose proved to be beneficial to control the NV generation. A pulsed plasma generator was used to reach higher power levels while maintaining an appropriate temperature by adjusting the duty cycle accordingly. Time resolved optical emission spectroscopy (OES) was used to observe the plasma composition during microwave pulses. A pulse length dependent activation of CN radicals was observed which led to a variation in NV densities in grown films. We present the results of variation of NV densities in diamond films caused by variation in pulse length, MW power and duty cycle.

HL 36.11 Wed 17:45 H13

Charge-tunable quantum dot single photon sources for quantum repeater experiments — •Peter Gschwandtner, Quirin Buchinger, Constantin Krause, Sebastian Krüger, Silke Kuhn, Tobias Huber-Loyola, and Sven Höfling — Julius-Maximilian-Universität Würzburg, Physikalisches Institut, Lehrstuhl für Technische Physik, Germany

Semiconductor quantum dots (QD) are promising candidates for entangled photon sources (SPS) for quantum network purposes [1]. Single charge spins in QDs could serve as the quantum memory in the quantum repeater [2] or as a local entangler to create a photonic state for a memory-free quantum repeater [3].

In this talk, we present our experimental results for electrically contacted charge-tuneable p-i-n InAs QDs embedded in a circular Bragg grating (CBG). The cavity design enables us to control the charged exciton states of the quantum dots. The CBG exhibits high Purcell enhancement in a broad wavelength range. A novel labyrinth design of the CBG allows for electrical contacting without impeding other performance characteristics [4].

HL 37: Focus Session: Physics of the van der Waals Magnetic Semiconductor CrSBr I (joint session HL/MA)

The session is the first part of the focus session on the physics of the van der Waals magnetic semiconductor CrSBr, with a main session on Friday morning. The focus session is jointly organized by HL and MA.

Time: Wednesday 15:00–15:30 Location: H15

HL 37.1 Wed 15:00 H15

Doping-control of excitons and magnetism in few-layer CrSBr — •Farsane Tabataba-Vakili[1,2,3], Anna Rupp[2], Huy Nguyen[2], Anvar Baimuratov[2], and Alexander Högele[2,3] — [1]Institute of Condensed Matter Physics, Technische Universität Braunschweig, Braunschweig, Germany — [2]Fakultät für Physik, Munich Quantum Center, and Center for NanoScience (CeNS), Ludwig-Maximilians-Universität München, München, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), München, Germany

In two-dimensional (2D) magnets, phenomena distinct from bulk magnetism have been revealed, such as sensitivity to charge doping and electric field in few-layer CrI3. Within the class of 2D magnets, air-stable CrSBr stands out as an antiferromagnetic semiconductor with a high Néel temperature, excitons coupled to the magnetic order, and exciton-magnon coupling. In this talk, I will present our work on doping-control of excitons and magnetism in few-layer CrSBr [1]. We demonstrate that both exciton and magnetic transitions are sensitive to field-effect charging, exhibiting bound exciton-charge complexes and doping-induced metamagnetic transitions. We further visualize magnetic domain formation induced by magnetic field or charge-doping at the metamagnetic transition all-optically by raster-scan reflectance imaging. Our work identifies few-layer CrSBr as a rich platform for exploring collaborative effects of charge, optical excitations, and magnetism.

HL 37.2 Wed 15:15 H15

Proximity-Induced Exchange Interaction and Prolonged Valley Lifetime in $MoSe_2$/CrSBr Van-Der-Waals Heterostructure with Orthogonal Spin Textures — •Andreas Beer[1], Klaus Zollner[1], Caique Serati de Brito[1,2], Paulo E. Feria Junior[1], Philipp Parzefall[1], Talieh S. Ghiasi[3], Josep Ingla Aynés[3], Samuel Mañas-Valero[4], Carla Boix-Constant[4], Kenji Watanabe[5], Takashi Taniguchi[5], Jaroslav Fabian[1], Herre S. J. van der Zant[3], Yara Galvão Gobato[2], and Christian Schüller[1] — [1]UR, Regensburg, Germany — [2]UFSCar, São Carlos, Brazil — [3]TU, Delft, Netherlands — [4]ICMol, València, Spain — [5]NIMSC, Tsukuba, Japan

We report a comprehensive optical study of a ML-$MoSe_2$ on the layered A-type antiferromagnetic semiconductor CrSBr. The band alignment of the material combination is under debate. Here, we adopt the type-III band alignment picture. By performing co-circular polarized PL and reflection contrast (RC) experiments, we observe that the atomic proximity of the materials leads to an unexpected breaking of time-reversal symmetry, despite the originally perpendicular spin texture in both materials, which are further supported by first-principles calculations. Moreover, time-resolved PL and time-resolved RC measurements identify a very long-lived dynamic charge-transfer process in the heterostructure, consistent with a type-III band alignment. Our findings suggest band bending, and efficient Förster resonance energy transfer within the heterostructure. Finally time resolved Kerr ellipticity measurements reveal a two magnitudes prolonged valley lifetime.

HL 38: Nanomechanical systems (joint session HL/TT)

The session covers the physics of nanomechanical systems.

Time: Wednesday 15:00–15:45 Location: H17

HL 38.1 Wed 15:00 H17

Optimizing an Integrated Photonic Racetrack Resonator for Optomechanical Synchronization — •Agnes Zinth[1] and Menno Poot[1,2,3] — [1]Department of Physics, TUM School of Natural Sciences, Technical University of Munich, Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany — [3]Institute for Advanced Study, Technical University of Munich, Garching, Germany

In the field of optomechanics, synchronization will be an essential tool in fields like sensing and quantum technologies. Towards this goal, we develop a photonic integrated optomechanical device consisting of a silicon nitride racetrack cavity with partly suspended waveguide that can vibrate freely. A second beam is added to improve the optomechanical coupling. The observed mechanical modes do not match in frequency, so we use a predisplaced beam instead [1]. The remaining frequency distance can be tuned by the laser power. As the light propagates in the predisplaced beam and only past the PhC beam, it shifts further than the photonic crystal one due to thermal effects. To synchronize them with optomechanical backaction, we also need to enhance the optical cavity. Therefore, we modify the transition from supported to suspended parts. Two different approaches lead to the desired improved optical quality. Currently, we are investigating their impact on the mechanics. We believe that, in the next generation of devices, we can synchronize the racetrack and photonic crystal beam.

[1] Geometric tuning of stress in predisplaced silicon nitride resonators. Nano Letters, 22(10), 4013-4019.

HL 38.2 Wed 15:15 H17

Quantum Mechanics in Two-Dimensional Dynamic Spaces — •Benjamin Schwager and Jamal Berakdar — Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Germany

In the study of systems with reduced dimensions one encounters quantum particles under spatial constraints. Their dynamics have to be modeled based on a configuration space that is a Riemannian manifold, in general, and the resulting quantum wave equations contain correction terms in dependence of its geometric properties. We consider particles which are confined to a flexible thin material shell by studying the Schrödinger equation on moving domains. The

model assumes a static observer and couples the deformation dynamics of the material to the quantum dynamics it hosts via additional potential fields. Effects caused by the interplay of geometry and the temporal evolution of the underlying configuration space will be discussed.

HL 38.3 Wed 15:30 H17

Towards cavity optomechanics using 2D materials — •Petricia Sara Peter[1,2], Lukas Schleicher[1,2], Anne Rodriguez[1,2], Leonard Geilen[2,3], Alexander Musta[2,3], Benedict Brouwer[2,3], Alexander Holleitner[2,3], and Eva Weig[1,2] — [1]Chair of Nano and Quantum Sensors, TU Munich, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany — [3]Walter Schottky Institute, TU Munich, Germany

Two-dimensional (2D) materials, such as hexagonal boron nitride (hBN), are promising candidates for advancing cavity optomechanics due to their low mass, high mechanical strength, and unique optical properties. This work focuses on the fabrication of freely suspended hBN membranes on silicon oxide (SiO_2) and silicon nitride (Si_3N_3) substrates, utilizing a water-assisted wet transfer technique. Compared to the dry transfer method, this approach minimizes inhomogeneous stress and preserves optimal mode shapes, improving mechanical quality factors. A Michelson interferometer is used to measure the mechanical properties of the resulting drumhead resonators, including vibrational resonances, mode shapes, and quality factors. These results provide important insights into the performance and quality of the resonator, laying the groundwork for incorporating 2D materials into cavity optomechanical studies.

HL 39: Poster III

The third poster session covers most recent results on the optical and thermal properties of semiconductors, as well as on nitrides and organic semiconductors, and semiconductor lasers.

Time: Wednesday 15:00–18:00 Location: P3

HL 39.1 Wed 15:00 P3

Termperature dependent electroluminescence spectroscopy of far-UVC-LEDs with varying AlGaN quantum well thickness — •Max Dittmer[1], Jakob Höpfner[1], Markus Blonski[1], Tim Kolbe[2], Sylvia Hagedorn[2], Hyun Kyong Cho[2], Jens Rass[2], Sven Einfeldt[2], Tim Wernicke[1], Markus Weyers[2], and Michael Kneissl[1] — [1]TU Berlin, Insitute of Solid State Physics, Berlin, Germany — [2]Ferdinand-Braun-Insitut (FBH), Berlin Germany

AlGaN far-UVC-LEDs with emission wavelengths below 240 nm require AlGaN layers with such high aluminium molefractions that p-doping with magnesium is inefficient due to its high ionization energy. An alternative method of p-doping is distributed polarization doping (DPD), which induces charge carriers by polarization charges. We will present the results of temperature dependent electroluminescence spectrocopy on 233 nm AlGaN LEDs with DPD gradient, grown by metal organic vapor phase epitaxy (MOVPE). We investigated the impact of the quantum well (QW) width from 1.3 nm to 7.6 nm. Most importantly we found the 2.6 nm LED to be the most efficient at room temperature. The LEDs exhibit an S-shape in the emission energy in dependence of the temperature and the highest internal quantum efficiency of 55%, was measured at 200 K.

HL 39.2 Wed 15:00 P3

MATRIX: GaN diode arrays for proton monitoring and imaging — •Nico Brosda[1], Stéphane Higueret[2], Thê-Duc Lê[2], Andreas Wieck[1], Maxime Hugues[3], Matilde Siviero[3], and Jean-Yves Duboz[3] — [1]Lehrstuhl für angewandte Festkörperphysik, Ruhr-Universität Bochum, D-44780 Bochum, Germany — [2]Université de Strasbourg, CNRS, IPHC UMR 7178, F-67000 Strasbourg, France — [3]Université Côte d'Azur, CNRS, CRHEA, 06560, Valbonne, France

The MATRIX project is pioneering advancements in proton therapy for cancer treatment by developing novel, highly durable detectors that enhance real-time control of irradiation doses. Proton detection is achieved by measuring the current induced in the active regions of PIN GaN diodes. Our GaN-based devices are fabricated as linear diode arrays of 128 elements and two-dimensional imaging arrays up to 11×11 elements, covering an area of 1 cm^2 with up to 500 μm spatial resolution. Thanks to the microelectronics processes, a much higher resolution can be obtained if needed. Results concerning the sample structure and fabrication process are presented. The design of bonding contacts proved to have a significant impact on the measured signal and, thus, the imaging quality. A bonding fanout on the GaN samples introduced notable signal distortions at the edges of the proton irradiation field. The underlying electron external emission mechanism responsible for this distortion was modeled, and a correction method was developed. An adapted sample design improved the device quality and removed the signal distortion. These findings pave the way for optimizing future GaN-based proton detector arrays.

HL 39.3 Wed 15:00 P3

Investigating the Electrical Properties of Distributed Polarization Doped $Al_xGa_{1-x}N$ Heterostructures via Capacitance-Voltage Measurements — •Thibaut Ehlermann[1], Marcel Schilling[1], Massimo Grigoletto[1,2], Jakob Höpfner[1], Tim Wernicke[1], and Michael Kneissl[1,2] — [1]Technische Universität Berlin — [2]Ferdinand-Braun-Institut (FBH)

Distributed Polarization Doping (DPD) enables the generation of charge carriers in wide-bandgap semiconductors like AlGaN by utilizing the material's inherent polarization properties without the introduction of impurities. Linearly graded AlGaN DPD layers were grown by metal-organic vapor phase epitaxy (MOVPE). The starting Al mole fraction was always 100%. The thickness and end mole fraction were varied. The charge carrier concentration N_A was determined from CV-measurements. For a 100 nm thick AlGaN DPD layer (x=100% –> 60%), the charge carrier concentration is $N_A = 1.4 \cdot 10^{18} \frac{1}{cm^3}$, closely matching the theoretical value of $N_A = 1.72 \cdot 10^{18} \frac{1}{cm^3}$, based on the calculated intrinsic polarization. Thicker DPD layers lead to a lower doping concentration and AlGaN DPDs (x=100% –> 80%) result in lower doping concentrations in agreement with the calculated values. The consistency of the results suggest that DPD is a reliable and promising way for p-type doping in AlGaN.

HL 39.4 Wed 15:00 P3

Temperature Dependence of the Quantum Efficiency of UV LEDs emitting from 226 nm to 300 nm — •Max Eysell[1], Jakob Höpfner[1], Marcel Schilling[1], Norman Susilo[1], Anton Muhin[1], Massimo Grigoletto[1,2], Tim Kolbe[2], Arne Knauer[2], Sylvia Hagedorn[2], Markus Weyers[2], Jens Rass[2], Hyun Kyong Cho[2], Tim Wernicke[1], Sven Einfeldt[2], and Michael Kneissl[1,2] — [1]Technische Universität Berlin, Institute of Solid State Physics, Berlin, Germany — [2]Ferdinand-Braun-Institut (FBH), Berlin, Germany

UV-LEDs are of huge interest for e.g. air, surface, and water disinfection. However, the widespread application of UV-LEDs is constrained by their external quantum efficiency (EQE) which is decreasing further as the emission wavelength shortens. To gain insight into the carrier transport and recombination mechanisms, a detailed analysis of the EQE of UV-LEDs and the three contributors: the carrier injection, the radiative recombination and the light extraction was performed.

The emission power of LEDs with emission wavelengths of 226 nm, 233 nm, 265 nm and 305 nm are investigated by temperature dependent electroluminescence measurements in the range of $25 - 80^{\circ}C$. A reduction in emission power and EQE has been observed going from UVB to the far-UVC spectral range. A thermal droop in the emission power was observed for all samples which is caused by the decline of all three contributions. The magnitude of this thermal droop becomes higher with decreasing wavelength which we attribute to an increased electron leakage suggested by Schrödinger-Poisson drift-diffusion simulations.

HL 39.5 Wed 15:00 P3

Theoretical Study on the (In, Ga)N/GaN heterojunction — •Maximilian Lauer[1,2], Jan M. Waack[1,2], Michael Czerner[1,2], and Christian Heiliger[1,2] — [1]Institut für theoretische Physik, Justus-Liebig-Universität Gießen, Germany — [2]Center for Materials Research (LaMa), Justus-Liebig-Universität Gießen, Germany

Semiconductor materials have a wide range of applications and their electronic properties can be easily tuned by alloying and changing their composition x. Understanding the properties of semiconductor alloys, such as indium gallium nitride $In_xGa_{1-x}N$, is therefore an important area of research. Two such properties are the band gap of the semiconductor and its band alignment with substrate and conduction materials.

While the band gap of the random alloy (In, Ga)N is a well-established quantity, the band alignment is less well understood.

Our research aims to better understand the band alignment and interface states at a GaN/(Ga,In)N heterojunction and its impact on the electronic properties of the system.To achieve this, we performed DFT calculations using the Korringa-Kohn-Rostoker (KKR) formalism with the coherent potential approximation (CPA). From these calculations we computed the layer-resolved density of states (DOS) for varying $In_xGa_{1-x}N$ compositions. This approach can be further used to simulate the effects of doping on the electronic properties or to study the transport properties of such a system.

HL 39.6 Wed 15:00 P3

Moiré exciton polaritons in twisted photonic lattices at room temperature — •Tobias Schneider[1], Chunzi Xing[2], Yu Wang[3], Xiaokun Zhai[2], Xinzheng Zhang[3], Haitao Dai[2], Xiao Wang[4], Anlian Pan[4], Zhenyu Xiong[5], Hao Wu[5], Yuan Ren[5], Stefan Schumacher[1,6], Xuekai Ma[1], and Tingge Gao[2] — [1]Physics dept. and CeOPP, Paderborn University, Germany — [2]Department of Physics, School of Science, Tianjin University, Tianjin 300072, China — [3]The MOE Key Laboratory of Weak-Light Nonlinear Photonics and International Sino-Slovenian Join Research Center on Liquid Crystal Photonics, TEDA Institute of Applied Physics and School of Physics, Nankai University, Tianjin 300457, China — [4]College of Materials Science and Engineering, Hunan University, Changsha 410082, China — [5]Lab of quantum detection and awareness, Space Engineering University Beijing 101416, China — [6]PhoQS, Paderborn University, Germany

Due to their support of many exotic physical phenomena such as Mott insulators or the fractal quantum Hall effect, moiré lattices have attracted great interest. In this work, rhombic optical moiré lattices are realized in microcavity exciton polaritons[1]. These lattices consist of two stacked 1D periodically patterned stripes which are twisted to a specific angle. This structure allows the resulting bands to be tuned via modulating the lattice parameters such as the periodicity, the potential depth of the stripes, and the rotation angle. In addition, moiré polaritons in twisted 2D honeycomb lattices are also observed. [1] C. Xing et al., arXiv:2408.02431 (2024).

HL 39.7 Wed 15:00 P3

Ultradoped GeSn plasmonic antennas for IR photodetection — •Guillermo Godoy[1,2], Ali Azimi[3], Fritz Berkmann[3], Oliver Steuer[1], Slawomir Prucnal[1], Shengqiang Zhou[1], Ing-Song Yu[4], Inga A. Fischer[3], and Yonder Berencén[1] — [1]Helmholtz Zentrum Dresden Rossendorf, Dresden Germany — [2]Dresden University of Technology, Dresden Germany — [3]BTU Cottbus-Senftenberg, Cottbus Germany — [4]National Dong Hwa University, Hualien Taiwan

Ligth mater interaction due to localized surface plasmon resonances (LSPRs) can generate hight electical field enhacement, enabling biosensing and hot-electron photodetection devices. While metallic nanoparticles like Au and Al are commonly used, their optical losses increase at longer wavelengths, limiting applications in the mid-infrared (MIR) range, such as air pollution detection. Highly doped group-IV semiconductors, particularly GeSn alloys, offer a cost-effective alternative with lower losses and CMOS compatibility. The cut-off wavelength for plasmonic resonances depends on the carrier effective mass, and GeSn alloys with its lower electron effective mass enables plasmonic resonances from shorter wavelengths.This work explores strategies to achieve highly doped GeSn alloys for plasmon-enhanced photodetection, utilizing MBE or CVD-grown GeSn layers on Si substrates. These layers will be doped in-situ or ex-situ via ion implantation, followed by non-equilibrium annealing to enhance crystal quality and dopant activation, showcasing their potential for advancing MIR photodetection.

HL 39.8 Wed 15:00 P3

Optical and phonon properties of In-rich InGaN alloys and InN/InGaN multiple quantum well structures — •Svitlana Polesya[1], Masako Ogura[1], Sergiy Mankovsky[1], Gregor Koblmüller[2], and Hubert Ebert[1] — [1]University of Munich, 81377 Munich, Germany — [2]Technical University of Munich, 85748 Garching, Germany

In two-dimensional systems like multiple quantum well structures, thermalization of hot carriers can be strongly suppressed. InN/InGaN multilayered (ML) materials are seen as promising candidates to show this property. In order to optimize these materials, ab initio calculations have been performed on the electronic and phonon band structure, as well as on the optical properties of In-rich $In_xGa_{(1-x)}N$ alloys and the short period ML systems $[InN]_m/[In_xGa_{(1-x)}N]_n$. All calculations have been done with the VASP package. The HSE exchange-correlation potential has been used with further GW0 corrections. Electron-hole interactions were taken into account by solving the Bethe-Salpeter equation. The calculations on alloys were done via the superlattice technique considering for each In concentration x all non-equivalent atomic arrangements. This is crucial as the atomic distribution has a significant impact on the phonon band structure of the alloys. For the layered $[InN]_m/[In_xGa_{(1-x)}N]_n$ system the optical properties were calculated for various concentrations x. The important role of the interface between the quantum well ($[InN]_m$) and the quantum barrier ($[In_xGa_{(1-x)}N]_n$) on the optical properties as well as phonon band gap is shown.

HL 39.9 Wed 15:00 P3

Ultra-sensitive absorption measurements of perovskites nanocrystals, protein crystals and photo-switchable lipids — •Ayesha Khan[1], Simone Strohmair[1], Ines Amersdorffer[1,2], David Hunger[3], and Thomas Hümmer[1,2] — [1]Qlibri GmbH, Munich, Germany — [2]Ludwig Maximilian University of Munich, Munich, Germany — [3]Karlsruhe Institute of Technology, Karlsruhe, Germany

Optical studies of nano-scale systems through spectroscopy and imaging can reveal intrinsic optical properties of materials including resolving the exitonic fine structure of systems. However, due to diminutive absorption of nano-scale systems, it is challenging to perform absorption spectroscopy. For a nano-scale system placed inside an optical resonator, the light passes through the sample thousands of times, enhancing the absorption and thus, allowing measurements.

Here we present the use of a fiber-based, open-access micro-cavity to image and obtain hyperspectral maps of absorption for different nano-scale, solid state materials including perovskites nanocrystals, protein crystals and photo-switchable lipids.

The successful measurements of different nano-scale systems promise that fiber-based microcavities can become standard tools for absorption measurements of these systems.

HL 39.10 Wed 15:00 P3

Intensity-dependence of the excitonic third-harmonic generation in bilayer MoS2 — •Ruixin Zuo[1], Matthias Reichelt[1], Cong Ngo[1], Xiaohong Song[2], and Torsten Meier[1] — [1]Department of Physics, Paderborn University, D-33098 Paderborn, Germany — [2]School of Physics and Optoelectronic Engineering, Hainan University, Haikou 570288, China

The large exciton binding energies make layered transition metal dichalcogenides an ideal platform for exploring exciton physics in two-dimensional systems. We numerically and theoretically investigate three-photon transitions to the excitonic states in a bilayer MoS2 and demonstrate that beyond the linear order intraband transitions dominate over interband transitions. Beyond the perturbative limit, transitions to and from the continuum that represent fifth- and higher-order nonlinearities contribute to the excitonic response at the third harmonic where they destructively interfere with the third-order excitations. Applying an in-plane static electric field characteristically modifies the k-resolved fourth-order and higher-order nonlinearities and accordingly the interference at the excitonic resonance. We demonstrate that the yield of the third harmonic generation may rise with increasing static field strength. This finding can be interpreted to arise from a shift from destructive to constructive interference between the lowest- and higher-order excitations. Exciton ionization prevails at even higher static field strengths and results in a decrease of the third harmonic generation.

HL 39.11 Wed 15:00 P3

Implementation and Validation of a Herzberg-Teller Approach for Phonon-Assisted Photoluminescence — •Tobias Dittmann, Torben Steenbock, and Gabriel Bester — Insitut für physikalische Chemie, Universität Hamburg

Phonon-assisted PL from electronically excited states leads to the occurrence of phonon side-bands, which can shape the PL spectrum. A Franck-Condon framework based on Huang-Rhys factors efficiently describes phonon side-bands in nanostructures containing up to a few hundred atoms.[1] However, the FC approximation is usually not suited for the emission from a dark state. Therefore, we extend the method towards a Herzberg-Teller (HT) level which allows a more accurate description of the emission from a dark state. Additionally, our method includes the description of spin-orbit effects, offering an advantage over other implementations of the HT framework, particularly for structures containing heavy elements.

In a first stage of the project, we investigate various graphene quantum dots and observe that the inclusion of HT terms introduces both quantitative and qualitative differences compared to the FC spectrum. These findings underscore the critical importance of incorporating HT terms for accurate modelling. In future work, we intend to apply this method to bigger structures containing heavy elements, in order to benefit from the advantages of our implementation.

HL 39.12 Wed 15:00 P3

Electronic structure and energy landscape of $B_{Si}Si_i$-related defects — Aaron Flötotto[1], Wichard Beenken[1], Kevin Lauer[1,2], Stefan Krischok[1], and •Erich Runge[1] — [1]Technische Universität Ilmenau, Institute for Physics, Ilmenau, Germany — [2]CiS Forschungsinstitut für Mikrosensorik GmbH, Erfurt, Germany

Boron is an important dopant for silicon. Together with an adjacent interstitial Si atom, it forms the so-called $B_{Si}Si_i$ defect, which has been proposed as a source of light-induced degradation (LID) in solar cells made from boron-doped Czochralski-grown silicon. Furthermore, the $B_{Si}Si_i$ defect is an intermediate configuration in many models for boron diffusion in silicon.

In a recent comprehensive density-functional-theory-based study [1], we have calculated the energy landscape around the $B_{Si}Si_i$ defect and related defects involving one B atom and one interstitial Si atom for different chemical potentials of electrons corresponding to neutral, positively, and negatively charged supercells. Among the found meta-stable defect configurations, we identify possible recombination centers based on the defect-dependent electronic density of states and the minimal energy paths between them. The resulting potential energy landscape is checked against empirical models for boron diffusion and LID.

HL 39.13 Wed 15:00 P3

Origin of strong interband transitions in antimony — •Julia Vehndel, Nils Holle, Sebastian Walfort, and Martin Salinga — Universität Münster, Institut für Materialphysik, Wilhelm-Klemm-Straße 10, 48149 Münster

In recent years, phase change materials (PCMs) have attracted considerable interest as photonic memory elements due to a high contrast in optical properties between crystalline and amorphous states. In order to identify ideal PCMs for specific applications, the intricate connection between electronic structure, bonding and permittivity needs to be understood.

Here, we employ ab-initio simulations based on density functional theory to calculate the optical properties of the single-elemental PCM antimony in the visible and near-infrared. We analyze the permittivity in k-space for both crystalline and amorphous states. Most strikingly, the strong interband transitions at lower energies can be related to the electron and hole pockets in the first Brillouin zone of the crystalline state.

HL 39.14 Wed 15:00 P3

Optical properties of α-$(Cr_xGa_{1-x})_2O_3$ — •Dmitry Sayenko, Clemens Petersen, Jakob Seifert, Christiane Dethloff, Holger von Wenckstern, Chris Sturm, and Marius Grundmann — Felix Bloch Institute for Solid State Physics, Leipzig University, Leipzig, Germany

Due to its high bandgap energy in the order of 4.6 – 5.0 eV and its high predicted electrical breakdown field of about 8 MV cm^{-1}, Ga_2O_3 is a promising material for transparent electronic devices and high power applications [1]. Of special interest is the corundum-structured α-phase as it has the largest band gap energy of the Ga2O3 polymorphs. Further, its band gap energy can be tuned by alloying with Cr without changing its crystal structure. Here we present the dielectric function of α-$(Cr_xGa_{1-x})_2O_3$ as a function of the cation composition. The sample was grown by combinatorial pulsed laser deposition. As expected, the onset of absorption increases with increasing Ga concentration from around 3.2 eV for $x \approx 0.74$ to 4.2 eV for $x \approx 0.13$. Whereas we observe for all concentrations a negative birefringence in the visible range, i.e. $n_{eo} < n_o$, the polarization of the energetically lowest transition changes with Cr concentration. For large Cr concentration the absorption sets in at first for light polarized perpendicular to the c-axis whereas for large Ga concentration the first absorption is observed for light parallel to the c-axis. This change of the polarizability leads to a decrease of the birefringence with decreasing Cr concentration, but $n_{eo} < n_o$ holds for all x.

HL 39.15 Wed 15:00 P3

Calibration methods in Raman spectroscopy — •Susanne Moritz, Ron Hildebrandt, Chris Sturm, and Marius Grundmann — Felix Bloch Institute for Solid State Physics, Leipzig University, Leipzig, Germany

For low symmetry materials, polarization resolved measurements are required for a precise investigation, especially of the Raman tensor [1, 2]. Here we present strategies for calibrating and determining the polarization state of the incident and scattered light. In addition to the polarizing optics, e.g. polarizers, we also consider the impact of all involved optical elements such as mirrors and beam splitters. We show, that these non-idealities can have an impact on the determined Raman tensor elements. Taken into account the non-idealities of the polarizing optics the uncertainty of the deduced tensor elements can be reduced by 20%.

HL 39.16 Wed 15:00 P3

Spectral Signatures and Kinetics of Y6 Aggregates and Disordered Phase via Absorption Spectroscopy — •Daniel Kroh[1,2], Xinyue Xu[2], Trevor Smith[2], and Anna Köhler[1] — [1]Soft Matter Optoelectronics, EPII, Universität Bayreuth, Bayreuth, Germany — [2]School of Chemistry, University of Melbourne, Melbourne, Australia

Recent advancements in single-junction organic solar cells (OSCs) utilizing nonfullerene acceptors (NFAs) have significantly increased power conversion efficiencies (PCEs) to over 19%. This remarkable progress is largely attributed to the introduction of the "Y-series" NFAs, with Y6 being the most notable example. Motivated by these achievements, numerous research groups are investigating the relationship between film morphologies and their exceptional optoelectronic properties, especially when blended with the donor material PM6.

In our study, we employed temperature-dependent steady-state UV-Vis absorption and photoluminescence spectroscopy combined with Franck-Condon analysis to identify the spectral signatures of two types of aggregates and the disordered phase of Y6 in solution. We observed that all three phases are also present in neat Y6 films and blend films with PM6. Through transient absorption measurements, we further explored the excitation kinetics and transient absorption spectral signatures of these phases, providing deeper insights into their behavior.

HL 39.17 Wed 15:00 P3

Empowering Thermoelectric Performance of ZnSb via Bonding Interaction Regulation — •Meng Jiang[1,2], Fangyi Hu[1], Qihao Zhang[2], Lianjun Wang[2], Wan Jiang[2], Matthias Wuttig[1], and Yuan Yu[1] — [1]Physical Institute 1, RWTH Aachen University, Aachen, 52074, Germany. — [2]Donghua University, Shanghai, 201620, China.

ZnSb compounds have garnered significant attention due to its green nature, low cost and high Seebeck coefficient. However, its thermoelectric performance has been limited by a relatively low power factor and high lattice thermal conductivity. Recent studies have demonstrated that regulating bonding interactions offers an effective strategy to optimize the thermoelectric properties. Specifically, metavalent bonding shows unprecedented success in predicting and optimizing a series of high-performance thermoelectric materials. This reignites research interest in ZnSb. We explored a one-step synthesis strategy for ZnSb and specifically investigated optimizing mechanisms of Cd and Mg. By regulating bonding interactions to optimize electrical conductivity, the room-temperature power factor was enhanced from 2.5 to 4 μW cm-1 K-2. This improvement, coupled with a reduction in lattice thermal conductivity, resulted in a zT of 0.6 at 600 K. Our work highlights the potential of bonding interaction regulation as an effective approach for enhancing the thermoelectric performance of ZnSb. More, future research would focus on unraveling the intricate mechanisms linking bonding and microstructure to achieve even higher performance.

HL 39.18 Wed 15:00 P3

Challenges and Opportunities for Thermoelectric Coolers — •Fangyi Hu, Meng Jiang, Matthias Wuttig, and Yuan Yu — I. Physikalisches Institut (IA), RWTH Aachen University, 52074 Aachen, Germany

Thermoelectric (TE) materials allow a direct interconversion between heat and electricity, providing an eco-friendly and sustainable energy solution. Particularly, thermoelectric coolers based on the Peltier effect achieve high-precision temperature control without any refrigerant. Bi2Te3-based materials have beenused in commercial TE cooling due to their high near-room-temperature figure-or-merit (ZT). Yet, the low earth abundance of Te restricts the large-scale application of this compound. Discovering Te-free materials with comparable cooling performance is an urgent task. This requires a small bandgap and low thermal conductivity for the material at low temperatures. The recently developed concept of metavalent bonding provides a new avenue for discovering potential candidates. Besides materials, the device design and effective heat dissipation on the hot side are of critical importance. This Poster will summarize the challenges and opportunities for TE cooling materials and devices. We hope that it can shed light on the development of new TE coolers.

HL 39.19 Wed 15:00 P3

Quantum-chemical calculations of structure, electronic properties, and spectra of a model for PBDB-T:ITIC heterojunctions — Montassar Chaabani[1], Samir Romdhane[2], and •Wichard J. D. Beenken[2] — [1]Advanced Materials and Quantum Phenomena Laboratory, Physics Department, Faculty of Sciences of Tunis, University of Tunis El Manar, Tuins, Tunesia — [2]Technische Universität Ilmenau, Institut für Physik, Ilmenau, Germany

We modeled PBDB-T:ITIC heterojunctions by applying DFT on dimers built of various conformers of a PBDB-T segment and the ITIC molecule. These variations represented the non-uniformity of the interface between the donor and the acceptor in the organic solar cell. Based on this model, we calculated electronic and optical properties most relevant for charge separation at the interface using DFT and TD-DFT, respectively. For almost half of our modeled dimers, we found that the band offsets between them and the pristine donor and acceptor materials resulted in charge carrier trapping leading to inefficient charge separation as well as non-geminate recombination. When we calculated the exciton binding energy by TD-DFT using either the B3LYP or the HSE06 functional, we obtained very different qualitative and quantitative results. We, therefore, compared our results with experimental data from ultraviolet photoelectron spectroscopy, CV, ER-EIS, PL, absorption spectroscopy, EQE and EL. Finally we discuss the impact of our findings on characteristic photovoltaic parameters, particularly the open circuit voltage and the short-circuit current.

HL 39.20 Wed 15:00 P3

Investigation of the optical coupling of lasing ZnO nanowires — •Ann-Kathrin Kollak, Lukas Raam Jäger, Francesco Vitale, and Carsten Ronning — Institute of Solid State Physics, Friedrich Schiller University Jena, Germany

Semiconductor nanowires offer potential for miniaturizing optical circuits. Good candidates for this application are ZnO nanowires, because their bottom-up growth via the Vapor-Liquid-Solid (VLS) mechanism allows for high quality crystal structures. When optically pumped, ZnO nanowires simultaneously act as an active medium and a laser cavity, emitting UV light mainly waveguided to their end facets. To study the interaction of these nanometer-scale lasers via evanescent field coupling, two nanowires were positioned in contact next to each other on a SiO_2 substrate using a nanomanipulator. In a micro-PL (photoluminescence) setup, the nanowire pair was optically excited using the

third harmonic of an Nd:YAG laser (355 nm). The pair's emission was collected with the same setup, allowing the investigation of the spatially resolved PL and lasing spectra, as well as their linear polarization parallel to the substrate. The data obtained indicate that ZnO nanowire cavities can couple with one another. Depending on the geometry of the nanowire pair and the pumping conditions, optical modes that extend into both cavities can appear in addition to modes confined to only one nanowire. In other cases, the coupled modes dominate the lasing behavior.

HL 39.21 Wed 15:00 P3

Impact of stress current on reverse-bias electroluminescence images of 850 nm oxide-confined VCSELs — •Arndt Jaeger[1], Nikolay Ledentsov Jr.[2], Sebastian Haberkern[1], Helmut Meinert[1], Alexander Moll[1], Ilya E. Titkov[2], Oleg Yu. Makarov[2], and Nikolay N. Ledentsov[2] — [1]Esslingen University of Applied Sciences, Flandernstrasse 101, 73732 Esslingen, Germany — [2]VI Systems GmbH, Hardenbergstrasse 7, 10623 Berlin, Germany

Vertical-cavity surface-emitting lasers (VCSEL) employing different doping of the cavity region are studied utilizing reverse current-voltage (*IV*) characteristics as well as reverse bias electroluminescence (ReBEL). Reverse *IV* characteristics exhibits avalanche breakdown enabling an estimation of the electric field in the cavity region. ReBEL emission is observed at locations where avalanche breakthrough current has its maximum. The oxide-confined VCSELs are characterised before and after high current operation. Virgin devices have a homogeneous device center in ReBEL images. Upon a short high current burn-in VCSELs evolved a homogeneous ring at the oxide-aperture perimeter. This ring structure decays into 2 point-like areas after long-term current stress. These observations in ReBEL images can be understood in terms of recently published VCSEL simulation results which gave evidence of local current crowding at the oxide-aperture during high current laser operation.

HL 39.22 Wed 15:00 P3

Tuning nanowire lasers via hybridization with organic molecules — •Philipp Swatosch, Edwin Eobaldt, Marco Grünewald, Olga Ustimenko, Kalina Peneva, and Carsten Ronning — Friedrich Schiller Universität Jena, Deutschland

Among the numerous nanomaterials, semiconductor nanowires have drawn significant scientific interest as promising candidates for nanoscale coherent light sources and all-optical circuits. This attention is due to their exceptional waveguiding properties and inherent ability to lase under high excitation. However, precise control over their lasing characteristics, such as emission wavelength and lasing threshold, is essential for various applications. In this regard, hybridizing nanowires with customized molecules presents a potential approach, providing new control mechanisms through efficient charge and energy transfer processes at the heterointerface. To demonstrate this concept, we hybridized ZnO nanowires with perylene-based organic dyes. These chromophores are particularly advantageous as their optical gap can be easily tuned over a wide spectral range through chemical functionalization. This study employs comparative micro-photoluminescence measurements to investigate the impact of these molecules on the lasing properties of the nanowires.

HL 39.23 Wed 15:00 P3

Development of a VCSEL-chip in the red spectral range with integrated photodiode for chlorophyll fluorescence analysis — •Raphael Buffler, Michael Zimmer, Michael Jetter, and Peter Michler — Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum-Science and Technology (IQST) and SCoPE, University of Stuttgart, Allmandring 3, 70569 Stuttgart

Chlorophyll fluorescence analysis provides information on photosynthetic activity of plants and thus also on their health. Changes in the environmental conditions can be monitored on large scale and, water and nutrients can be added as needed. In order to induce the fluorescence of chlorophyll in the range from 660 nm to 750nm , optical excitation at 650 nm can be used. In this work, a semiconductor chip will be developed that contains both, the light source for excitation and the photodiode for fluorescence detection. The chip is based on the AlGaAs & AlGaInP material systems, which can realise the band gaps for the required wavelengths. The light source is designed as a vertical-cavity surface-emitting laser (VCSEL), which allows for the vertical emission of the excitation light and the vertical irradiation of the photodiode. A stacked arrangement is used, where the VCSEL is grown by metal-organic vapor-phase epitaxy (MOVPE) on top of the photodiode structure on a GaAs wafer. First electro-optical characteristics of the VCSEL and the photodiode such as P-U-I curves, emission wavelength and photodiode responsivity are presented.

HL 39.24 Wed 15:00 P3

Monolithic 850 nm VCSEL array for Quantum Key Distribution via the Decoy State Protocol — •Katharina Dahler, Michael Zimmer, Michael Jetter, and Peter Michler — Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology (IQST) and SCoPE, University of Stuttgart, Allmandring 3, 70569 Stuttgart, Germany

The need for secure data communication has increased in recent years. In contrast to classical key distribution, the use of quantum key distribution (QKD) offers fundamental advantages, such as complete secrecy. However, QKD poses numerous challenges regarding the use of single photons. With this in mind, the decoy-state protocol offers the possibility of realizing QKD with classical light sources such as attenuated semiconductor lasers. Here, we present the electro-optical characterization of a monolithic 850 nm vertical-cavity surface-emitting laser (VCSEL) array, for QKD via the BB84 and decoy state protocol. The complete VCSEL array consists of eight individual VCSELs arranged in a coplanar contact design, with four VCSELs serving as signal states and four as decoy states. A highly homogeneous growth is needed due to the requirement of indistinguishable light pulses regarding the emission wavelength. In order to realize the four necessary polarization states and to counteract the electro-optical effect, each VCSEL features a monolithically integrated surface grating in the top layer of its light emission window. Electro-optical device characteristics regarding light polarization via surface gratings and spectral homogeneity of the VCSEL array are presented.

HL 39.25 Wed 15:00 P3

A machine learning potential for tellurium — •Andrea Corradini, Giovanni Marini, and Matteo Calandra — Department of Physics, University of Trento, Via Sommarive 14, 38123 Povo, Italy

Elemental tellurium has drawn attention in recent years, due to its possible technological application as switching device in phase change memories [1]. Recent computational studies are addressing the behaviour of elemental Te under operating conditions with a focus on the crystallization dynamics [2]. In addition, experiments have found anomalous thermodynamic maxima in undercooled liquid Te around 615 K, i.e. 130 K below the melting point [3]. Thermodynamic maxima behave in a very similar way as those in undercooled liquid water. Hence the question whether elemental Te shows a liquid-liquid phase transition, analogously to what is claimed for water. In this work, we develop a robust machine learning potential to study elemental Te and try to answer this question.

HL 40: 2D Semiconductors and van der Waals Heterostructures IV

The session covers the magnetic and topological properties of 2D semiconductors and van der Waals heterostructures.

Time: Wednesday 15:30–19:00 Location: H15

HL 40.1 Wed 15:30 H15

Dielectric tensor of the layered magnetic semiconductor CrSBr — •Pierre-Maurice Piel[1], Sebastian Schaper[1], Marie-Christin Heissenbüttel[1], Aleksandra Lopion[1], Zdenek Sofer[2], and Ursula Wurstbauer[1] — [1]Institute of Physics, Muenster University, Germany — [2]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Prague, Czech Republic

Two-dimensional materials exhibit unique properties due to their atomically thin structure and weak van der Waals (vdW) coupling between layers resulting in layer dependent properties. As in the case of the layered magnetic semiconductor CrSBr, individual layers are ferromagnetically ordered below the Neel temperature (TN= 132K), while adjacent layers are coupled antiferromagnetically. Due to the highly anisotropic electronic bands in CrSBr, electronic and excitonic states at the fundamental band-gap behave quasi-one-dimensional [1]. To develop a better understanding of the extraordinary light-matter interaction in CrSBr, we access the materials dielectric tensor in the paramagnetic phase by spectroscopic imaging ellipsometry that is hard to access by alternative approaches such as reflectance measurements due to the strong anisotropy. In

agreement with theory, we extract highly anisotropic dielectric functions along the crystallographic main axes with strong excitonic resonances particularly in the plane. [1] J. Klein et al. ACS Nano, 17, 6, 5316-5328 (2023).

HL 40.2 Wed 15:45 H15

Raman Polarization Switching in CrSBr — •Priyanka Mondal[1], Daria I. Markina[1], Lennard Hopf[1], Lukas Krelle[1], Sai Shradha[1], Julian Klein[2], Mikhail M. Glazov[3], Iann Gerber[4], Kevin Hagmann[1], Regine v. Klitzing[1], Kseniia Mosina[5], Zdenek Sofer[5], and Bernhard Urbaszek[1] — [1]TU Darmstadt, Darmstadt, Germany — [2]Massachusetts Institute of Technology, Cambridge, United States — [3]St. Petersburg, Russia — [4]Université de Toulouse,Toulouse, France — [5]University of Chemistry and Technology, Prague,Czech Republic

Semiconducting CrSBr is a layered A-type antiferromagnet, with individual layers antiferromagnetically coupled along the stacking direction. Due to its unique orthorhombic crystal structure, CrSBr exhibits highly anisotropic mechanical and optoelectronic properties acting itself as a quasi-1D material. CrSBr demonstrates complex coupling phenomena involving phonons, excitons, magnons, and polaritons. Here we show through polarization-resolved resonant Raman scattering the intricate interaction between the vibrational and electronic properties of CrSBr. For samples spanning from few-layer to bulk thickness, we observe that the polarization of the A_g^2 Raman mode can be rotated by 90 degrees, shifting from alignment with the crystallographic *a* (intermediate magnetic) axis to the *b* (easy magnetic) axis, depending on the excitation energy. In contrast, the A_g^1 and A_g^3 modes consistently remain polarized along the *b* axis, regardless of the laser energy used. We access real and imaginary parts of the Raman tensor in our analysis, uncovering resonant electron-phonon coupling.

HL 40.3 Wed 16:00 H15

Resonant Inelastic Light Scattering on CrSBr — •Jan-Hendrik Larusch[1], Pierre-Maurice Piel[1], Nicolai-Leonid Bathen[1], Zdenek Sofer[2], and Ursula Wurstbauer[1] — [1]Institute of Physics, University of Münster, Germany — [2]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Prague, Czech Republic

The van der Waals material CrSBr is an optically active semiconductor and an air-stable 2D magnet with ferromagnetic (FM) ordering within each layer and antiferromagnetic (AFM) coupling between adjacent layers, alongside triaxial magnetic anisotropy. Additionally, CrSBr has a highly anisotropic electronic band structure, rendering it a quasi-one-dimensional electronic system, resulting in linearly polarized excitons that are strongly bound [1]. Distinct differences in excitonic emission signatures arise depending on the transition in magnetic ordering from AFM to FM states [2]. To study the coupling between excitons and collective excitations, we employ magnetic field-dependent resonant inelastic light scattering (RILS) experiments at temperatures well below the Néel temperature (~4K). While first-order phonon modes in Raman spectra remain mostly unaffected by magnetic ordering, RILS reveals resonantly enhanced as well as additional, magnetic field-dependent modes. The later are interpreted as spin-density excitations aka magnon modes. The combined PL and RILS study reveal strong interactions between electronic, excitonic, lattice and spin degrees of freedom. [1] J. Klein et al. ACS Nano, 17, 5316-5328 (2023) [2] M.C. Heißenbüttel et al. (2024). arXiv:2403.20174.

HL 40.4 Wed 16:15 H15

Disentangling three anisotropic resistivities of the topological insulator α-Bi_4Br_4 — •Jonathan K. Hofmann[1,2], Serhii Kovalchuk[1,3], Yuqi Zhang[4,5,6], Vasily Cherepanov[1], Timofey Balashov[1], Zhiwei Wang[4,5,6], Yugui Yao[4,5,6], Irek Morawski[3], F. Stefan Tautz[1,2], Felix Lüpke[1,7], and Bert Voigtländer[1,2] — [1]Peter Grünberg Institut, Forschungszentrum Jülich, Germany — [2]Lehrstuhl für Experimentalphysik IV A, RWTH Aachen University, Germany — [3]Institute of Experimental Physics, University of Wrocław, Poland — [4]Key Laboratory of Advanced Optoelectronic Quantum Architecture and Measurement, Ministry of Education, School of Physics, Beijing Institute of Technology, China — [5]Beijing Key Lab of Nanophotonics and Ultrafine Optoelectronic Systems, Beijing Institute of Technology, China — [6]International Center for Quantum Materials, Beijing Institute of Technology, China — [7]II. Physikalisches Institut, Universität zu Köln, Germany

The higher-order topological insulator α-Bi_4Br_4 is a promising, highly anisotropic quasi one-dimensional van der Waals material. Using a four-tip scanning tunneling microscope, we combine four-point resistance measurements in the square geometry on a bulk sample of α-Bi_4Br_4 with four-point resistance measurements on thin flakes in a linear configuration to disentangle the anisotropic resistivity tensor at room temperature (RT) and at 77 K: At RT, the resistivity along the chain direction is 6.4 times smaller than the resistivity perpendicular to the chains. At 77 K, this anisotropy reduces to 5.0. The vertical anisotropies are ~ 1300 and ~ 6500, at RT and 77 K, respectively.

15 min. break

HL 40.5 Wed 16:45 H15

Spin Hall effect in van-der-Waals ferromagnet — •Tomoharu Ohta[1,2], Nan Jiang[3,4,5], Yasuhiro Niimi[3,4,5], Kohei Yamagami[6], Yoshinori Okadada[6], Yoshichika Otani[7,8], and Kouta Kondou[4,8] — [1]Walter Schottky Institute and Physics Department, Technical University of Munich, Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), München, Germany — [3]Depertment of Physics, Osaka University, Osaka, Japan — [4]Institute for Open and Transdisciplinary Research Initiatives (OTRI), Osaka, Japan — [5]Center for Spintronics Research Network (CSRN), Osaka, Japan — [6]Okinawa Institute of Science and Technology, Graduate University, Okinawa, Japan — [7]Institute for Solid State Physics, The University of Tokyo Chiba, Japan — [8]RIKEN Center for Emergent Matter Science (CEMS), Saitama, Japan

We investigated the spin Hall effect (SHE) in a vdW ferromagnet Fe5GeTe2 (FGT) with a TC of 310 K utilizing the spin torque ferromagnetic resonance method. In synchronization with the emergence of the ferromagnetic phase resulting in the anomalous Hall effect (AHE), a noticeable enhancement in the SHE was observed below TC. On the other hand, the SHE shows a different temperature dependence from the AHE below 120 K: the effective spin Hall conductivity clearly enhanced below TC unlike the anomalous Hall conductivity, might be reflecting variation of band-structure accompanied by the complicated magnetic ordering of the FGT. The results provide a deep understanding of the SHE in magnetic materials to open a new route for novel functionalities in vdW materials-based spintronic devices.

HL 40.6 Wed 17:00 H15

Pseudo-magnetotransport simulations in strained graphene — •Alina Mrenca-Kolasinska[1] and Ming-Hao Liu[2] — [1]AGH University, Krakow, Poland — [2]National Cheng Kung University, Tainan, Taiwan

Graphene, a 2D material consisting of carbon atoms, despite its simple structure and composition can host intriguing phenomena. Application of inhomogeneous strain can lead to pseudomagnetic field (PMF), predicted to have opposite sign in the K and K 0 valley. Special strain profiles have been designed to generate uniform pseudomagnetic field in graphene [1, 2].

In this work we consider transport in pseudo magnetic field in these strain configurations. By deforming the sheet we can control the PMF, and design geometries which allow us to demonstrate interesting transport phenomena. These include electron focusing and snake states observed without external magnetic field present. For efficient modeling of quantum transport within these scenarios in large-scale systems close to realistic size devices, we extend the scalable tight-binding model [3] to accurately capture the effect of displacement field in the Hamiltonian. Our investigations open new possibilities for control over the valley degree of freedom.

HL 40.7 Wed 17:15 H15

Strong magnetic proximity effect in van der Waals heterostructures driven by direct hybridization — •Claudia Cardoso[1], Antonio T. Costa[2], Allan H. McDonald[3], and Joaquin Fernandez-Rossier[2] — [1]S3 Centre, Istituto Nanoscienze, CNR, Via Campi 213/a, 41125 Modena, Italy — [2]International Iberian Nanotechnology Laboratory, 4715-330 Braga, Portugal — [3]Physics Department, University of Texas at Austin, Austin, Texas 78712, USA

Proximity effects may induce an electronic property of a material, to an adjacent material in which that property is not present. Here we propose a class of magnetic proximity effects based on the spin-dependent hybridisation. We consider the hybridisation between the electronic states at the Fermi energy in a nonmagnetic conductor and the narrow spin-split bands of a ferromagnetic insulator.

Unlike conventional exchange proximity, this proximity effect has a strong impact on the nonmagnetic layer and can be further modulated by application of an electric field.

Using density functional theory calculations, we illustrate this effect in graphene placed next to a monolayer of CrI_3, a ferromagnetic insulator. The calculations show a strong hybridisation of the graphene bands with the narrow conduction band of CrI_3 in one spin channel only. Furthermore, the results confirm that the hybridisation strength can be modulated by an out-of-plane electric field, paving the way for applications.

HL 40.8 Wed 17:30 H15

Magnetotransport in heterostructures of MBE-grown BS/BSTS and graphene — •Marina Marocko[1], Matthias Kronseder[1], Tobias Rockinger[1], Takashi Taniguchi[2], Kenji Watanabe[2], Dieter Weiss[1], and Jonathan Eroms[1] — [1]Institute of Experimental and Applied Physics, University of Regensburg, 93040 Regensburg, Germany — [2]NIMS, 1-1 Namiki, Tsukuba, Ibaraki 305-0044, Japan

A number of novel phenomena have been observed or predicted in heterostructures of topological insulators and graphene. Similar to transition metal dichalcogenides, topological insulators are expected to dramatically increase the intrinsically very low spin-orbit coupling (SOC) in graphene due to the proxim-

ity effect. This opens the way for a range of potential applications, including a spin transistor based on the spin-orbit valve effect.

In our recent experiments, we used a thin MBE-grown film of BS/BSTS topological insulator to induce SOC in graphene. This material has the advantage of adjustable stoichiometry and thus increased possibilities of band structure engineering. The SrTiO3 substrate used for the MBE growth of BS/BSTS also serves as a gate dielectric.

Magnetotransport measurements at 1.7K show a very distinct and narrow weak antilocalization peak around zero magnetic field, which is a sign of induced SOC in graphene. The fitting procedure yields approximate values of the Rashba and valley-Zeeman spin-orbit coupling. We discuss how the extracted SOC values compare with theoretical predictions.

HL 40.9 Wed 17:45 H15

Exploring the valley splitting and valley dynamics of WSe_2 proximity-exchange coupled to CrI_3 — •Natalie Kuhn[1], Marc Schütte[1], Jo Henri Bertram[1], Frank Volmer[1], K. Watanabe[2], T. Taniguchi[3], Christoph Stampfer[1,4], Lutz Waldecker[1], and Bernd Beschoten[1] — [1]2nd Institute of Physics and JARA-FIT, RWTH Aachen University, 52074 Aachen, Germany — [2]Research Centre for Functional Materials, National Institute for Materials Science, 1-1 Namiki, Tsukuba 305-0044, Japan — [3]International Center for Materials Nanoarchitectonics, National Institute for Materials Science, 1-1 Namiki, Tsukuba 305-0044, Japan — [4]Peter Grünberg Institute (PGI-9), Forschungszentrum Jülich, 52425 Jülich, Germany

Proximity exchange coupling between 2D magnets and monolayers of transition metal dichalcogenides (TMDs) can lift valley degeneracy of the TMD. This is promising for the field valleytronics, as valley splitting is expected to increase valley lifetimes.

In this study, we investigate the proximity exchange coupling in van der Waals heterostructures made of monolayer WSe_2 and few-layer CrI_3, a 2D antiferromagnet. The proximity-induced valley splitting of WSe_2 is spatially probed by reflection contrast measurements of WSe_2 excitons. We observe distinctly different regions in WSe_2 identified by their reversed valley splitting. Their origin is explored by their magnetic field dependent reversals, i.e. hysteresis curves that are induced by reversing the magnetization of the interface layer of CrI_3. Using time-resolved Kerr rotation measurements we find a strong enhancement of WSe_2 valley lifetimes of the spin split valence bands.

HL 40.10 Wed 18:00 H15

Excitonic traps in freely suspended 2D membranes — •Alexander Musta[1,3], Leonard Geilen[1,3], Lukas Schleicher[2,3], Benedict Brouwer[1,3], Petricia Sara Peter[2,3], Anne Rodriguez[2,3], Eva Weig[2,3], and Alexander Holleitner[1,3] — [1]Walter Schottky Institute, TU Munich, Germany — [2]Chair of Nano and Quantum Sensors, TU Munich, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany

We present studies on the strain profile of large-area suspended transition-metal-dichalcogenides monolayers by photoluminescence measurements. Variations in the strain profile lead to band bending, which results in a redshift of the excitonic spectrum. Additionally, we observe an increase in intensity at the center of the suspended structures. We correlate the excitonic luminescence profiles with mechanical characterizations of the membranes, including AFM measurements and spatial mode mapping.

HL 40.11 Wed 18:15 H15

Rabi Splitting in Quantum Wells and TMDCs: Influence of Many-Particle Coulomb Correlations — •Henry Mittenzwey[1], Felix Schäfer[2], Markus Stein[2], Oliver Voigt[1], Lara Greten[1], Daniel Anders[2], Isabel Müller[2], Florian Dobener[2], Marzia Cuccu[3], Christian Fuchs[4], Kenji Watanabe[5], Takashi Taniguchi[5], Alexey Chernikov[3], Kerstin Volz[4], Sangam Chatterjee[2], and Andreas Knorr[1] — [1]ITP, Technische Universität Berlin, D-10623 — [2]LaMa, Justus-Liebig-University Giessen, D-35392 — [3]IAPP and ct.qmat, Technische Universität Dresden, D-01062 — [4]WZMW, Philipps-University Marburg, D-35032 — [5]NIMS, Namiki 1-1, Tsukuba, Ibaraki 305-0044, Japan

In this joint theory-experiment collaboration, we study the Rabi splitting of excitons under simultaneous strong light-matter and Coulomb interaction on ultrafast timescales.

It turns out, that in a setting, where Coulomb and optical interaction are comparable (MQW), the Rabi splitting almost linearly follows the optical field amplitude similar to an ideal two-level system. On the other hand, in a setting with dominating Coulomb interaction ($MoSe_2$), the Rabi splitting depends sublinearly on the optical field strength and it significantly deviates from an ideal two-level system. Within the developed theoretical approach based on Heisenberg equations of motion and a correlation expansion of many-body interactions, we identify the origin of this sublinear trend due to six-particle exciton-to-biexciton transitions.

HL 40.12 Wed 18:30 H15

Inhomogeneous Broadening of Dark Rydberg Excitons in TMDC Monolayers Probed by Ultrafast Frequency-Resolved Autocorrelation Spectroscopy — •Katem Mitkong, Tom Jehle, Daniel C. Lünemann, Lukas Lackner, Juanmei Duan, Christian Schneider, and Christoph Lienau — Institute of Physics, Carl von Ossietzky University, Oldenburg, Germany

Monolayers of Transition Metal Dichalcogenides (TMDCs), as two-dimensional materials, exhibit unique optical properties influenced by their dielectric environment. The reduced dimensionality enhances the exciton binding energy, enabling the formation of Rydberg exciton series even at room temperature. In this study, broadband nonlinear Interferometric Frequency-Resolved Autocorrelation (IFRAC) spectroscopy with few-cycle time resolution is used to probe the optically dark 2p exciton state in WS2 monolayers. The result readily distinguishes coherent second harmonic generation (SHG) from incoherent two-photon photoluminescence emission (TPPLE) without requiring polarization control. We observe the 2p dark exciton state at 2.20 eV, with TPPLE linewidths that depend on excitation power. Comparison with Lindblad Master equation solutions shows significant inhomogeneous broadening of the 2p resonance, about three times greater than that of 1s excitons. This broadening, attributed to the extended spatial wavefunction of 2p excitons relative to 1s excitons, underscores their increased sensitivity to inhomogeneities such as local strain and dielectric fluctuations. This finding suggests potential applications in nanoscale sensing technologies.

HL 40.13 Wed 18:45 H15

Expanding the lithography toolbox - 2D devices and beyond — •Vasilis Theofylaktopoulos — Heidelberg Instruments Nano AG, Bändliweg 30, 8048 Zurich, Switzerland

Lithography is used in 2D devices to contact them with precisely placed electrodes, shape the building blocks or to control other properties such as doping or strain. Thermal scanning probe lithography is an up and coming method that can assist in all of the above.[1] In this talk the working principle of tSPL will be introduced and examples of its application will be given in the field of 2D electronics, photonics and metasurfaces.[2,3,4]

The NanoFrazor is a tSPL tool offering complimentary features to established lithography techniques such as photolithography, ebeam and focused ion beam. It uses a heated cantilever to write features with sizes bellow 15nm. At the same time grayscale patterning is possible with a resolution of 2nm. A reader is integrated at the tip allowing for parallel imaging to the patterning enabling markerless overlay. This simplifies the placement of features on 2D materials which are easily imaged under the resist. A laser can be used with the same resist stacks to create larger features >500nm such as contact pads. Finally, the process patterning the resist through sublimating it can yield devices with better electronics properties compared to ebeam.[5]

HL 41: Spin Phenomena in Semiconductors

Time: Wednesday 15:45–16:30 Location: H17

HL 41.1 Wed 15:45 H17

The charge cycle of the silicon vacancy in diamond — •Joshua Claes, Bart Partoens, and Dirk Lamoen — University of Antwerp, Antwerp, Belgium

Color centers in wide bandgap semiconductors are point defects with strongly localized electrons, resembling atom-like systems that can be optically controlled. These defects hold great promise for advancing quantum technologies, including quantum sensing and quantum computing. Among them, the silicon vacancy (SiV) center in diamond stands out as a particularly promising candidate due to its narrow optical emission and long spin coherence time, lasting up to 1 second at cryogenic temperatures in its neutral state.

A key challenge for the practical use of such defects is the precise measurement of their spin state. Photoelectric detection of magnetic resonance (PDMR) is a promising technique that measures the spin state by inducing charge state transitions and capturing the released electron or hole. In this work, we employ density functional theory with the HSE06 hybrid functional to calculate the onset energies and optical cross-sections for charge state transitions of the SiV center in diamond, ranging from -2 to 0.

Using this data, we model the PDMR experiment to predict charge transitions as a function of the laser frequency applied, providing insights into the defect's behavior under experimental conditions.

HL 41.2 Wed 16:00 H17

Carrier spin coherence in inas/inalgaas quantum dots emitting in the telecom range — •Vitalie Nedelea — Technische Universität Dortmund, Dortmund, Germany

This study focuses on the carrier spin coherence in quantum dots(QDs), which are promising candidates for entanglement with an emitted photon as well as entanglement of two remote spins induced by measuring of two indistinguishable photons. The Samples, grown by molecular beam epitaxy, consist of 5.5nm InAs monolayers separated by InAlGaAs barriers. A Si δ-doped layer, at a distance of 15 nm from the QD layer, provides resident electrons. Differential transmission reveals a double exponential decay behaviour, with a short exciton(X) decay time of 0.5ns and the long indirect molecular X decay time of 2ns. The dependence of the Larmor frequencies on the transversal magnetic field (BV) gives us information about the carrier g-factor, |ge|=1.88 for the electron and |gh|=0.6 for the hole. The hole spin dephasing saturates at a higher value of T2*=1.4ns than the electron T2*=0.6ns, which could be explained by the weaker hyperfine coupling of the hole. The decay of the FR signal as a function of fm gives TS=0.3μs and extrapolating the power dependence to zero gives the spin relaxation time T1=0.5μs. The wide spread of g-factors and long spin relaxation times are promising candidates for the spin mode locking (SML) effect. In the ensemble of QDs, the sum of the multiple oscillating signals with Larmor frequencies corresponding to ωR contributes to the SML. Measured dependence of the SML on the BV reveal that the signal is related to the hole spins.

HL 41.3 Wed 16:15 H17

Optically induced spin electromotive force in ferromagnetic-semiconductor quantum well structure — •Olga Ken[1,2], Igor Rozhansky[2], Ina Kalitukha[1,2], Grigory Dimitriev[2], Mikhail Dorokhin[3], Boris Zvonkov[3], Dmitri Arteev[2], Nikita Averkiev[2], and Vladimir Korenev[2] — [1]TU Dortmund, Dortmund, Germany — [2]Ioffe Institute, St. Petersburg, Russia — [3]Lobachevsky State University of Nizhny Novgorod, Russia

We study hybrid structures which consist of ferromagnetic (FM) layer and a semiconductor quantum well (QW) and present here a systematic approach combining the optical and electrical detection of the spin-dependent electron transfer with nanoscale spatial resolution. Spin-dependent transfer is manifested in three spectacular effects: PL circular polarization under unpolarized excitation, dependence of the PL intensity from the QW on the circular polarization degree of the excitation, and spin-dependent photo-voltage across the junction. We show that in GaMnAs/GaAs/InGaAs heterostructure all the three parameters demonstrates similar non-linear magnetic field dependences with hysteresis loop saturating in ~100 mT [1]. This indicates the interaction of charge carriers in the QW with the FM, i.e. the FM proximity effect [2].

HL 42: Quantum Dots and Wires: Optics I

Time: Wednesday 16:45–18:30 Location: H17

Invited Talk HL 42.1 Wed 16:45 H17

Quantum key distribution with single photons from quantum dots — Joscha Hanel[1], •Jingzhong Yang[1], Jipeng Wang[1], Vincent Rehlinger[1], Zenghui Jiang[1], Frederik Benthin[1], Tom Fandrich[1], Jialiang Wang[1], Fabian Klingmann[2], Raphael Joos[3], Stephanie Bauer[3], Sascha Kolatschek[3], Ali Hreibi[4], Eddy. Patrick Rugeramigabo[1], Michael Jetter[3], Simone. Luca Portalupi[3], Michael Zopf[1,5], Peter Michler[3], Stefan Kueck[4], and Fei Ding[1,5] — [1]Leibniz Universität Hannover, Hannover, Germany — [2]Fraunhofer-Institut für Photonische Mikrosysteme, Dresden, Germany — [3]Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology (IQST) and SCoPE, University of Stuttgart, Stuttgart, Germany — [4]Physikalisch-Technische Bundesanstalt, Braunschweig, Germany — [5]Laboratorium für Nano-und Quantenengineering, Hannover, Germany

Quantum key distribution (QKD) ensures secure communication against eavesdroppers. On-demand quantum light sources, such as semiconductor quantum dots (QDs), enhance QKD security and loss tolerance due to their deterministic single-photon emission with high brightness and low multiphoton rates. Here, we demonstrate high-speed modulation of telecom C-band single photons emitted from a QD embedded in a circular Bragg grating. Using a phase-modulator in a Sagnac-loop interferometer, a 16-bit pseudo-random sequence is encoded into polarisation states in real time at a 76 MHz clock rate, achieving an ultra-low quantum bit error rate of ~1%.

HL 42.2 Wed 17:15 H17

Development and deterministic fabrication of electrically controlled quantum dot molecule bullseye resonators — •Setthanat Wijitpatima[1], Normen Auler[2], Binamra Shrestha[2], Sven Rodt[1], Arne Ludwig[3], Dirk Reuter[2], and Stephan Reitzenstein[1] — [1]Institute of Solid-State Physics, Technische Universität Berlin, D-10623 Berlin, Germany — [2]Department of Physics, Universität Paderborn, Warburger Str. 100, 33098 Paderborn, Germany — [3]Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum, Universitätsstraße 150, 44780 Bochum, Germany

Quantum information can be encoded in the polarization states of photons as flying qubits and decoded in the spin states of solid-state systems as stationary qubits, providing robust platforms for quantum information processing. Quantum dot molecules (QDMs) are particularly promising for this purpose, as their singlet-triplet qubits are immune to spin dephasing, enabling temporally stable spin-photon interfaces. Toward real-world applications, QDM devices with high photon extraction efficiency (PEE) are required, motivating the integration of QDMs into nanophotonic structures, such as circular Bragg gratings (CBGs) which yield broadband enhancement of PEE and moderate Purcell enhancement. However, applying the CBG concept to QDMs has been challenging since precise electrical control is crucially needed to operate QDMs properly. In this work, we demonstrate the fabrication of QDM-CBG devices, providing a crucial step toward scalable and efficient quantum technologies.

HL 42.3 Wed 17:30 H17

Magnetic field dependence of the Auger recombination rate in a single quantum dot — •Nico Schwarz[1], Fabio Rimek[1], Hendrik Mannel[1], Marcel Zöllner[1], Britta Maib[1], Arne Ludwig[2], Andreas D. Wieck[2], Axel Lorke[1], and Martin Geller[1] — [1]Faculty of Physics and CENIDE, University Duisburg-Essen, Germany — [2]Chair of Applied Solid State Physics, Ruhr-University Bochum, Germany

In solid state physics, the quantum dot (QD) as a single photon emitter is an ideal system to study the Auger effect in a confined nanostructure. The Auger effect is an electron-electron scattering effect in which the energy of the electron-hole recombination is transferred to a third carrier, leading to a non- radiative recombination of, e.g., the trion [1]. This Auger recombination should be suppressed in high-photon-yield, low-dephasing single-photon emitters. We used two-color, time resolved resonance fluorescence spectroscopy with a high spectral resolution on a single quantum dot to differentiate between the differ- ent recombination paths: Auger, spin-flip and spin-flip Raman recombination [2]. We observe an unexpected behaviour of the Auger recombination rate, which shows a decrease from B = 0 to 2 T, followed by an increase to 4 T , before decreasing again by a factor of approx. three up to 8 T. These new findings may be the starting point for further theoretical and experimental studies to unterstand or even supress this scattering effect, in which the environment seems to play an important role. [1] P. Lochner et al., Nano Lett. **20**, 1631-1636 (2020). [2] H. Mannel et al., JAP **134**, 154304 (2023).

HL 42.4 Wed 17:45 H17

Studying the optical properties of AgInS2-based quanutm dots — •Yizhuo Xi, Julian Mann, Jochen Feldmann, and Sushant Ghimire — Chair for photonics and optoelectronics, Nano-institute Munich and department of physics, Ludwig-Maximilians-University, Königstr.10, 80539 Munich, Germany

I-III-VI quantum dots have attracted considerable interest for their non-toxic nature, tunable bandgap, and excellent stability. However, these quantum dots contain intrinsic sub-gap defects, which can act as donor-acceptor pairs. In this work, we synthesize AgInS2 quantum dots showing a dual emission spectrum. A narrow but weak free-exciton emission is observed near the band edge, while a broad and intense emission, associated with donor-acceptor-type defects, appears in the lower energy region. After coating the core particles with a gallium sulfide shell, the free-exciton luminescence is strongly improved, and the recombination at donor-acceptor pairs is suppressed. This demonstrates the successful elimination of defects in AgInS2/GaSx core/shell quantum dots, which is further evidenced in the absorption spectrum by the removal of a defect-related Urbach tail. In essence, we find that the donor-acceptor pair defects in these AgInS2 quantum dots are mainly located on the surface, and the excitonic character emerges upon their elimination through the growth of a gallium sulfide shell.

HL 42.5 Wed 18:00 H17

Deoxidization induced InAs(P) single photon emitter formation on InP substrate — •Yiteng Zhang[1], Xin Cao[1], Doaa Abdelbarey[1], Zenghui Jiang[1], Markus Etzkorn[2], Chenxi Ma[1], Tom Fandrich[1], Arijit Chakraborty[1], Tom Rakow[1], Eddy Rugeramigabo[1], Michael Zopf[1,3], and Fei Ding[1,3] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, Appelstraße 2, 30167, Hannover, Germany — [2]Technische Universität Braunschweig,LENA, Institut für Angewandte Physik, Universitätsplatz 2, 38106 Braunschweig — [3]Laboratorium für Nano- und Quantenengineering, Leibniz Universität Hannover, Schneiderberg 39, 30167, Hannover, Germany

Efficient quantum light sources at telecom O-band and C-band are essential for long-haul quantum communication to minimize photon dispersion and loss. While semiconductor quantum dots (QDs) grown by Stranski-Krastanov and droplet epitaxy methods show promise, their reproducibility is hindered by complex growth parameters. Here, we present a straightforward method to fabricate self-assembled InAs(P) QDs emitting single photons at telecom O-band using molecular beam epitaxy. By deoxidizing and annealing InP(001) substrates in an arsenic atmosphere, QDs form naturally without additional metal deposition. Statistical analysis reveals size distribution and density comparable to QDs from conventional methods. Cryogenic photoluminescence confirms single-photon emission. This approach offers a reproducible and efficient pathway to telecom-wavelength single-photon sources, advancing quantum information technologies.

HL 42.6 Wed 18:15 H17

Excitonic structure of G center computed by unfolded tight-binding model — •Jakub Valdhans[1] and Petr Klenovský[1,2] — [1]Masaryk University, Brno, Czech Republic — [2]Czech Metrology Institute, Brno, Czech Republic

We have studied the carbon G center in bulk silicon and germanium using the empirical tight-binding (ETB) model for calculating unfolded band structures with configuration interaction (CI) correction for an exciton. The G center in B configuration (emissive) being a candidate for a telecom single photon source has two substitutional carbons and one interstitial atom embedded in the bulk for 6 possible configurations. Using advantage of low computation effort of ETB, it is possible to calculate and analyze behavior of electronic transitions with respect to a variation of bond distance between substitutional carbons and interstitial atom, and with using band offset as external tuning parameter.

HL 43: Twisted Materials / Systems (joint session TT/HL)

Time: Wednesday 17:00–18:30 Location: H31

See TT 39 for details of this session.

HL 44: Focus Session: Quantum Technologies in Deployed Systems I

Recent advancements in quantum cryptography, quantum computing, and quantum sensing are driving researchers to develop a universal quantum network*known as the quantum internet, which will enable secure connections among quantum computers, as well as to networks of quantum sensors, through quantum cryptography. Building a functional quantum internet is one of the most ambitious goals in quantum technology for the coming decades.

The focus sessoin aims to provide a comprehensive overview of the corresponding platforms and advances in quantum technologies, and is organized by Simone L. Portalupi (U. Stuttgart), Michal Vyvlecka (U. Stuttgart) and Michael Zopf (U. Hannover).

Time: Wednesday 18:00–18:45 Location: H13

HL 44.1 Wed 18:00 H13

Advancing Quantum Communication with Deterministic Quantum Light Sources from Laboratory- to Field-Experiments — •Mareike Lach, Koray Kaymazlar, Pratim Saha, Martin von Helversen, and Tobias Heindel — Institut für Festkörperphysik, Technische Universität Berlin, 10623 Berlin, Germany

The advances in the field of non-classical light generation using solid-state quantum light sources fostered the exploration of applications in quantum communication and networking. This interdisciplinary field thereby increasingly evolves from laboratory-scale to field-experiments [1]. In this contribution we address the design, set-up and characterization of stand-alone compact modules for field-deployable quantum communication systems. In this context key components of the transmitter- and receiver-stations for quantum key distribution protocols are discussed, including mobile quntum light sources, fast qubit-state encoders, and qubit-state analyzers. Advancing the field-deployment of quantum technologies will foster both the progress in explorativ research projects as well as the transfer to their commercialization.

HL 44.2 Wed 18:15 H13

Automated in situ optimization and disorder mitigation in a quantum device — •Jacob Benestad[1], Torbjørn Rasmussen[2,3], Bertram Brovang[2], Oswin Krause[4], Saeed Fallahi[5,6], Geoffrey C. Gardner[6], Michael J. Manfra[5,6,7,8], Charles M. Marcus[2], Jeroen Danon[1], Ferdinand Kuemmeth[2], Anasua Chatterjee[2,3], and Evert van Nieuwenburg[9] — [1]Department of Physics, Norwegian University of Science and Technology — [2]Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen — [3]QuTech and Kavli Institute of Nanoscience, Delft University of Technology — [4]Department of Computer Science, University of Copenhagen — [5]Department of Physics and Astronomy, Purdue University — [6]Birck Nanotechnology Center, Purdue University — [7]Elmore Family School of Electrical and Computer Engineering, Purdue University — [8]School of Materials Engineering, Purdue University — [9]Lorentz Institute and Leiden Institute of Advanced Computer Science

We investigate automated in situ optimisation of a quantum point contact (QPC) device with 9 adjustable electrostatic gates atop the split-gate constriction, using the Covariance Matrix Adaptation Evolutionary Strategy (CMA-ES) with a metric for how "step-like" the conductance is when the channel is constricted. The optimization algorithm is first tested on tight-binding simulations to show how it could adapt to a disorder potential, followed by implementing it in an experiment to show a marked improvement in the quantization of device conductance.

HL 44.3 Wed 18:30 H13

Fast and high-fidelity composite gates in superconducting qubits: Beating the Fourier leakage limit — •Hristo Tonchev[1], Boyan Torosov[2], and Nikolay Vitanov[1] — [1]Center for Quantum Technologies, Department of Physics, Sofia University, James Bourchier 5 blvd., 1164 Sofia, Bulgaria — [2]Institute of Solid State Physics, Bulgarian Academy of Sciences, 72 Tsarigradsko chaussée, 1784 Sofia, Bulgaria

We present a method for quantum control in superconducting transmon qubits, which overcomes the Fourier limit for the gate duration imposed by leakage to upper states. The technique utilizes composite pulses, which allow for the correction of various types of errors that naturally arise in a system. We use our approach to produce complete and partial population transfers between the qubit states, as well as two basic single-qubit quantum gates. Our simulations show a substantial reduction of the typical errors and gate durations. Three different independent verifications are made to justify these claims.

HL 45: Perovskite and Photovoltaics II (joint session HL/KFM)

Time: Thursday 9:30–13:00 Location: H13

HL 45.1 Thu 9:30 H13

Optical Simulations of Nanophotonic Back Contacts for Light Management in Ultrathin CIGSe Solar Cells — •Daniel Jiménez Tejero[1], Merve Demir[1], Bodo Fuhrmann[2], Roland Scheer[1], Ralf Wehrspohn[1], and Alexander Sprafke[1,2] — [1]Martin-Luther-Universität Halle-Wittenberg, Institut für Physik, Von-Danckelmann-Platz 3, 06120 Halle (Saale) — [2]MLU, Interdisziplinäres Zentrum für Materialwissenschaften, Nanotechnikum Weinberg, Heinrich-Damerow-Str. 4, 06120 Halle (Saale)

The development of ultrathin-film Cu(In,Ga)Se_2 (CIGSe) solar cells aims to reduce material usage and expand applications such as bifacial or tandem solar cells. However, CIGSe absorber layers with thicknesses below 1 μm exhibit diminished light absorption, particularly for wavelengths near the bandgap, leading to decreased power conversion efficiency. This can be counteracted by utilising functional back contacts that effectively increase the optical path length within the absorber layer through scattering, reflection, and nanophotonic mechanisms.

This work employs nano-optical simulations to investigate the potential of SiO_2 nanostructures on a flat gold back contact for enhancing the performance of CIGSe solar cells. By solving the Maxwell equations using the finite element method, the quantum efficiency and photocurrent under ideal charge carrier collection conditions are computed, enabling a comparison of various nanostructure geometries viable for fabrication. We find photocurrents higher than those of conventional CIGSe solar cells with an absorber thickness of 4 μm, indicating the potential of our light management approach.

HL 45.2 Thu 9:45 H13

Stabilizing Perovskite Solar Cells by Organic Salts Under One Full Sun and Maximum Power Point Tracking — •Zekarias Teklu Gebremichael[1,2], Niklas Manikowsky[2,3], Chikezie Williams Ugokwe[1,2], Bashudev Bhandari[2,3], Ulrich S. Schubert[1,2], and Harald Hoppe[1,2] — [1]Laboratory of Organic and Macromolecular Chemistry (IOMC Jena), Friedrich-Schiller- University Jena, Jena, Germany — [2]Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich-Schiller-University Jena, Jena, Germany — [3]Faculty of Physics and Astronomy, Friedrich-Schiller- University Jena, Jena, Germany

The use of organic halide salts to passivate metal halide perovskite (MHP) surfaces have been studied extensively. Passivating the surface defects of the MHP is of critical importance for realizing high-efficiency and stability of perovskite solar cells (PSCs). Here we discuss the success of a multifunctional organic salt used as passivation material for grain boundary defects and as molecular sealing layer in terms of stabilization. To assess the stability of PSCs, maximum power point tracking is seemingly the most realistic condition for the ageing test. Here, PSCs made from the four cation RbCsMAFA based perovskite absorber layer were aged under full light with maximum power point tracking and in addition they were tested periodically by IV-characterization, in order to yield all photovoltaic parameters for improved understanding of the ageing process.

HL 45.3 Thu 10:00 H13

Hyperuniform discordered structures for Light Management in Ultrathin CIGSe Solar Cells — •Katharina Trockel[1], Merve Demir[1], Frank Syrowatka[2], Ralf Wehrspohn[1], Roland Scheer[1], and Alexander Sprafke[1,2] — [1]Martin Luther University Halle-Wittenberg, Institute of Physics, 06120 Halle, Germany — [2]Martin Luther University Halle-Wittenberg, Interdisciplinary Center of Materials Science, 06120 Halle, Germany

Ultrathinfilm Cu(In,Ga)Se2 (CIGSe) solar cells are highly attractive due to their reduced material consumption and low manufacturing costs. While conventional CIGSe solar cells can achieve efficiencies of up to 21 %, increasing the efficiency of ultrathin solar cells remains a key research objective to enhance their competitiveness. A promising approach involves extending the optical path length in the absorber layer by integrating textured structures at the back or front contact of the solar cell. Most studies focus on periodic textures.

In this work, we investigate hyperuniform disordered (HuD) structures for light management in ultrathin CIGSe solar cells. The HuD structures are fabricated using polymethyl methacrylate (PMMA) particles deposited onto the back contact of the solar cells. These particles are covered with an indium tin oxide (ITO) layer and subsequently removed via a calcination process. The resulting ITO layer functions as a textured back contact, improving both light scattering and electrical performance.

First experimental results on the implementation of CIGSe solar cells with integrated HuD structures will be presented.

HL 45.4 Thu 10:15 H13

A Theoretical study of charge transport properties in perovskite analogues for high performance solar cells. — •Prerna Prerna[1,2] and Harald Oberhofer[1,2] — [1]University of Bayreuth — [2]Bavarian Center for Battery Technology, Bayreuth, Germany

Perovskite materials have emerged as promising candidates in solar cell technology, offering exceptional efficiency and affordability. Their remarkable performance, surpassing that of conventional inorganic materials, has placed them at the forefront of next-generation solar cell research, attracting significant attention from both academic and industry.

To harness their potential, we are investigating their charge transport properties using first-principles calculations (DFT) within the band transport regime. Our focus includes the calculation of carrier mobility, scattering rates and relaxation time through a detailed analysis of effective mass, deformation potential, and elastic properties. Our studies also incorporate the effects of structural deformations, aiming to align theoretical predictions with experimental results, providing deeper insights into the transport mechanisms in perovskites.

Furthermore, we are exploring the anisotropic nature of perovskites to understand directional dependencies in their electronic and mechanical properties. This anisotropy analysis is crucial for optimizing their performance and tailoring their application in advanced solar technologies. Together, these studies offer a comprehensive approach to enhancing the functionality of perovskites for cutting-edge solar energy solutions.

HL 45.5 Thu 10:30 H13

THz-Driven Phonon Fingerprints of Hidden Symmetry Breaking in 2D Layered Hybrid Perovskites — •Joanna M. Urban[1], Michael S. Spencer[1], Maximilian Frenzel[1], Gaëlle Trippé- Allard[2], Marie Cherasse[1,3], Charlotte Berrezueta Palacios[4], Olga Minakova[1], Luca Perfetti[3], Stephanie Reich[4], Martin Wolf[1], Emmanuelle Deleporte[2], and Sebastian F. Maehrlein[1,5,6] — [1]FHI Berlin — [2]LuMIn, Université Paris-Saclay, ENS Paris-Saclay, CentraleSupélec, CNRS — [3]LSI, CEA/DRF/IRAMIS, CNRS, École Polytechnique, Institut Polytechnique de Paris — [4]FU Berlin — [5]HZDR — [6]TU Dresden

Metal halide perovskites (MHPs) are emerging as promising candidates for spintronic applications. In MHPs which lack inversion symmetry, strong spin-orbit coupling induces the Rashba-Dresselhaus effect, allowing spin current control. Here we use intense THz fields to coherently drive lattice dynamics in Ruddlesden-Popper 2D layered perovskites. We identify simultaneous IR and Raman activity of specific inorganic cage modes, suggesting the presence of inversion symmetry breaking despite the globally centrosymmetric crystal structure. By exploring the driving pathways of coherent phonons bearing the signatures of broken inversion symmetry, we lay the groundwork for simultaneous ultrafast control of optoelectronic and spintronic properties in 2D MHPs.

HL 45.6 Thu 10:45 H13

Analysis of real-space transport channels in halide perovskites — •Frederik Vonhoff[1], Maximilian J. Schilcher[1], David R. Reichman[2], and David A. Egger[1] — [1]Physics Department, TUM School of Natural Sciences, Technical University of Munich, James-Franck-Straße 1, 85748 Garching, Germany — [2]Department of Chemistry, Columbia University, New York, NY 10027, USA

The charge carrier transport is a crucial factor for the performance of halide perovskites as solar energy conversion material. However, standard semiconductor transport theories fail to model the transport properties of halide perovskites because of their unusual transport behavior triggered by the anharmonic nuclear dynamics and its dynamic disorder [1]. For an accurate prediction of electron and hole mobilities of $MAPbI_3$ and $MAPbBr_3$, we capture the anharmonicity with molecular dynamics trajectories as a backbone for a time-dependent real-space hopping model [2,3] parametrized with hybrid density functional theory. With our transport model, we trace back the transport behavior of $MAPbI_3$ and $MAPbBr_3$ to their band structures via the projected density of states and the dynamics in the orbital occupation configurations. The real-space nature of our

model allows us to determine the microscopic transport mechanisms which are driven by three transport channels.

HL 45.7 Thu 11:15 H13

Unravelling how solvated PbI_2 Crystallites precede the Crystallization of Lead Halide Perovskites by UV/VIS In-Situ measurements — •Maximilian Spies[1], Simon Biberger[1], Fabian Eller[2], Eva M. Herzig[2], and Anna Köhler[1] — [1]Soft Matter Optoelectronics, University of Bayreuth, Bayreuth, Germany — [2]Dynamics and Structure Formation, University of Bayreuth, Bayreuth, Germany

The fabrication of reproducible, high-quality lead iodide perovskite films via solution-based methods requires a comprehensive understanding of crystallization dynamics. The formation of perovskite films is primarily dictated by the composition of the precursor solution and its processing conditions. In this study, we present an in-situ absorption study, i.e. during spin-coating, of the critical pre-nucleation stage to unravel the formation mechanisms of lead iodide perovskite films. We tracked the evolution of iodoplumbate complexes within the precursor solution and identified a distinctive absorption feature at 3.15 eV, emerging prior to film formation. We attribute this feature to the development of a crystalline PbI_2-DMF solvated (PDS) phase. In particular, we propose that PDS crystallites serve as precursors to the crystalline perovskite phase, acting as nucleation sites within the precursor solution. Notably, the amount of this PDS phase correlates closely with the concentration of the solution layer during spin coating, suggesting that increasing concentration promotes PDS formation. These findings provide valuable insights into the early stages of perovskite crystallization.

HL 45.8 Thu 11:30 H13

Effect of a 2D/3D Heterostructure on Contact Formation of the Double Perovskite $Cs_2AgBiBr_6$ with Hole Transport Layers Revealed by In-Situ KPFM Growth Studies — •Tim P. Schneider and Derck Schlettwein — Justus-Liebig-Universität Gießen, Institut für Angewandte Physik, Heinrich-Buff-Ring 16, D-35392 Gießen

The application of a 2D perovskite interlayer caused by surface modification with organic amines between the absorber and contact layers is widely known to significantly improve the performance of perovskite solar cells. This has already been approved as well for the lead-free double perovskite absorber $Cs_2AgBiBr_6$. To better understand the interaction of the contact layer with the 2D/3D heterostructure, in this work, film growth of Copper Phthalocyanine (CuPc), used as a model hole conductor, onto $Cs_2AgBiBr_6$ modified by different 2D phases was investigated and compared to bare $Cs_2AgBiBr_6$. Employing solar cell geometry, the morphology and work function were inspected intermittently to the evaporation of CuPc by Kelvin Probe Force Microscopy at different average film thickness. The energy alignment was revealed to be more confined on the 2D/3D heterostructures and the growth of CuPc was improved: a more homogenous growth led to formation of closed films even at early stages of deposition. These changes in growth and energy alignment are accompanied by preferential formation of different crystal phases in the CuPc.

HL 45.9 Thu 11:45 H13

The influence of oxygen and water on $MAPbI_3$ absorber materials measured with in-situ TRPL and PES — •P. Stötzner[1], M. Müller[1], T. Schulz[1], P. Pistor[2], R. Scheer[1], and S. Förster[1] — [1]Martin-Luther-Universität Halle-Wittenberg, Germany — [2]Universidad Pablo de Olavide Sevilla, Spain

Methylammonium lead halide perovskites ($MAPbI_3$) are promising thin-film solar cell absorber materials, but their response to environmental conditions like moisture and oxygen is not well understood. Here, we present a combined photoelectron spectroscopy (PES) and in-situ time-resolved photoluminescence (TRPL) study conducted in one ultrahigh vacuum system, which allows for studying changes in the chemical composition, the electronic structure and charge carrier lifetime. The setup is completed by a high-pressure gas cell enabling for controlled exposure to specific environments.

For $MAPbI_3$, we observe a significant reduction of the charge carrier lifetime compared to ex-situ TRPL measurements. To bridge between the different measurement environments, we conducted additional TRPL measurements in a closed cell having the as-grown sample in nitrogen atmosphere, which is pumped to high vacuum. These results show a decreased lifetime in vacuum but an increased lifetime linked to air contact. Consequently, we exposed $MAPbI_3$ samples to water vapor to mimic air contact, resulting in increased lifetime but also in a decomposition of $MAPbI_3$. Pure oxygen exposure did not affect the lifetime. Surprisingly, the simultaneous exposure to both gases did not show the detrimental effect of water.

HL 45.10 Thu 12:00 H13

On the Nature of Light Induced Defects in MAPI Thin Films: Long Pulses in TrPL — •Maxim Simmonds and Eva Unger — Kekuléstraße 5, 12489 Berlin, Germany

Metal-halide perovskite (MHP) semiconductors are highly relevant candidates for the fabrication of next generation solar cells but suffer from instability under continuous irradiation. This has been shown with a non-constant steady state PL during illumination. In order to better understand the evolution of recombination mechanisms at play, we usetime resolved photoluminescence (trPL) and differential lifetime plots.

Therefore, in this presentation, we will focus on methylammonium-lead-iodide (MAPI) thin films and the (ir)reversible introduction of traps triggered by quasi-continuous illumination. For this, we develop a method that uses long pulses of light in combination with trPL counting schemes, calling it long pulsed trPL (LP-trPL). From the method, we observe the inclusion of long lived and non-deep trapping sites due to continuous illumination. The data also suggests a highly asymmetric mechanism of trap formation, where trap annihilation is much slower than observed formation. We conclude that previously described mechanisms of iodine outgassing is compatible with the observed shallow nature of traps introduced as well as the asymmetric process of formation/annihilation.

HL 45.11 Thu 12:15 H13

Phase evolution of sequential evaporated (FA/Cs)SnI_3 halide perovskite thin films via in situ X-ray diffraction — •Pu-Chou Lin[1], Josha Damm[1], Roland Scheer[1], and Paul Pistor[2] — [1]Institute of Physics, Photovoltaics Group, Martin-Luther-University, 06120 Halle, Germany — [2]Departamento de Sistemas Físicas, Universidad Pablo de Olavide, 41013 Sevilla, Spain

Tin-based halide perovskites, particularly $FASnI_3$ and $CsSnI_3$, offer promising potential for photovoltaic applications. This study employs in situ X-ray diffraction to investigate these materials' real-time growth mechanisms and thermal stability during sequential vapor deposition and annealing. Our results demonstrate that the deposition sequence significantly impacts the resulting perovskite film quality. For $FASnI_3$, the SnI_2-FAI stack yields superior, cavity-free films compared to the FAI-SnI_2 stack. This suggests that FAI is the primary diffusing species, with $FASnI_3$ forming at interfaces and completing its formation around 160°C. In contrast, the $CsSnI_3$ system exhibits more complex behavior. The SnI_2-CsI sequence leads to the formation of the intermediate phase Cs_2SnI_6, while the CsI-SnI_2 sequence directly forms $CsSnI_3$ with minimal defect formation. This suggests that SnI_2 is the dominant diffusing species in the Cs-based system. $FASnI_3$ and $CsSnI_3$ undergo thermal degradation at 200°C and 240°C, respectively, through co-desorption of their constituent elements. These findings provide valuable insights into tin-based perovskites' growth mechanisms and thermal stability, which can guide future efforts to improve their performance and long-term stability.

HL 45.12 Thu 12:30 H13

Determining the key parameters of 3C-SiC photoelectrodes for water splitting application — •Marius Wasem[1,2], Sebastian Benz[1,3], Philip Klement[1,2], Joachim Sann[1,3], Jürgen Janek[1,3], Sangam Chatterjee[1,2], and Matthias T. Elm[1,2,3] — [1]Center for Materials Research, Heinrich-Buff-Ring 16, 35392 Giessen — [2]Institute of Experimental Physics I, Heinrich-Buff-Ring 16, 35392 Giessen — [3]Institute of Physical Chemistry, Heinrich-Buff-Ring 17, 35392 Giessen

We investigated the photoelectrochemical properties of n- and p-doped 3C-SiC thin films on n- or p-doped Si substrates, respectively, in a phosphate buffer solution. Key parameters such as the flat band potential and open-circuit potential were determined using various electrochemical methods. The combination of ultraviolet photoelectron spectroscopy and low energy inverse photoelectron spectroscopy measurements yields the estimation of the positions of the Fermi level, as well as the positions of the valence and conduction bands of the differently doped 3C-SiC thin films. Impedance spectroscopy characterized the interfacial processes in more detail. The flat band potential was derived from the space-charge layer capacitance using Mott-Schottky analysis. The determination of these key parameters enabled the construction of an energy level diagram, which explains the electrochemical behavior of n- and p-type 3C-SiC thin films under both dark conditions and illumination.

HL 45.13 Thu 12:45 H13

Circular Dichroism Engineering via Bismuth Doping and Cation Substitution in 2D Lead-Halide Perovskites — •Jan-Heinrich Littmann[1], Keito Mizukami[1,2], Henrik Spielvogel[1], Philip Klement[1], Satoko Fukumori[2], Hirokazu Tada[2], and Sangam Chatterjee[1] — [1]Institute of Experimental Physics I and Center for Materials Research (ZfM), Justus Liebig University Giessen, Giessen, Germany — [2]Graduate School of Engineering Science, Osaka University, Japan

Hybrid lead halide perovskites have garnered significant attention for their remarkable semiconductor properties. Their building blocks allows for tuneable features such as the crystal structure and the electronic bandgap. Introducing chiral cations into these materials endows them with chiroptical proper-

ties, such as circularly polarized luminescence (CPL) and spin-polarized charge transport, promising applications in optoelectronics and spintronics. However, the mechanism of chirality transfer remains poorly understood due to complex structure-property relationships. This study delves into the impact of heterovalent Bi^{3+} doping on the genuine circular dichroism (CD) of 2D lead iodide perovskites incorporating methylbenzylamine (MBA) and (pyridyl)ethylamine (PyEA) cations. Bi^{3+} doping, while preserving the band gap, significantly influences the genuine CD, suggesting a doping-dependent chirality transfer mechanism. Our findings provide valuable insights into the structure-property relationships in chiral perovskites and pave the way for the rational design of advanced chiroptical materials.

HL 46: Optical Properties

Time: Thursday 9:30–13:00 Location: H15

Invited Talk HL 46.1 Thu 9:30 H15

Exploring Auto-Oscillations in Semiconductor Electron-Nuclear Spin System — •Alex Greilich, Nataliia E. Kopteva, Vladimir L. Korenev, and Manfred Bayer — Experimentelle Physik 2a, TU Dortmund University, Dortmund, Germany

We demonstrate self-sustained auto-oscillations in a dissipative electron-nuclear spin system (ENSS) in semiconductors, where spontaneous breaking of translational symmetry in time produces robust limit-cycle dynamics across a broad range of parameters, including laser power, temperature, and magnetic field. These periodic oscillations exhibit coherence times extending to hours, reflecting ideal "time atom" ordering within the auto-oscillatory system.

Additionally, we uncover synchronization within excited subsystems without additional modulation, identifying its microscopic origins. Under periodic driving, modulation of parameters such as excitation power and pump polarization yields parametric resonances, signaling a transition to discrete auto-oscillatory behavior. Key phenomena include frequency entrainment, Arnold tongues, bifurcation jets, and a devil's staircase, showcasing the ENSS's versatility in exploring nonlinear dynamics, with broad implications for both fundamental physics and semiconductor applications.

HL 46.2 Thu 10:00 H15

Material selective Nonlinear Optics on Transition-metal Dichalcogenide - ZnO Nanowire Hybrid Structures — •Maximilian Tomoscheit, Benedikt Mathes, Edwin Eobalt, Alexander Zaunick, Carsten Ronning, and Giancarlo Soavi — Institute of Solid State Physics, Friedrich Schiller University Jena

The nonlinear optical (NLO) properties of any material are described by the complex tensor $\chi^{(n)}$, where, for each element of the tensor, the imaginary part mainly appears close to optical resonances. A direct measurement of the complex NLO suscebility is challenging because any NLO measurement is proportional to $|\chi^{(n)}|^2$. A second harmonic generation (SHG) interference measurement from two different materials with $\chi_\nu^{(2)}$ ($\nu = 1, 2$), is also proportional to $\left|\chi_1^{(2)}\right|\left|\chi_2^{(2)}\right|\cos\theta$, where θ is the phasemismatch. For a hybrid system with non overlapping resonances, if the SH photon energy is off-resonant for one material and resonant for the other, the interference term directly probes the complex NLO suscebility of the resonant material. In this work, we study SH interference in a transition-metal dichalcogenide (TMD) ZnO-nanowire (NW) hybrid structure, and we characterize the complex NLO suscebility of the TMD close to the A-exciton resonance. To be able to measure such interference, the ZnO NW needs to be placed along the armchair direction of the TMD, in our case WSe_2. Preliminary measurements and the results of SH polarization and wavelength dependent measurements will be be presented in this talk.

HL 46.3 Thu 10:15 H15

Nonempirical hybrid functional based on metaGGA — •Stefan Riemelmoser[1], Xun Xu[1,2], and Alfredo Pasquarello[1] — [1]École Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland — [2]Beijing Computational Science Research Center, Beijing, China

Semi-local density functionals such as PBE typically underestimate experimental band gaps by 50%. Hybrid functionals address this "band gap problem" by admixing a fraction of exact exchange to semi-local exchange. The optimal mixing parameter depends on the specific material and can be identified as the inverse dielectric constant. Recently, we have show that dielectric constants obtained using the r^{2}SCAN metaGGA functional are significantly more accurate than dielectric constants obtained using PBE. This can be understood through the improved treatment of electronic self-interaction within the metaGGA framework.

In this talk, we will show that a dielectric-dependent hybrid functional based on r^{2}SCAN can outperform the standard PBE based hybrid in terms of band gaps. Particularly impressive improvements are obtained for narrow gap semiconductors such as Ge and InAs, where PBE wrongly predicts a metallic phase, but r^{2}SCAN can open a gap. The hybrid functional based on r^{2}SCAN also yields accurate effective masses and ionization potentials. Finally, we showcase that our new hybrid functional is an excellent choice for semiconductor applications such as defect calculations.

HL 46.4 Thu 10:30 H15

Room-temperature polariton condensate in a two-dimensional hybrid perovskite — •M. Struve[1], C. Bennenhei[1], H. P. Adl[1], K. W. Song[2], H. Shan[1], N. Mathukhno[1], J. Drawner[1], F. Eilenberg[3], N. P. Jasti[4], D. Cahen[4], O. Kyriienko[2], C. Schneider[1], and M. Esmann[1] — [1]Institut for Physics, Carl von Ossietzky Universität Oldenburg — [2]University Exeter, United Kingdom — [3]Frauenhofer IOF, Jena — [4]Weizmann Instutute of Science, Israel

Chemically synthesized 2D halide perovskites form naturally grown quantum well stacks. Their large binding energy, tunable emission spectra and high oscillator strength makes them promising platforms for room temperature polaritonics but bosonic condensation and polariton lasing at ambient conditions are yet to be shown. In this work we demonstrate cavity exciton-polariton condensation of 2D Ruddelson-Popper iodine perovskites $(BA)_2(MA)_2Pb_3I_{10}$ crystal at room temperature [1]. A polariton condensation threshold of $P_{th}\approx$6.8 fJ with a strong non-linear response is observed. The emergence of spontaneous spatial coherence across the condensate with interferometric measurements is confirmed with a first-order autocorrelation reaching $g^{(1)}\approx$0.6. With our results we lay the foundation for a new class of 2D halide perovskite based room-temperature polariton lasers that offer great potential for hetero-integration with other van-der-Waals materials and combination with photonic crystals. [1] M.Struve et al., arXiv 2024, https://doi.org/10.48550/arXiv.2408.13677

HL 46.5 Thu 10:45 H15

Determination of optical losses at 265 nm in multimode AlGaN waveguides — •Verena Montag[1], Martin Guttmann[2], Bruno Marx[1], Tim Wernicke[1], and Michael Kneissl[1,2] — [1]Technische Universität Berlin, Institute of Solid State Physics, Hardenbergstraße 36, 10623 Berlin, Germany — [2]Ferdinand-Braun-Institut, Gustav-Kirchhoff-Straße 4, 12489 Berlin, Germany

Many applications for ultraviolet photonic integrated circuits (UV PICs) like, e.g., biochemical sensing, solar-blind communication, and UV Raman spectroscopy require materials with a large bandgap energy to enable low optical losses. Currently, no ideal material has been identified that enables low loss waveguides and simultaneously the implementation of active and passive components in the UV spectral range. AlGaN is a promising material which is already successfully employed for the fabrication of UV light emitting diodes (UV-LEDs) and UV lasers. However, the optical properties of AlGaN, especially the absorption losses in AlGaN waveguides have not yet been studied in detail in the UVC spectral range. In this work, 200 μm wide AlGaN waveguides, UV-LEDs, and detectors were monolithically fabricated on AlN/sapphire wafers and the waveguide losses are determined. We were able to measure photocurrents > 1 nA using an integrated AlGaN-based photodiode. Also, an exponential decrease of the photocurrent with increasing waveguide length could be observed. However, Monte Carlo ray tracing simulations show that apart from absorption losses in the AlGaN waveguides also scattering losses from surface roughness have to be considered in order to fully explain the results.

Prize Talk HL 46.6 Thu 11:15 H15

Development and Application of Computational Simulations to Optimize Organic Photovoltaic Modules — •Annika Janssen — Technische Hochschule Nürnberg — Laureate of the Georg-Simon-Ohm-Prize 2025

Organic photovoltaics (OPV) is one of the emerging solar technologies and has the possibility of more cost-effective and sustainable production compared to conventional silicon cells. The printing technique considered in this thesis is doctor blade printing. In research, this is mainly used to produce OPV, as it is fast and the coating physics is similar to slot-die coating, the technique that is most commonly used for large-scale R2R printing. To produce large modules, a homogeneous coating is important, since the thickness of the layers has an influence on the efficiency of the device. In this work, the influence of the film thickness on the efficiency is investigated experimentally on cell level and the influence of layer thickness variations is studied by means of electrical finite element method (FEM) simulations for large-area modules. Formulas describing the behavior of the injected ink during printing are established. A special focus was put on the analysis of the non-accelerated and the accelerated printing. Using simulations, this work shows that a homogeneous coating achieved by ac-

celerating the doctor blade can improve the efficiency of organic solar modules by 16.22 %.

HL 46.7 Thu 11:45 H15

Ultraflat excitonic dispersion in single layer g-C3N4 — •Francesca Martini, Pietro Nicolò Brangi, Pier Luigi Cudazzo, and Matteo Calandra — Department of Physics, University of Trento, Via Sommarive 14, 38123 Povo, Italy

Single-layer graphitic carbon nitride (g-C3N4) is widely regarded as one of the most promising two-dimensional photocatalysts for hydrogen generation via water splitting. Despite its extensive study, limited information is available on its excitonic dispersion and velocity, critical parameters for achieving high charge mobility and efficient photogeneration. In this work, we employ many-body perturbation theory and the Bethe-Salpeter equation to provide a comprehensive description of the optical absorption and finite-momentum energy loss function for both s-triazine and tri-s-triazine structures. Our findings reveal the exciton dispersion and velocity, emphasizing the significant role of localized nitrogen lone pairs in producing remarkably flat excitonic bands with velocities that are two orders of magnitudes smaller than the typical one in two-dimensional materials and of the same order or smaller than the optical phonon frequencies in single layer g-C3N4. As the time-scale for inter-site exciton hopping is longer or similar to a phonon period, our results point to a highly non-conventional exciton propagation.

HL 46.8 Thu 12:00 H15

Investigation of PLD-grown β-CuI — •Aaron Giess, Lukas Trefflich, Gabrielle Benndorf, Marius Grundmann, and Chris Sturm — Universität Leipzig, Felix-Bloch-Institut für Festkörperphysik, Germany

Copper iodide (CuI) is a transparent semiconductor that is currently of great interest due to its inherent p-type behavior and its high exciton binding energy of 62 meV. Typically, CuI crystallizes in the zincblende structure (γ-CuI) at room temperature. However, CuI can also crystallize in other phases, which are thermodynamically not stable at ambient pressure and temperature. One of these phases is the rhombohedral phase, which is often also called β-phase. Under certain growth conditions, this β-phase appears simultaneously with the γ-phase.

We grew closed thin films of CuI on c-sapphire, using pulsed laser deposition. The influence of the growth-parameters on the occurrence of β-CuI seems to be a multidimensional problem. The most important parameter is the film thickness, with thinner films favouring a higher fraction of the β-phase. The appearance of the β-phase causes additional features in the 2θ-ω scan in XRD, the dielectric function and the optical transmittance. Furthermore, photoluminescence spectra reveal a change of the emission spectra with time, which indicates that a photobleaching processes takes place.

HL 46.9 Thu 12:15 H15

Luminescent Microthermometers Based on ALD-encapsulated Ga_2O_3:Cr DBR Microcavities — •Ruben Neelissen[1], Daniel Carrasco[1,2], Anton Schäning[1], Marco Schowalter[1], Andreas Rosenauer[1], Emilio Nogales[2], Bianchi Mendez[2], Martin Eickhoff[1], and Manuel Alonso-Orts[1] — [1]Institute of Solid State Physics, University of Bremen, Otto-Hahn-Allee 1, 28359 Bremen, Germany. — [2]Departamento de Fisica de Materiales, Plaza Ciencias 1, Universidad Complutense de Madrid, 28040 Madrid, Spain.

The ability to measure temperature non-invasively, accurately and reliably is an ever reoccurring challenge in various fields such as micro- and nanosystems. Luminescent thermometry sensors can operate in environments where electronic counterparts are ineffective, thanks to their capability for remote sensing while being minimally intrusive.

Gallium oxide (β-Ga_2O_3) is a semiconductor with an ultra-wide bandgap of 4.8 eV and high resilience. Chromium-Ions (Cr^{3+}) in β-Ga_2O_3 result in two well-defined peaks, superimposed to a red-NIR emission, which can be utilized for temperature sensing.

In this work [1] it is demonstrated how confined light of β-Ga_2O_3:Cr microcavities (MCs) can be enhanced by encapsulating them in ALD-grown distributed Bragg reflectors (DBRs). With increasing temperature, the resonant wavelength redshifts due to changes in both the refractive index and the optical length of the MCs. A temperature accuracy of < 0.5 °C for temperatures above -80 °C is demonstrated.

HL 46.10 Thu 12:30 H15

Theoretical and Experimental Study of Lead Tungstate (PWO-II) Crystal Properties for Electromagnetic Calorimetry — •Ather Ahmad[1], Pavel Orsich[1], Valera Dormenev[1], Hans-Georg Zaunick[1], Kai-Thomas Brinkmann[1], Simone Sanna[2], Martin Becker[3], and Limei Chen[3] — [1]II. Physikalisches Institut, Gießen, Germany — [2]Institut für Theoretische Physik, Gießen, Germany — [3]I. Physikalisches Institut, Gießen, Germany

Lead tungstate ($PbWO_4$ or PWO) is widely recognized as a high-performance scintillator for electromagnetic calorimeters due to its fast response, high density, and radiation hardness. PWO scintillator material is used in several experiments, such as CMS at the LHC (CERN), and the next-generation PWO-II crystals, which are doped to enhance their properties, have been optimized for the PANDA experiment at FAIR in Darmstadt.

To gain a deeper understanding of the material's performance, we have combined theoretical and experimental approaches to study the electronic and optical properties of PWO-II. Raman spectra and light transmission measurements were conducted on PWO-II samples and compared with results from density functional theory (DFT) calculations. In our models, we consider the crystal phases stable at room temperature, revealing characteristic differences in both Raman spectra and light transmission between these phases.

These combined efforts aim to refine the characterization of PWO-II and support the development of advanced calorimeter materials.

Rabi splitting mediated dual electromagnetically induced transparency in metamaterial — •Amit Haldar[1], Kshitij V Goyal[1], Ruturaj Puranik[2], Vivek Dwij[2], Shriganesh Prabhu[2], and Shovon Pal[1] — [1]NISER, HBNI, Jatni, India. — [2]TIFR, HBNI, Mumbai, India.

Electromagnetically Induced Transparency (EIT) and strong coupling are pivotal phenomena in light-matter interactions with profound implications for quantum and material sciences. EIT, resulting from destructive interference in three-level quantum systems, creates a transparency window within an absorption spectrum [1] and is classically emulated in metamaterials via bright-dark-mode interference. This enables applications such as slow-light devices, sensors, and cloaking technologies. Strong coupling, achieved when the interaction strength between a quantum emitter and an electromagnetic field surpasses system losses, leads to hybridized states (Rabi splitting), facilitating coherent energy exchange and insights into coupling mechanisms [2]. This study combines these phenomena using terahertz metamaterials to achieve tunable transitions between single and dual EIT states through strong coupling. This integration enhances the tunability of metamaterial-based devices and deepens our understanding of EIT and strong coupling, bridging classical and quantum perspectives for future applications.

HL 47: Focus Session: Quantum Technologies in Deployed Systems II

Recent advancements in quantum cryptography, quantum computing, and quantum sensing are driving researchers to develop a universal quantum network*known as the quantum internet, which will enable secure connections among quantum computers, as well as to networks of quantum sensors, through quantum cryptography. Building a functional quantum internet is one of the most ambitious goals in quantum technology for the coming decades.

The focus sessoin aims to provide a comprehensive overview of the corresponding platforms and advances in quantum technologies, and is organized by Simone L. Portalupi (U. Stuttgart), Michal Vyvlecka (U. Stuttgart) and Michael Zopf (U. Hannover).

Time: Thursday 9:30–12:30 Location: H17

Invited Talk HL 47.1 Thu 9:30 H17

Quantum-Dot Quantum Light Sources in Deployed Systems — •Peter Michler — Institute for Semiconductor Optics and Functional interfaces, Center for Integrated Quantum Science and Technology (IQST) and SCoPE, University of Stuttgart, Stuttgart, Germany

Quantum photonic networks require sources of single, indistinguishable and entangled photon pairs with high brightness [1]. Semiconductor quantum dots (QDs) hold great promise to meet these requirements. In many foreseen implementations of quantum photonic networks, full- photonic quantum teleportation is a cornerstone, and the photons must be able to propagate over long

distances in silica fibers with limited absorption and wave packet dispersion. Photons in the so-called telecom bands will experience minimum absorption (C-band) and dispersion (O-band). Moreover, from a practicable point of view, portable rack single- and entangled photon sources are advantageous in deployed systems.

In this talk, we report on the performance of quantum-dot quantum light sources in deployed fibers [2], and demonstrate quantum teleportation with telecom photons from remote quantum emitters [3]. Moreover, QKD with entangled photons is demonstrated in deployed fibers and the performance of a QD based portable rack single- and entangled photon source, which can be operated down to 4 K, is presented.

Invited Talk HL 47.2 Thu 10:00 H17

Field test of semiconductor quantum light sources — •Fei Ding — Leibniz University Hannover, Germany

Semiconductor quantum dots (QDs) are among the most promising quantum light sources, with the potential to revolutionize quantum communication research. For instance, utilizing on-demand single photons and entangled photons in quantum key distribution (QKD) protocols can significantly enhance security and increase the maximum tolerable loss. However, several critical challenges must be addressed to bridge the gap between laboratory experiments and long-distance field tests using QDs. In this talk, I will first review our work over the past years on QD-based single-photon and entangled-photon sources. Following that, I will present our recent field tests of single photon transmissions over a 79 km link between Hannover and Braunschweig, with 25.49 dB loss, equivalent to 130 km in direct-connected optical fiber.

Invited Talk HL 47.3 Thu 10:30 H17

Quantum dot based quantum communication in urban networks — •Rinaldo Trotta — Sapienza University of Rome, Italy

The last two decades have witnessed an impressive progress in the development of single and entangled photon sources based on quantum dots. It has now arrived the moment to explore their full potential in urban quantum-communication scenarios.

In this talk, I will first discuss how single and entangled photons generated by quantum dots can be used to implement advanced quantum communication protocols in a controlled laboratory environment. Then, I will show our efforts towards the construction of a hybrid quantum network, harnessing both fibre and free-space links, within the University campus in the centre of Rome. Finally, I will present field demonstrations of point-to-point entanglement-based quantum key distribution and three-node quantum teleportation with dissimilar quantum dots. A discussion on future challenges and perspectives will conclude the talk.

Invited Talk HL 47.4 Thu 11:15 H17

Quantum communication protocols over a 14-km urban fiber link — •Jürgen Eschner — Universität des Saarlandes, Experimentalphysik, 66123 Saarbrücken, Germany

Quantum communication over urban telecom fibers poses challenges such as environmentally induced polarization fluctuations and lossy splices. We report on the characterization and operation of a 14-km long fiber link across Saarbrücken for quantum communication. The dark fiber has underground and overground sections and ~ 9 dB attenuation. We stabilize its polarization with > 99% process fidelity up to 60 s. For implementing quantum communication protocols we employ a $^{40}Ca^{+}$ single-ion quantum memory, an ion-resonant entangled photon-pair source, and quantum frequency conversion.

We distribute photonic entanglement without significant fidelity degradation. Using heralded absorption of one photon of the entangled pair, we also demonstrate atom-to-photon quantum state teleportation over the fiber link with ~ 84% average fidelity [1].

In a laboratory experiment we also realize a quantum repeater cell based on two $^{40}Ca^{+}$ ions that are asynchronously entangled with their emitted photons. By entanglement swapping via a Mølmer-Sørensen quantum gate on the ions, which are located in the same trap, we generate photon-photon entanglement with ~ 76% average fidelity [2].

HL 47.5 Thu 11:45 H17

Quantum cryptography at deployed communication networks with quantum dots at telecommunication wavelengths — •Anna Friederike Köhler[1], Tim Strobel[1], Michal Vyvlecka[1], Raphael Joos[1], Ilenia Neureuther[1], Timo Schnieber[1], Tobias Bauer[2], Marlon Schäfer[2], Nand Lal Sharma[3], Weijie Nie[3], Ghata Bhayani[3], Caspar Hopfmann[3], Simone Luca Portalupi[1], Christoph Becher[2], and Peter Michler[1] — [1]Institut für Halbleiteroptik und Funktionelle Grenzflächen (IHFG), Center for Integrated Quantum Science and Technology (IQST) and SCoPE, University of Stuttgart, Allmandring 3, 70569 Stuttgart, Germany — [2]Fachrichtung Physik, Universität des Saarlandes, Campus E2.6, 66123 Saarbrücken, Germany — [3]Institute for Integrative Nanosciences, Leibniz IFW Dresden, Helmholtzstraße 20, 01069 Dresden, Germany

Quantum cryptography leverages quantum effects to achieve unprecedented security. Quantum dot-based nonclassical light sources hold a promise for efficient cryptographic applications, offering on-demand generation of entangled photon pairs with high brightness and negligible multi-photon contribution. These features enable high-speed quantum communication while minimizing security risks. In this work, we demonstrate the BBM92 quantum key distribution protocoll using a GaAs quantum dot source to produce high-fidelity entangled photon pairs. Frequency conversion to telecommunication wavelengths is implemented to enhance transmission efficiency in a deployed intracity silica-based fiber network.

HL 47.6 Thu 12:00 H17

Experimental Quantum Strong Coin Flipping using a Deterministic Single-Photon Source — Daniel Vajner[1], •Koray Kaymazlar[1], Fenja Drauschke[2], Lucas Rickert[1], Martin von Helversen[1], Shulun Li[3], Zhichuan Niu[3], Anna Pappa[2,4], and Tobias Heindel[1] — [1]Institute of Solid State Physics, Technische Univeristät Berlin, Germany — [2]Electrical Engineering and Computer Science Department, Technische Univeristät Berlin, Germany — [3]Institute of Semiconductors, Chinese Academy of Sciences, Beijing, China — [4]Fraunhofer Institute for Open Communication Systems - FOKUS, Technical University Berlin, Germany

Strong coin flipping (SCF) is a fundamental cryptographic protocol allowing two distrustful parties to agree on randomly generated bit. In this work, we report the first implementation of a quantum strong coin flipping protocol that yields a quantum advantage compared to both its classical counterpart and an implementation using weak coherent pulses.

The quantum advantage is enabled by employing a state-of-the-art deterministic single-photon source based on a quantum dot embedded in a high-Purcell microcavity. Using a fiber-based electro-optic modulator (EOM) in single-pass configuration in combination with a self-built arbitrary waveform generator we realize fast dynamic, random polarization-state encoding at 80 MHz clock-rate.

Our QSCF implementation enables a coin flipping rate of 1.5 kHz and an average quantum bit error ratio (QBER) below 3%, sufficient to realize a quantum advantage.

HL 47.7 Thu 12:15 H17

Establishing a Quantum Local Area Network in Berlin City using Deterministic Quantum Light Sources — •Martin von Helversen[1], Lucas Rickert[1], Anne Rohwäder[1], Kinga Zolnacz[2], Koray Kaymazlar[1], Daniel Vajner[1], Anna Musial[3], Grzegorz Sek[3], Hanqing Liu[4], Zhichuan Niu[4], and Tobias Heindel[1] — [1]Institute of Solid State Physics, Technical University Berlin, Berlin, Germany — [2]Department of Optics and Photonics, Wroclaw University of Science and Technology, Wroclaw, Poland — [3]Department of Experimental Physics, Wroclaw University of Science and Technology, Wroclaw, Poland — [4]Institute of Semiconductors, Chinese Academy of Sciences, Beijing, China

Applications of quantum information enabled by solid-state quantum light sources currently witness the transition from laboratory proof-of-concept to field-experiments. In this contribution we present our recent progress in establishing a quantum local area network at the Campus Charlottenburg of TU Berlin. We show results of an actively stabilized free-space optical link with an effective length of 400 m and an end-to-end transmission of >70%. In addition, we operate a fiber-link between two buildings consisting of 6x 650 m of dark optical fiber. Moreover, we discuss the deployment of mobile deterministic single-photon sources based on compact cryocoolers and fiber-pigtailed quantum dot microcavities [FC-CBG] and evaluate the suitability for implementations of different types of cryptographic primitives. HL 48: Focus Session: Ising Superconductivity in Monolayer Transition Metal Dichalcogenides (joint session TT/HL/MA)

Superconducting monolayer transition metal dichalcogenides (TMDs) like $NbSe_2$, TaS_2, and gated WSe_2 or MoS_2, have attracted lot of interest in recent years. On the one hand Ising spin-orbit coupling pins the electron's spin out of plane, and hence is responsible for critical in-plane magnetic fields by far exceeding the Pauli limit. On the other hand, while the underlying pairing mechanism is still under debate, recent experiments provide strong evidence for its unconventional, multiband, nature. The Focus Session will feature experimental and theoretical advances on the superconductivity in monolayer TMDs, with focus on universal features, a possible Luttinger-Kohn mechanism, a nodal or even chiral nature of the gap functions, and their phase diagram.

HL 51: Transport Properties (joint session HL/TT)

Time: Thursday 15:00–17:15 Location: H13

HL 51.1 Thu 15:00 H13

Quasi-Ballistic Transport in Phase-Pure GaAs/InAs Core/Shell Nanowires — •Farah Basarić[1,2], Vladan Brajović[1,2], Gerrit Behner[1,2], Kristof Moors[1], William Schaarman[1], Raghavendra Juluri[3], Ana M. Sanchez[3], Hans Lüth[1,2], Detlev Grützmacher[1,2], Alexander Pawlis[1,2], and Thomas Schäpers[1,2] — [1]Peter Grünberg Institut (PGI9), Forschungszentrum Jülich, 52425 Jülich, Germany — [2]JARA-Fundamentals of Future Information Technology, Jülich-Aachen Research Alliance, Forschungszentrum Jülich and RWTH Aachen University, Germany — [3]Department of Physics, University of Warwick, Coventry CV4 7AL, UK

Core/shell GaAs/InAs nanowires represent tubular conductors due to their insulating core and confined conducting states in the InAs shell. We investigate nanowires with a crystalline phase purity of the InAs shell, where reduced scattering in electronic transport is expected. Low-temperature gate-dependent transport measurements give us insight into different contributions to the oscillatory behavior in the magnetoconductance, as well as the possibility to probe non-local transport phenomena due to large phase coherence length. With temperature-dependent measurements, we resolved the quasi-ballistic transport regime, and estimate the phase coherence length. Both measurements indicate superior transport properties of phase-pure GaAs/InAs nanowires in contrast to previous reports on non-phase pure nanowires. Our findings are an important optimization step for further development of nanowire-based hybrid devices.

HL 51.2 Thu 15:15 H13

Influence of defects and shape of thin InAs nanowires on their thermal conductivity, assessed via machine-learning potentials — •Sandro Wieser[1], Yu-Jie Cen[1], Georg K. H. Madsen[1], and Jesús Carrete[2] — [1]Institute of Materials Chemistry, TU Wien, Wien, Austria — [2]Instituto de Nanociencia y Materiales de Aragón (INMA), CSIC-Universidad de Zaragoza, Zaragoza, Spain

Nanowires (NWs) grown from the zincblende (ZB) phase of InAs in the (111) direction commonly contain twin boundary defects consisting of narrow wurtzite (WZ) (001) phase regions between ZB sections. To investigate the impact of these and other defects on heat transport, we employ Green-Kubo equilibrium molecular dynamics simulations utilizing cepstral analysis to efficiently process the noise, and an accurate MACE model trained via active learning strategies to achieve transferability for a wide range of surface conditions.

We show that these twin boundaries reduce the thermal conductivity with respect to that of defect-free WZ-phase (001) NWs by a factor of more than two and that surface conditions lead to lower thermal conductivity values for defect-free ultrathin InAs ZB NWs. Analysis of the shape of twinning NWs reveals that structures mimicking experimentally measured surface configurations can enhance heat transport compared to strictly hexagonal NWs. Additional insights are gained from an analysis of line-group symmetries and vibrational properties for various NW shapes. Furthermore, experimentally motivated symmetric and symmetry-breaking surface defects are studied to reveal more and less influential defect sites.

HL 51.3 Thu 15:30 H13

Ab-initio heat transport in defect-laden quasi-1D systems from a symmetry-adapted perspective — •Yujie Cen[1], Sandro Wieser[1], Georg Kent Hellerup Madsen[1], and Jesús Carrete Montaña[2] — [1]Institute of Materials Chemistry, TU Wien, A-1060 Wien, Austria — [2]Instituto de Nanociencia y Materiales de Aragón (INMA), CSIC-Universidad de Zaragoza, Zaragoza, Spain

Due to their aspect ratio and wide range of thermal conductivities, nanotubes hold significant promise as heat-management nanocomponents. However, one major limitation preventing their widespread use is the typically high thermal resistance that arises from defects or contact with other materials. An intriguing question is the role that structural symmetry plays in thermal transport through those defect-laden sections. However, the ab-initio study of lattice thermal transport is hindered by factors such as the large number of atoms involved and the artifacts introduced by formalism designed for 3D systems.

We employ an Allegro-based machine learning potential to calculate the force constants and phonons of single and multi-layer MoS_2-WS_2 nanotube with near-DFT accuracy and efficient scaling. Subsequently, we combine representation theory with the mode-resolved Green's function method to calculate detailed phonon transmission profiles across defects, and connect the transmission probability of each mode to structural symmetry. while more drastic symmetry breakdowns might be expected to increase scattering and thermal resistance, our results show they actually reduce it by the suppression of selection rules and opening more phonon transmission channels.

HL 51.4 Thu 15:45 H13

Analysis of the electrical transport properties of MBE grown cubic Galliumnitride (c-GaN) sample structures — •Hannes Hergert[1,2], Mario F. Zscherp[1,2], Silas A. Jentsch[1,2], Jörg Schörmann[1,2], Sangam Chatterjee[1,2], Peter J. Klar[1,2], and Matthias T. Elm[1,2,3] — [1]Center for Materials Research, Heinrich-Buff-Ring 16, 35392 Giessen — [2]Institute of Experimental Physics I, Heinrich-Buff-Ring 16, 35392 Giessen — [3]Institute of Physical Chemistry, Heinrich-Buff-Ring 17, 35392 Giessen

Due to its lack of internal polarization fields cubic gallium nitride (c-GaN) is a promising semiconductor system for 'more-than-Moore' applications such as high-power electronics or optoelectronic devices. The analysis of its electri-

cal transport properties is challenging since the molecular beam epitaxy (MBE) growth of high-quality c-GaN thin films requires a complex substrate architecture in order to accommodate the lattice mismatch between c-GaN and the 3C-SiC template. However, a reliable characterization of the electrical transport properties of c-GaN is crucial for the design of advanced functional devices. Here we analyze the electrical transport properties of the whole sample structure (MBE grown c-GaN/c-AlN thin films onto a 3C-SiC/Si template) with different c-GaN thicknessses using electrochemical impedance spectroscopy (EIS) as well as angle- and temperature-dependent magnetoresistance (MR) measurements. MR measurements reveal the existence of a highly conductive channel while EIS measurements allow the determination of the position of the channel between the c-AlN thin film and the 3C-SiC layer.

HL 51.5 Thu 16:15 H13

Fabrication and Characterisation of Short-channel Junctionless Nanowire Transistors — •Alessandro Puddu — Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

The downscaling limitations of conventional planar transistors require the investigation of alternative device configurations. Because of their excellent electrostatic control and intrinsic scalability, junctionless nanowire transistors (JNTs) present a feasible solution and are highly desirable for next-generation electronics. The key factor that characterizes the JNTs is the absence of pn-junctions. This provides several benefits, such as an easier fabrication process since the devices do not require abrupt doping profiles within the nanowire channel, which is now uniformly doped.

This work focuses on the fabrication and characterisation of short-channel Si JNTs. A top-down approach based on e-beam lithography (EBL) and inductively coupled plasma reactive ion etching (ICP-RIE) was used to fabricate the Si nanowires. The device characterisation showed improved performances due to the channel length shrinking.

HL 51.6 Thu 16:30 H13

***Ab initio* investigation of drag effect in germanium** — •Dwaipayan Paul and Nakib Protik — Humboldt-Universität zu Berlin, Zum Großen Windkanal 2, 12489 Berlin, Germany

In a system of interacting electrons and phonons, the transport of one induces transport in the other. This phenomenon is known as the electron-phonon drag effect [1]. Now, an important milestone in the history of drag physics is the first recorded measurement of this phenomenon in germanium [2]. Here we present the results of our *ab initio* computations of the thermoelectric transport coefficients of germanium for various temperatures and charge carrier concentrations using the `elphbolt` code [3]. We investigate how the various scattering channels in the system enable this material to exhibit strong drag phenomena.

[1] Gurevich, Yu G., and O. L. Mashkevich. "The electron-phonon drag and transport phenomena in semiconductors." Physics Reports 181.6 (1989): 327-394.

HL 51.7 Thu 16:45 H13

Anomalous Knudsen effect signaling long-lived modes in 2D electron gases — •Grigorii Starkov and Björn Trauzettel — Institute for Theoretical Physics and Astrophysics, University of Würzburg, D-97074 Würzburg, Germany

Careful analysis of electron collisions in two spatial dimensions leads to the conclusion, that the odd harmonics of the electron distribution function decay much slower in comparison to the even ones at finite temperatures. Focusing on a channel geometry with boundary scattering, we show, that such behaviour of the odd decay rates leads to a characteristic behaviour of the resistance that we dub anomalous Knudsen effect: increasing temperature leads to decreasing resistance, that quickly slows down and turns into growth. The further increase of temperature exhibits the usual Gurzhi peak in the resistance related to the crossover from ballistic to hydrodynamic transport. The simultaneous observation of the Gurzhi peak preceded by an anomalous Knudsen dip can serve as a concrete signature of the long-lived modes in the 2D electron transport at low temperatures.

HL 51.8 Thu 17:00 H13

Quantum confinement and stoichiometry fluctuations in nm-thin SiGe layers — •Daniel Dick[1,2,3,4], Florian Fuchs[1,2,3], Sibylle Gemming[2,4], and Jörg Schuster[1,2,3] — [1]Center for Micro- and Nanotechnology, TU Chemnitz, Germany — [2]Center for Materials, Architecture and Integration of Nanomembranes, TU Chemnitz, Germany — [3]Fraunhofer Institute for Electronic Nanosystems (ENAS), Chemnitz, Germany — [4]Institute of Physics, TU Chemnitz, Germany

We simulate biaxially strained SiGe layers of varying thickness in the range of a few nanometers, as found in the base layer of heterojunction bipolar transistors (HBTs). At this length scale, local fluctuations in atomic concentrations can strongly influence the electronic properties of the device, especially the distribution of dopants like e.g. boron. Even at high doping concentrations, only a single atom is present at a 1 nm^2 cross section of the layer on average.

Employing a new parameterization of silicon and germanium in the framework of extended Hückel theory (EHT), we calculate the local band gap for different permutations of the atomic structure. Various distributions of boron atoms are simulated. We study the impact of locally increased and decreased concentrations on the band gap. By varying layer thickness, we evaluate the effects of quantum confinement and how it impacts transport properties of the thin layer in contrast to bulk material.

HL 52: Oxide Semiconductors II

HL 52.1 Thu 15:00 H14

Connection between electronic structure and crystal symme- try in bismuth vanadate — •Philip Schwinghammer, Franziska Hegner, Frederico Delgado, and David A. Egger — Physics Department, TUM School of Natural Sciences, Technical University of Munich, Germany

The electronic and structural properties of bismuth vanadate (BVO) were characterized using density functional theory (DFT). Previous work in the literature indicated that semi-local exchange was incapable of correctly reproducing the ground-state structure of BVO, but disagreed on which functional would improve the description. We found that the Heyd-Scuseria-Ernzerhof hybrid functional could accurately predict the monoclinic ground state structure, provided spin-orbit coupling was included. Semi-local density functionals mischaracterize the hybridization of the lone pair Bi6s states and O2p states near the valence band edge, which is corrected by hybrid functionals. Due to the large mass of bismuth, spin-orbit coupling is required for an accurate description of the electronic structure. When both corrections are taken into account, we find that the valence and conduction band edges in BVO are extremely flat, leading to large effective masses along one direction in reciprocal space. The effective carrier masses are affected by the ionic structure, indicating a possible reason for the different photo-catalytic efficiencies of tetragonal and monoclinic scheelite BVO.

HL 52.2 Thu 15:15 H14

Blue shift of the absorption onset and bandgap bowing in rutile $Ge_xSn_{1-x}O_2$ — •Elias Kluth[1], Yo Nagashima[2], Shohei Osawa[3], Yasushi Hirose[3], Jürgen Bläsing[1], André Strittmatter[1], Rüdiger Goldhahn[1], and Martin Feneberg[1] — [1]Institut für Physik, Otto-von-Guericke-Universität Magdeburg, Universitätsplatz 2, 39106 Magdeburg, Germany — [2]Department of Chemistry, The University of Tokyo, 7-3-1 Hongo, Bunkyo, Tokyo, 113-0033, Japan — [3]Department of Chemistry, Tokyo Metropolitan University, 1-1 Minamiosawa Hachioji, Tokyo 192-0397, Japan

Rutile-GeO_2 has recently attracted increasing research interest as an ultra wide bandgap oxide similar to Ga_2O_3 with the unique advantage that theoretical calculations predict the possibility of ambipolar doping. In contrast rutile-SnO_2 is a well-established transparent conductive oxide (TCO) widely used in solar cells and displays. Alloying SnO_2 with Ge offers a promising pathway to developing deep ultraviolet (DUV) TCOs. However, investigations into the optical properties of the $Ge_xSn_{1-x}O_2$ system remain limited.

In this study, we employed spectroscopic ellipsometry in the visible and ultraviolet region to determine the ordinary dielectric functions of $Ge_xSn_{1-x}O_2$ thin films grown by pulsed laser deposition (PLD) on rutile-TiO_2 substrates. Our analysis reveals a systematic blue shift of the onset of absorption with increasing Ge content. By evaluating the dielectric functions, we extracted the characteristic transition energies at the absorption onset and determined the bowing parameter of the dipole-allowed direct bandgap to be $b = 0.70$ eV.

HL 52.3 Thu 15:30 H14

$NaNbO_3$, $KNbO_3$, and their solid solutions: A *first-principles* and special quasirandom structures investigation — •Daniel Fritsch — Zuse Institute Berlin, Takustr. 7, 14195 Berlin, Germany — University of Potsdam, Karl-Liebknecht-Str. 24/25, 14476 Potsdam, Germany

Ferroelectric materials crystallising in the perovskite structure, like $NaNbO_3$ and $KNbO_3$, have come into focus as lead-free and environmentally friendly alternatives to the widely used piezoelectric ceramic $Pb[Zr_xTi_{1-x}]O_3$ (PZT) [1].

They both exhibit a large range of structural phase transitions and accompanying changes in their ferroelectric behaviour. While the material properties of both end members are relatively well known, this is much less the case for their solid solutions.

Here, we present results for $Na_{1-x}K_xNbO_3$ solid solutions based on *first-principles* calculations for the structural and electronic properties, and so-called special quasirandom structures to investigate the solid solutions [2]. The obtained results will be compared to available experimental findings and other theoretical investigations.

HL 52.4 Thu 15:45 H14

Spintronic properties of the two-dimensional electron gas in KTaO3-based heterostructures. — •Sonali Kakkar[1] and Chandan Bera[2] — [1]Department of Physics, Noida Institute of Engineering and Technology, 19, Institutional Area, Knowledge Park II, Greater Noida, Uttar Pradesh 201306, India — [2]Institute of Nano Science and Technology, Sector-81, Knowledge City, Sahibzada Ajit Singh Nagar, Punjab, 140306, India

A two-dimensional electron gas (2DEG) in oxide interfaces offers a single platform for a wide range of functionalities. Compared to STO-based 3d-2DEG, 2DEG in the polar perovskite oxide KTaO3 (KTO) with 5d-t2g orbitals shows a greater atomic spin-orbit coupling. Moreover, the electronic and spintronic properties of oxide heterostructures are greatly influenced by the inherent crystal structure symmetry. In this work, we have investigated the electronic and spintronic properties in KTO-based heterostructures using density functional theory calculations with the Hubbard parameter (DFT+U). The dependence of the Rashba spin-splitting and the corresponding spin texture in the reciprocal space for 2DEG at the KTO surface and LVO/KTO interface on the crystal orientation highlights the importance of crystal symmetry for the 5d-2DEG in KTO [1]. Furthermore, highly confined, spin-polarized 2DEG at the interfacial TaO2 layer in the 5dxy orbitals of Ta at the interface between the ferromagnetic insulator EuO and the non-magnetic KTO shows Rashba spin texture [2]. [1] S. Kakkar, et al., Physica E Low Dimens. Syst. Nanostruct. 144, 115394 (2022). [2] S. Kakkar, et al., Adv. Phys. Res. 2, 2200026 (2023).

HL 52.5 Thu 16:15 H14

Unraveling the mechanism of resistive switching in titanate-based perovskites — Wahib Aggoune[1,2], •Parrydeep Kaur Sachdeva[1], and Matthias Scheffler[1] — [1]The NOMAD Laboratory at Fritz-Haber-Institut der Max-Planck-Gesellschaft, Faradayweg 4-6, 14195, Berlin, Germany — [2]Physics Department and IRIS Adlershof, Humboldt-Universität zu Berlin, 12489 Berlin, Germany

Memristors capable of switching between high and low resistance states while retaining memory, hold promise for non-volatile memory. A recent fascinating experimental work observed high resistive switching (RS) in *off*-stoichiometric paraelectric titanate-based perovskites $ATiO_3$ (A=Sr, Ca) [1]. It suggests that RS is driven by defects, though their exact role remains unclear. Here, we investigate the defects behavior using density functional theory. Under the experimental growth conditions, the complex defect (Ti-interstitial with *A*-vacancies) is thermodynamically stable, pinning the Fermi level close the conduction band. Remarkably, the *off*-center shift of the interstitial atom induces a local polarization and gives rise to localized mid-gap states. Switching between the equivalent *off*-center sites faces energy barriers of 0.1–0.8 eV, depending on the pathway. This switches both polarization direction and the defect charge distribution. Therefore, upon applying a voltage, the overall polarization driven by the local shifts of the defects can be switched. As this also redistributes the defect charge states, it switches the resistance state. Our findings provide insights into the origin of RS toward memristor development.

HL 52.6 Thu 16:30 H14

Ultraviolet Emission from $^6P_{7/2}$ Stark Manifold in Gd-Implanted β-Ga_2O_3 Thin Films — •Martin S. Williams[1,2], Mahmoud Elhajhasan[1], Marco Schowalter[1], Lewis Penman[3], Alexander Karg[1], Fabien C.-P. Massabuau[3], Andreas Rosenauer[1], Gordon Callsen[1], Carsten Ronning[4], Martin Eickhoff[1,2], and Manuel Alonso-Orts[1,2] — [1]Institute of Solid State Physics, University of Bremen, Otto-Hahn-Allee 1, 28359 Bremen, Germany — [2]MAPEX Center for Materials and Processes, University of Bremen, Bibliothekstraße 1, 28359 Bremen, Germany — [3]Department of Physics, SUPA, University of Strathclyde, Glasgow, United Kingdom — [4]Institute of Solid State Physics, Friedrich-Schiller-University Jena, Helmholtzweg 3, 07743 Jena, Germany

Monoclinic gallium oxide (β-Ga_2O_3) is a promising ultra-wide band gap semiconductor for the next generation of optoelectronic devices. Despite its attractive material properties, its luminescence spectrum is dominated by defect emission in the visible spectral range and a dominating UV emission in β-Ga_2O_3 has rarely been observed. An enhancement of the UV emission in β-Ga_2O_3 by optically active ion doping in β-Ga_2O_3 is only achieved with gadolinium (Gd^{3+}).

In this work, β-Ga_2O_3 thin films grown by molecular beam epitaxy and atomic layer deposition are implanted with Gd and thermally activated. Four separate luminescence peaks, from the Stark-split $^6P_{7/2} \rightarrow {}^8S_{7/2}$ transition in Gd^{3+}, are individually resolved with linewidth ≤ 2 meV. The influence of growth technique, implantation parameters and annealing temperature is investigated.

HL 52.7 Thu 16:45 H14

Investigation of the bond length dependence and lattice relaxation in zincblende Cu(Br,I) alloys — •Sandra Montag[1], Stefan Merker[2], Michael Bar[1], Richard J. Schenk[1], Eva Zollner[1], Konrad Ritter[1], Timo Pfeiffelmann[1], Sergiu Levcenko[1], Edmund Welter[3], Holger von Wenckstern[1], Marius Grundmann[1], Harald Krautscheid[2], and Claudia S. Schnohr[1] — [1]Felix Bloch Institute for Solid State Physics, Leipzig University, Germany — [2]Institute of Inorganic Chemistry and Crystallography, Leipzig University, Germany — [3]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany

CuI is a promising p-type wide-bandgap semiconductor with various applications in the field of transparent electronics. Among the numerous doping and alloying candidates, the Cu(Br,I) alloy system offers the opportunity to tailor the free hole concentration in functional layers, enabling optimized performance of active devices, such as pn-diodes and transistors. Using X-ray absorption spectroscopy, the fine structure of $CuBr_{1-x}I_x$ powder and thin film samples, with anion composition x varying from 0 to 1, was measured. The analysis of the extended fine structure reveals a nonlinear change of the Cu-Br and Cu-I bond lengths with composition x. This behaviour is different from that reported for III-V and II-VI zincblende alloys, but comparable to the rocksalt $RbBr_{1-x}I_x$ alloy. The observed bond length bowing may therefore be a characteristic feature of group I-VII alloys. To uncover the degree of lattice relaxation with increasing distance from the absorbing atom, the higher neigbour scattering signal is evaluated.

HL 52.8 Thu 17:00 H14

Revealing the incorporation site and local structure of Ni and Se in doped CuI thin films — •Mustafa G. Yazlak[1], Christiane Dethloff[1], Philipp Storm[1], Michael Lorenz[1], Sandra Montag[1], Hans H. Falk[1], Edmund Welter[2], Sofie Vogt[1], Marius Grundmann[1], and Claudia S. Schnohr[1] — [1]Felix Bloch Institute for Solid State Physics, Leipzig University, Germany — [2]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany

This study investigates polycrystalline CuI thin films with varying nickel (Ni) and selenium (Se) concentrations, grown on glass substrates using Pulsed Laser Deposition (PLD) and co-sputtering. CuI:Ni thin films, with 1*30 at% Ni and thicknesses between 0.1*1.0 μm, and CuI:Se thin films, with 0.4*3.8 at% Se and ~1.0 μm thickness, were prepared and capped with Al_2O_3 layers to prevent oxidation. X-ray Absorption Spectroscopy (XAS) at low temperatures (~10 K) was conducted at the Cu, Se, and Ni K-edges to study the local structure of Ni and Se in the CuI matrix. The near edge structure and extended fine structure for a pure CuI thin film at the Cu K-edge suggests possible Cu oxidation. For CuI:Ni thin films, an increase in Ni concentration correlates with reduced Cu oxidation because Ni prefers to bond with oxygen rather than iodine, forming disordered NiO as seen from the Ni K-edge spectra. For CuI:Se thin films, the Cu K-edge spectra show small changes but no clear trend with Se content and the Se K-edge spectra indicate a Cu neighborhood similar to Cu_2Se and CuSe. Quantitative analyses are in progress to provide a deeper understanding of how Ni and Se content affects local structural changes.

HL 53: 2D Semiconductors and van der Waals Heterostructures V

The session covers excitonic properties of 2D semiconductors and van der Waals heterostructures.

Time: Thursday 15:00–17:15 Location: H15

HL 53.1 Thu 15:00 H15

1D exciton confinement in monolayer $MoSe_2$ near ferroelectric domain walls in periodically poled $LiNBo_3$ — •Pedro Soubelet, Yao Tong, Asier Astaburuaga Hernandez, Andreas V. Stier, and Jonathan J. Finley — Walter Schottky Institut and TUM School of Natural Sciences, Technische Universität München, Am Coulombwall 4, 85748 Garching, Germany

Monolayer transition metal dichalcogenides are an emergent platform for exploring and engineering quantum phenomena in condensed matter. Due to their atomic thickness, the excitonic response is highly influenced by the dielectric environment. In this work, we explore the optical properties and exciton kinetics of monolayer thick $MoSe_2$ straddling domain wall boundaries in ferroelectric periodically poled $LiNbO_3$ (PPLN). Spatially resolved photoluminescence (PL) experiments reveal sorting of neutral and charged excitons across the boundary. Our results reveal evidence for extremely large in-plane electric fields (≃4000 kV/cm) at the domain wall (DW), whose effect is manifested in the routing of free charges and trions towards oppositely poled domains, resulting in a nonintuitive spatial PL intensity pattern. In a second step, we engineer the PPLN substrate and the 2D heterostructure to exploit the non-uniform in-plane electric field exerted by the DW to confine neutral excitons in a 1D dipolar gas. Reducing the dimensionality holds an excellent potential for unlocking strong exciton-exciton interaction regimes, enabling exploration of exotic quantum phases of matter and designing advanced optoelectronic devices.

HL 53.2 Thu 15:15 H15

Collective charge excitations between moiré minibands in twisted WSe_2 bilayers probed with resonant inelastic light scattering — •Hendrik Lambers[1], Nihit Saigal[1,2], Nicolai-Leonid Bathen[1], Veljko Antić[1], Lennart Klebl[3], Dante M. Kennes[4], Tim O. Wehling[3], and Ursula Wurstbauer[1] — [1]Institute of Physics, University of Münster, Germany — [2]EMBL Imaging Centre, Heidelberg, Germany — [3]Institute of Theoretical Physics, University of Hamburg, Germany — [4]Institute for Theory of Statistical Physics, RWTH Aachen University, Germany

The weak van der Waals coupling between monolayers of transitionmetal dichalcogenides (TMDCs) allows the realization of twisted van der Waals structures resulting in precisely tailored 2D quantum systems with superimposed moiré superlattice structures. These are dependent on twist angle and lattice constant mismatch and can cause flat moiré mini bands in the reduced Brillouin zone of the superlattice. Here we study these moiré minibands in $tWSe_2$ homobilayers encapsulated in hBN by low temperature resonant inelastic light scattering (RILS) [1]. Guided by theoretical predications, we identify single particle-like collective inter moiré miniband excitations. Thereby, we establish RILS as a tool to quantitatively probe the formation of moiré minibands. Furthermore, we identify local twist angle variations by lateral force microscopy and correlate these findings with optical (Raman) spectroscopy. [1] N. Saigal et al., Phys. Rev. Lett. 133, 046902 (2024).

HL 53.3 Thu 15:30 H15

Unraveling Rashba spin-orbit coupling in TMDs — •Miguel Morales Cocera[1,2], Marta Prada[1], and Gabriel Bester[1] — [1]University of Hamburg, Institute of Physical Chemistry, 22761 Hamburg, Germany — [2]Max Planck Institute for the Structure and Dynamics of Matter, 22761 Hamburg, Germany

Transition metal dichalcogenides (TMDs) possess unique optical and electronic properties, making them ideal candidates for exploring new physical phenomena. Their significant spin-orbit coupling enables a rich landscape of spin-valley physics within the realm of excitonic effects or topologically non-trivial materials, to name a few. However, there are still unanswered questions concerning the mechanisms that rule Rashba spin-orbit coupling (RSOC), such as the role of the atomic and orbital composition, number of layers, or band character. In this work, we employ ab-initio calculations together with perturbative approaches to unravel the intricacies of bilayer TMDs with an intrinsic dipole, which is far from trivial. We deliver with high numerical precision the Rashba parameters in Rmx (Bernal stacking) bilayers (M= Mo, W. X=S, Se, Te).

HL 53.4 Thu 15:45 H15

Theory of Magnetic Field Dependence of Excitonic Spectra in Atomically Thin Semiconductors — •Michiel Snoeken and Henry Mittenzwey — Technische Universität Berlin, Institut für Theoretische Physik, Nichtlineare Optik und Quantenelektronik, Hardenbergstraße 36, 10623 Berlin, Germany

The linear absorption spectrum of TMDC monolayers under the influence of an in-plane magnetic field is theoretically studied in an excitonic picture. It is shown that in-plane magnetic fields induce a hybridization between spin-bright and spin-dark exciton transitions, resulting in a brightening of spin-dark excitons in the linear absorption spectrum with increasing in-plane field-strength. Numerical evaluation shows that with increasing field strength, not only the energy splitting between bright and dark excitonic resonances increases, but also an impact on the respective excitonic linewidths can be observed. Some limiting cases are investigated analytically, allowing to discuss a detailed physical picture of the magnetic field-dependent excitonic energies and linewidths.

15 min. break

HL 53.5 Thu 16:15 H15

Spatial mapping of the tunable band gaps of bilayer graphene using a WSe_2 sensor layer — David Tebbe[1], •Alexander Polkowski[1], Sophia Lackhoff[1], Jonas Blum[1], Takashi Taniguchi[2], Kenji Watanabe[2], Bernd Beschoten[1,3], Lutz Waldecker[1], and Christoph Stampfer[1,4] — [1]2nd Institute of Physics A, RWTH Aachen University, Aachen — [2]National Institute for Materials Science, Namiki, Tsukuba, Japan — [3]JARA-FIT Institute for Quantum Information, Forschungszentrum Jülich GmbH and RWTH Aachen University, Aachen, Germany — [4]Peter Grünberg Institute (PGI-9) Forschungszentrum Jülich, Jülich, Germany

Bernal bilayer graphene (BLG) is a 2D material with promising properties for future quantum technologies, due to its tunable band gap and rich correlated phases, which have been detected by electrical transport measurements. However, due to their nature, these measurements have not been able to spatially resolve the bandgap and other electronic properties of BLG. Here, we show optical sensing can overcome this limitation. To achieve this we place a sensing monolayer of WSe_2 in direct contact to BLG in a double-gated device structure. The sensor layer hosts excitons, with the ability to sense changes in the electronic configuration of the BLG. The WSe_2 hosts Rydberg excitons, which are sensitive to the surrounding dielectric environment and thus sense small changes in carrier density within the BLG, allowing to observe the band gap opening. These excitonic states can be resolved using white light reflection spectroscopy, which allowed us to spatially map the potential landscape in the BLG.

HL 53.6 Thu 16:30 H15

Beyond the K-Valley: Exploring Unique Trion States in Indirect Band Gap Monolayer WSe_2 — •Franz Fischer[1,2], Carl Emil Mørch Nielsen[1], and Gabriel Bester[1] — [1]University of Hamburg, Institute of Physical Chemistry, 22761 Hamburg, Germany — [2]Max Planck Institute for the Structure and Dynamics of Matter, 22761 Hamburg, Germany

Atomically thin layers of transition metal dichalcogenides are of great interest due to their exceptional electronic and optical properties. Their lack of inversion symmetry and strong spin-orbit interaction from heavy metal atoms leads to an additional valley degree of freedom and significant spin splittings in the Brillouin zone. The reduced dimensionality and dielectric screening make these materials ideal for studying Coulomb-bound many-body states, such as excitons and trions.

We will discuss calculations of the optical properties of monolayer WSe_2 using *ab initio* many-body screened configuration interaction. We'll highlight our findings on additional species of negatively charged trions including the **Q**-valley, which we found to be more energetically favorable than those in the **K**-valley. Our results align well with experimental data and provide new insights into previously observed but unexplained optical features. Furthermore, we will analyze the many-body interactions that reveal the mechanisms behind the increased singlet-triplet splitting and the redshifted energies in the **Q**-valley trions compared to those in the **K**-valley.

HL 53.7 Thu 16:45 H15

Trion saturation and trion filtering in MoS_2 and MoS_2/graphene heterostructures — Omid Ghaebi[1], Tarlan Hamzayev[1], •Till Weickhardt[1], and Giancarlo Soavi[1,2] — [1]Institute of Solid State Physics, Friedrich Schiller University Jena — [2]Abbe Center of Photonics, Friedrich Schiller University Jena

Optical excitation of electron-hole pairs in transition-metal dichalcogenides leads to the formation of excitons, that can join with free carriers to form trions [1]. Since trions display an efficient non-radiative decay, tuning their relative density with respect to neutral excitons by external knobs is fundamental to engineer the light emitting efficiency of TMD opto-electronic devices. In this work, we investigate the interplay of excitons, trions, and free electrons with regards to gating and excitation power. By carrying out these experiments on a pristine MoS_2 monolayer as well as on a MoS_2/graphene heterostructure where the graphene facilitates fast charge transfer from the TMD [2,3], we study the interdependent dynamic of excitons and trions. Most prominently, this effect can be seen in a super-linear power-scaling of the exciton density due to saturation of trions in the monolayer MoS_2 [4]. When the graphene is added to form the heterostructure, this effect vanishes due to the elimination of trions.

HL 53.8 Thu 17:00 H15

Engineering carrier density and exciton polarization in WSe2 monolayers via photochlorination — •Eirini Katsipoulaki[1,2], George Vailakis[1,3], Delphine Lagarde[4], Vishwas Jindal[4], Konstantinos Mourtzidis[4], Xavier Marie[4], Ioannis Paradisanos[1], George Kopidakis[1,3], George Kioseoglou[1,3], and Emmanouel Stratakis[1,2] — [1]FORTH/IESL, Heraklion, Greece — [2]Dpt. of Physics, UoC, Heraklion, Greece — [3]Dpt. of Materials Science and Engineering, UoC, Heraklion, Greece — [4]Universite de Toulouze, INSA-CNRS-UPS, LPCNO, Toulouze, France

Transition Metal Dichalcogenides (TMDs) represent a special class of 2D van der Waals materials. Unlike their 3D-counterparts, which are indirect gap semiconductors, the monolayers exhibit a direct bandgap, leading to a significant enhancement in photoluminescence quantum yield. TMDs feature valley dependent optical selection rules, establishing them as promising candidates for atomically thin optoelectronic devices. A key factor influencing the performance of TMDs in these applications is the carrier density. To address this, we demonstrate the modulation of the Fermi level in WSe2 monolayers using an UV-assisted photochlorination method. Systematic shifts and relative intensities between charged and neutral excitons indicate a controllable decrease of the electron density and switch WSe2 from n- to a p-type semiconductor. DFT calculations predict Cl2 adsorption at Se vacancies. Furthermore, this method can strongly impact the circular polarization degree of excitons. These findings indicate that photochlorination can tailor nanopatterned lateral p-n junctions.

HL 54: Ultra-fast Phenomena II

Time: Thursday 15:00–17:15 Location: H17

HL 54.1 Thu 15:00 H17

Effect of the acceptor strength on intermolecular conical intersection dynamics in aggregates of quadrupolar dyes — •Katrin Winte[1], Somayeh Souri[1], Daniel Lünemann[1], Teresa Kraus[2], Elena Mena-Osteritz[2], Peter Bäuerle[2], Sergei Tretiak[3], Antonietta De Sio[1], and Christoph Lienau[1] — [1]Oldenburg University, Germany — [2]Ulm University, Germany — [3]Los Alamos National Laboratory, USA

Aggregated films of quadrupolar acceptor-donor-acceptor (A-D-A) molecules have emerged as promising materials for organic photovoltaics. The optoelectronic properties in the molecule are governed by an interplay between electronic and vibronic couplings in the molecule. In aggregated films, we have uncovered the existence of intermolecular conical intersections (CoIn) occurring on timescales of less than 50 fs, which funnel energy from the photoexcited bright state into the lower-lying dark electronic state of the aggregate [1]. This raises the question whether the quantum dynamics of the aggregates can be altered by modifying the intramolecular charge transfer character of the A-D-A monomers. Chemical intuition suggests that increasing the acceptor strength might accelerate charge transfer and with it the passage through the CoIn. To explore this hypothesis, we synthesize thin films of A-D-A molecules with varying acceptor strengths and study their ultrafast dynamics by femtosecond time-resolved spectroscopy. Our results show only minimal effects on the CoIn dynamics, suggesting that intermolecular vibronic couplings play the dominant role in the quantum dynamics. [1] A. De Sio et al., Nature Nano 16, 63 (2021).

HL 54.2 Thu 15:15 H17

Ultrafast decay of spin-polarization of semiconductor holes measured by attosecond transient absorption spectroscopy — •Lauren Drescher[1,2], Kylie Gannan[1], and Stephen Leone[1] — [1]Department of Chemistry, University of California, Berkeley, California 94720, USA — [2]Max-Born-Institut, Max-Born-Str. 2A, 12489 Berlin, Germany

Carrier excitation by light can lead to spin-polarization in semiconductor conduction and valence bands. While the dynamics of the spin-polarization of conduction band electrons are often well characterized, comparably little is known about the counterpart polarization of valence band holes, due to its much shorter lifetime.

Here we introduce circular dichroic attosecond transient absorption spectroscopy which allows to follow the spin-polarization of materials on attosecond timescales through coupling to the angular momentum of light. Corroborated by real-time time-dependent density functional theory calculations, our experimental results reveal the few femtosecond decay of semiconductor hole spin-polarization in germanium. Our method opens the door to measure spin dynamics in non-magnetic materials with extreme temporal resolution, high spectral resolution and core-level specificity.

HL 54.3 Thu 15:30 H17

Picosecond Femtojoule Resistive Switching in Nanoscale VO2 Memristors — •Sebastian Schmid[1,2], Laszlo Posa[1,3], Timea Török[1,3], Botond Santa[1,4], Zsigmond Pollner[1], György Molnar[3], Yannik Horst[5], Janos Volk[3], Juerg Leuthold[5], Andras Halbritter[1,4], and Miklos Csontos[5] — [1]Department of Physics, Institute of Physics, Budapest University of Technology and Economics, H-1111 Budapest, Hungary — [2]Experimental Physics V, Center for Electronic Correlations and Magnetism, University of Augsburg, Augsburg 86159, Germany — [3]Institute of Technical Physics and Materials Science, HUN-REN Centre for Energy Research, 1121 Budapest, Hungary — [4]HUN-REN-BME Condensed Matter Research Group, H-1111 Budapest, Hungary — [5]Institute of Electromagnetic Fields, ETH Zurich, 8092 Zurich, Switzerland

The dynamics of the Mott transition in correlated electron oxides could provide a sustainable alternative to the von Neumann computation by exploiting device-level functional complexity at low energy consumption. We fabricated nanoscale VO2 devices and tested them in our picosecond timeresolution, real-time resistive switching experiments, using 20 ps short and <1.7 V amplitude voltage pulses. There we observed tunable resistance states from insulator-metal transitions with down to 15 ps incubation times and switching energies starting from a few femtojoule. These orders of magnitude improvements from other memristive devices open up new possibilities for neuromorphic computing applications, outperforming the human brain at size and speed, with competitive energy consumption.

HL 54.4 Thu 15:45 H17

Agreement between Theoretically Predicted and Measured Bragg Peak Decay in Bismuth Following Femtosecond Laser Excitation — •Bernd Bauerhenne[1], Jimiben Patel[1], Sahar Bakhshi[1], Sascha Epp[2], and Martin Garcia[1] — [1]Institute of Physics, University of Kassel, Heinrich-Plett-Straße 40, D34132 Kassel, Germany — [2]Max-Planck-Institut für Struktur und Dynamik der Materie, 3 Luruper Chaussee 149, 22761 Hamburg, Germany

We investigated the time-resolved Bragg peak decay in bismuth films, 30 nm and 50 nm thick, following excitation with femtosecond (fs) laser pulses. These measurements were conducted using x-ray pulses sourced from a free-electron laser. To explain the observed Bragg peak decay, we developed an electronic temperature (Te) dependent interatomic potential for bismuth, generated using forces and energies from ab initio molecular dynamics (MD) simulations at elevated Te levels. Additionally, we computed the optical properties and the Te-dependent electron-phonon coupling constant for bismuth using ab initio methods. Employing these calculated quantities, we conducted MD simulations on similarly laser-excited antimony films, 30 nm and 50 nm thick. The comparison between our theoretical predictions and experimental measurements of Bragg peak decay exhibited an agreement, affirming the accuracy of our model. This model effectively incorporates the fs-laser induced modifications of the potential energy surface and the dynamic influences of electron-phonon coupling, providing a robust framework for understanding laser-material interactions in ultrafast processes.

HL 54.5 Thu 16:15 H17

Ultrafast Time-Domain Spectroscopy Reveals Coherent Vibronic Couplings Upon Electronic Excitation in Crystalline Organic Thin Films — •Naby Hadilou[1], Somayeh Souri[1], Daniel Timmer[1], Daniel C. Lünemann[1], Katrin Winte[1], Antonietta De Sio[1], Martin Esmann[1], Sebastian Anhäuser[2], Michele Guerrini[1], Ana M. Valencia[1], Caterina Cocchi[1], Gregor Witte[2], and Christoph Lienau[1] — [1]Oldenburg university, Germany — [2]Philipps-Universität Marburg, Germany

Coherent coupling between electronic excitations and molecular vibrations significantly influences the optical and charge transport properties of organic semiconductors and may have profound effect on technologically relevant processes such as excitons fission. Highly ordered crystalline films are ideal for probing such couplings since they enable studies of individual domain. Here, we report first polarization-resolved pump-probe experiments probing the ultrafast dynamics of crystalline perfluoropentacene thin films grown on different substrates with 10-fs time resolution. Coherent oscillations in the spectra reveal vibronic couplings to a high-frequency, 25-fs, in-plane deformation mode that is insensitive to the optical polarization, while the coupling to a lower-frequency, 85-fs, out-of-plane ring bending mode depends significantly on the crystalline and molecular orientation. Raman spectra confirm this interpretation and highlight the dominance of solid-state effects on vibronic couplings. Our results represent a first step toward uncovering the role of anisotropic vibronic couplings for singlet fission processes in crystalline molecular thin films.

HL 54.6 Thu 16:30 H17

Attosecond light-driven charge injection in germanium — •Giacomo Inzani[1,9], Lyudmyla Adamska[2,3], Amir Eskandari-asl[4], Nicola Di Palo[1], Gian Luca Dolso[1], Bruno Moio[1], Luciano Jacopo D'Onofrio[4,5], Alessio Lamperti[6], Alessandro Molle[6], Rocio Borrego-Varillas[7], Mauro Nisoli[1,7], Stefano Pittalis[2], Carlo Andrea Rozzi[2], Adolfo Avella[4,5,8], and Matteo Lucchini[1,7] — [1]Dept. of Physics, Politecnico di Milano, Italy — [2]CNR - Istituto Nanoscienze, Modena, Italy — [3]Dept. of Physics, Mathematics and Informatics, University of Modena & Reggio Emilia, Italy — [4]Dip. di Fisica, Università degli Studi di Salerno, Italy — [5]CNR - SPIN, UoS di Salerno, Italy — [6]CNR - IMM, Unit of Agrate Brianza, Italy — [7]IFN - CNR, Milano, Italy — [8]Unità CNISM di Salerno, Università degli Studi di Salerno, Italy — [9]Present address: Dept. of Physics, University of Regensburg, Germany

The injection of charges from the valence to the conduction band of a semiconductor induced by an ultrashort pulse can tailor its electro-optical properties. This process typically occurs on time scales shorter than the laser period - for visible light, in the order of one femtosecond. Despite its relevance, few experiments studied the charge excitation process with attosecond temporal resolution. In this work, we combine attosecond transient reflection spectroscopy measurements to a dual cutting-edge theoretical approach, demonstrating that photoexcitation in Ge cannot be ascribed to a single physical mechanism. The interplay of multi-photon absorption, light-induced band dressing, and intra-band motion is crucial for determining the overall charge injection.

HL 54.7 Thu 16:45 H17

Dephasing Effects in High-Harmonic Generation from Solids — •Francisco Navarrete and Dieter Bauer — Institut für Physik, Universität Rostock, 18051 Rostock, Deutschland

In the calculation of high-order harmonic generation (HHG) in solids, introducing a dephasing time is often crucial for accurately reproducing the distinct spectral peaks observed experimentally in the first plateau region [1,2]. In this contribution, we present analytical and numerical studies on the non-integer contributions to the interband HHG spectrum and investigate how dephasing affects not only the spectral structure but also the amplitude and wavelength dependence of the harmonics. Using a simplified two-band model, we numerically solve and also approximate the semiconductor Bloch equations via a saddle-point method [3] to elucidate these effects. Our findings provide closed analytical expressions for these contributions, offering insights into the interplay between dephasing and electron dynamics in solids and the mechanisms shaping the HHG spectrum.

Ultrafast Dynamics of Vanadium Dioxide Phase Transformation — •Liuyue Yang, Daniel Sandner, and Hristo Igle — Laser and X-Ray Physics E11, TUM School of Natural Sciences, TUM, James-Franck-Str. 1 85748 Garching, Germany

Vanadium dioxide has been discovered to have a metal-to-insulator transformation (MIT) at 68 °C. To investigate the dynamics of MIT, we use the pump-probe experiment to obtain the reflective transient mid-infared spectrum of VO2. In the photoinduced VO2 MIT, the phase transformation can occur at high pump power. The reflectivity of VO2 increases significantly at the metal state. At high temperature, the phase transformation occurs at lower pump power. Moreover, we observed a reflectivity oscillation in wavelength around the zeropoint of pump delay. The oscillation frequency decreases rapidly with the delay time

Deterministic Generation of Linear Photonic Cluster States with Semiconductor Quantum Dots: A Detailed Comparison of Different Schemes — •Nikolas Köcher, David Bauch, Nils Heinisch, and Stefan Schumacher — Physics Department, CeOPP, and PhoQS, Paderborn University, Germany

Graph and cluster states are types of multipartite entangled states with applications in quantum communication [1] and measurement-based quantum computation [2]. We theoretically investigate and compare different schemes for the deterministic generation of linear photonic cluster states using spins and trions in charged semiconductor quantum dots under strong Purcell enhancement. The schemes differ in the method used for spin control and whether the emitted photonic qubits are polarization or time-bin encoded. We efficiently track the fidelity and the usable length of the cluster states by calculating the expectation values of their stabilizer generators, assessing their fidelity beyond the calculation of gate fidelities [3]. We find that the performance of the different schemes and which scheme is optimal strongly depend on the cavity environment and the coherence time of the spin qubit.

HL 57.2 Fri 9:45 H13

Scalable integration of site-controlled quantum dots into circular Bragg grating resonators — •Kartik Gaur, Avijit Barua, Sarthak Tripathi, Sam Baraz, Lukas Dworaczek, Neha Nitin, Imad Limame, Aris Koulas-Simos, Priyabrata Mudi, Sven Rodt, and Stephan Reitzenstein — Institut für Festkörperphysik, Technische Universität Berlin, D-10623 Berlin

The buried-stressor approach [1] is one of the pivotal methods for the growth of site-controlled quantum dots (SCQDs). This growth technique makes use of the strain from a partially oxidized AlAs layer to induce site-selective nucleation of InGaAs quantum dots. Here, we report on growth, fabrication, and surface and optical characterizations of such SCQDs. A systematic investigation of the effects of variation of SCQD growth parameters on QDs density, surface morphology, and optical properties is done using atomic force microscopy (AFM), cathodoluminescence (CL), and microphotoluminescence (μPL) spectroscopy. Moreover, these SCQDs are integrated into circular Bragg gratings (CBGs) in a scalable manner highlighting the advantage of our advanced growth approach. Quantum optical characterizations are also performed on these SCQD-CBGs. The comprehensive understanding of the intricacies involved in the growth and characterization of SCQDs and their scalability in device integration offers a roadmap for the advancement of nanophotonic technologies and quantum information.

Spectral correlations of dynamical resonance fluorescence — •Santiago Bermúdez Feijóo[1], Eduardo Zubizarreta Casalengua[2], Kai Müller[2], and Klaus D. Jöns[1] — [1]PhoQS Institute, CeOPP, and Department of Physics, Paderborn University, Paderborn, Germany — [2]Walter Schottky Institute, School of Computation, Information and Technology and MCQST, Technische Universität München, Garching, Germany

In this work, we explore the time-dependent, frequency-filtered [1] photon statistics of a two-level system under pulsed excitation, whose dynamical emission spectrum [2] has been recently experimentally measured using semiconductor QDs [3]. Our results show that photon statistics are not fixed [4] but vary between bunching and antibunching, depending on the applied frequency filters. This reveals an intricate interplay between pulse area, photon frequencies, and correlations, extending insights from the CW case [5]. Notably, frequency-filtering enhances time-bin applications: for odd pulses, it suppresses two-photon events by up to two orders of magnitude, while for even pulses, it restores single-photon purity. This approach simplifies entanglement generation by enabling photon-number control [6] via frequency selection, eliminating the need for complex excitation schemes. [1] E. del Valle et al. HL 57.4 Fri 10:15 H13

Resonance fluorescence measurements on rapid thermally annealed self-assembled quantum dots — H. Mannel[1], •F. Rimek[1], M. Zöllner[1], N. Schwarz[1], N. Bart[2], A. Ludwig[2], A. D. Wieck[2], A. Lorke[1], and and M. Geller[1] — [1]Faculty of Physics and CENIDE, University Duisburg-Essen, Germany — [2]Chair of Applied Solid State Physics, Ruhr-University Bochum, Germany

A single self-assembled quantum dots (QD) is one of the promising candidate as a bright (high photon rate) and stable (fourier-limited) linewidth single photon source [1]. They are typically grown by molecular beam epitaxy (MBE) and have photon emission energies in the near-infrared spectrum. There are several techniques to control the size, which shift the emission wavelength. The so-called indium flush is often used, where the tip of the dot is thermally flushed away [2]. Alternatively, the confinement can be altered by rapid thermal annealing (RTA) [3], which lets indium and gallium diffuse. Here, we investigate the optical properties of rapidly thermally annealed quantum dots. In particular, we study the effects of RTA on the resonance fluorescence line width. This is done by three different measurements. First, we scan over the applied gate voltage and calculate the linewidth using the Stark shift of the exciton. Second, we scan the linewidth directly with a tunable laser. In addition, we study the lifetime in pulsed resonant measurements. The change in the confinement potential might also change dephasing processes such as photoemission or the Auger effect. [1] N. Tomm et al., Nat. N. **16**, 399-403 (2021). [2] H. HL 57.5 Fri 10:30 H13

Exploring the limits of absolute position accuracy in single emitter localization microscopy — •Maximilian Heller, Chenxi Ma, Timon Handrup, Yiteng Zhang, Xian Zheng, Micheal Zopf, and Fei Ding — Leibniz Universität Hannover, Institut für Festkörperphysik, Appelstraße 2, 30167 Hannover

Solid-state single photon emitters (SPEs) integrated in photonic nanostructures provide highly efficient light-matter interfaces for quantum information applications. Wide-field optical positioning has shown the potential to be an inexpensive method with high troughput to achieve the desired spatial matching of SPEs to the nanostructure. However, the accuracy of optical positioning setups has been overlooked so far and mainly the fitting uncertainty has been used as figure of merit. Here, we use arrays of gold nanodisks with pre-defined positions to systematically quantify the main sources of error in fabrication and imaging. From this, we develop a comprehensive calibration model to render the systematic errors insignificant compared to the uncertainties. We demonstrate that the careful calibration of the optical positioning process leads to an increased yield of quantum photonic devices by fabricating and characterizing a large number of circular Bragg gratings around epitaxial quantum dots.

HL 57.6 Fri 10:45 H13

On-demand storage and retrieval of single photons from a semiconductor quantum dot in a room-temperature atomic vapor memory — •Avijit Barua[1], Benjamin Maass[1,2], Norman Vincenz Ewald[1,2], Elizabeth Robertson[2], Kartik Gaur[1], Suk In Park[3], Sven Rodt[1], Jin-Dong Song[3], Stephan Reitzenstein[1], and Janik Wolters[2] — [1]Technische Universität Berlin (TUB), Berlin, Germany — [2]German Aerospace Center (DLR), Berlin, Germany — [3]Korea Institute of Science and Technology (KIST), Seoul, Republic of Korea

Interfacing light from solid-state single-photon sources with scalable and robust room-temperature quantum memories has been a long-standing challenge in photonic quantum information technologies due to inherent noise processes and time-scale mismatches between the operating conditions of solid-state and atomic systems. Here, we demonstrate on-demand storage and retrieval of single photons from a semiconductor QD device in a room-temperature atomic vapor memory. A deterministically fabricated InGaAs QD light source emits single photons at the wavelength of the cesium D1 line at 895 nm which exhibit an inhomogeneously broadened linewidth of 5.1(7) GHz and are subsequently stored in a low-noise ladder-type cesium vapor memory. We show control over the interaction between the single photons and the atomic vapor, allowing for variable retrieval times of up to 19.8(3) ns at an internal efficiency of 0.6(1)%. Our results significantly expand the application space of both room-temperature vapor memories and semiconductor QDs in future quantum network architectures.

HL 57.7 Fri 11:15 H13

Effects of atomistic fluctuations on the excitonic fine-structure in alloyed colloidal quantum Dots — •Anne Nadine Tewonoue Djota, Surender Kumar, and Gabriel Bester — Institute of physical chemistry and physics, University of Hamburg

The electron-hole exchange interaction in the presence of spin-orbit coupling leads for an atomistic calculation to a small energy splitting of the excitonic state known in this context as the fine structure splitting (FSS). Although this splitting is typically small, it has large consequences for the optical properties. For instance, the photoluminescence originates from these few states and is governed by the splitting (giving rise to temperature dependence) and polarization of these low energy excitonic states. So far most of the theoretical modeling has assumed that high symmetry structures lead to a simple dark-bright splitting with a large degeneracy of the excitonic states. In this work, we show based on atomistic calculations, that even globally perfectly symmetric structures (i.e., as far as an atomistic construction permits a "spherical" quantum dot) show a qualitatively different FSS as soon as alloying is introduced. The alloying effect is significantly stronger than any global shape anisotropy where the symmetry is broken for instance by geometrical elongation of the quantum dot. On the other hand, alloying a quantum dot through processes such as cation exchange is inherently random. As a result, different random alloy configurations with the same size and composition can exhibit significantly different FSS.

HL 57.8 Fri 11:30 H13

How Surface Defects Shape the Excitons and Photoluminescence of Ultrasmall CdSe Quantum Dots — •Torben Steenbock[1], Emilia Drescher[1], Tobias Dittmann[1], and Gabriel Bester[2,3] — [1]Department of Chemistry, University of Hamburg, HARBOR, Hamburg 22761, Germany. — [2]Department of Chemistry and Physics, University of Hamburg, HARBOR, Hamburg 22761, Germany. — [3]The Hamburg Centre for Ultrafast Imaging, Hamburg 22761, Germany.

Ultrasmall CdSe quantum dots (QDs) with diameters up to 2 nm show broad photoluminescence (PL) spectra presumably due to emission from band-edge excitons and defect states. However, the origin of the defect emission and the effect of defects on the band-edge excitons is not fully understood. Based on spin-orbit density functional theory and screened configuration interaction singles, we show that Cd-dimer and Se defects form in-gap defect states. In comparison with experiment, we discuss the role of deep and shallow defect states for the PL and cover the dependence of their contributions to the PL with respect to the QD size. Further, we observe that these defects lead to a localization of the molecular orbitals (MOs) involved in the band-edge excitons creating large electric dipoles in the MOs. In the excitonic states, these dipoles cause multiexponential PL decay from the band-edge states with a highly anisotropic polarization of the emission. The polarization is found to be very sensitive with respect to the exact composition of the surface.

HL 57.9 Fri 11:45 H13

Room-temperature single photon emitters in hexagonal boron nitrite coupled to an open optical cavitiy — •Anthony Ernzerhof, Lukas Lackner, Martin Esmann, Ivan Solovev, and Christian Schneider — Carl von Ossietzky Universität Oldenburg, Germany

Single photon emitters (SPEs) are a key component in photonic quantum technologies. Potential applications include secure communications and quantum metrology. Here, we present SPEs at room temperature (RT) based on hexagonal boron nitride (hBN) nano crystallites, which exhibit remarkable optical properties[1]. Our work focuses on the integration of these SPEs in an optical cavity with open access and full tunability. The cavity device allows to enhance the emitter performance via the Purcell effect, which significantly improves the emitter emission rate and source collection efficiency[2]. We discuss our technological approach towards engineering the open cavity yielding a flexible, transportable, compact and userfriendly opto-mechanically tunable emitter-cavity device, which, in principle, is of universal use beyond hBN based single photon sources. We further discuss challenges associated to the implementation of hBN nano-crystallites in such a cavity.

HL 57.10 Fri 12:00 H13

Silicon nitride-based photonic integrated circuit interfaced via photonic wire bonds with InGaAs-QDs emitting at telecom wavelength — •Ulrich Pfister[1], Daniel Wendland[2,3], Florian Hornung[1], Lena Engel[1], Hendrik Hüging[2], Elias Herzog[1], Ponraj Vijayan[1], Raphael Joos[1], Erik Jung[3], Michael Jetter[1], Simone L. Portalupi[1], Wolfram H. P. Pernice[2,3], and Peter Michler[1] — [1]Institut für Halbleiteroptik und Funktionelle Grenzflächen (IHFG), Center for Integrated Quantum Science and Technology (IQ^{ST}) and SCoPE, University of Stuttgart, Allmandring 3, 70569 Stuttgart, Germany — [2]Institute of Physics and Center for Nanotechnology, University of Münster, 48149 Münster, Germany — [3]Kirchhoff-Institute for Physics, University of Heidelberg, 69120 Heidelberg, Germany

Photonic integrated circuits (PICs) play a crucial role for realizing several quantum technologies in a small footprint. In this regard, hybrid approaches are beneficial for combining the highly developed silicon platform with the on-demand single-photon emission of III-V semiconductor quantum dots (QDs). We employed 3D laser writing technology to realize photonic wire bonds (PWBs) for funnelling single-photons from the III-V-based chip, containing the QDs emitting at 1550nm, into a Si_3N_4-based PIC [1]. An on-chip beamsplitter was used to measure a $g^{(2)}(0) = 0.11 \pm 0.02$, demonstrating the functionality of the hybrid approach on a single-photon level. Additionally, the average efficiency of the PWBs was precisely quantified.

Efficient fiber coupling of telecom single photons from circular Bragg gratings — •Nam Tran[1], Pavel Ruchka[2], Sara Jakovljevic[2], Benjamin Breiholz[1], Peter Gierss[1], Ponraj Vijayan[1], Carlos Eduardo Jimenez[3], Alois Herkommer[3], Michael Jetter[1], Simone Luca Portalupi[1], Harald Giessen[2], and Peter Michler[1] — [1]Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology (IQ^{ST}) and SCoPE, University of Stuttgart — [2]4. Physikalisches Institut, Center for Integrated Quantum Science and Technology (IQ^{ST}) and SCoPE, University of Stuttgart — [3]Institut für Technische Optik, Research Center of Photonic Engineering, SCoPE, University of Stuttgart

This work aims at quantitatively investigating the spatial stability and coupling efficiency of telecom C-band photons, generated by an epitaxial quantum dot embedded in a circular Bragg grating, into single mode optical fibers. These results are then compared to a bare single mode fiber without the 3D printed lens and a collection via a microscope objective. In terms of the total fiber coupling efficiency, the lensed and bare fiber outperform the microscope objective by up to a factor of 2.9 corresponding to a measured count rate at the detectors of 0.44MHz and 1.11MHz, respectively. The lateral (vertical) displacement showed that within a few (a few tenths) of microns the coupling degrades less than a factor of two.

HL 57.13 Fri 12:45 H13

Development of Stark-tuned InGaAs quantum dots emitting in the telecom O-band on silicon substrate — •Sarthak Tripathi, Kartik Gaur, Imad Limame, Priyabrata Mudi, Sven Rodt, and Stephan Reitzenstein — Institut für Festkörperphysik, Technische Universität Berlin, D-10623 Berlin

Quantum dots (QDs) are promising for single-photon emission, essen tial for quantum technologies like secure communication and quantum key distribution (QKD). In particular, InGaAs QDs that emit photons in the telecom O-band are especially valuable due to their compatibility with current metropolitan fiber-based QKD systems. Additionally, it is interesting to develop Si-compatible device concepts. Achieving High quality QDs on silicon are challenging due to lattice mismatch with III-V materials, leading to defects and performance degradation. To overcome this, we use a GaP buffer layer to reduce strain, improve lat tice matching, enabling high-quality QD growth with low defect den sities.By integrating epitaxial n- and p-doped GaAs layers with ohmic contacts, we apply an electric field to modify the QD energy levels via Stark effect, allowing controlled tuning of the emission wavelength. This tunability is crucial for aligning the QD emission with telecom standards or compensating for fabrication-induced variations. Optical and quantum optical characterizations confirm the effectiveness of this approach, demonstrating excellent quantum optical properties. These results highlight the potential of electrically tunable InGaAs QDs on Si as a scalable platform for quantum communication, compatible with Si-based technologies and fiber-based telecom networks.

HL 58: Nitrides: Preparation and Characterization II

Time: Friday 9:30–10:30 Location: H14

HL 58.1 Fri 9:30 H14

Random Alloy and Ordered Phases of Cubic Indium Gallium Nitride From a First-Principle Perspective — •Jan M. Waack[1,2], Markus Kremer[1,2], Nils Andre Schäfer[1,2], Michael Czerner[1,2], and Christian Heiliger[1,2] — [1]Institut für theoretische Physik, Justus-Liebig-Universität Gießen, Germany — [2]Center for Materials Research (LaMa), Justus-Liebig-Universität Gießen, Germany

Although the miscibility gap in cubic zincblende indium gallium nitride ($In_xGa_{1-x}N$) has been overcome, the specific role of ordered phases in this process remains unclear. First-principle density functional theory calculations provide a reference point for addressing this question. Ordered phases, such as CuPt-type and chalcopyrite-type structures, exhibit unique structural and electronic properties that differentiate them significantly from the random alloy. An understanding of these distinctive features of ordered phases provides a basis for their experimental identification.

We present a comprehensive data set on key structural parameters, including lattice constants and bond lengths, as well as elastic properties such as elastic constants and phonon modes. Furthermore, we explore electronic properties including the band gap and Bloch spectral function using *ab-initio* approaches such as LDA-1/2 and the mBJ functional. The presented insights into the physical properties of ordered phases and the random alloy offer a robust foundation for their experimental detection and further exploration.

HL 58.2 Fri 9:45 H14

Characterization of structural and optical properties of a red InGaN/GaN MQW LED — •Niklas Dreyer[1], F. Bertram[1], G. Schmidt[1], H. Eisele[1], S. Petzold[1], O. August[1], A. Dempewolf[1], K. Wein[1], J. Christen[1], B. Sheng[2], and X. Wang[2] — [1]Otto-von-Guericke-Universität Magdeburg, 39106 Magdeburg, Germany — [2]Peking University, Beijing 100871, China

An InGaN/GaN LED with an intended red emission (> 600 nm) was grown by MOVPE on a sapphire substrate. On an undoped GaN buffer followed by a doped n-GaN layer, the active region consists of a stack of three identical sequences, each with three quantum wells (QWs). The first two QWs nominally contain 15 % In (blue) and the third 40 % In (red). Each sequence is confined by an $Al_{0.32}Ga_{0.68}N$ layer. Finally, a p-doped $Al_{0.17}Ga_{0.83}N$ EBL is positioned, which is further capped by a dielectric DBR and processed, including metal contacts.

The LED is comprehensively characterized by cross-sectional cathodoluminescence performed in scanning transmission electron microscopy (STEM-CL) and by electroluminescence (EL). The luminescence along the growth direction is directly visualized in CL linescans: in particular, each QW can be spectrally and spatially resolved and shows a distinct emission. A wavelength shift for all QWs is observed. Furthermore, the n-GaN exhibits near-band-edge (NBE) luminescence at 356.7 nm at $T = 16$ K corresponding with a high free carrier concentration due to Burstein-Moss Shift.

The EL spectrum shows intense, broad emission around 650 nm, with a weak shift to shorter wavelengths for higher injection current.

HL 58.3 Fri 10:00 H14

Advanced nano-characterization of doped and undoped InGaN/GaN MQW-LED structures — •Luca Greczmiel, F. Bertram, G. Schmidt, P. Veit, H. Eisele, A. Dempewolf, S. Petzold, J. Christen, C. Berger, A. Dadgar, and A. Strittmatter — Otto-von-Guericke-Universität Magdeburg, 39106 Magdeburg, Germany

In this study, we comprehensively investigate structural and optical properties of InGaN/GaN MQW-LED-structures by cathodoluminescence (CL) directly performed in a scanning transmission electron microscope (STEM). The LEDs are grown by MOVPE on top of an optimized GaN/sapphire template. The first pn-junction is formed by an 1.6 μm thick GaN:Si layer and a 345 nm thick GaN:Mg layer, which are nominally doped with a concentration of $7 * 10^{18}\ cm^{-3}$ and $2 * 10^{19}\ cm^{-3}$, respectively. In between the n- and p-layer a MQW is located, which is composed of a stack of five InGaN QWs being separated by GaN:Si barriers, with a thickness of 3 nm and 7 nm, respectively. The InGaN wells have a nominal In content of 12 %. In STEM-linescans of the active region along the sample cross-section, the first QW shows emission at shorter wavelengths with respect to the subsequent following QWs. For comparison, a second MQW structure was investigated, which was identically grown, but sandwiched between uGaN. In contrast to the first sample, the CL of the 1st QW shifts to longer wavelengths, with respect to the subsequently following QWs. Hence, this spectral shift of the 1st QW is supposed to depend on the electric field in the space charge region.

HL 58.4 Fri 10:15 H14

Physical properties and thermal stability of zirconium platinum nitride thin films — Rebecca Gallivan[1], Ana Michelini[1], Nensi Toncich[1], Nerea Abando Beldarrain[1], Julia Manser[1], Arnold Müller[2], Christof Vockenhuber[2], and •Henning Galinski[1] — [1]Laboratory for Nanometallurgy, Department of Materials, ETH Zurich,8093 Zurich, Zurich, Switzerland — [2]Laboratory of Ion Beam Physics, Department of Physics, ETH Zurich, 8093 Zurich, Zurich, Switzerland

By providing new functionality, ternary transition metal nitrides (TMNs) have the potential to greatly broaden the material design space. Nevertheless, the majority of systems have only been studied computationally, and translation to experimental synthesis is restricted by a lack of knowledge about their stabilizing mechanisms. In this talk, we discuss the fabrication of ternary Zr-Pt-N thin films and examine their physical properties [1]. We show that Pt replaces nitrogen on the nonmetallic sublattice, destabilizing the rock salt structure and forming a complicated cubic phase. Additionally, we observe the exsolution of Pt nano precipitates from the Zr-Pt-N films upon annealing as well as degradation in the nitridic film's thermal stability. Even at low concentrations, Pt facilitates a solid reaction with the Si substrate that is otherwise inaccessible in ZrN films.

HL 59: 2D Semiconductors and van der Waals Heterostructures VI

The sesssion covers the physics of interlayer excitons and allied phenomena in van der Waals heterostructures.

Time: Friday 9:30–11:45 Location: H15

HL 59.1 Fri 9:30 H15

Interlayer excitons in electric and magnetic fields — •Thorsten Deilmann — Institute of Solid State Theory, University of Münster, Germany

Over the past years, more and more two-dimensional (2D) materials have been stacked to heterostructures. Due to the coupling interlayer excitations can form.

Here we report on a trilayer heterostructure of MoS_2 and WS_2. In contrast to bilayers, the coupling may lead to quadrupolar excitons. These can be clearly identified by the quadratic response of the corresponding excitons in our GW/BSE calculations in electric fields. In the second example, we report our studies of bulk CrSBr [1]. In a magnetic field the lowest bright excitations of the antiferromagnetically coupled CrSBr shift quadratically. Our calculations reveal the symmetry forbidden dark excitons and the increasing interlayer character. We develop a minimal model to explains this spin-dependent coupling. Despite its simplicity, the proposed model is generally applicable to any coupled 2D magnet.

HL 59.2 Fri 9:45 H15

Signature of Rydberg-like states of interlayer excitons in MoSe2/WSe2 heterostructures — •Chirag Chandrakant Palekar[1], Paulo E. Faria Junior[2], Tobias Manthai[1], Maximilian Nagel[1], Bhabani Sankar Sahoo[1], Shachi Machchhar[1], Avijit Barua[1], Jaroslav Fabian[2], Barbara Rosa[1], and Stephan Reitzenstein[1] — [1]Institut für Festkörperphysik, Technische Universität Berlin, Hardenbergstrasse 36, 10623 Berlin, Germany — [2]Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany

The heterostructures of transition metal dichalcogenides (TMDCs), formed by the stacking of different TMDC monolayers (MLs), facilitates the formation of spatially indirect interlayer excitons (IX). Due to the higher binding energy, the excited excitonic states have typically been observed in TMDC monolayers for over a decade. Nevertheless, the Rydberg-like higher-order states of the IX in WSe2/MoSe2 HSs have thus far remained undetected due to their weak oscillator strength. In this work, we employ photoluminescence excitation (PLE) spectroscopy to identify the signatures of Rydberg-like higher order states of IX in WSe2/MoSe2 HSs. By examining HSs with varying twist angles, we are able to gain comprehensive insight into the twist angle dependence of such excited states of IX. We compare experimental and theoretical results on the twist angle-dependent behavior of observed states, providing a systematic investigation that advances current understanding of the optical and electronic properties of TMDC HS systems.

HL 59.3 Fri 10:00 H15

Twisted MoSe2 Homobilayer Behaving as a Heterobilayer — •Arka Karmakar — Institute of Experimental Physics, Faculty of Physics, University of Warsaw, 02-093 Warsaw, Poland

Heterostructures (HSs) formed by the transition-metal dichalcogenides (TMDCs) materials have shown great promise in next-generation (opto)electronic applications. Traditionally, at atomically closed proximity the charge transfer (CT) process dominates due to its fast timescale (< 50 fs). In this talk, I introduce our latest work [1] on the ET process in a twisted molybdenum diselenide (MoSe2) homobilayer without any charge-blocking interlayer, i.e., in atomically closed proximity. We fabricated an unconventional homobilayer (i.e., HS) with a large twist angle (~57°) by combining the chemical vapor deposition (CVD) and mechanical exfoliation (Exf.) techniques to fully exploit the lattice parameters mismatch and indirect/direct (CVD/Exf.) bandgap nature. These result in weakening the CT process and allowing the ET process to take over the carrier recombination channels. We employ a series of optical and electron spectroscopy techniques, complementing by the density functional theory (DFT) calculations, to describe a massive room temperature photoluminescence enhancement from the HS area due to an efficient ET process. Our results show that the electronically decoupled MoSe2 homobilayer is coupled by the ET process, mimicking a 'true' heterobilayer nature.

[1] A. Karmakar et al., "Twisted MoSe2 Homobilayer Behaving as a Heterobilayer", Nano Lett. 2024, 24, 31, 9459-9467.

HL 59.4 Fri 10:15 H15

Tailoring Interlayer Exciton Dyanamics of TMDC Heterostructures: From Bilayers to Trilayers embeded in Broadband DBR Cavities — •Bhabani Sankar Sahoo, Shachi Machchhar, Chirag Chandrakant Palekar, and Stephan Reitzenstein — Technische Universität Berlin, Berlin, Germany

The photoluminescence yield of interlayer excitons (IX) at room temperature remains limited due to electrons and holes residing in different layers. In this work we propose and implement a novel way to enhance the IX emission in transition metal dichalcogenide (TMDC) heterostructures. We first introduce an additional WSe2 on top of a heterobilayers (HBL) of WSe2/MoSe2 to form a heterotrilayer (HTL) with different twist angles which significantly boost the PL emission upto one order magnitude, attributed to improved overlap of the electronic wavefunctions and additional radiative pathways. Further embedding this HTL within a chirped multiresonant distributed Bragg reflector (DBR) microcavity provides strong exciton confinement, enhancing the radiative recombination rate and modifying the exciton lifetime. Compared to the HBL, the HTL displays a reduced exciton lifetime, indicative of stronger light-matter coupling within the cavity, and a pronounced increase in PL intensity due to enhanced photon density of states. Our study highlights the potential of tailored stacking and cavity integration to manipulate light-matter interactions in advanced TMDC heterostructure devices for next-generation optoelectronic applications.

HL 59.5 Fri 10:30 H15

Effect of the Direct-to-Indirect Bandgap Crossover on the Reverse Energy Transfer — •Gayatri Gayatri[1], Debashish Das[2], Natalia Zawadzka[1], Takashi Taniguchi[3], Kenji Watanabe[3], Adam Babiński[1], Saroj K. Nayak[2], Maciej R. Molas[1], and Arka Karmakr[1] — [1]University of Warsaw, Warsaw, Poland — [2]Indian Institute of Technology Bhubaneswar, Odisha, India — [3]National Institute for Materials Science, Ibaraki, Japan

Heterostructures (HSs) made by the vertical stacking of van der Waals monolayers (1Ls) have shown great potential in (opto)electronic devices. In the type-II transition metal dichalcogenide HSs, long-range energy transfer (ET) happens via the dipole-dipole coupling (Förster type). To investigate this, we studied HS made by the 1L tungsten disulfide (WS2) and 1L-5Ls molybdenum disulfide (MoS2), with hexagonal boron nitride (hBN) as a charge-blocking interlayer, using differential reflection contrast, photoluminescence (PL), and photoluminescence excitation. At room temperature, PL enhancement has been observed in the neutral exciton of WS2 in the WS2-hBN-1L MoS2 and WS2-hBN-2L MoS2 regions as compared to the isolated WS2 emission. This enhancement confirms an efficient ET from MoS2 B excitonic level to WS2 A excitonic level. As the number of MoS2 layers increases, bandgap changes from direct-to-indirect, promoting more immediate carrier scattering from the K-valley. Consequently, carrier population decreases and ET becomes less effective.

HL 59.6 Fri 10:45 H15

Interlayer Exciton Traps in TMD heterobilayers — •Thomas Klokkers[1,2], Mirco Troue[1,2], Johannes Figueiredo[1,2], Andreas Knorr[3], Ursula Wurstbauer[4], and Alexander Holleitner[1,2] — [1]Walter Schottky Institute, Technical University of Munich, Am Coulombwall 4a, 85748 Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 Munich, Germany — [3]Institute for Theoretical Physics, Nonlinear Optics and Quantum Electronics, Technical University of Berlin, 10623 Berlin, Germany — [4]Institute of Physics, Münster University, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany

Long-lived interlayer excitons in MoSe2/WSe2 heterostructures constitute a promising platform to explore many-body physics in a two-dimensional solid-state system. Introducing a trapping potential facilitates exploring the many-body regime by providing a platform to control the density of the interlayer exciton ensemble. Realizations of such exciton traps range from electrostatic strip gates to strain-induced potentials. In this work, we realize enhanced emission from interlayer excitons based on an optical trap. The laterally changed potential landscape allows the investigation of ensembles at high densities without the direct influence of temperature, excess charge carriers and laser-induced coherence.

Hybridized excitons in 2D van der Waals materials — •Andreas Stier — Walter Schottky Institut und TUM School of Natural Sciences, TU München, Garching, Deutschland

I will review our recent progress on magneto optical spectroscopy of atomically thin materials in magnetic fields up to 91 T with an emphasis on the spin-valley physics of neutral and charged excitons.

In monolayer (ML) semiconductors, magneto-absorption spectroscopy revealed the diamagnetic shifts of the exciton Rydberg states, which allowed the first direct experimental measure of the reduced mass and binding energy. Surprisingly, investigating the photoluminescence, we observe the emergence of a new excitonic peak, which we discuss in the framework of the theoretically predicted linear dispersing exciton branch originating from intervalley exchange interactions.

For heterostructures (HS) of a 2D semiconductor with graphene, we find a new multi-step proximity effect due to band folding in the HS, where we show that the spin-valley physics can be used to quantify interlayer hybridization. In HS from ML MoSe2 and the layered antiferromagnetic (AFM) semiconductor CrSBr, we show the formation of new exciton states depending on the twist angle. These excitons exhibit clear signatures of proximity coupling to the magnetic state of the AFM layer, such as hysteretic response to in- and out of plane B fields. We discuss these results in the framework of Ising-type spin-orbit proximity coupling.

HL 59.8 Fri 11:30 H15

Laterally extended states of interlayer excitons in reconstructed $MoSe_2/WSe_2$ heterostructures — •Johannes Figueiredo[1,2], Marten Richter[3], Mirco Troue[1,2], Jonas Kiemle[1,2], Hendrik Lambers[4], Torsten Stiehm[4], Ursula Wurstbauer[4], Andreas Knorr[3], and Alexander Holleitner[1,2] — [1]Walter Schottky Institute, TU Munich — [2]Munich Center for Quantum Science and Technology (MCQST) — [3]Institut für Theoretische Physik, Nichtlineare Optik und Quantenelektronik, TU Berlin — [4]Institute of Physics, Münster University

Heterostructures made from 2D transition-metal dichalcogenides are ideal platforms for exploring excitonic phenomena, including correlated moiré excitons and degenerate interlayer exciton ensembles. While atomic reconstruction is often assumed to localize excitons, we demonstrate that excitonic states in reconstructed $MoSe_2/WSe_2$ heterostructures can extend beyond the moiré periodicity [1]. Using real-space calculations, we provide lateral potential maps and corresponding excitonic wavefunctions for interlayer excitons in strain-relaxed heterostructures [2]. Cryogenic photoluminescence experiments corroborate the computed level structure and exciton relaxation dynamics. These findings align with recent coherence measurements on degenerate interlayer excitons and suggest potential many-body phenomena in dense, cold exciton ensembles [3].

Invited Talk HL 60.1 Fri 9:30 H17

Constructing Artificial Matter in the Electron Microscope - Atomic Fabrication at Scale in CrSBr — •Julian Klein — Department of Materials Science and Engineering, Massachusetts Institute of Technology, Cambridge, 02319 MA, USA

The ability to control the arrangement of individual atoms has transcended naturally occurring configurations of matter, enabling experimental breakthroughs in quantum physics. I will show how we can now use scanning transmission electron microscopy to construct artificial atomic arrangements at scale and demonstrate it with the layered magnetic quasi-1D semiconductor CrSBr. By developing strategies to position the electron beam with picometer precision and perform rapid, targeted beam actions, we achieve deterministic control over the movement of Cr atoms in space and time. With this capability, we selectively steer Cr atoms into interstitial positions, forming localized quantum states while simultaneously monitoring atomic movements in real time with microsecond resolution. Fully automating the electron microscope enables us to construct ordered arrays of Cr interstitial superlattices atom by atom as well as nonperiodic structures, spanning hundreds of locations over tens of nanometers, all within minutes. Our results show that atomic fabrication at scale in the electron microscope is now a reality, unlocking unprecedented opportunities to construct quantum defects and phases, atom by atom, in the solid state, that extend over macroscopic length scales.

Invited Talk HL 60.2 Fri 10:00 H17

Tuning the structure and magnetism in CrSBr via external pressure — •Ece Uykur — Helmholtz-Zentrum Dresden-Rossendorf, Institute of Ion Beam Physics and Materials Research, 01328 Dresden, Germany

As one of the two-dimensional (2D) van der Waals (vdW) magnets, CrSBr regained significant attention recently because it is air-stable even in the monolayer form making this compound very attractive. It shows strong coupling between its magnetic, electronic, structural, and optical properties [1]. Several ab initio calculations put forward the importance of the balance between Cr-Cr direct exchange and Cr-anion-Cr superexchange interactions and showed that the A-type antiferromagnetism in this compound is delicately balanced with these short- and long-range magnetic interactions [2]. Therefore, studies exploring the tunability of the inter- and inralayer coupling are important and one plausible experimental strategy is the external pressure.

In this talk, I will summarize our recent efforts on high-pressure single crystal XRD and magnetization studies on CrSBr. We performed single crystal XRD studies up to ~20 GPa, which reveals a non-monotonous behavior of Cr-ion in the structure along with a structural phase transition above 17 GPa. The movement of this Cr-ion has also direct link with the magnetization of the compound that is studied with the high-pressure magnetic susceptibility measurements up to ~8 GPa.

Invited Talk HL 60.3 Fri 10:30 H17

A theoretical perspective on exciton-magnon coupling and its implications — •Akashdeep Kamra — Department of Physics, Rheinland-Pfälzische Technische Universität (RPTU) Kaiserslautern-Landau, Kaiserslautern, Germany

The dependence of exciton energies on the magnetic order in CrSBr has opened avenues for controlling optical properties using magnetic fields. Conversely, it has enabled an optical time-resolved sensing of the magnetic degrees of freedom. This has further been exploited to investigate the interplay between excitons and magnons, the excitations of the magnetic order. We will discuss how excitonic energies offer a convenient access to coherent as well as thermal magnon dynamics. Focusing on transport, we will discuss the recent observation of the magnon-exciton drag effect that makes it feasible to leverage thermal magnon currents for transporting excitons at unexpectedly fast velocities. Finally, we will conclude with a brief discussion of emergent non-linearities in exciton energies mediated by the magnonic modes in the canted magnetic state of CrSBr.

Exciton and valley properties of monolayer transition metal dichalcogenides on the van der Waals magnetic semiconductor CrSBr — •Yara Galvao Gobato — Universidade Federal de Sao Carlos, Sao Carlos, Brazil

Chromium sulfide bromide is a promising van der Waals (vdW) magnetic material, undergoing a magnetic phase transition to an A type antiferromagnetic state below the Neél temperature of about 132K in its bulk form. VdW heterostructures composed of monolayer transition metal dichalcogenides (TMDs) and vdW magnetic materials such as CrSBr are an interesting platform to modify valley and excitonic properties of non-magnetic TMDs. In this talk, we will present our recent results on optical and magneto-optical properties of monolayer TMDs on CrSBr under different magnetic field orientations. Remarkably, we have observed a clear influence of the CrSBr magnetic order on the exciton and valley properties of monolayer TMDs, such as an anomalous linear polarization dependence, unsual temperature dependence of emission energies, magnetic field dependence of the emission intensity, and valley g-factor values with clear signatures of an asymmetric magnetic proximity exchange interaction. Our results are explained by asymmetric magnetic proximity effects, charge transfer and a possible contribution of exciton/trion magnon coupling. Our studies suggest that vdW heterostructures with antiferromagnetic nonmagnetic interfaces are interesting platforms to modify the valley and excitonic properties of TMDs for possible applications in opto-spintronics and quantum technology.

HL 60.5 Fri 11:45 H17

Ab initio studies on the electronic and optical properties of magnetic CrSBr — •Marie-Christin Heissenbüttel[1], Pierre-Maurice Piel[2], Julian Klein[3], Thorsten Deilmann[1], Ursula Wurstbauer[2], and Michael Rohlfing[1] — [1]Institute of Solid State Theory, University of Münster, Germany — [2]Physical Institute, University of Münster, Germany — [3]Department of Materials Science and Engineering, MIT, Massachusetts, USA

CrSBr recently emerged as a van der Waals layered material exhibiting intriguing electronic and optical properties arising from the intricate interplay between crystal structure and layered magnetic order. A thorough understanding of these effects is essential to assess its potential for applications in spintronic and quantum devices. Due to the large crystal anisotropy, the monolayer, multilayer, and bulk crystal CrSBr show a quasi-one-dimensional behaviour of effective masses and exciton wavefunctions [1]. The interlayer antiferromagnetic (AFM) coupling suppresses layer to layer interactions in the magnetic ordered low temperature phase, resulting in strong quantum confinement of electrons and excitons within the individual layers [2]. Using ab-initio *GW*/Bethe-Salpeter equation calculations, we analyze electronic and excitonic properties on the same footing and elucidate how the AFM van der Waals stacking, symmetry properties and the large crystal anisotropy govern the electronic and optical properties of this material.

HL 60.6 Fri 12:00 H17

Internal structure and ultrafast dynamics of quasi- 1D excitons controlled by magnetic order — •N. Nilforoushan[1], M. Liebich[1], M. Florian[2], F. Mooshammer[1,3], A. D. Koulouklidis[1,3], L. Wittmann[1], K. Mosina[4], Z. Sofer[4], F. Dirnberger[5], M. Kira[2], and R. Huber[1,3] — [1]Dept. of Physics, University of Regensburg, Germany — [2]Dept. of Electrical Engineering and Computer Science, University of Michigan, USA — [3]RUN, University of Regensburg, Germany — [4]Dept. of Inorganic Chemistry, University of Chemistry and Technology Prague, Czech Republic — [5]Dept. of Physics, Technical University of Munich, Germany

In van der Waals (vdW) layered crystals, Coulomb correlations are often tuned by structural engineering, giving rise to emergent phenomena such as tightly bound excitons and exotic electronic and magnetic phases. Magnetic vdW materials offer a unique platform for in situ control of Coulomb correlations enabled by their intrinsic magnetic order. Here, we present quantitative experiment-theory proof that excitonic correlations can be tailored through spin order in the vdW magnet CrSBr. By probing internal transitions of excitons with phase-locked mid-infrared pulses, we reveal their binding energy and strong anisotropy of their quasi-1D orbitals resulting in significant fine-structure splitting. We switch excitons from monolayer-localized to interlayer-delocalized species by pushing the system from the antiferromagnetic to the paramagnetic phase. The exciton's ultrafast dynamics further support this scenario. In future applications, excitons may be interfaced with spintronics enabling on-demand phase transitions.

HL 60.7 Fri 12:15 H17

Raman controlled lithium intercalation into CrSBr van der Waals structure — •Kseniia Mosina, Aljoscha Söll, Martin Veselý, Jiří Šturala, and Zdenek Sofer — Department of Inorganic Chemistry, University of Chemistry and Technology Prague, 166 28 Prague 6, Czech Republic.

Lithium intercalation into the van der Waals crystalline structure of layered transition metal dichalcogenides by means of chemical and electrochemical intercalation is a well-known method for studying semiconductor-metallic phase transitions. The layered semiconductor chromium sulphur bromine (CrSBr) in recent years becomes an ultimate playground for the studies of low-dimensional magneto-optical properties. The interlayer distance of CrSBr allows the easy cleavage and intercalation of the guest molecules within the crystalline structure. Conveniently air-stable, this material exhibits a direct band gap of 1.5 eV, an antiferromagnetic state in bulk and ferromagnetism in the monolayer. Here, we present the lithium intercalation method into the CrSBr structure by lithium-solvated electron solution. To monitor the lithiation process in real-time, we investigated the Raman spectra evolution upon lithium ion intercalation into a few-layered CrSBr flake. Our findings suggest that the quasi-one dimensional nature of CrSBr leads to weak interlayer hybridization along the b-direction, which facilitates the diffusion of guest ions by lowering the migration energy barrier and enables anisotropic Li+ diffusion. The reliable intercalation methodology allows tracking the intercalation process directly in the desired area favorable for device fabrication.

Invited Talk HL 60.8 Fri 12:30 H17

Electric field control of intra- and interlayer excitons in CrSBr — •Nathan Wilson[1], Amine Ben Mhenni[1], Ferdinand Menzel[1], Alain Dijkstra[1], Zdenek Sofer[2], and Jonathan Finley[1] — [1]Walter Schottky Institute, TU Munich, Garching, Germany — [2]Institute of Chemistry and Technology, Prague, Czech Republic

In the 2D magnetic semiconductor CrSBr, the interplay between a direct bandgap for all layer thicknesses and layered antiferromagnetism with strong magneto-electronic coupling give rise to rich but poorly understood excitonic physics. So far, the presence of two closely spaced conduction bands and existence of both intra and interlayer excitons in multilayers has complicated interpretation of the optical spectrum of its excitons. Here, we study monolayers and bilayers of CrSBr in dual-gated structures, allowing for independent tuning of electric field and charge doping. Our study reveals the existence of the previously unobserved ground state exciton in monolayers, which is darkened both by charge doping and electric field. We find that both intralayer and hybrid intra/interlayer excitons are highly sensitive to the vertical electric field, implying a reasonably large exciton polarizability and control over wavefunction symmetry. With this information, we are able to form a more complete picture of the real space and band character of the excitons in CrSBr.

HL 61: THz and MIR physics in semiconductors

The session covers the THz and MIR physics in semiconductors.

Time: Friday 10:45–11:45 Location: H14

HL 61.1 Fri 10:45 H14

Multi-photon Stark spectroscopy of ultrafast THz waveforms — •Fabian Brütting, Moritz B. Heindl, and Georg Herink — Experimental Physics VIII, University of Bayreuth, Germany

Microscopic electric waveforms can be encoded into luminescence modulations through the quantum-confined Stark effect, enabling ultrafast "videography" of local electric fields up to THz frequencies. This technique, known as Quantum-probe field microscopy (QFIM), relies on the coupling of momentary electric fields with electronic transitions in colloidal quantum dots, with detection achieved via pump-probe microscopy [1].

Here, we propose two-photon absorption (TPA) as a novel probing regime for accessing the THz-driven Stark effect. Unlike conventional Stark spectroscopy, which relies on linear one-photon absorption, TPA operates under different selection rules, resulting in distinct interaction dynamics. In particular, depending on the specific transitions being probed, we observe a sign flip of the nonlinear electro-absorption contribution relative to the linear signal. Consequently, the overall electro-absorption signal is either enhanced, reduced or even inverted compared to the linear signal.

Therefore, two-photon Stark spectroscopy offers potential for improving QFIM detection sensitivity and provides a novel strategy for the ultrafast manipulation of the optical properties in low-dimensional semiconductors.

[1] Heindl, Moritz B., et al. "Ultrafast imaging of terahertz electric waveforms using quantum dots." *Light Sci. Appl.* 11.1 (2022): 5.

HL 61.2 Fri 11:00 H14

Characterization of SiC epilayers with terahertz time-domain spectroscopy — •Joshua Hennig[1,2], Jens Klier[1], Stefan Duran[1], Christian Röder[3], Franziska Beyer[3], Kuei-Shen Hsu[4], Jan Beyer[4], Nadine Schüler[5], Nico Vieweg[6], Katja Dutzi[6], Georg von Freymann[1,2], and Daniel Molter[1] — [1]Department of Materials Characterization and Testing, Fraunhofer ITWM, Kaiserslautern — [2]Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern-Landau — [3]Department Energy Materials and Test Devices, Fraunhofer IISB, Erlangen — [4]Institute of Applied Physics, Technische Universität Bergakademie Freiberg — [5]Freiberg Instruments GmbH, Freiberg — [6]TOPTICA Photonics AG, Gräfelfing

Silicon carbide (SiC), being a wide-bandgap and robust, temperature-stable semiconductor, is an up-and-coming material that already has applications in power electronics and in high-temperature environments. While the characterization of the electrical and optical properties of bulk semicondcutors with terahertz time-domain spectroscopy (TDS) has already been demonstrated, many applications make use of thin layers with thicknesses of a few tens of microns. Using the Drude model, we performed simulations with varying thicknesses and charge carrier densities of SiC epilayers showcasing the opportunities and possible limitations of TDS to characterize SiC epilayers. Finally, TDS measurements demonstrating the validity of the simulations were used to determine the charge carrier density of SiC epilayers.

HL 61.3 Fri 11:15 H14

Diminishing topological Faraday effect in thin layer samples — Christian Berger, Florian Bayer, Laurens W. Molenkamp, and •Tobias Kiessling — Physikalisches Institut, University of Würzburg, Am Hubland, D-97074 Würzburg, Germany

A striking feature of three-dimensional topological insulators (TIs) is the theoretically expected topological magnetoelectric (TME) effect, which gives rise to additional terms in Maxwell's laws of electromagnetism with an universal quantized coefficient proportional to half-integer multiples of the fine-structure constant. In an ideal scenario one therefore expects also quantized contributions in the magnetooptical response of TIs.

We review this premise by taking into account the trivial dielectric background of the TI bulk and potential host substrates, and the often present contribution of itinerant bulk carriers. We show (i) that one obtains a nonuniversal magnetooptical response whenever there is impedance mismatch between different layers and (ii) that the detectable signals due to the TME rapidly approach vanishingly small values as the impedance mismatch is detuned from zero.

HL 61.4 Fri 11:30 H14

Unraveling the Microscopic Mechanism of Displacive Excitation of Coherent Phonons in a Bulk Rashba Semiconductor — •Peter Fischer[1], Julian Bär[1], Moritz Cimander[1], Volker Wiechert[1], Oleg Tereshchenko[2], and Davide Bossini[1] — [1]Department of Physics and Center for Applied Photonics, University of Konstanz, D-78457 Konstanz, Germany — [2]Nowosibirsk, Russia

Optically driven lattice excitations have recently been intensively investigated as a means to manipulate the macroscopic properties of quantum materials. In solids with an electronic band gap, it is well-established that coherent phonons can be excited by laser pulses with photon energies exceeding the band-gap energy. However, the dominant microscopic mechanism has still not been pinpointed: Neither experimentally nor theoretically has it been possible to disentangle the effect of a photo-induced change in the charge-carrier density from an increase of the carrier temperature. We perform time-resolved pump-probe spectroscopy on the Rashba semiconductor BiTeI. Tuning the pump-photon energy from the visible to the mid-infrared allows us to excite both interband and barely accessible intraband transitions. As a result, we determine that the lattice modes are mainly driven by the increased carrier temperature. In addition, the phonon coherence time in the intraband regime proves robust against an increase in laser fluence. These findings provide new insights for the development of schemes addressing the coherent structural manipulation of solids.

HL 62: 2D Semiconductors and van der Waals Heterostructures VII

The session covers the physics of quantum emitters and defects in 2D materials and their heterostructures. Note, the session starts directly after the session "2D Semiconductors and van der Waals Heterostructures VI".

Time: Friday 11:45–13:00 Location: H15

HL 62.1 Fri 11:45 H15

Deterministic Purcell enhancement of single photon emission from a WSe_2 monolayer quantum emitter — •Ivan Solovev[1], Victor Mitryakhin[1], Sven Stephan[1,2], Jens-Christian Drawer[1], Lukas Lackner[1], Seth Tongay[3], Kenji Watanabe[4], Takashi Taniguchi[5], Martin Esmann[1], and Christian Schneider[1] — [1]Institute for Physics, Carl von Ossietzky University of Oldenburg, Oldenburg, Germany — [2]University of Applied Sciences Emden/Leer, Emden, Germany — [3]Materials Science and Engineering, School for Engineering of Matter, Transport and Energy, Arizona State University, Tempe, Arizona, USA — [4]Research Center for Functional Materials, National Institute for Materials Science, Tsukuba, Japan — [5]International Center for Materials Nanoarchitectonics, National Institute for Materials Science, Tsukuba, Japan

Bright and easily fabricated quantum emitters in two-dimensional semiconductors have emerged as a promising platform for scalable quantum communication [1,2]. Here, we show, how their performance can be markedly elevated by integrating a monolayer into a versatile open plano-concave Fabry-Pérot microcavity. We managed to modulate radiative decay rate of a zero-phonon line by tuning a high Q-factor cavity. Reached five-fold shortening of the lifetime opens the route towards higher rates of quantum key distribution and generation of indistinguishable single photons in 2D semiconductors.

HL 62.2 Fri 12:00 H15

Deterministic generation of single-photon emitters in 2D materials by in-situ electron beam lithography — •Shachi Machchhar, Bhabani Sankar Sahoo, Yuhui Yang, Imad Limame, Chirag Chandrakant Palekar, and Stephan Reitzenstein — Technische Universität Berlin, Berlin, Germany

The development of on-demand sources of single photons with high indistinguishability represents a crucial step in the creation of photonic quantum systems, such as those required for the construction of large-scale quantum networks for the secure transfer of data. One potential avenue for the realization of such sources in a scalable and cost-effective manner is the exploitation of defect centres in transition metal dichalcogenides (TMDCs). The fabrication of these defect centres in TMDC monolayers can be achieved through the introduction of strain, ion implantation, and the structuring or patterning of the substrate. In this study, we employ cathodoluminescence (CL) spectroscopy at cryogenic temperatures to probe hBN-encapsulated WSe* and utilise in-situ electron beam lithography (iEBL) to structure pre-determined patterns on the emission active region. This nanopatterning of the monolayer facilitates the deterministic gener-

ation of single-photon emitters (SPEs) with distinct quantum optical properties. Furthermore, we demonstrate the single-photon nature of these SPEs through second-order correlation measurements on the MLs. Additionally, we study the temperature dependence of such SPEs generated in various patterned geometries.

HL 62.3 Fri 12:15 H15

Generation of luminescent defects in hBN by focused helium ion beam irradiation — •Amedeo Carbone[1,2], Martijn Wubs[1], Alexander W. Holleitner[2], Christoph Kastl[2], Alexander Huck[3], and Nicolas Stenger[1] — [1]Department of Electrical and Photonics Engineering, Technical University of Denmark, 2800 Kgs. Lyngby, Denmark — [2]Walter Schottky Institute, Physik Department, Technical University of Munich, Am Coulombwall 4, 85748 Garching, Germany — [3]Center for Macroscopic Quantum States (bigQ), Department of Physics, Technical University of Denmark, 2800 Kgs. Lyngby, Denmark

Among the luminescent centres in hBN, which have recently gained attention because of their brightness and exceptional quantum properties at room temperature, the charged boron vacancy (V_B^-) defect stands out for its magnetic properties, which have significant applications in quantum sensing schemes [1]. In the present work [2] we irradiate hBN flakes with a focused helium ion beam to generate V_B^- defects, conduct optical and magnetically resolved characterization, and apply a theoretical model [3] to infer the generated density of charged emitters. These results are further compared to the estimated vacancy density from Molecular Dynamics simulations. Our work provides a systematic study of the defect generation efficiency by comparing different irradiation doses.

HL 62.4 Fri 12:30 H15

Impact of low-energy ion-irradiation induced defects on optical and vibrational properties of molybdenum disulfide — •Philipp Kraus, Eileen Schneider, Tobias Dierke, Stefan Wolff, Yuri Koval, and Janina Maultzsch — Chair of Experimental Physics, FAU Erlangen-Nürnberg, Erlangen

We present the controlled creation of vacancies in 2D materials, in particular graphene and molybdenum disulfide (MoS_2), by low-energy ion-irradiation. With Raman spectroscopy on exfoliated graphene flakes before and after irradiation, we determined the defect density to calibrate the ion dose of our setup. Then, we irradiated MoS_2 monolayers, grown via chemical vapor deposition (CVD), and determined the impact of the ion-induced defects on Raman and photoluminescence (PL) spectra. These results are additionally compared with density functional theory (DFT) calculations.

HL 62.5 Fri 12:45 H15

Composition- and strain-dependent quantum dot states in transition metal dichalcogenide nanobubbles — •Stefan Velja, Jannis Krumland, and Caterina Cocchi — Carl von Ossietzky Universität Oldenburg

Mechanical deformations in transition metal dichalcogenide monolayers can appear both spontaneously and artificially, giving rise to peculiar nanostructures, such as nanobubbles, or nanowrinkles. These systems have been observed to harbor localized states in the gap region, a known prerequisite for single-photon emission. While recent theoretical studies have attempted to explain these phenomena on selected systems [1,2], a detailed analysis concomitantly examining the role of the chemical constituents and the amount of applied strain is essential to gain full insight. In this work, we investigate the electronic properties of MX_2 nanobubbles (M=Mo, W and X=S, Se) characterized by varying levels of local strain. For materials composed of lighter elements, localized states appear in the gap region when the deforming force reaches the order of 0.01 a.u./atom. A thorough analysis of these states sets the stage for predicting and interpreting the optical fingerprints of these nanostructures.

HL 63: Focus Session: Nanoscale Light-matter Interaction II

The focus session highlights recent breakthroughs in resolving the optoelectronic properties of individual nanostructures down to the atomic scale. Moreover, the session introduces the rich field of surface polaritons, confined electromagnetic modes through which light can be guided on subwavelength scales.

The session is the second part of the focus session on nanoscale light-matter interaction.

Time: Friday 12:00–13:15 Location: H14

HL 63.1 Fri 12:00 H14

Super-resolution imaging of nanoscale inhomogeneities in hBN-covered and encapsulated few-layer graphene — •Lina Jäckering, Konstantin G. Wirth, Lukas Conrads, and Thomas Taubner — I. Institute of Physics (IA), RWTH Aachen University

Encapsulating few-layer graphene (FLG) in hexagonal boron nitride (hBN) can cause nanoscale inhomogeneities in the FLG, including changes in stacking domains and topographic defects.[1] Due to the diffraction limit, characterizing these inhomogeneities is challenging. Recently, the visualization of stacking domains in encapsulated four-layer graphene (4LG) has been demonstrated with phonon polariton (PhP)-assisted near-field imaging.[2] However, the underlying coupling mechanism and ability to image subdiffractional-sized inhomogeneities remain unknown. Here, we retrieve direct replicas and magnified images of subdiffractional-sized inhomogeneities in hBN-covered trilayer graphene (TLG) and encapsulated 4LG, enabled by the hyperlensing effect.[3] This hyperlensing effect is mediated by hBN*s hyperbolic PhP that couple to the FLG*s plasmon polaritons. Using near-field microscopy, we identify the coupling by determining the polariton dispersion in hBN-covered TLG to be stacking-dependent. Our work demonstrates super-resolution and magnified imaging of inhomogeneities, paving the way for the realization of homogeneous encapsulated FLG transport samples to study correlated physics.

HL 63.2 Fri 12:15 H14

Optical and Electrical Properties of Copper Oxide * Polyvinyl Alcohol Nanocomposites for Solar Cell Applications — •Ahed AL-Faouri[1,2], Mahmoud Abu-Kharma[1], and Mahmoud Hatem[1] — [1]Department of Physics, Faculty of Science, Al-Balqa Applied University, Al-Salt, Jordan — [2]Basic Sciences Department, Faculty of Arts and Sciences, Al-Ahliyya Amman University, Amman, Jordan

Copper oxide nanoparticles (CuO-NPs) were successfully synthesized at ambient temperature using an easy and eco-friendly method, employing the aqueous extract of bougainvillea leaves as reducing and stabilizing agents. First, a thin film of pure polyvinyl alcohol (PVA) was prepared via solution casting. Subsequently, four CuO-PVA nanocomposites were fabricated through solution casting at concentrations of (13, 30, 40, and 51) wt%. The optical and electrical properties of the synthesized CuO NPs, pure PVA, and CuO-PVA thin films were investigated using a UV-Vis spectrophotometer and a Keithley electrometer.

The band gap (Eg) of prepared CuO-NPs was 2.74 eV. The separation of this band gap renders CuO-NPs a suitable material for solar energy conversion and could potentially be used as an active layer material in solar cells., Furthermore, the four prepared CuO-PVA showed that the optical band gap decreased from 4.42 eV (pure PVA) to 3.34 eV (50%CuO-PVA). Further, increased DC electric conductivity was observed

HL 63.3 Fri 12:30 H14

Accessing phase and group velocities of terahertz surface plasmon polaritons in graphene using near-field spacetime imaging — •Simon Anglhuber[1], Martin Zizlsperger[1], Eva A. A. Pogna[2], Yaroslav A. Gerasimenko[1], Anastasios D. Koulouklidis[1], Imke Gronwald[1], Svenja Nerreter[1], Leonardo Viti[3], Miriam S. Vitiello[3], Rupert Huber[1], and Markus A. Huber[1] — [1]Regensburg Center for Ultrafast Nanoscopy (RUN) and Department of Physics, University of Regensburg, 93040 Regensburg, Germany — [2]Istituto di Fotonica e Nanotecnologie, Consiglio Nazionale delle Ricerche (CNR-IFN), Milano, I-20133, Italy — [3]NEST, CNR - Istituto Nanoscienze and Scuola Normale Superiore, Piazza San Silvestro 12, 56127, Pisa, Italy

The combination of light and matter properties in surface polaritons offers unprecedented opportunities for controlling energy flow and information processing at the nanoscale. Here, we present a novel THz near-field imaging approach to visualize polariton propagation directly in the time domain. Our method allows for the extraction of phase and group velocities, as well as damping. Thus, it

reveals substantial insights into the polariton dispersion curve, even for strongly damped modes. Additionally, we show that our analysis can be expanded to two dimensions, directly visualizing polariton propagation in arbitrary directions, which is especially valuable for anisotropic materials. Finally, the method offers an intuitive approach to visualize non-equilibrium polariton propagation, e.g. upon photoexcitation. Thereby, we achieve subcycle control over polariton dynamics.

HL 63.4 Fri 12:45 H14

Inelastic electron-light interaction probed by holographic scanning transmission electron microscopy — •Nora Bach[1,2], Tim Dauwe[1,2], Murat Sivis[1,2], and Claus Ropers[1,2] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]4th Physical Institute, University of Göttingen, Germany

Quantitative phase-contrast imaging of electrostatic potentials is an important application in transmission electron microscopy. Recently developed techniques have overcome the challenge to measure phase profiles inherited from optical fields, but offer only limited variability in tailoring the electron-light interactions and require a highly coherent electron source [1,2]. In this contribution, we introduce scanning transmission electron microscopy with spatially separated coherent electron probes [3] for the full imaging of complex optical near fields at a nanostructure with high spatial resolution. In the far field, these electron probes interfere to form a hologram from which we reconstruct phase shifts induced both by elastic scattering processes and by stimulated inelastic interactions. One particular advantage of STEM holography is the relaxed coherence requirements, which could be central to improving time-resolved imaging of electric and magnetic fields on the nanoscale.

HL 63.5 Fri 13:00 H14

Unraveling ultrafast exciton dynamics in a monolayer of the magnetic semiconductor CrSBr — •Jakob Schlosser[1], Christian Meineke[1], Martin Zizlsperger[1], Marlene Liebich[1], Niloufar Nilforoushan[1], Kseniia Mosina[2], Sophia Terres[3], Alexey Chernikov[3], Zdenek Sofer[2], Markus A. Huber[1], Matthias Florian[4], Mack Kira[4], Florian Dirnberger[3], and Rupert Huber[1] — [1]University of Regensburg, Regensburg — [2]University of Chemistry and Technology Prague, Prague — [3]Dresden University of Technology, Dresden — [4]University of Michigan, Ann Arbor

Among van der Waals semiconductors, CrSBr stands out as both its bulk and monolayer forms host tightly bound, quasi-1D excitons in a magnetic environment. Despite the strong attention these quasiparticles have attracted, their lifetimes remained unknown. Terahertz spectroscopy can directly probe the dynamics of all electron-hole pairs, independently of interband selection rules. Yet the corresponding far-field foci substantially exceed the lateral sample dimensions. Here, we combine terahertz polarization spectroscopy with near-field microscopy to study the dynamics of bound and unbound electron-hole pairs in bulk CrSBr and extract the nonequilibrium dielectric function of the monolayer in a model-free manner. Interestingly, the femtosecond decay of paramagnetic excitons in monolayer CrSBr is found to be 30 times shorter than the determined lifetime in bulk material. Our results mark the first direct access to the ultrafast dielectric response of quasi-1D excitons in CrSBr, to advance the development of quantum devices based on ultrathin van der Waals magnets.

Sessions

– Invited Talks, Contributed Talks, and Posters –

KFM 1: (Multi)ferroic States: From Fundamentals to Applications (I)

This focus session explores the intricate properties of (multi)ferroic states, spanning from fundamental understanding to cutting-edge applications. Topics include the design and control of (multi)ferroic states and domain structures at interfaces, domain walls, and in heterostructures. Emphasis will be placed on theoretical models, advanced characterization techniques, and the engineering of emergent properties for use in nano-electronic devices.

Chair: Johanna Nordlander (University of Zurich)

Time: Monday 9:30–11:15 Location: H9

Invited Talk KFM 1.1 Mon 9:30 H9

Epitaxial films of layered perovskite-based ferroelectrics: phase stability, polarization enhancement, and pathways to polar metallicity — •Elzbieta Gradauskaite — Laboratoire Albert Fert, CNRS/Thales, Palaiseau, France

Layered perovskite-based compounds offer a range of unconventional properties stemming from their pronounced unit-cell anisotropy. While most renowned for the superconductivity observed in the Ruddlesden-Popper phases, many of these layered compounds are also ferroelectric and exhibit a sizeable in-plane polarization. In this talk, I will review different classes of layered perovskite-based ferroelectrics and the unique functionalities arising from their structural anisotropy.

In particular, the focus will be placed on Carpy-Galy $A_nB_nO_{3n+2}$ phases characterized by 110-oriented perovskite planes interleaved with additional oxygen layers. These compounds have been proposed as platforms for hosting both metallicity and polar displacements. However, their synthesis challenges have hindered integration into devices. Addressing this, our study focuses on $La_2Ti_2O_7$, an n=4 representative of the Carpy-Galy family, exploring its epitaxial growth and concurrent phase stability. Surprisingly, we find that high tensile strain facilitates a controlled layer-by-layer growth mode, yielding films that are ferroelectric from a single unit cell and exhibit polarization enhanced by a factor of four compared to bulk crystals. Most importantly, we show that metallicity in Carpy-Galy films can be induced via interfacial redox processes with a reactive metal, laying the foundation for exploring them as functional polar metals.

KFM 1.2 Mon 10:00 H9

Tailoring ferroelectric to antipolar phase interconversion in multiferroic thin films — •Bixin Yan[1], Marvin Müller[1], Hyeon Ko[1], Yen-Lin Huang[2,3,4], Haidong Lu[5], Alexei Gruverman[5], Ramamoorthy Ramesh[3,4,6], Marta D. Rossell[7], Manfred Fiebig[1], and Morgan Trassin[1] — [1]ETH Zurich, Switzerland — [2]National Yang Ming Chiao Tung University, Taiwan — [3]University of California, Berkeley, USA. — [4]Lawrence Berkeley Laboratory, USA. — [5]University of Nebraska-Lincoln, USA — [6]Rice University, USA. — [7]Empa, Switzerland.

Inversion-symmetry breaking and the emergence of a polar state are essential for technologically relevant effects such as ferroelectricity and nonlinear optical properties. Hence, the ability to reversibly control the onset of such symmetry breaking can be instrumental in establishing emergent computing schemes. In this work, we present a novel approach for reversible control over the ferroelectric-to-antipolar phase transition in epitaxial multiferroic La-substituted $BiFeO_3$ (LBFO) thin films using local pressure and electric field. Utilizing local stress application via a scanning-probe-microscopy tip, we stabilize the antipolar phase. An electric field restores the original ferroelectric phase. Leveraging these insights, we establish the continuous tuning of the ferroelectric/antipolar phase coexistence and can set the net polarization of LBFO to any desired value between its saturation limits. Finally, using optical second harmonic generation as a non-invasive probe, we control the net polarization of our films in device-compliant capacitor heterostructures.

KFM 1.3 Mon 10:15 H9

Unconventional Polarization Response in Titanite-type Oxides due to Hashed Antiferroelectric Domains — •Hiroki Taniguchi[1], Takumi Watanabe[1], Taro Kuwano[2], Akitoshi Nakano[1], Yukio Sato[3], Manabu Hagiwara[4], Hiroko Yokota[2], and Kazuhiko Deguchi[1] — [1]Department of Physics, Nagoya University, Nagoya, Japan — [2]School of Materials and Chemical Technology, Institute of Science Tokyo, Yokohama, Japan — [3]Research and Education Institute for Semiconductors and Informatics, Kumamoto University, Kumamoto, Japan — [4]Department of Applied Chemistry, Keio University, Yokohama, Japan

$CaTiSiO_5$, a titanite-type oxide, consists of one-dimensional chains of TiO_6 octahedra bridged by SiO_4 tetrahedra and CaO_7 polyhedra. While $CaTiSiO_5$ has potential antiferroelectric properties, these have not been directly verified until now. In this study, we demonstrate the antiferroelectricity of $CaTiSiO_5$ by observing a double $P-E$ hysteresis loop. Moreover, we show an unconventional enhancement of permittivity through partial substitution of Si with Ge, resulting in a doubling of permittivity over a wide temperature range in the antiferroelectric phase. Transmission electron microscopy and second harmonic generation measurements have revealed the formation of microscopic polar regions in the antiferroelectric phase of $CaTi(Si_0.5Ge_0.5)O_5$. Antiphase boundaries are suggested to play a role in the generation of these microscopic polar regions. This study provides new insights into boosting the permittivity of antiferroelectric materials from the perspective of domain engineering.

KFM 1.4 Mon 10:30 H9

Dielectric crossover and its structure-function relationship in pseudo Ruddlesden-Popper-type oxides — •Akitoshi Nakano and Hiroki Taniguchi — Nagoya University, Nagoya, Japan

A phase variation of a pseudo-Roddlesden-Popper-type ferroelectric oxide Li2Sr1-xCax(Nb1-xTax)2O7 is systematically investigated using dielectric measurements, and x-ray diffraction experiments. We find an exotic x-T phase diagram, including paraelectric Cmcm, antiferroelectric Pmcn, and in-plane antiferroelectric and out-of-plane ferroelectric P21cn phases. At low x, we observe large and divergent dielectric anomalies associated with phase transitions from Cmcm to P21cn, whereas it crosses over into a small kink as x increases. Structural analyses reveal an internal distortion, and the rotation of octahedra also strongly depends on x. These results demonstrate the great tunability of dielectric properties in layered perovskite-type oxides by tuning the chemical bonding state in the octahedron.

KFM 1.5 Mon 10:45 H9

Stoichiometry of CoFe2O4 as a key to phase control and improved functional properties of multiferroic BaTiO3-CoFe2O4 bulk composites — •Daniil Lewin, Sofia Shamsulbahrin, Vladimir V. Shvartsman, and Doru C. Lupascu — Institute for Materials Science and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Universitätsstrasse 15, 45141, Essen, Deutschland

Composite multiferroics have been widely studied as materials with a large magnetoelectric effect at room temperature. Barium titanate – cobalt ferrite composites are among the first and most reliable composite systems of such kind. Unfortunately, high-temperature sintering can result in the formation of secondary phases and undesirable chemical modifications, particularly that of barium hexaferrite (BaFe12O19). We present a method to suppress the formation of this phase both by sintering in nitrogen and by changing the stoichiometry of cobalt ferrite to incorporate more cobalt. The latter restricts the diffusion of the iron cations into the barium titanate during sintering. Moreover, composite samples with non-stoichiometric cobalt ferrite show up to a threefold improvement in magnetoelectric coefficient when compared to samples made with stoichiometric cobalt ferrite.

KFM 1.6 Mon 11:00 H9

Stabilization and Characterization of the LiNbO3-type Phase in NiTiO3 Thin Films: Towards Ferroelectricity — •Meriem Chettab[1], Quentin Simon[1], Mustapha Zaghrioui[1], Oleg I. Lebedev[2], Xavier Rocquefelte[3], Gwenhael Duplaix-Rata[3], Richard Retoux[2], and Patrick Laffez[1] — [1]University of Tours, GREMAN, UMR 7347-CNRS, IUT de Blois 15 Rue de la Chocolaterie, 41029 Blois Cedex, France — [2]University of Caen, CRISMAT, UMR 6508 - CNRS, ENSICAEN 6 Bd Maréchal Juin, 14000 Caen, France — [3]Univ Rennes, CNRS, ISCR (Institut des Sciences Chimiques de Rennes) UMR 6226 - F-35000 Rennes, France

Nickel titanate (NiTiO3) exhibits polymorphic structures, including ilmenite (IL), LiNbO3-type (LN), and corundum (CR), with the LN phase being potentially ferroelectric. NiTiO3 thin films were deposited by RF sputtering in an Ar/O2 plasma on Si(100) substrates at temperatures between 400 °C and 650 °C. XRD, Raman spectroscopy, and HRTEM revealed a mixture of IL, LN, and CR

phases at lower temperatures, with pure IL films obtained at 650 ˚C. All films showed a [00W] fiber texture. Post-annealing at 800 ˚C transformed the films into pure IL while preserving the texture. DFT simulations predicted Raman spectra for LN and CR phases, offering insight into phase behavior. This study highlights the potential of the LN phase for ferroelectric applications.

KFM 2: Perovskite and Photovoltaics I (joint session HL/KFM)

Time: Monday 9:30–13:00 Location: H13

See HL 1 for details of this session.

KFM 3: Multiferroics and Magnetoelectric Coupling (joint session MA/KFM)

Time: Monday 9:30–12:15 Location: H16

See MA 2 for details of this session.

KFM 4: (Multi)ferroic States: From Fundamentals to Applications (II)

This focus session explores the intricate properties of (multi)ferroic states, spanning from fundamental understanding to cutting-edge applications. Topics include the design and control of (multi)ferroic states and domain structures at interfaces, domain walls, and in heterostructures. Emphasis will be placed on theoretical models, advanced characterization techniques, and the engineering of emergent properties for use in nano-electronic devices.

Chair: Nives Strkalj (Institute of Physics, Zagreb)

Time: Monday 11:30–13:00 Location: H9

KFM 4.1 Mon 11:30 H9

Oersted Mapping of Current Flow in Ferrorelectric Domain Walls with a Single-spin Magnetometer — •James Dalzell, Conor McCluskey, Marty Gregg, and Amit Kumar — Queen's University Belfast

Nitrogen vacancy (NV) [1] based magnetometers offer outstanding sensitivity for detecting static or dynamic magnetic fields at the nanoscale. As a result, this technique can be employed to evaluate current flow in materials with complex topologies and microstructures through direct measurement of the Oersted fields generated along any current pathways [2]. This creates an opportunity to evaluate fundamental aspects of electron transport in conducting ferroelectric domain walls, employed recently in lab-level ephemeral transistors and neuromorphic domain-wall based computing. We exploit the capability of the NV-AFM system to measure the current density along conducting domain walls in erbium manganite. By integrating high field sensitivity with exceptional spatial resolution, NV-based Oersted mapping has been shown to potentially offer a non-invasive approach to characterizing current flow in ferroelectrics. This advancement paves the way for a deeper understanding of electron transport phenomena in ferroelectric systems with current densities >1x104A/cm2, with improvements capable of being achieved by following pulse probe methods.

[1] Rondin, L. et al, Rep.Prog.Phys. 77 056503,(2014) [2] Tetienne, Jean-Philippe. et al, Sci. Adv. 3, e1602429 (2017). [3] Broadway,D.A, et al, Physics Review Applied 14(2) (2020).

KFM 4.2 Mon 11:45 H9

Transport behavior at domain walls in a depleted ferroelectric semiconductor — •Jiali He[1], Ruben Dragland[1], Leonie Richarz[1], Zewu Yan[2,3], Edith Bourret[3], Gustau Catalan[4,5], and Dennis Meier[1] — [1]NTNU Norwegian University of Science and Technology — [2]ETH Zurich, Switzerland — [3]Lawrence Berkeley National Laboratory, USA — [4]Institut Català de Nanociencia i Nanotecnologia (ICN2), Spain — [5]Institucio Catalana de Recerca i Estudis Avançats (ICREA), Spain

Electronic depletion regions naturally form at metal-semiconductor interface, which enables control of electrical currents in pn-junctions and is widely used in CMOS technology. Here, we expand the research towards ferroelectric domain walls, studying their functional properties under electronic depletion. Using ferroelectric p-type semiconductor $ErMnO_3$ as the model system, we deposit W electrodes and systematically investigate changes in the local transport behavior as the material is thinned down to the sub-10 nm range. Combined imaging experiments in terms of scanning electron microscopy (SEM) and scanning probe microscopy (SPM) reveal that for a critical thickness, t_c, a steplike drop occurs in the electronic conduction, which we associate with the width of the depletion region at the W/$ErMnO_3$ interface. Interestingly, ferroelectric domain walls within the depletion region exhibit qualitatively different transport behavior than in the p-type regions. Our results give new insight into the physics of domain walls and demonstrate additional opportunities for controlling their electronic responses, which is of interest for domain-wall-based electronics.

KFM 4.3 Mon 12:00 H9

Domain and domain wall conductance in the vicinity of metal-semiconductor contacts — •Ruben Dragland[1], Leonie Richarz[1], Ingvild Hansen[1], Manuel Zahn[1], Jiali He[1], Zewu Yan[2], Edith Bourret[2], Mario Hentschel[3], and Dennis Meier[1] — [1]NTNU Norwegian University of Science and Technology, Trondheim, Norway — [2]Lawrence Berkeley National Laboratory, Berkeley, CA,USA — [3]University of Stuttgart, Stuttgart, Germany

Ferroelectric domain walls hold promise as functional quasi-2D systems and are intensively studied as key electronic elements for next-generation nanotechnology. Despite their outstanding application potential, however, little is known about the performance in actual device geometries and the contact phenomena that co-determine the current injection. In this study, we perform a systematic analysis of the local transport behavior of the ferroelectric semiconductor $ErMnO_3$ in the vicinity of different electrode materials. By applying electron beam lithography and evaporation, we design metal-semiconductor contacts with varying work functions and investigate the impact on the electronic conductance and respective barrier formation. Combining conductive atomic force microscopy (cAFM), Kelvin probe force microscopy (KPFM), as well as mesoscopic probe techniques, we correlate the band bending at the interface to the measured conductance of domains and domain walls. Our results are relevant for the integration of ferroelectric domain walls and the understanding of the nanoscale physics at metal-semiconductor junctions in ferroelectrics in general.

KFM 4.4 Mon 12:15 H9

Exploring ferroelectric oxides for reservoir computing — •Yan Meng Chong[1], Atreya Majumdar[2], Ingvild Hansen[1], Karin Everschor-Sitte[2], and Dennis Meier[1] — [1]Department of Materials Science and Engineering, Norwegian University of Science and Technology (NTNU), Trondheim, Norway — [2]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Duisburg, Germany

In reservoir computing, input data is mapped into higher dimensional space, translating non-linear problems into linearly solvable ones. In general, any physical system that possesses non-linearity, complexity, short-term or fading memory, and reproducibility can serve as reservoir. Here, we investigate ferroelectric semiconductor $ErMnO_3$ as potential candidate material for reservoir computing. We show that the system displays pronounced non-linear changes in photocurrent under varying light intensity. The response can be tuned by changing the metal-semiconductor contacts (Schottky or Ohmic) used for readout, determining the timescale on which photocurrents vanish after illumination. This relaxation behavior in the OFF state gives the fading memory. We perform training for recognition on variations in the output (photocurrent), which allows for reconstructing the sequential input (light pulses). Interestingly, both ferroelectric domains and domain walls can be used as reservoirs with characteristic photocurrent signals, giving new opportunities for downscaling or enhancing the complexity of physical reservoirs.

KFM 4.5 Mon 12:30 H9

Coupling between small polarons and ferroelectricity in $BaTiO_3$ — •Darin Joseph[1] and Cesare Franchini[1,2] — [1]Dipartimento di Fisica e Astronomia, Università di Bologna, 40127 Bologna, Italy — [2]University of Vienna, Faculty of Physics, Center for Computational Materials Science, Vienna, Austria

Ferroelectric properties of materials are found to be modified upon polaron formation. In this study, we investigate the formation of electron and hole small polarons in the prototypical ferroelectric material barium titanate ($BaTiO_3$), with a focus on their interaction with ferroelectric distortive fields. To accurately describe the ferroelectric phase in $BaTiO_3$, we employ the HSE06 hybrid functional, which addresses the limitations of conventional DFT and DFT+U models, providing a more precise depiction of both ferroelectric and polaronic behaviours. Our analysis spans three structural phases of $BaTiO_3$: cubic, tetragonal, and rhombohedral. We uncover a phase-dependent trend in electron polaron stability, which progressively increases across the structural phases, peaking in the rhombohedral phase due to the constructive coupling between the polaron and ferroelectric phonon fields. In contrast, hole polarons exhibit a stability pattern largely unaffected by the phase transitions. Furthermore, we observe that polaron self-trapping significantly alters the local ferroelectric distortive pattern, which propagates to neighbouring sites but has a minimal effect on the long-range macroscopic spontaneous polarization. Charge trapping is also associated with localized spin formation, opening new possibilities for enhanced functionalities in multiferroic materials.

KFM 4.6 Mon 12:45 H9

Energy barriers for small electron polaron hopping in bismuth ferrite from first principles — •Sabine Körbel[1,2] and Harini Priyanka Shanmugasundharam Swaminathan[2,3] — [1]Institute of Physical Chemistry, Friedrich Schiller University Jena — [2]Institute of Condensed Matter Theory and Optics, Friedrich Schiller University, Fürstengraben 1, 07743 Jena, Germany — [3]University of Applied Sciences Jena, Carl-Zeiss-Promenade 2, 07745 Jena, Germany

Evidence from first-principles calculations indicates that excess electrons in $BiFeO_3$ form small polarons with energy levels deep inside the electronic band gap. Hence, *n*-type transport could occur by hopping of small electron polarons rather than by band-like transport. Here, by means of first-principles calculations, small electron polaron hopping in $BiFeO_3$ was investigated. Both bulk $BiFeO_3$ and a typical ferroelectric domain wall, the neutral 71° domain wall, were considered. The latter was included to account for experimental observations of currents that appear to be localized within domain-wall planes. The object of this study is to shed light on the intrinsic *n*-type conduction mechanism in rhombohedral $BiFeO_3$ and the role of the ferroelectric domain walls in electrical conductivity. Based on the computed energy barriers for small electron polaron hopping, the intrinsic *n*-type mobility in bulk $BiFeO_3$ and at 71° domain walls is estimated.

Simulation study of beam splitting of vortex electron beams inside crystals — •Christian Bick and Dorothee Hüser — Physikalisch-Technische Bundesanstalt, Braunschweig, Germany

Electron vortex beams have long been of interest for applications such as electron magnetic circular dichroism (EMCD), beam shaping and nanoparticle manipulation. They have attracted new attention with the recent development of an orbital angular momentum (OAM) sorter, theoretical developments in analysis of momentum transfer and as a quantum logic gate.

When propagating through a crystal, the vortex electron wave interacts with the asymmetric crystal potential, causing the wave to split into intensity centres around atomic columns, called channelling. This behaviour gives rise to a total OAM that can no longer be described by an integer vortex quantum number. In this simulation-based study we track the behaviour of electron beams inside different crystals. We show an in-depth analysis of the wave phase propagating through the crystal for different materials, focussing our research on beam splitting into intensity centres with their own OAM. This study was carried out using multislice simulations of the electron beam propagation through the crystal potential together with vector analysis to identify the local vortex centres.

KFM 5.2 Mon 15:15 H9

Single-phase valence band structure of a $Ge_{0.85}Si_{0.15}$ Crystal - Insights by momentum microscopy — •Andreas Fuhrberg[1], Pia M. Düring[1], Kevin Gradwohl[2], Olena Fedchenko[3], Yaryna Lytvynenko[3], Olena Tkach[3], Sergii Chernov[4], Christoph Schlueter[4], Gerd Schönhense[3], Hans-Joachim Elmers[3], and Martina Müller[1] — [1]Universität Konstanz — [2]IKZ, Berlin — [3]Universität Mainz — [4]DESY, Hamburg

Spin qubits are the fundamental components of quantum computing devices. Planar $Ge/Ge_{1-x}Si_x$ heterostructure qubits have proven to be advantageous for upscaling and fabrication. The Si concentration of the $Ge_{1-x}Si_x$ buffer has been shown to be an important parameter for tuning the valence band (VB) electronic structure of $Ge/Ge_{1-x}Si_x$ qubits by homoepitaxial strain, which is difficult to realize experimentally without phase separation.

Synchrotron-based hard X-ray momentum microscopy (MM) is used to study the VB electronic structure of a $Ge_{0.85}Si_{0.15}$ single crystal grown to provide well-defined small strain. Our MM experiments reveal an individual VB structure of $Ge_{0.85}Si_{0.15}$, that is clearly distinct from Si and Ge references. The shape of the heavy/light hole band and split-off band follows that of Ge, but with lower binding energies at Γ, X and L points and a reduced split-off band gap, hence no evidence for phase separation. Additional diffraction experiments, supported by Bloch wave calculations, show that the Si atoms occupy Ge lattice positions within the crystal. This result is very promising for the future experimental realization of single-phase GeSi-based spin qubits.

KFM 5.3 Mon 15:30 H9

Miniature device for in situ application of strain inside Scanning Tunnelling Microscope — •Uladzislau Mikhailau, Rashed Alhamli, and Peter Wahl — University of St Andrews, St Andrews, United Kingdom

Recent studies [1] have demonstrated that uniaxial strain significantly affects the macroscopic properties of strongly correlated electron systems. Scanning Tunneling Microscopy (STM) is a powerful technique for investigating changes in the electronic structure induced by such lattice deformation. Controlled application of strain adds an additional degree of freedom to tune, e.g., Van Hove singularities in quantum materials [2] and thereby control their ground state. To perform such studies, we have developed a specialized STM sample holder capable of applying strain at cryogenic temperatures and in high magnetic fields. Strain is applied by bending a plate beneath the sample, with stress adjustable up to the crystal's buckling limit. The device allows for the application of uniaxial or biaxial strain, depending on the configuration of the bending plate. With these capabilities, the system provides a versatile platform for exploring strain-induced phenomena through a powerful combination of atomic scale imaging in strain tuning.

Defects in Materials: Limitations of the Trapping Model - the Influence of Corrupt Components in Positron Lifetime Spectra — •Torsten Staab, Dominik Boras, and Danny Petschke — LCTM / IFB, Department of Chemistry, University of Wuerzburg, Roentgenring 11, D-97070 Wuerzburg, Germany

Since the early days of positron lifetime spectroscopy, the meaningful decomposition of lifetime spectra into two or more components has been highly disputed. This procedure is extremely important to extract correct defect densities. Since the procedure of fitting several exponential decays folded by a mimicked instrumental resolution function to extract positron lifetimes and intensities is an "ill-posed problem", the goodness of the fit relies heavily on the quality of the recorded data. In the past there have been several simulation attempts to create and decompose spectra into two or three components (lifetimes and intensities). However, those attempts always assumed "ideal", random number Monte Carlo simulated data. Hence, the following data analysis has been fairly straight forward. By our recently developed digital twin of a positron lifetime spectrometer we could clearly see the strong influence of back scattered and corrupted coincidences on the lifetime spectrum. Unfortunately, those events cannot be removed by physically filtering digitised pulses. Changes in the geometry of the set-up lead to much more realistic bulk positron lifetimes of light materials (Mg, Al, Si) in accordance with calculations and correct decompositions in accordance with the trapping model, while the efficiency is reduced by 95%.

KFM 5.5 Mon 16:15 H9

Investigating Mechanical Properties of Porous Materials with Brillouin Light Scattering and Machine-Learned Force Fields — •Florian Lindner[1], Nina Strasser[1], Sandro Wieser[2], Egbert Zojer[1], and Caterina Czibula[3] — [1]Institute of Solid State Physics, Graz University of Technology, Austria — [2]Institute of Materials Chemistry, TU Wien, Austria — [3]Institute of Bioproducts and Paper Technology, Graz University of Technology, Austria

Brillouin light scattering (BLS) is based on the inelastic scattering of light from thermally activated gigahertz acoustic phonons. As the later are correlated with a material's elastic tensor via the Christoffel dispersion the elastic constants can be determined in a non-destructive and contactless manner. From these, practically relevant mechanical properties like the Young's modulus can be derived. In this contribution we show, how BLS can be used to study the mechanical properties of metal organic frameworks (MOFs), a class of porous crystalline materials with a plethora of possible applications. The measured mechanical properties are then compared to state-of-the-art dispersion corrected DFT calculations and simulations based on machine learned interatomic potentials [1], which speed up simulations by many orders of magnitude [2]. This allows to additionally determine thermoelastic properties of MOFs at elevated temperatures, which in combination with suitable experiments will portray the full potential of the used methodology.

TwinPALS: A Digital Twin for Laboratory-Based Positron Annihilation Lifetime Spectroscopy — •Dominik Boras — Julius-Maximilians University, Würzburg, Germany

In this work, we present a comprehensive digital twin of a laboratory-based Positron Annihilation Lifetime Spectroscopy (PALS) system. This digital twin is capable of simulating entire spectra while incorporating all effects of the hardware used in the PALS system, as well as varying source strengths. For the first time, it is possible to visualize unwanted components within the lifetime spectrum and assess their impact on the interpretability of these spectra. The digital twin enables the identification of issues within one's own setup and allows for digital testing of potential optimizations before physical implementation. The TwinPALS system is designed in a modular structure. The first module is responsible for constructing the digital world, taking into account the influences of position, dimension, and the materials used. The second module combines a customized version of the DLTPulsgenerator with software to process the information from the first module, incorporating considerations of radioactivity, positron lifetime, and PMT blurring. The third and final module serves to visualize the output stream from the second module, utilizing the DDRS4PALS software. In summary, this system is a modular digital twin that can be adapted to the requirements of the system being simulated.

Invited Talk KFM 8.1 Tue 9:30 H9

Ferrolectric bubble currents — •Hugo Aramberri — Luxembourg Institute of Science and Technology

Frustrated ferroelectrics can display complex dipole textures displaying rich physical phenomena. In ferroelectric/paraelectric superlattices, built-in or applied electric fields can result in bubble domains of nanometric size akin to magnetic skyrmions.

Our atomistic calculations predict these bubbles to be quasiparticles that display thermally activated Brownian motion, enabling the conceptualization of some of the all-electric unconventional computing schemes that have already been developed for their magnetic counterparts.

However, control over the bubble motion, which is key for many potential technological applications, is still essentially lacking. In this talk I will present our latest ideas to induce bubble currents. Our simulations indicate that bubbles can be accelerated up to at least 50 m/s in the absence of electric currents, which holds the promise of a competitive alternative to magnetic skyrmion-based technologies.

KFM 8.2 Tue 10:00 H9

Exploring (110) epitaxial strain in ferroelectric films and superlattices — •Lan-Tien Hsu, Chien-Wen Hao, and Anna Grünebohm — Interdisciplinary Centre for Advanced Materials Simulation (ICAMS) and Center for Interface-Dominated High Performance Materials (ZGH), Ruhr-University Bochum, Universitätsstr. 150, 44801 Bochum, Germany

Epitaxial strain in low-symmetry orientations significantly influences the phase stability and polarization orientation of ferroelectric thin films and superlattices,[1] offering the potential for advanced nanoelectronic applications.[2] We

explore the phase diagrams of (110)-oriented $BaTiO_3$, $KNbO_3$, and superlattice $BaTiO_3/SrTiO_3$ under strain and electric field using ab initio based coarse-grained molecular dynamics.[3] We reveal how the epitaxial (110) strain affects polarization, transition temperatures, and the emergence of topological features. Complex multidomain structures appear, particularly in superlattices due to depolarization fields.

KFM 8.3 Tue 10:15 H9

Vortex dynamics in incommensurate 2D and 3D bulk ferroics — •Aaron Merlin Müller[1], Quintin Meier[2], Andrés Cano[2], Manfred Fiebig[1], and Thomas Lottermoser[1] — [1]Department of Materials, ETH Zurich, 8093 Zurich, Switzerland — [2]Univ. Grenoble Alpes, CNRS, Grenoble INP, Institut Néel, 25 Rue des Martyrs, 38042, Grenoble, France

We reveal that in 3D ferroic systems with competing incommensurate stripe phases of ferroic order and topological defects in the form of vortex lines, these vortex lines exhibit fundamentally different dynamics compared to their 2D counterparts. We show that loops of vortex lines can exhibit long relaxation times resulting from their positioning at saddle points in the energy landscape. Using phase-field simulations and analytical approaches, we demonstrate that the distinctive relaxation behavior in 3D systems arises from the interplay between dimensionality and the energy landscape of incommensurate stripe phases. Many ferroically ordered materials, such as hexagonal manganites and planar spin systems, feature periodic order parameters that support such competing orders. Hence, we employ a general model of two-component ferroic order whose findings generalize to all ferroic systems that exhibit vortices and incommensurate stripe phases. We analyze the dynamics of topological defects during the transition from inhomogeneous order without stripes to an incommensurate stripe phase in both 2D and 3D systems. We conclude by discussing the critical role of dimensionality in shaping the system's energy landscape and broader implications for ferroic systems.

KFM 8.4 Tue 10:30 H9

Valence bond solid states in IrTe2 — •Sergey Artyukhin[1], Francesco Foggetti[2], and Daniel Khomskii[3] — [1]Italian Institute of Technology — [2]Uppsala University — [3]University of Cologne

We study the phase diagram of IrTe2. This material manifests, below 280 K, a sequence of states where some Ir-Ir bonds shorten forming dimers, which results in a striped order. Ab-initio calculations suggest that the total energy is decreasing approximately linearly with the dimer fraction for the previously observed phases. The phonon density of states is shifted to higher frequencies, into the dimer-localized phonon bands. We describe the interactions between dimers using the force constant matrix from ab-initio calculations, and find features, similar to those driving striped orders in orthorhombic manganites. The strain texture is consistent with the observed striped orders. A simplified model, based on dimer energetics and phonon entropy, is formulated and the phase diagram of IrTe2 is obtained.

KFM 8.5 Tue 10:45 H9

Ultrafast control of interlayer ferroelectricity in h-BN — •Pooja Rani and Dominik M. Juraschek — Eindhoven University of Technology, Eindhoven, Netherlands

Two-dimensional ferroelectrics in nanoscale systems have received increasing interest due to their potential applications in the areas of memory storage and sensing. Among these materials, bilayer hexagonal boron nitride (h-BN) is a promising material for studying interlayer ferroelectricity because of its out-of-plane polarization that can be reversed by changing the stacking order. Using the first-principles simulation, we investigate the theoretical aspects of ultrafast control of interlayer ferroelectricity in h-BN to determine how the polarization can switch by light-induced shear motion. This phononic sliding mechanism would be particularly favourable since it provides a potential way of modulating ferroelectric behaviour at the nanoscale, creating an entirely novel path for the development of tuneable ferroelectric materials. Specifically, we focus on the excitation of the high-energy degenerate modes by an ultrashort mid-infrared pulse coupled to the low-energy shear and out-of-plane modes. Our findings suggest that the shear modes can significantly enhance the ferroelectric polarisation in h-BN, and we explore whether the ferroelectricity can be switched through this mechanism. With this, observing how out-of-plane modes affect ferroelectric polarization or interlayer ferroelectricity in h-BN will be interesting.

KFM 8.6 Tue 11:00 H9

Phonon-induced multiferroicity — Carolina Paiva[1], Michael Fechner[2], and •Dominik Juraschek[3] — [1]Tel Aviv University, Tel Aviv, Israel — [2]Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — [3]Eindhoven University of Technology, Eindhoven, Netherlands

A well-known mechanism for multiferroicity involves an electric polarization arising from a spatially varying magnetization, such as a spin spiral or cycloid. Reciprocally, optical phonons can produce a magnetization through a temporally varying electric polarization, an effect also known as dynamical multiferroicity. Here, we go a step beyond this phenomenon and describe a mechanism by which both a ferroelectric polarization and a magnetization can be created in nonpolar, nonmagnetic materials. Using a combination of phenomenological modeling and first-principles calculations, we demonstrate that a ferroelectric polarization, a magnetization, or both simultaneously can be transiently induced by an ultrashort laser pulse upon linearly, circularly, or elliptically polarized excitation of phonon modes in γ-$LiBO_2$. The direction and magnitude of the multiferroic polarization can be controlled by the chirality of the laser pulse and the phonon modes, offering a pathway for controlling multiferroicity and magnetoelectricity on ultrafast timescales.

KFM 8.7 Tue 11:15 H9

Ferroelectric and piezoelectric molecular crystals: From database mining to computational design — •Kristian Berland[1], Elin D. Sødahl[1], Seyedmojtaba Seyedraofi[1], Carl H Gørbitz[2], Ola Nilsen[2], Manjunath Balagopalan[2], Maxi Litterst[3], Martijn Kemerink[3], Jesus Carrete[4], Georg K. H. Madsen[4], Graeme Day[5], and Julian Walker[6] — [1]NMBU, Ås, Norway — [2]U. Oslo, Norway — [3]Heidelberg University, Heidelberg, Germany — [4]TU Wien, Vienna, Austria — [5]U. Southampton, UK — [6]NTNU, Trondheim, Norway

Molecular crystals offer great potential for piezoelectric and ferroelectric devices due to their vast chemical tuneability. Plastic (ionic) crystals hosts malleable orientationally disordered mesophases and their rotational freedom can yield high shear piezoelectric response[CrystGrowthDes. 2023, 23, 729]. Proton-transfer Making new crystals with desired properties, however, is not straightforward. We devised new tools to screen the Cambridge Structural Database (CSD), identifying 60 new potential ferroelectrics[PhysRevMaterials 8, 054413, 2024; CrystGrowthDes 2023, 23, 8607], 5 of which we have experimentally confirmed. Crystal structure prediction (CSP) was used to design additional ones [arXiv:2410.20481]. Finally, machine-learning force fields (MLFFs) can provide insight into dynamical properties of mesopphases [arXiv:2410.15746]. With these examples, I will argue how computational methods can be pivotal in advancing the field of small-molecule ferroic crystals.

KFM 9: (Multi)ferroic States: From Fundamentals to Applications (IV)

This focus session explores the intricate properties of (multi)ferroic states, spanning from fundamental understanding to cutting-edge applications. Topics include the design and control of (multi)ferroic states and domain structures at interfaces, domain walls, and in heterostructures. Emphasis will be placed on theoretical models, advanced characterization techniques, and the engineering of emergent properties for use in nano-electronic devices.

KFM 9.1 Tue 11:45 H9

Investigating Self-Heating of Conducting Domain Walls Using Scanning Thermal Microscopy — •Lindsey Lynch, Kristina Holsgrove, Marty Gregg, and Raymond McQuaid — Queen's University Belfast

Domain walls (DWs) in ferroelectrics are an exciting category of reconfigurable functional interface, with properties that can differ from bulk. Lab-level transistor [1] and memristor devices [2] have been demonstrated, where functionality is derived entirely from electrically conducting DWs. Here, the DWs perform the equivalent role of conductive nanofilaments in metal-oxide resistive switching memories. While self-heating and local temperature are important factors in oxygen-vacancy based resistive switching [2,3], much less is known about the intrinsic self-heating of domain walls and its influence on device operation. We have been investigating the electrothermal properties of LiNbO3 domain wall devices using Scanning Thermal Microscopy (SThM). This involves using the scanning probe as a mobile nanoscale temperature sensor to map self-heating in

domain wall devices. Temperature hot spots on the order of 10K are detected and PFM corroborates that their origin is due to sub-surface domain wall heating. Since heat spreading occurs within the surrounding ferroelectric film and top electrode, the measured surface temperatures likely represent a lower bound for the intrinsic rise in domain wall temperature.

[1] Nat. Commun. 11, 2811 (2020). [2] Adv. Funct. Mater. 30, 2000109 (2020). [3] Sci. Adv. 8, eabk1514 (2022). [4] ACS Appl. Mater. Interfaces 14, 29025 (2022).

KFM 9.2 Tue 12:00 H9

Thermoelectricity from domain wall formation in a polar metal — •Feifan Wang[1,2], Carl Romao[1], and Manfred Fiebig[1] — [1]Dept. of Materials, ETH Zurich, Switzerland — [2]Institute of Physics, Beijing 100190, China

Simultaneous optimization of the electronic and phononic properties of a thermoelectric material is essential to achieve a high thermoelectric performance. This has been realized in the polar metal compounds by making use of the high configurational entropy, Rashba effect and ferroelectric anharmonicity, tuned at the atomic level. What has been overlooked in this process is the role of macroscopic effect such as the role of domain and domain wall formation in further enhancing the thermoelectric performance. Using GeTe as a prototype, we show that microdomain formation determines the thermal conduction in the polar metal examined by the spatial correlation between the domain structure and the thermal conductivity. In particular, the thermal conductivity decreased by a factor of five following the appearance of the micro-sized antiparallel-aligned domains. Conductive force microscopy shows that the electrical conduction does not change in spite of the presence of domain discontinuities. This is in line with the band gap reduction and the electron–phonon decoupling from density-functional theory calculations. The direct visualization of the association between microdomain formation and thermal/electrical transport suggests the domain and domain wall engineering as a key ingredient in advancing polar-metal-based thermoelectrics.

KFM 9.3 Tue 12:15 H9

Hybrid ferroelectric-antiferroelectric domain walls in noncollinear antipolar oxides — •Ivan N. Ushakov[1], Mats Topstad[1], Muhammad Z. Khalid[1], Niyorjyoti Sharma[2], Christoph Grams[3], Ursula Ludacka[1], Jiali He[1], Kasper A. Hunnestad[1], Mohsen Sadeqi-Moqadam[1], Julia Glaum[1], Sverre M. Selbach[1], Joachim Hemberger[3], Petra Becker[3], Ladislav Bohaty[3], Amit Kumar[2], Antonius T. J. van Helvoort[1], and Dennis Meier[1] — [1]Norwegian University of Science and Technology — [2]Queen's University Belfast — [3]University of Cologne

Antiferroelectrics are emerging as advanced functional materials and are fertile ground for unusual electric effects. For example, they enhance the recoverable energy density in energy storage applications and give rise to large electromechanical responses. In my talk, I will present noncollinearity in dipolar order as an additional degree of freedom, unlocking physical properties that are symmetry-forbidden in classical antiferroelectrics. I will show that noncollinear order of electric dipole moments in $K_3[Nb_3O_6|(BO_3)_2]$ leads to a coexistence of ferroelectric and antiferroelectric behaviors. Besides the double-hysteresis loop observed in antiferroelectrics, a pronounced piezoresponse and electrically switchable domains are observed, separated by atomically sharp and micrometer-long charged domain walls. Similar hybrid ferroelectric-antiferroelectric responses are expected in a wide range of noncollinear systems, giving a new dimension to the research on antiferroelectrics and multifunctional oxides in general.

KFM 9.4 Tue 12:30 H9

Step sintering process on sol-gel synthetized Bi0.5Na0.5TiO3 for enhanced temperature stability of relaxor ferroelectric state and energy storage properties — •Thomas Fourgassie[1], Cécile Autret-Lambert[1,2], and Pierre-Eymeric Janolin[2] — [1]Laboratoire GREMAN, UMR 7347 Université de Tours, CNRS, INSA CVL, Université de Tours UFR Sciences & Techniques, 37200 Tours, France — [2]Laboratoire SPMS, UMR 8580 Université Paris-Saclay, CNRS, CentraleSupélec, 91190 Gif-sur-Yvette, France

With the ever-growing need for energy in our society, researchers are striving to obtain new materials with better energy storage properties capable of replacing current lead-based materials. Among all lead-free materials that have been synthesized, Bi0.5Na0.5TiO3 (BNT) has attracted the attention of many. The main reasons are his high temperature of maximum permittivity called Tm at 320°C, a huge maximum polarization and relaxor ferroelectric properties making his phase transition very diffuse in temperature. However, the good energy storage properties only apply at a temperature higher than the depolarization temperature Td (200°C). Usually, to reduce Td, researchers either make solid solutions with other perovskite ceramics or use donor dopants. Here we show the results we obtained while keeping the pristine BNT phase by optimizing the sol-gel synthesis process used. The BNT exhibits sub-micrometric grain size thanks to a multi-step sintering process lowering Td (around 160°C). This BNT has enhanced relaxor ferroelectric at lower temperatures. Results about donor dopants reducing dielectric losses on this BNT will also be shown.

KFM 9.5 Tue 12:45 H9

Composite quadrupole order in ferroic and multiferroic materials — •Matthias Geilhufe — Department of Physics, Chalmers University of Technology, 412 96 Göteborg, Sweden

The formalism of composite and intertwined orders has been remarkably successful in discussing the complex phase diagrams of strongly correlated materials and high-Tc superconductors. Here, we propose that composite orders are also realized in ferroelectric and ferromagnetic materials when lattice anisotropy is taken into account. This composite order emerges above the ferroic phase transition, and its type is determined by the easy axis of magnetization or polarization, respectively. In multiferroic materials, where polarization and magnetization are coupled, composites of both orders are possible. This formalism of composite orders naturally accounts for magnetoelectric monopole, toroidal, and quadrupole orders. More broadly, composite orders may explain precursor phenomena in incipient ferroic materials, arising at temperatures above the ferroic phase transition and potentially contributing to the characterization of currently hidden orders.

Time: Wednesday 9:30–10:45 Location: H9

Invited Talk KFM 11.1 Wed 9:30 H9

Towards 3D nanoscale chemical mapping with atom probe tomography — •Kasper Hunnestad, Constantinos Hatzoglou, Antonius van Helvoort, and Dennis Meier — Norwegian University of Science and Technology, Trondheim, Norway

The discovery of new physical phenomena in materials is closely linked to the progress in characterization, and is propelled by the ability to observe and study physical processes occurring at the atomic level. Nanoscale structural characterization has been a cornerstone for many discoveries related to ferroic phenomena. Chemical characterization at the atomic level, however, remains a major challenge.

In the first part of this talk, I will present how atom probe tomography (APT) can be incorporated into the toolkit of nanoscale research to study ferroic oxide materials. In the second part of this talk, a special emphasis will be put on various ferroic phenomena, such as ferroelectric domain walls and interface effects. The focus will be on understanding their chemical state and the role of defects in controlling their physical properties.

The presentation will demonstrate that correlations between defect chemistry and ferroic phenomena can be experimentally probed with nanoscale spatial resolution using APT, opening an avenue to obtain a deeper understanding of ferroic materials.

KFM 11.2 Wed 10:00 H9

Tuning of ferroelectric polarization by lattice chemistry — •Ipek Efe[1], Alexander Vogel[2], William S. Huxter[1], Elzbieta Gradauskaite[1], Christian L. Degen[1], Marta D. Rossell[2], Manfred Fiebig[1], and Morgan Trassin[1] — [1]ETH Zurich — [2]Empa, Switzerland

Engineering the lattice chemistry in oxide thin film systems opens up new possibilities for tuning electrostatic boundary conditions beyond the depolarizing-field tuning approaches. Controlling the formation of polarizing charged layers may stabilize highly desired polar textures such as charged domain walls and charge planes, offering great promises for future ultralow-energy-consuming oxide electronics. Here, we demonstrate lattice-chemistry engineering of perovskite oxide ferroelectrics in a heterostructure utilizing Aurivillius-type layering. We insert functional perovskite oxides, including $BiFeO_3$ and $BaTiO_3$, into the layered framework of the Aurivillius phase. By exploiting the characteristic charged interfaces present in the Aurivillius crystal structure and varying the perovskite constituent, we fine-tune the electric-dipole configurations within our composite heterostructures. Using in-situ optical second harmonic generation, we directly resolve the influence of controlled atomic-scale poling of the Aurivillius charged layers on the perovskite constituent. As a result, we achieve new properties while preserving the functionalities of the parent compounds.

KFM 11.3 Wed 10:15 H9

Vector Scanning Electron Microscopy for Domain Imaging in Ferroelectric Polycrystals — •Ellinor Benedikte Anjali Lindström, Ruben Skjelstad Dragland, Jonas Åmli Ingdal, Jan Schultheiss, Jiali He, and Dennis Meier — NTNU Norwegian University of Science and Technology, Norway

Domain imaging in polycrystalline ferroelectrics is challenging due to the non-uniform crystallographic orientation of grains. To gain the full information including the domain polarization and orientational information, imaging techniques such as piezoresponse force microscopy (PFM) and scanning electron microscopy (SEM) are often complimented by electron backscatter diffraction (EBSD) experiments.

Here, we introduce a new SEM-based approach that allows simultaneous mapping of domains and grain orientation information. By performing systematic SEM measurements as a function of the stage rotation angle on the model system $ErMnO_3$, we observe distinct contrast intensity changes within the same grain. Notably, the domain contrasts invert when the stage is rotated by 180°. Complementary PFM and EBSD data confirm that these changes in contrast correlate with both the domain state and the orientation of the polar axis relative to the surface. Our approach offers a contact-free alternative to vector PFM and partially reduces the need for EBSD, giving new opportunities for domain imaging in ferroelectrics.

KFM 11.4 Wed 10:30 H9

Ranges and limits of p-doping in Y:HfO_2 - an electronic structure study by HAXPES — •Oliver Rehm[1], Lutz Baumgarten[2], Florian Wunderwald[3], Andrei Gloskovskii[4], Christoph Schlueter[4], Thomas Mikolajick[3,5], Uwe Schroeder[3], and Martina Müller[4] — [1]Universität Konstanz — [2]Forschungszentrum Jülich — [3]NaMLab, Dresden — [4]DESY, Hamburg — [5]TU Dresden

Ferroelectric HfO_2-based thin films exhibit huge potential for the next generation of nonvolatile memory applications, such as FeRAM or FeFET. However, the application of HfO_2-based thin films as active ferroelectrics (FE) in devices still faces reliability issues like wake-up, imprint, and fatigue. A critical concentration of oxygen vacancies (OVs) determines both the stabilization of a FE phase as well as the breakdown during electrical cycling. For p-doped HfO_2, the electronic limits of OV formation remain an experimentally open question.

We investigated Y:HfO_2 samples synthesized via atomic layer deposition (ALD) with Y doping concentrations from 2.1% to 8.6%. TiN/Y:HfO_2 interfaces are investigated regarding the local chemistry and electronic properties by hard X-ray photoelectron spectroscopy (HAXPES). The Hf 4f core level is analyzed to identify Hf^{3+} components and rigid binding energy (BE) shifts, both of which serve as indicators for OVs. We determine the (unexpected) formation of OVs as a function of Y doping, with the conclusion that Y doping above a threshold limit has a detrimental effect on interface stability, thereby promoting increased OV formation at the interface that finally speeds up fatigue and breakdown.

KFM 12: Holistic Structural and Safety Assessment of Lithium-ion and Post-Lithium Cells and their Materials (Modelling of Battery Materials and Degradation)

The focus session is dedicated to the characterization of microstructure, electrochemical, thermal and safety properties of Lithium-ion and Post-Lithium cells and their individual active and passive materials. This is required to obtain quantitative and reliable data, which are necessary to improve the current understanding in order to design and develop better and safer materials and cells. Potential topics include, but are not limited to electrochemical characterization techniques , thermal characterization techniques, safety testing, development of safer materials and cell designs, thermodynamic modelling of materials, modelling of thermal runaway and propagation.

Time: Wednesday 11:00–12:45 Location: H9

Invited Talk KFM 12.1 Wed 11:00 H9

Model-assisted Insight into Degradation of Li-Ion Batteries during Thermal Abuse — •Ulrike Krewer, Leon Schmidt, and Jorge Valenzuela — Karlsruhe Institute of Technology, Institute for Applied Materials -Electrochemical Technologies, Karlsruhe, Germany

The electrolyte in Li-ion batteries is inherently thermodynamically instable; this leads to formation of the solid-electrolyte interphase and capacity loss. Exposing batteries to high temperatures above ca. 60°C accelerates interphase growth, but also leads to its dissolution and renewed formation. If the related exothermic heat is not sufficiently fast removed, this leads to self-heating and a thermal runaway of the cell. This talk uses modelling to give a deep insight into the processes and properties causing self-heating and thermal runaway of Li-ion batteries. A complex interaction of exothermic and endothermic reactions is revealed, and the effects of evaporative cooling [1], conditions during battery manufacturing and battery age. [2] Gas analysis with online electrochemical mass spectrometry aids in identifying the network and further sensitivities. [3]

KFM 12.2 Wed 11:30 H9

Computational investigation of lignin based anode ma- terials for Li- and post-Li ion batteries* — •Jafar Azizi[1], Holger Euchner[2], and Axel Gross[1] — [1]Institute of Theoretical Chemistry, Ulm University, 89069 Ulm, Germany — [2]2 Institute of Physical and Theoretical Chemistry, Tübingen University, 72076 Tübingen, Ger- many

Post-lithium ion batteries have gained a lot of attention as a promising energy storage technology for large-scale grid applications due to their high energy density and low cost. Hard Carbon is one of the most promising anode materials, but is still associated with some performance problems. It is anticipated that improved hard carbon-based cells with a higher energy density and better electrochemical performance will be highly interesting in electrochemical energy storage. Hence, in this work, we propose a novel anode material based on the structure of lignin, one of the most prevalent biomass materials. Based on ab initio molecular dynamic (AIMD) simulations and density functional theory (DFT) calculations we study the formation of lignin-based hard carbon at different temperatures which results show a promising new amorphous structure. We find a noticeable structure stability, and higher energy capacity (AMC_n, $n < 6$) compared to the usual graphite system.

KFM 12.3 Wed 11:45 H9

Stability Enhancement of Cubic $CsSnCl_3$ as Solid Electrolyte - A Computational Approach — •Johannes Döhn[1], Martin Uhrin[2], and Axel Gross[1,3] — [1]Institute of Theoretical Chemistry, Ulm University, Germany — [2]Multidisciplinary Institute in Artificial Intelligence, Université Grenoble Alpes, France — [3]Helmholtz Institute Ulm, Germany

For the transition towards renewable energy systems, efficient and reliable technologies for energy storage are needed. Batteries are one of the most widely used

storage devices, but current technology based on the transfer of Li-ions faces several challenges including their dependence on critical materials with respect to both, scarcity and toxicity.

In our contribution, we will present atomic-scale investigations of potential future battery materials carried out using a combination of density functional theory (DFT) and machine learning interatomic potential (MLIP) calculations. We employed a high-throughput approach in order to evaluate potential dopants for the well-known Cl-ion conductor $CsSnCl_3$; a solid electrolyte material for chloride ion batteries (CIBs) which is ascribed the capability to fully exploit the potential of this alternative battery type. The investigated dopants where chosen based on a dual doping strategy: Cation doping aims at enhancing the stability of the material while the introduction of mobile species, i.e., Cl vacancies/interstitials, balances the formal charge of the system and aims at improving the Cl-ion conductivity.

KFM 12.4 Wed 12:00 H9

Stability of $MgSc_2Se_4$ Surfaces — •Sebastian Utz[1] and Axel Gross[1,2] — [1]Ulm University, Ulm, Germany — [2]Helmholtz Institute Ulm, Ulm, Germany

Magnesium metal anodes are a promising material for post-lithium battery systems because of their high theoretical gravimetric energy density. One issue that hinders their application is the low ionic conductivity of many magnesium electrolytes. One of the few electrolytes that show good magnesium ion conductivity is the solid electrolyte $MgSc_2Se_4$ with a spinel structure. While the structural and diffusion properties of the bulk material are already well understood, its surfaces and interfaces are hardly explored. To shed some light on the surface properties of this solid-state electrolyte, first principles calculations within the framework of periodic density functional theory were conducted. The stability of low index {100} and high index {222} surfaces are being compared. Additionally, common structural features of the different surfaces that may lead to a stabilisation or destabilisation will be explored.

KFM 12.5 Wed 12:15 H9

Hybrid Interfaces in Focus – Decoding the Berlinite Surface with a Synergetic NMR-DFT Approach — •Javier Valenzuela Reina[1], Vera Barysch[2], Simone Köcher[2,1], and Christoph Scheurer[1,2] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Institute of Energy Technologies (IET-1), Forschungszentrum Jülich GmbH

One of the milestones in the development of the next generation of high-performance lithium batteries is the understanding and improvement of hybrid electrolytes and their interfaces. Nuclear magnetic resonance (NMR) spectroscopy is a non-destructive, powerful technique for unraveling the intricate interface structure and ion dynamics in these materials.

We exploit the synergies between NMR experiments and density-functional theory (DFT) simulations for investigating Berlinite ($AlPO_4$) as a model for the surface of the well-known solid ion conductor $Li_{1+x}Al_xTi_{2-x}P_3O_{12}$ with $0 \leq x \leq 1$ (LATP), a promising candidate for a hybrid electrolyte. By supporting surface-selective NMR techniques such as cross-polarization (CP) and transfer of populations in double resonance (TRAPDOR) on $AlPO_4$ powder with DFT calculations of NMR observables, we study multiple surface models, infere structural characteristics of the sample, and study its interactions with water as well as organic molecules. We demonstrate that the joint experimental-theoretical approach holds future potential for understanding and improving materials whose performance relies on the properties and behavior of complex organic/ceramic interfaces.

KFM 12.6 Wed 12:30 H9

Pits and Traps in the Impedance Analysis of Ionic Conductors — •Janis K. Eckhardt — Center for Materials Research (ZfM), Justus Liebig University, Giessen D-35392, Germany

The development of innovative electrochemical storage systems, such as solid-state batteries, is critical for achieving climate neutrality and sustainability goals. Several hurdles must be overcome before such technologies are ready for the market. Impedance spectroscopy is a powerful method for characterizing the electrical transport properties of new materials and for monitoring systems in operation. Although it is an older measurement technique, the interpretation of data for inhomogeneous solid-state systems lacks established concepts for reliable results. Therefore, we use 3D electrical network models for spatially-resolved transport simulations and systematic investigation of the influence of sample microstructure and solid-solid interface morphology. The material-specific transport quantities derived from 1D models (e.g., brick layer model) sometimes exhibit inaccuracies of several orders of magnitude. In addition, the impedance response of the system exhibits geometric signatures that cannot be adequately represented in physically motivated circuit models, e.g., current constriction phenomena.

KFM 13: Holistic Structural and Safety Assessment of Lithium-ion and Post-Lithium Cells and their Materials (Experimental Characterisation and Safety Testing)

The focus session is dedicated to the characterization of microstructure, electrochemical, thermal and safety properties of Lithium-ion and Post-Lithium cells and their individual active and passive materials. This is required to obtain quantitative and reliable data, which are necessary to improve the current understanding in order to design and develop better and safer materials and cells. Potential topics include, but are not limited to electrochemical characterization techniques , thermal characterization techniques, safety testing, development of safer materials and cell designs, thermodynamic modelling of materials, modelling of thermal runaway and propagation.

Chair: Philipp Finster (Karlsruhe Institute of Technology)

KFM 13.1 Wed 15:00 H9

Are Li-ion batteries safe for 2nd-life applications? - The case of aged cells with SEI growth — •Thomas Waldmann[1,2,4], Gabriela G. Gerosa[1], Jihed Ayari[2,3], Abdelaziz A. Abd-El-Latif[1], Philipp Moosmann[1,5], Max Feinauer[1], Olaf Böse[1], Markus Hölzle[1], and Margret Wohlfahrt-Mehrens[1,2] — [1]Zentrum für Sonnenenergie- und Wasserstoff-Forschung Baden-Württemberg (ZSW), Helmholtzstrasse 8, Ulm, 89081, Germany — [2]Helmholtz Institute Ulm (HIU), Helmholtzstrasse 11, Ulm, 89081, Germany — [3]Karlsruhe Institute of Technology (KIT), Karlsruhe, 76021, Germany — [4]Institute of Surface Chemistry and Catalysis, Ulm University, Albert-Einstein-Allee 47, 89081 Ulm, Germany — [5]Porsche AG, Porschestrasse 911, 71287 Weissach, Germany

Re-using aged Li-ion batteries in 2nd-life applications can increase sustainability. However, there is a lack of knowledge on the safety of aged cells with regard to the underlying aging mechanisms. Room temperature and high temperature aging often lead to growth of the solid electrolyte interphase (SEI) on the surface of graphite or Si/graphite anodes as commonly observed by post-mortem analysis of Li-ion battery cells with physico-chemical analysis methods. We show results on the influence of aging of commercial Li-ion cells in the 1st-life on safety in 2nd-life. Our safety tests (ARC, nail penetration, overcharge, overdischarge) reproducibly show similar or better safety levels for cells with SEI growth in contrast to aged cells with the different mechanism of lithium plating. Possibilities are pointed out to avoid critical mechanisms and for early detection of unsafe behavior.

KFM 13.2 Wed 15:15 H9

Diffraction computed tomography for non-destructive analysis of li-ion batteries — •Vladislav Kochetov — Heinz Maier-Leibnitz-Zentrum (MLZ), Technische Universität München, Lichtenbergstr. 1, 85748 Garching, Germany

This contribution discusses the application of Diffraction Computed Tomography (DCT), including both X-ray and neutron probes, as a powerful method for non-destructive structural analysis in materials science. DCT uses a pencil-beam scanning technique to yield the reconstructed images of internal structure and chemical gradients of materials, extending the traditional imaging approaches. A notable application of DCT is in the study of commercial lithium-ion batteries, where it has been used to resolve inhomogeneities in lithium distribution and structural evolution during cycling. We apply DCT to various commercial battery types, specifically focusing on cylindrical cells with different diameters, featuring diverse chemistries such as NCA, NMC, and graphite anodes. By employing high-resolution DCT, we map lithiation distributions and investigate electrode degradation mechanisms, providing key insights in battery performance and aging. The efficiency of the method, state-of-the-art resolution capabilities, and technique's extension to neutrons are discussed.

KFM 13.3 Wed 15:30 H9

Optical, structural and electrochemical properties of re-synthesized Graphite powder for Anode battery application — •Slaheddine Jabri[1], Anna Rollin[2], Sukanya Sukanya[3], René Wilhelm[2], Michael Kurrat[3], Uta Schlickum[1], and Markus Etzkorn[1] — [1]Technische Universität Braunschweig, Institute of Applied Physics, Meldensohn Straße2, 38106 Braunschweig, Germany — [2]Mendelssohnstraße 2 — [3]Technische Universität Clausthal, Institute of Organic Chemistry, Leibnitzstraße 6, 38678 Clausthal-Zellerfeld, Germany

By focusing on preserving the components of Li-Ion battery material through cheaper and envi-ronmental friendly methods, recycling process could introduce scavenged impurities into resyn-thesized material and modify its structural and morphological properties. In this work, we investi-gate the optical, structural and electrochemical properties of recycled Graphite compared to the new material. Our findings reveal that a proper recycling process can remove the Solid Electrolyte Interphase (SEI) layer, which is of significant importance in battery performance. The analysis showed that proper cleaning can significant reduce the amounts of organic and inorganic impuri-ties in the graphite, leading to an improvement in material quality. As a result, the battery perfor-mance can even be enhanced by 89% after 200 charge-discharge cycles compared to the commer-cial base material, demonstrating the potential of recycling methods for improving battery life and efficiency.

KFM 13.4 Wed 15:45 H9

Facilitating Sodium-Ion Diffusion in Fe-Doped Co3O4 for High-Rate Performance — •Yonghuan Fu, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Due to its high theoretical capacity, cobalt oxide (Co3O4) has attracted attention to sodium-ion battery (SIB) anodes. However, its low conductivity and poor rate performance have limited its practical application. This work proposes a co-precipitation doping strategy to synthesize iron-doped Co3O4 nanoparticles (FexCo3-xO4 NPs). Both experimental and theoretical results confirm that iron (Fe) doping at octahedral sites within spinel structures is a critical factor in enhancing rate performance. The decreased band gap and enlarged ion transport spacing originate in Fe doping. This effectively facilitates the electron and Na+ transport during discharge/charge processes, delivering an impressive rate capability of 402.9 mA h g-1 at 3 A g-1. The FexCo3-xO4 NPs demonstrate remarkable cycling stability. They maintain a high specific capacity of 786.2 mA h g-1 even after 500 cycles at 0.5 A g-1, with no noticeable capacity fading. This work provides valuable insights into the functional design of high-rate electrodes, offering a promising approach to addressing the critical challenges faced by sodium anodes.

KFM 13.5 Wed 16:00 H9

Reversible Structural Evolution of 3D Vanadium Sulfide Anodes in Sodium-Ion Battery Applications — •Osamah Ali Fayyadh, Yulian Dong, Huaping Zhao, and Yong Lei — Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau

Sodium-ion batteries (SIBs) are a promising alternative to lithium-ion batteries due to sodium's abundance and wide distribution. However, SIBs face challenges such as low capacity, poor cycling, and sluggish ion diffusion, due to the large ionic radius of Na+. Thus, extensive research has focused on advanced anode materials, among which vanadium sulfides (VSx) have gained significant attention due to their large interlayer spacing, high theoretical capacities, and versatile electrochemical mechanisms. However,VSx suffer from mechanical pulverization, severe volume changes, and limiting their practical application. Here, we demonstrate a 3D micro/nanostructured VSx anode fabricated, achieving a remarkable reversible capacity of 961.4 mAh g-1 after 1500 cycles at 2 A g-1. The sodiation-driven reconfiguration of 3D-VSx into a stable structure mitigates volume changes, enhances ion diffusion, and improves structural stability.[1] The sodiation-driven reconfiguration enhances ion diffusion, mitigates volume changes, and stabilizes the structure. Electrochemical studies and density functional theory calculations reveal significantly improved Na+ storage capabilities, offering a pioneering strategy for developing high-performance SIB anodes with excellent capacity and stability. [1] Y. Dong, Y. Lei et.al. Adv. Energy Mater. 2023, 13, 2204324.

KFM 13.6 Wed 16:15 H9

synergizing nickel (II) oxide-based catalyst for sodium-carbon dioxide battery — •Tzu-Chin Huang, Changfan Xu, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Na-CO2 battery is a novel and environmentally friendly green energy device. Conceptually, it demonstrates excellent capabilities. However, during the operation of batteries, undecomposed discharge products, sodium carbonate, accumulate continuously, which is highly insulating, thermodynamically stable, and difficult to decompose. This increases the ohmic resistance within the battery, resulting in high charging potential and excessive polarization, which leads to serious side reactions, such as the decomposition of the electrolyte and cathode material, reducing the battery's reversibility. Herein three Ni oxide-based catalysts, NiO, NiCoO, and CuNiCoO, attached to carbon clothe cathode were synthesized and employed in Na-CO2 batteries. Electrochemical testing demonstrated that CuNiCoO exhibits the best battery stability and long-term performance. This superior performance is driven by the ability of CuNiCoO catalyst to effectively promote the generation and decomposition of discharge products. Cyclic voltammetry (CV) analysis revealed strong redox peaks, underscoring the outstanding catalytic activity of CuNiCoO catalyst. Furthermore, XRD and Raman characterizations confirmed this by showing the appearance and gradual disappearance of sodium carbonate peaks during charge and discharge cycles, indicating remarkable reversibility.

KFM 13.7 Wed 16:30 H9

A Solar Battolyzer Approach: On-Demand Hydrogen Production and Energy Storage in a 2D Niobium-Tungstate Material — Yang Wang[1], •Yu-Te Chan[2], Takayoshi OshimaViola[1], Viola Duppel[1], Sebastian Bette[1], Kathrin Küster[1], Andreas Gouder[1], Christoph Scheurer[2,3], and Bettina Lotsch[1,4] — [1]Max Planck Institute for Solid State Research, Stuttgart — [2]Fritz-Haber-Institut der MPG, Berlin — [3]IEK-9 Forschungszentrum, Jülich — [4]Ludwig-Maximilians-Universität, Munich

In the quest to overcome the limitations of solar intermittency, materials that can simultaneously capture and store solar energy offer promising avenues for clean energy solutions. Here, we introduce the 2D niobium-tungstate $TBA^{+}NbWO_{6}^{-}$ as a novel solution capable of harnessing light energy and storing it either for direct grid integration or as fuel through on-demand hydrogen production. This dual-functionality is central to the emerging concept of "battolyzers," devices that combine battery and electrolyzer capabilities to provide both energy storage and fuel generation. Exposure to light triggers ion intercalation and stable polaron formation within the material, reducing resistance and allowing electron storage for extended durations. Introducing Pt as the catalyst allows the stored electrons to be released to generate hydrogen, demonstrating the material's capability for efficient, on-demand solar energy conversion. Our findings on optoionic processes in $NbWO_6$ lay the groundwork for future solar battolyzers, bridging solar energy storage and hydrogen fuel generation in a single system. [1] Y. Wang et al., J. Am. Chem. Soc. **146**, 25467 (2024)

KFM 14: Poster

KFM 14.1 Wed 17:00 P1

Stability of Machine-Learned Interatomic Potentials in Molecular Dynamics Simulations for Organic Semiconductors and Metal-Organic Frameworks — •Martin Tritthart and Egbert Zojer — Institute for Solid State Physics, Graz, Austria

Organic semiconductors (OSCs) and metal-organic frameworks (MOFs) are two classes of materials that have garnered significant interest in materials science. To optimize their performance, it is crucial to understand the physical properties of these crystalline polymer materials, such as heat transport and mechanical stability. This understanding can lead to improvements in properties like thermal stability. Molecular dynamics (MD) simulations are commonly used for this purpose, as they are orders of magnitude less computationally expensive than first-principles calculations. While machine learning interatomic potentials (MLIPs) are much faster than ab initio methods, they approximate the true potential energy surface, which can result in significant errors for atomic configurations outside the training data space. Such shortcomings lead to incorrect predictions of forces and energies in MD simulations, potentially causing molecular instability during simulations. To address this issue and improve the robustness of MLIPs, a reliable estimation of their uncertainty is necessary. This enables the identification of uncertain structures, which can then be incorporated into the training set to enhance accuracy. With this iterative approach, larger and more complex molecules can be simulated with relatively efficient computational effort.

KFM 14.2 Wed 17:00 P1

Assessment of new cocrystals of amphotericin B and miltefosine (leishmanicidal pharmaceuticals) via powder X-ray diffraction analysis. — •Memoona Bibi, muhammad Iqbal Choudhary, and Sammer Yousuf — H.E.J. Research Institute of Chemistry, ICCBS, University of Karachi, Pakistan.

Cocrystals and other cutting-edge technologies offer substantial opportunities for patents that present multiple strategies for managing the life cycle of existing and novel drugs. The creation of cocrystals by employing suitable coformers represents a valuable approach toward stability, enhancement, and bio availability of pharmaceutical medications. The focal point of current study was cocrystallization of well-known commercially available anti-leishmanial drugs i.e. Amphotericin B and Miltefosine. Multiple cocrystals of amphotericin B and miltefosine were successfully synthesized. To prepare the co-crystals neat grinding method via mixer mill was applied. The characterization was conducted through powder X-ray diffraction revealing unique crystallinity and significant variation in 2θ values of cocrystals. DSC/TGA, UV, FTIR and melting point were also proceeded for further evaluation. The solubility studies of amphotericin B at pH 6.8, 7.4 and in distilled H2O in comparison with their co-crystals revealed promising results. Invitro testing of all co-crystals against L. major, L. donovani, and L. tropica demonstrated potent anti-leishmanial activity in comparison with reference standard drugs i.e. amphotericin B and miltefosine. However, cytotoxicity results revealed none of them exhibited cytotoxic effect against MTT (3T3) cell line.

KFM 14.3 Wed 17:00 P1

High-temperature properties of $LiNbO_3$ and $LiTaO_3$ — •Eva Westenferlder Gil, Felix Bernhardt, and Simone Sanna — Institut für Theoretische Physik and Center for Materials Research, Justus-Liebig-Universität Gießen, Germany

Lithium niobate (LN) and lithium tantalate (LT) are ferroelectric crystals with a wide range of applications, extending from piezoelectric sensors [1] to integrated photonics [2]. Both, LN and LT, undergo a phase transition towards a paraelectric (PE) phase at around 1400K and 870K, respectively. Since devices employing LN and LT as functional materials are often operated at high temperatures, extensive research has been conducted in order to describe the materials high-temperature properties [3,4]. Here, we show that the high symmetry PE structure for both LN and LT is energetically favoured, which is in contrast to previously suggested models representing the PE phase as a superposition of differently oriented ferroelectric phases [5]. The electronic band structures indicate that both crystals remain electronic insulators in the PE phase. Furthermore, we provide thermal expansion coefficients and elastic constants, calculated from machine-learned potentials. Our results show a good agreement to recent experimental measurements.

KFM 14.4 Wed 17:00 P1

Optimizing pre-annealing growth for obtaining pattern fidelity of highly ordered GaAs nanowires — •Juliane Koch[1], Jiajia Qiu[2], Chris Bohlemann[1], David Ostheimer[1], Peter Kleinschmidt[1], Huaping Zhao[2], Yong Lei[2], and Thomas Hannappel[1] — [1]TU Ilmenau, Institute for Physics, Fundamentals of Energy Materials, Ilmenau, Germany — [2]TU Ilmenau, Institute for Physics, Applied Nanophysics, Ilmenau, Germany

Bottom-up grown III-V semiconductor nanowires (NWs) offer significant potential for advanced electrical and optoelectronic device applications. This study presents a fabrication strategy for highly ordered GaAs NW arrays by combining a non-lithographic nanostructuring technique with metalorganic vapor phase epitaxy (MOVPE). Uniform Au nano-disk arrays, created using anodic aluminum oxide templates, act as catalysts for the subsequent NW growth. The special fabrication process of the Au nano-disks prevents undesired substrate imprinting, which leads to a different behavior than previously utilized methods, namely to an Au particle diffusion during the MOVPE process. The nucleation duration, optimized in terms of the Au particle volume, is crucial for maintaining array uniformity. A short nucleation period fails to anchor particles, resulting in undesired diffusion. To resolve this, pre-annealing nucleation is extended to initiate III-V growth of a pedestal structure that secures the array's highly ordered geometry. A detailed analysis of MOVPE sub-processes supports the development of a refined growth model.

KFM 14.5 Wed 17:00 P1

Synthesis, Properties, and Phase Transitions analysis of ferroelectric TMCM-MnCl3 hybrid halide — •Chithra Kandappanthodi, Sobhan Fathabad, Doru C.Lupascu, and Vladimir V.Shvartsman — Institute for material science, Essen, Germany

Organic-inorganic hybrid halides have gained significant attention in material science due to their environmentally friendly, cost-effective fabrication and exceptional piezoelectric or optoelectronic properties. In this study, we synthesized trimethyl chloromethyl ammonium manganese trichloride (TMCM-MnCl3) and Fe-doped TMCM-MnCl3 crystals. We demonstrate that TMCM-MnCl3 exhibits a monoclinic crystal structure at room temperature, which transforms into a hexagonal structure upon heating, as confirmed by temperature-dependent x-ray diffraction. The phase transitions at 408 K for TMCM-MnCl3 and 404 K for TMCM-Mn0.95Fe0.05Cl3 were further corroborated by differential scanning calorimetry. The step-like anomaly in the temperature dependence of dielectric permittivity observed in TMCM-MnCl3 indicates an improper ferroelectric transition. Piezoresponse force microscopy revealed regular ferroelectric domains. Additionally, Raman spectroscopy identify the vibrational modes of the crystal. Through UV-vis spectroscopy, we observed that the bandgap is tunable through moderate Fe doping. This comprehensive characterization highlights the potential of TMCM-MnCl3 for advanced applications.

KFM 14.6 Wed 17:00 P1

Investigation of hydrogen diffusion in $LiNbO_3$ and $LiTaO_3$ from density-functional theory — •Christa Fink and Simone Sanna — Institute for Theoretical Physics, Justus-Liebig-University, Heinrich-Buff-Ring 16, 35392 Giessen, Germany

Hydrogen is always present in $LiNbO_3$ and $LiTaO_3$ crystals. Therefore, the lattice locations of hydrogen within the crystal as well as its diffusion and mobility have been a matter of research for many years. While the energetically most favorable positions of hydrogen within the atomic lattice have been investigated intensely, there exist less investigations of diffusion paths and energy barriers. To fully understand the diffusion of hydrogen in $LiNbO_3$, $LiTaO_3$ and their solid solutions, we calculate energy barriers and three-dimensional minimum energy paths for hydrogen diffusion using the nudged elastic band method based on density-functional theory as implemented in VASP [1, 2]. Starting from the energetically most favorable position, we calculate minimum energy paths through the crystal towards the next equivalent position. We extend our calculations from the stoichiometric material to crystals with Lithium vacancies, which are the most common defects in LN and LT, for a better comparison to experimental results [3, 4].

KFM 14.7 Wed 17:00 P1

Epitaxial Growth of Phase-Pure LiNbO3 Thin Films on LiTaO3 by Pulsed Laser Deposition (PLD) — •Hyeyeon Cho, Steffen Ganschow, René Bararugurika, and Jutta Schwarzkopf — Leibniz-Institut für Kristallzüchtung, Max-Born-Straße 2, 12489 Berlin, Germany

Lithium niobate (LiNbO3) is a widely used material in electro-optical and electroacoustic devices due to its outstanding ferroelectric, piezoelectric, electro-optical, and nonlinear optical properties. Thin-film LiNbO3 offers significant advantages, including component miniaturization, broader bandwidths at higher frequencies, and reduced operational voltages. However, achieving these benefits requires the growth of phase-pure films with excellent crystalline quality, stoichiometric composition, and low surface roughness. Pulsed Laser Deposition (PLD) is a reliable method for growing LiNbO3 thin films, providing precise control over stoichiometry and the ability to produce high-quality epitaxial layers. However, high volatility of Li2O at enhanced temperatures during deposition often leads to Li-poor secondary phase formation. In this study, we investigated the effects of various deposition parameters to optimize the growth of phase-pure LiNbO3 films on LiTaO3. Key parameters, including substrate temperature, oxygen partial pressure, laser fluence, laser frequency, and target-substrate distance, were systematically varied. We also explored the use of lithium-rich targets to address lithium loss at high temperatures. X-ray diffraction (XRD) and atomic force microscopy (AFM) analyses confirmed the epitaxial growth of high-quality films with smooth surfaces.

KFM 14.8 Wed 17:00 P1

PALS of Hot-Rolled and Subsequently T4-Treated AlCuMgAg — •Lucian Mathes[1], Leon Heinl[2], Andreas Wagner[3], Maik Butterling[3], and Christoph Hugenschmidt[1] — [1]Heinz Maier-Leibnitz Zentrum, TU München — [2]Institute of Casting Research, Montanuniversität Leoben, Austria — [3]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Radiation Physics

Positron annihilation lifetime spectroscopy (PALS) is a unique tool for studying the concentration and types of open-volume defects. We performed depth-resolved PALS to investigate such defects and the properties of precipitates in differently (heat) treated AlCuMgAg samples. Alloying AlCu with Ag has been shown to leverage the formation of the so-called $\Omega(Al_2Cu)$ phase, known for its high strength and thermal stability. We present PALS measurements of Al-4Cu-0.3Mg-0.7Ag containing Ω phase precipitation after hot-rolling and subsequent T4-treatment. Our findings showcase the high thermal stability of the Ω phase and that positron annihilation studies help in understading and optimizing the process of strength hardening AlCuMgAg alloys.

KFM 14.9 Wed 17:00 P1

Polycrystalline FeS as ultra-fast charging sodium-ion battery anode — •Zidong Wang and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Fast charging is considered a key development trend and a competitive advantage for sodium-ion battery (SIB) technology. Achieving fast-charging SIBs relies on developing electrode materials that combine high rate performance with excellent capacity retention. While iron sulfide, known for its high theoretical capacity, has shown potential, its fast-charging performance is hindered by poor rate performance due to volume expansion. Conventional approaches, such as compositing with carbon materials or adjusting the cut-off voltage, come with drawbacks*carbon composites reduce volumetric energy density, while cut-off voltage adjustments compromise capacity. Neither approach aligns well with practical applications. To address these challenges, we capitalized on the crystalline structural diversity of iron sulfides and successfully synthesized carbon-free polymorphic FeS. This material achieves high rate performance without relying on carbon additives or cut-off voltage adjustments, marking a significant step forward in SIB development. Impressively, anode demonstrates the best rate performance reported to date at an exceptionally high current density, achieving 236 mAh/g at 50 A/g.

KFM 14.10 Wed 17:00 P1

Nanoscale Thermal Expansion in Crystals Probed by Echo-Resolved Terahertz Spectroscopy — •Nicolas Sylvester Beermann, Andreas Gebauer, Wentao Zhang, Tomoki Hiraoka, Savio Fabretti, Hassan Hafez, and Dmitry Turchinovich — Fakultät für Physik, Universität Bielefeld, Universitätsstraße 25, 33615 Bielefeld, Germany

Thermal expansion of solids is a ubiquitous phenomenon in condensed matter physics [1]. However, its observation was out of limits for terahertz time-domain spectroscopy (THz-TDS) due to the relatively long sub-millimeter wavelength of THz radiation. To address this, we introduce echo-resolved THz spectroscopy (ERTS) that utilizes THz main and echo pulses in time-domain measurements to simultaneously determine frequency-dependent complex optical constants and material thickness [2]. By numerically solving complex transcendental transmission equations, ERTS allows for sample thickness measurements with deep-subwavelength precision on the order of $\lambda/1000$. We used the ERTS to analyze the THz-TDS data of magnesium oxide, sapphire, and gallium arsenide crystals measured in the temperature range of 10-300 K. The thermal expansion of the crystals on a sub-micrometer scale was measured, and the simple phonon model was applied to determine the material-specific Grüneisen parameters.

KFM 14.11 Wed 17:00 P1

Two Photon Absorption in Lithium niobate tantalate inspected via z-scan technique — •Niklas Dömer[1], Anton Pfannstiel[1], Steffen Ganschow[2], Mike Pionteck[2], Simone Sanna[3], and Mirco Imlau[1] — [1]Inst. Physics, Barbarastr. 7, Osnabrück Univ., Germany — [2]Leibniz-Institut für Kristallzüchtung, Max-Born-Straße 2, Berlin, Germany — [3]Center for Materials Research J.L.-Univ. Giessen, Heinrich-Buff-Ring 16 , Giessen, Germany

The knowledge of the nonlinear optical properties of polar oxide crystals, such as the two-photon absorption (TPA) coefficient β in lithium niobate (LN), is of significant importance for tailoring technological applications in (integrated) photonics. Here, we present the results of our studies on the dispersion properties $\beta(\lambda)$, i.e. the imaginary part of the third-order susceptibility $\chi^{(3)}_{\mathrm{Im}}$, in the model system lithium niobate tantalate (LNT, $LiNb_xTa_{1-x}O_3$ with $0 \leq x \leq 1$). Experimentally, an open-aperture z-scan experiment pumped by fs-pulses in the spectral range of 330 - 600 nm from an optical parametric amplifier (OPA) is used. The obtained results are compared with literature data for LN ($x = 0$) and LT ($x = 1$) and the non-vegard-like behavior of the band gap. In extension, the study is applied for the determination of the density of states with LN as an example. We discuss our findings with ab-initio calculations for LN and in the framework of transient absorption phenomena induced by TPA in LNT [N. Dömer, J. Koelmann *et al.*, New J. Phys. **26** (2024) 083027]. This work is financially supported by the DFG (projects IM37/13-1, GA 2403/7-1 and SA1948/3-1 within the research unit FOR 5044, ID: 426703838).

KFM 14.12 Wed 17:00 P1

Refractive Indices and Birefringence Behavior of Lithium Niobate Tantalate Solid Solutions — •Tobias Hehemann[1], Anton Pfannstiel[1], Steffen Ganschow[2], and Mirco Imlau[1] — [1]Institute of Physics, Osnabrueck University — [2]Leibniz-Institut für Kristallzüchtung, IKZ, Berlin

Lithium niobate tantalate solid solutions (LNT, $LiNb_{1-x}Ta_xO_3$ with $0 \leq x \leq 1$) exhibit a wide range of linear and nonlinear optical properties, that can be tuned by composition x. A unique feature is the disappearance of the birefringence Δn for x between $0.93 \leq x \leq 0.96$ [Wood *et al.*, J. Phys.: Condens. Matter **20** 235237 (2008)] enabling customized applications in photonics. While the dispersive behavior of the ordinary $n_o(\lambda)$ and extra-ordinary $n_e(\lambda)$ indices are well documented for the edge compositions $LiNbO_3$ (LN, x=0) and $LiTaO_3$ (LT, x=1), there remains a lack for LNT along x. In particular, nearly nothing is known about the structural relation between the index of refraction and composition. We here present our results for the dispersion behavior of n_o and n_e of LNT for several x, measured using an interferometric technique at specific wavelengths in the visible spectrum. Our data allow for a more detailed inspection of the birefringence $\Delta n = n_o - n_e$ of LNT at room temperature. The obtained data are analyzed and discussed in the context of existing literature, providing deeper insights into the relation between structure and optical properties of LNT. Funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) – Project-ID 426703838 (IM 37/13-1, GA 2403/7-1 of the FOR 5044).

KFM 14.13 Wed 17:00 P1

Surface and near-surface positron annihilation spectroscopy at very low positron energy — •Maximilian Suhr[1], Lucian Mathes[1,2], Vassily V. Burwitz[2], Danny R. Russell[1], and Christoph Hugenschmidt[1] — [1]Heinz Maier-Leibnitz Zentrum, TU München — [2]School of Natural Sciences, Physics Department, TU München

Positron annihilation spectroscopy is a highly sensitive tool for defect characterization in solids. We present the Setup for Low-Energy Positron Experiments (SLOPE) at TUM. This monoenergetic positron beam is realized via a high-activity ^{22}Na source, a W moderator, a sophisticated electromagnetic beam guidance system and two high purity Ge detectors. Our instrument features a state-of-the-art range of implantation energy, namely 3 eV to 40 keV, enabling bulk measurements as well as investigations of surfaces. With three different measurements we showcase the versatile applications of SLOPE: a full range depth profile of a W monocrystal, coincidence ratio curves of H-loaded Ni, and a valley-to-peak (positronium formation) scan of Cu and Kapton at very low implantation energies.

KFM 14.14 Wed 17:00 P1

Microscopic view into non-volatile resistive switching in Au/Prussian blue/Ag layer stacks — •Mohammed Fayis Kalady[1], Daniel Wolf[1], Michael Pohlitz[2], Christian Mueller[2], and Axel Lubk[1,3] — [1]Leibniz Institute for Solid State and Materials Research (IFW) Dresden, Helmholtzstraße 20, 01069 Dresden — [2]University of Applied Sciences Zwickau, 08056 Zwickau, Germany — [3]Institute of Solid State and Materials Physics, TU Dresden, Haeckelstraße 3, 01069 Dresden, Germany

Due to their distinct electrochemical properties, Prussian blue (PB) and its analogs (PBA) are emerging materials for memristor applications. This study uses transmission electron microscopy (TEM) techniques to explore resistive switching in PB-based memristors. Our work will utilize in-situ TEM to apply electrical bias, correlating nanoscale structural changes with electronic properties and employing methods like high-resolution TEM, electron energy-loss spectroscopy, and energy-filtered TEM. By changing the polarity of the external voltage, the Au/PB(A)/Ag is switched between two stable resistance states, the high resistance state and the low resistance state. The experimental technique seeks to elucidate the resistive switching mechanism, contributing to designing efficient and reliable memristor devices for advanced memory applications.

KFM 14.15 Wed 17:00 P1

Phonon Properties of perovskite oxides and halides — •Mwanaidi Mauwa Namisi and Benyao Sun — Interdisciplinary Centre for Advanced Materials Simulation (ICAMS), Ruhr-University Bochum, Germany

Perovskite materials, which have proven useful in many areas including photovoltaics and ferroelectrics [1], are highly structurally unstable due to the dynamic nature of the metal-halide octahedra and cation off-centering. It is therefore evident that understanding the vibrational properties of these materials is crucial in their modelling and applications. Meanwhile, there is considerable research value in developing high-performance, environmentally friendly, and health-conscious lead-free ferroelectric materials [2, 3]. Particularly, BaTiO3- based lead-free perovskites have become a major research focus. However, systematic studies on BaTiO3-based superlattices combined with BaSnO3 remain scarce. Here, we investigate the phonon properties of perovskite oxides (BaSnO3) and halides (CsPbX3, (X=I, Br, Cl) and discuss the distortions, do- main structures by the anharmonicity. We also investigate how these instabilities couple with an external field and discuss the differences in the ferroelectric nature between perovskite oxides and halides. Additionally, structural optimization was performed on BaTiO3/BaSnO3 superlattices with varying Sn concentration gradients. References (1) Bergenti, I. Appl. Phys. 2022, 55, 033001. (2) Grunebohm, A., Madhura, M., Claude, E. Appl. Phys. Lett. 2015, 107,102901. (3) Grunebohm, A.; Marathe, M. Phys. Rev. Mat. 2020, 4,4417.

KFM 14.16 Wed 17:00 P1

Thermodynamics of Barium Boranate using DFT — •Markus Mehlhorn[1], Konrad Burkmann[2], Angus Demmer[2], Jakob Kraus[1], Franziska Habermann[2], Jürgen Seidel[2], Klaus Bohmhammel[2], Jens Kortus[1], and Florian Mertens[2] — [1]Institut für Theoretische Physik, TU Bergakademie Freiberg — [2]Institut für Physikalische Chemie, TU Bergakademie Freiberg

Materials containing high hydrogen content are interesting candidates for solid hydrogen storage. However, there are well-known fundamental challenges to address like the reversibility of the (de)-hydrogenation and sufficiently fast kinetics for these processes before possible applications. Here we present results on thermodynamic properties of $Ba(BH_4)_2$. Unfortunately, the isobaric heat capacity function of this material is not accessible experimentally. $Ba(BH_4)_2$ could not be synthesized in sufficient purity. Therefore we attempt to fill this gap by means of computations based on density functional theory using the PBEsol functional. The quasi harmonic approximation is used to describe volume expansion due to thermal effects assuming that for each fixed volume the harmonic approximation can be employed. For each volume the phonon density of states has been calculated via density functional perturbation theory. This procedure allows to calculate the Gibbs free energy and therefore gives access to thermodynamic properties like entropy and isobaric heat capacity. Comparing the heat capacity to other metal boranates, which have been synthesized and measured, one finds very similar behavior.

KFM 14.17 Wed 17:00 P1

3D nanoscale chemical analysis of WO_3 using Atom Probe Tomography — •Katharina Wolk[1], Jack T. Eckstein[2], Kasper A. Hunnestad[1], Constantinos A. Hatzoglou[1], Gustau Catalán[3], Ekhard K. H. Salje[2], Julia Glaum[1], and Dennis Meier[1] — [1]Department of Materials Science and Engineering, NTNU Norwegian University of Science and Technology, Trondheim, Norway — [2]Department of Earth Sciences, University of Cambridge, Cambridge, UK — [3]Institut Català de Nanociència i Nanotecnologia, Campus Universitat Autònoma de Barcelona, Bellaterra, Catalonia

The functional properties of oxides are closely linked to their chemical composition. The transition metal oxide WO_3 is notable for its structural versatility and unusual physical properties, such as the formation of superconducting ferroelastic domain walls. To understand the relation between local variations in chemical composition and material properties, we apply atom probe tomography (APT). APT offers compositional mapping in 3D with sub-nanometer spatial resolution and chemical sensitivity of 100 ppm. Using scanning electron microscopy, we image the ferroelastic domain structure in WO_3 single crystals and extract specimens from different regions of interest with a focused ion beam for the APT analysis. Based on 3D reconstructions, we investigate site-specific variations in chemical composition, exploring the oxidation state and potential formation of oxygen defects. Varying experimental APT parameters, such as laser energy, enables insights into optimizing compositional accuracy.

KFM 14.18 Wed 17:00 P1

Isovalent exchange of Al, Mg and Zr in strontium hexagallate (SrGa12O19) — •Finn. H. Bietz[1], Ch. Rhode[2], and S. Sanna[1,3] — [1]Institut für Theoretische Physik, Justus-Liebig-Universität Gießen, Gießen 35392, Germany — [2]Leibniz Institut für Kristallzüchtung, Max Born Straße 2, 12489 Berlin — [3]Center for Materials Research (ZfM), Justus Liebig University Gießen, Gießen 35392, Germany

$SrGa_{12}O_{19}$ can be used as a substrate for the growth of barium hexaferrite, a ferrimagnetic and quantum paraelectric material. The lattice parameters of $SrGa_{12}O_{19}$ can be adjusted by substitution of Ga by Al or Mg and Zr respectively for lattice-matched growth and strain engineering of barium hexaferrite. A microscopic picture of the doping mechanisms and their effect on the lattice parameters is missing.

In this contribution, we report on first-principles calculations performed to determine the lattice site of Al, Mg and Zr atoms in the $SrGa_{12}O_{19}$ structure, and support corresponding experiments performed at the IKZ in Berlin. Thereby the defect formation energies of Al, Mg and Zr atoms incorporated in the dilute limit at different lattice sites were calculated within density functional theory.

The atomistic models reveal that Mg populates the so called $Ga^{(3)}$ position, Al prefers the $Ga^{(1)}$ site, but also populates the $Ga^{(4)}$ and $Ga^{(5)}$ sites, and that the Zr is incorporated the $Ga^{(4)}$ site. While the results are in very good agreement with the experimental results in the case of Mg and Al doping, the experimentally determined lattice site of Zr differs from the theoretical predictions, suggesting the formation of defect complexes or co-doping related effects.

KFM 14.19 Wed 17:00 P1

Tailoring ferroelectric and magnetic properties in polycrystalline hexagonal manganites — Jonas Åmli Ingdal[1], •Ruben Skjelstad Dragland[1], Catalina Salazar[2], Ellinor Benedikte Anjali Lindström[1], Katharina Wolk[1], Tino Gottschall[2], Jiali He[1], Jan Schultheiss[1], and Dennis Meier[1] — [1]Norwegian University of Science and Technology (NTNU), Trondheim, Norway — [2]Dresden High Magnetic Field Laboratory, Dresden, Germany

Rare-earth hexagonal manganites are extensively studied for their diverse physical phenomena, including tunable electronic behavior at ferroelectric domain walls, pronounced magnetocaloric effects, and significant thermal Hall conductivity, which make them highly interesting as advanced multi-functional materials. The intriguing effects arise from the unique combination of improper ferroelectricity and antiferromagnetic ordering, which are intimately linked to the rare-earth ions.

In this study, we systematically investigate the role of the rare-earth atom on the ferroelectric and magnetic properties of h-RMnO3. Polycrystalline samples with R = Tm, Er, Y, Ho, and Dy are synthesized using a solid-state approach. Ferroelectric order is verified across all compositions using piezoresponse force microscopy. Direct adiabatic temperature change measurements in the cryogenic regime reveal a strong correlation between rare-earth magnetism and the caloric response. Our results highlight the possibility to tune both the ferroelectric order and magnetic responses, offering new opportunities for optimizing the system for envisioned applications.

KFM 14.20 Wed 17:00 P1

Characterizing Domains in GeTe using Atom Probe Tomography — •Jan Köttgen[1], Maria Häser[1], Lina Jäckering[1], Julian Pries[1], Carl-Friedrich Schön[1], Pengfei Cao[3], Yuan Yu[1], and Matthias Wuttig[1,2] — [1]I. Institute of Physics (IA), RWTH Aachen University, Germany — [2]Peter Grünberg Institute - JARA-Institute Energy Efficient Information Technology (PGI-10), Jülich, Germany — [3]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons ER-C, Forschungszentrum Jülich GmbH, 52425 Jülich, Germany

The thermoelectric GeTe undergoes a solid-state phase transition from its cubic to its rhombohedral crystal structure when cooled from the melt to room temperature. This phase transformation results in domains. In this study a polycrystalline GeTe bulk sample was investigated using atom probe tomography (APT), which enables the determination of the sample*s stoichiometry with atomic resolution. The APT analysis revealed that different domains evaporate with different probabilities of multiple events (PME). Metavalent solids such as GeTe are known generally to exhibit a high PME in APT. Our experiments additionally show an anisotropy between different grains as observed in the PME. Using a correlative approach involving TEM, EBSD, AFM, SNOM, and DFT calculations, this effect can be attributed to an expansion of the unit cell and a concomitant change of the dielectric function. Our experiments open new avenues for atom probe tomography as a tool to investigate domains and the atomic distribution simultaneously crucial to improve the performance of thermoelectrics.

KFM 14.21 Wed 17:00 P1

Long-lived, pulse-induced transient absorption in $LiNb_{1-x}Ta_xO_3$ ($0 \leq x \leq 1$) solid solutions — •Julian Koelmann[1], Niklas Dömer[1], Mira Hesselink[1], Tobias Hehemann[1], Anton Pfannstiel[1], Felix Sauerwein[1,2], Laura Vittadello[1,2], Steffen Ganschow[3], and Mirco Imlau[1] — [1]Institute of Physics, Barbarastr. 7, Osnabrück University, Osnabrück, Germany — [2]Research Center for Cellular Nanoanalytics, Osnabrueck (CellNanOs), Osnabrueck University, Barbarastr. 11, Osnabrueck, 49076, Germany — [3]Leibniz-Institut für Kristallzüchtung, Max-Born-Straße 2, Berlin, Germany

Femto-/nanosecond pulse-induced, red and near-infrared absorption is studied in $LiNb_{1-x}Ta_xO_3$ (LNT) solid solutions with the aim of studying transient optical nonlinearities associated with optically generated small bound electron polarons. As a result, a long-lived transient absorption is uncovered for LNT which exceeds lifetimes and starting amplitudes of $LiNbO_3$ (LN) and $LiTaO_3$ (LT) by a significant factor. The transients provide strong evidence for an underlying hopping transport mechanism of small bound polarons. All findings are discussed in comparison to the model systems LN and LT within the framework of appropriate band models and optical generation of polarons via two-photon excitation. To explain the significant differences, the simultaneous presence of Nb_{Li}^{5+}, Ta_{Li}^{5+} antisites, and Ta_V^{5+} interstitial defects is assumed for LNT. Funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) * Project-ID 426703838 (IM 37/13-1, GA 2403/7-1 of the FOR 5044).

KFM 14.22 Wed 17:00 P1

Investigation of Pressure-Induced Dimerization in a Pyrene-based Dyad Crystal: Associated with Auxiliary exhibition of thermally Induced Intramolecular Charge Transfer — •Argha Barman[1], Agniezska Huć[2], and Krishnayan Basuroy[1] — [1]DESY, Hamburg, Germany — [2]University of Warsaw, Poland

We present the design and photophysical properties of a D-B-A dyad with N, N-dimethylaniline (DMA) as the electron donor and pyrene (Py) as the acceptor, linked by a -CH=CH- chain. The molecule crystallizes in the triclinic space group P-1, undergoing a reversible phase transition with solvent-dependent transition temperatures (e.g., 200K in cyclohexane, 198K in toluene, 209K in dichloromethane). Structural changes include variations in bond lengths and pyramidalization at the tertiary nitrogen atom, with persistent strong $\pi^{***}\pi$ stacking. Photophysical analysis reveals a small HOMO-LUMO gap (3.06 eV) and temperature-dependent dual fluorescence from locally excited (LE) and intramolecular charge transfer/excimer (ICT) states, with ICT emission diminishing above 220K. Under hydrostatic pressure (0.5*2.0 GPa), the crystals exhibit

piezochromic behavior with emission redshift and quenching. These multifunctional properties make Py-CH=CH-DMA crystals promising for optoelectronics and pressure sensors.

KFM 14.23 Wed 17:00 P1

Multiscale modeling of intergranular corrosion in iron — •Vahid Jamebozorgi[1], Karsten Rasim[2], and Christian Schröder[1] — [1]Bielefeld Institute for Applied Materials Research, Bielefeld University of Applied Sciences and Arts, Interaktion 1, 33619 Bielefeld, Germany — [2]Faculty of Physics, Bielefeld University, Universitätsstraße 4, 33615 Bielefeld, Germany

Localized corrosion, particularly intergranular corrosion, causes a significant economical and structural challenge across various industries. An accurate predictive intergranular corrosion modeling should incorporate atomic scale details, including crystallographic aspects of grain boundaries, and their evolution by time increment. However, the size and scale limitations imposed by atomistic methods hinder the development of realistic models. To overcome these limitations, we propose a novel multiscale modeling approach that combines the detailed atomistic insights provided by reactive molecular dynamics with the computationally tractable finite element method. This multiscale strategy not only ensures the preservation of crucial atomistic details but also enables the simulation of larger spatial and temporal scales, thereby offering a comprehensive view on the microstructure*s evolution during the intergranular corrosion process.

KFM 14.24 Wed 17:00 P1

Theoretical Investigation of [100] Edge Dislocations in Ferroelectric Perovskites — •Himal Wijekoon[1], Pierre Hirel[2], and Anna Grünebohm[1] — [1]Interdisciplinary Center for Advanced Materials Simulation (ICAMS) and Center for Interface-Dominated High-performance Materials (ZGH), Ruhr Universität Bochum, Germany — [2]Université de Lille, CNRS, INRAE, Centrale Lille, UMET, F-59000 Lille, France

Ferroelectric switching is critically influenced by nucleation and pinning at defects within the material. Despite their significance particularly at strained interfaces, the role of dislocations on switching is however largely unexplored. We employ atomistic core-shell potentials [1] to demonstrate that edge dislocations can facilitate domain nucleation and reduce the coercive field. These findings suggest that a more comprehensive understanding of these defects could lead to improved material performance.

[1] M. Sepliarsky, A. Asthagiri, S.R. Phillpot, M.G. Stachiotti, and R.L. Migoni, Atomic-level simulation of ferroelectricity in oxide materials, Current Opinion in Solid State and Materials Science, 9(3):107-113, June 2005.

KFM 14.25 Wed 17:00 P1

Interaction of $NaYF_4$:Yb:Er Upconversion Nanoparticles with ultrashort laser pulses — •Leon Siemon[1], Felix Sauerwein[1], Thibault Mengis[1], Leonie Birk[2], Eike Wienbeuker[2], Markus Haase[2], Jacob Piehler[2], and Mirco Imlau[1] — [1]Institute of Physics, Osnabrück University, Germany — [2]Dept. of Biology/Chemistry, Osnabrück University

Lanthanide-doped upconversion nanoparticles (ucNP), such as $NaYF_4$:Yb:Er, play a significant role for future all-optical interrogation techniques of cellular systems due to their ability to convert infrared excitation light (980 nm/Yb-absorption) into green/red luminescence (520, 540, 660 nm/Er-emission). The corresponding conversion characteristics and energy transfer mechanisms have been studied extensively under continuous-wave illumination - however, so far, the interaction of ucNPs with ultrashort laser pulses has not been studied. We have adressed this question via diffuse fs-pulse reflectometry [C. Kijatkin *et al.*, Photonics **4** (2017) 11] of $NaYF_4$:Yb:Er nanoparticles ($d \approx 18\,nm$) exposed to 980 nm sub-ps-pulses ($\tau_{pulse} > 40$ fs) at peak intensities up to 10^{14}W/m^2 and repetition rates down to 50 Hz. We observe severe differences in the intensity dependence, quantum yield and average power density that are attributed to modified population pathways in the energy diagram if the pulse duration falls below the resonant energy transfer time between Yb and Er ions. The impact of our findings for ucNP applications in cellular environments, particularly to reduce laser-induced cell damages, is discussed. Financial support DFG/RTG2900, 'nanomaterials@biomembranes'.

KFM 14.26 Wed 17:00 P1

Harmonic Nanoparticles: State-of-the-knowledge and future applications — •Moritz Domack[1], Jan Klenen[1], Mirco Imlau[1], and Laura Vittadello[2] — [1]Inst. Physics, Barbarastr. 7, Osnabrück Univ., Germany — [2]Laboratoire SYMME, 7 Chemin de Bellevue, Université Savoie Mont Blanc, France

Harmonic nanoparticles (HNPs) are receiving growing attention in anorganic chemistry, nanophotonics and life sciences due to their potential for upcoming imaging techniques. For instance, HNPs are successfully used as nanophotonics markers in the near-infrared (NIR) bio-optical windows (III) and (IV), so-called NIR-to-NIR imaging [L. Vittadello *et al.*, Nanomaterials **11** (2021) 3193], as well as for destruction free in-vivo imaging [L. Vittadello *et al.*, Opt. Mater. Express **11.7** (2021) 1953-1969]. HNPs are based on polar oxide nanocrystals with pronounced nonlinear optical response, such as sodium niobate ($NaNbO_3$) or potassium niobate ($KNbO_3$) and can already be synthesized at the nanometer scale (<100 nm), e.g. via hydrothermal synthesis [N. Kohlenbach *et al.*, Nanoscale **12** (2020) 19223], but also surface-functionalized. Nonlinear Diffuse femtosecond-pulse reflectometry of powder-pressed-HNP-samples has been established as major tool for characterization of the nonlinear optical properties [C. Kijatkin *et al.*, Photonics **4.1** (2017) 11]. We here give insight to the state-of-the-art processing routine of HNPs from synthesis, via characterization to applications and highlight upcoming fields, particularly in the framework of all-optical interrogation of cellular environments. Financial support by the DFG/RTG2900, 'nanomaterials@biomembranes'.

KFM 15: Crystal Structure Defects / Real Structure / Microstructure

Invited Talk KFM 15.1 Thu 9:30 H9

Is CVD diamond now ready to become an electronic material? — •Philippe Bergonzo — University College London UK — Seki Diamond System, San Jose CA, USA

CVD Diamond is an exceptional material combining superlative properties like electronic properties, thermal conductivity, biocompatibility, radiation resistance, and optical properties. These advantages make diamond an excellent material for a broad range of applications, including radiation detectors, high transparency windows, electronic devices, quantum devices, sensors, etc. Remarkable devices have been fabricated and are still respected as a reference. But still, can diamond come out of the lab to become a competitive device material? Although diamond synthesis is a pretty well-established technique, there are still more than 80% of the machines growing diamond on the planet that grow it to make gemstones. And this has always inhibited the progress this material deserved. Only very recently, and with the recent huge downturn that affects the gem business, one can consider that we may have reached an inflection point where CVD diamond may soon benefit from being something else than a gemstone. Potentially, innovative developments for physics may not be kept secret because they could be more valuable for the gem market, if this latter one is collapsing. In this context, how can we facilitate this progress? Drawing from typical cases where diamond-based devices are used for specific applications, examples will be used to illustrate material opportunities and challenges towards diamond to become a standard for device applications.

KFM 15.2 Thu 10:00 H9

Numerical analyses and loss tangent measurements for the W7-X ECRH gyrotron diamond output windows — •Gaetano Aiello[1], Andreas Meier[1], Heinrich Peter Laqua[2], Theo Scherer[1], Sabine Schreck[1], and Dirk Strauss[1] — [1]KIT, Karlsruhe, Germany — [2]IPP, Greifswald, Germany

The 140 GHz 1 MW gyrotron for the electron cyclotron resonance heating (ECRH) system at the stellarator Wendelstein 7-X (W7-X) is being upgraded to 1.5 MW continuous wave operation to increase the total heating power for achieving operating regimes with high plasma beta and low collisionality. The gyrotron features a chemical vapor deposition (CVD) polycrystalline diamond window with an aperture of 88 mm and a disk of 1.8 mm thickness and 106 mm diameter. In this work, numerical analyses of the window are shown with loss tangent values provided by experimental measurements on 25 bare diamond disks. Computational fluid dynamics (CFD) conjugated heat transfer and structural analyses were carried out to check the window performance at 1.5 MW operation, when cooled by water and silicon oil Dow Corning 200(R) 5cSt.

KFM 15.3 Thu 10:15 H9

Single- and polycrystalline diamond characterization with superconducting microresonators — •Francesco Mazzocchi[1], Martin Neidig[2], Sebastian Kempf[2], Dirk Strauss[1], and Theo Scherer[1] — [1]Karlsruhe Institute Of Technology IAM-AWP — [2]Karlsruhe Institute Of Technology IMS

The development of high optical quality, ultra-low-loss single-crystal diamond windows is essential for the realization of future nuclear fusion facilities, such

as DEMO, due to the anticipated increase in power for microwave ECRH systems. So far, accurate measurement of the dielectric properties (ϵr and $\tan\delta$) of these materials has primarily relied on Fabry-Perot microwave resonators in different setups, with a resolution limit around 1E-5 in the determination of the loss tangent. Superconducting thin-film resonators, capable of reach Q factors in excess of 1E6, have the potential to assess the dielectric characteristics of ultra-low-loss materials like single- and polycrystalline diamond while offering a significant boost in resolution when compared to the state-of-the-art Fabry-Perot resonance cavities. We hereby report measurements performed at low (4 - 9 K) an ultra-low (10 - 700 mK) temperatures of several samples including single and poly-crystalline diamond. The samples have been grown with different techniques, including CVD, cloning and HPHT processes.

KFM 15.4 Thu 10:30 H9

Simulated nano-extrusion of graphene hyperbolic pseudosphere surfaces — •Peter Klaver[1], Alfredo Iorio[2], Ruggero Gabbrielli[3], and Dominik Legut[1] — [1]VSB Technical University of Ostrava, Ostrava, Czech Republic — [2]Charles University, Prague, Czech Republic — [3]Independent researcher

We produce curved graphene hyperbolic pseudosphere surfaces in molecular dynamics (MD) simulation of a nano-scale extrusion process. During the extrusion process the carbon atoms form pentagons, hexagons and heptagons and such a mixture is unrealistically less stable than pure graphite or diamond. During relaxation and lengthy high temperature annealing after the extrusion process, polycrystalline curved graphene with a limited number of point defects is formed. The point defects cause bending of the graphene and the pseudosphere edges even more. When these free edges are removed from the simulations by attaching periodic flat graphene sheets to the pseudosphere edges, the carbon atoms assume positions with a root mean square deviation of some tenths of Å from the mathematical hyperbolic pseudosphere surface. The hyperbolic pseudospheres proved to be mechanically stable against large shearing and elongation deformations as well as against annealing at 1500 K. Our methodology is easy to use, employing the REBO2 carbon interaction potential within the open source MD code LAMMPS. Our method offers a practical way to create simulated stable, curved graphene surfaces with a wide variety of desired shapes. It allows for the testing in advance of the stability of graphene shapes that are to be produced experimentally.

KFM 15.5 Thu 10:45 H9

Inverted Designs of Dielectric Metasurfaces Based on TiO_2.: A Study on Quasi-Bound States in Continuum (qBIC) — •Justin Schulz[1], Jack Dobie[1,2], Oisin McCormack[1,2], Yongliang Zhang[1], Hodjat Hajian[1], Owen Moynihan[2], Brian Corbett[2], and A. Louise Bradley[1,2] — [1]School of Physics, Trinity College Dublin, Dublin 2, Ireland — [2]IPIC, Tyndall, University College Cork, Cork, Ireland

Dielectric metasurfaces, engineered to manipulate light primarily by controlling the phase and amplitude of the scattered light, have garnered significant interest in recent years, particularly due to their ability to support quasi-Bound States in Continuum (qBIC).

Building upon previous work on slotted disk metasurfaces fabricated in Si_3N_4, we investigate inverted TiO_2-based designs. TiO_2, with its high refractive index, offers distinct advantages in enhancing the resonance properties of dielectric metasurfaces, enabling more efficient light-matter interactions. A key objective of this work is to perform a comparative analysis between slotted disk structures and their inverted counterparts, with a focus on their respective lattice and qBIC modes. Future prospects of TiO_2-based dielectric metasurfaces and the potential applications in low-energy switching and polariton lasing are discussed, with a particular focus on their integration with transition-metal dichalcogenide (TMDC) monolayers or quantum dots. This project is funded through; Taighde Éireann/Research Ireland Frontiers for the Future Award - SFI-21/FFP-P/10187, 12/RC/2278_2, and 12/RC/2276_P2.

KFM 15.6 Thu 11:15 H9

Phase modifications in Beta-Gallium Oxide via Focus ion beam irradiations — •Umutcan Bektas, Nico Klingner, Paul Chekhonin, Fabian Ganss, Rene Hübner, Maciej Oskar Liedke, and Gregor Hlawacek — Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

Gallium oxide (Ga2O3) is a highly versatile material with power electronics, optoelectronics, and battery technologies applications. Among its polymorphs, monoclinic β-Ga2O3 is the most chemically and thermally stable phase. However, managing the metastable polymorph phases remains challenging, and the fabrication technology for nanoscale structures is still under development. We aim better to understand the polymorph conversion mechanisms under ion irradiation. In this study, we investigate the β-Ga2O3 samples irradiated with different ions and fluences, together with α- and κ-Ga2O3 thin films. Focused ion beam (FIB) irradiation was used to locally modify the samples under controlled conditions by varying the ion beam current, size, spacing, scan type, and ion species. The irradiated regions were characterized using electron backscatter diffraction and transmission electron microscopy to analyze structural changes. Broad beam irradiation experiments were complemented by positron annihilation spectroscopy methods to determine defect types and concentrations. Initial results indicate that spatially resolved polymorph transitions can be achieved using FIB irradiation. In addition, the defect size and concentration were found to depend on the polymorph and the implanted ion species, providing critical into defect engineering in Ga2O3.

KFM 15.7 Thu 11:30 H9

An EXAFS analysis of the laser-driven tetragonal to cubic phase-transition in $BaTiO_3$ — •Janosch Tasto[1], Rajdwip Bhar[1], Simon Rauls[1], Marco Reinhard[2], Dimosthenis Sokaras[2], Uwe Bovensiepen[1], and Heiko Wende[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen — [2]SLAC National Accelerator Laboratory, Stanford University

This work aims to establish time-resolved Extended X-ray Absorption Fine Structure (tr-EXAFS) spectroscopy as a methodology for solids where the structural information of the EXAFS is combined with a pump-probe setup to study local dynamic lattice processes in the time domain. As a first step along this road, the information contained in a difference-EXAFS scan between the pumped and unpumped state is analyzed.

As proof of concept, the structural cubic to tetragonal phase transition in ferroelectric $BaTiO_3$ is analyzed. The coexistence of displacive and order-disorder phenomena accompanying this transition is debated in the literature of this widely investigated material. Difference-EXAFS scans at the Ti-K and Ba-L_3 edge between the tetragonal and cubic phase provide a direct way to investigate changes in structure and thermal induced disorder in the vicinity of the absorbing atom. We correlate our spectroscopic findings with *ab initio* multiple-scattering calculations using the FEFF10 code to quantify thermal and structural contributions.

We thank the Deutsche Forschungsgemeinschaft (in the framework of the Collaborative Research Center 1242) for financial support.

KFM 15.8 Thu 11:45 H9

Dislocation correlations in GaN epitaxial films revealed by EBSD and XRD — •Domenik Spallek, Vladimir M. Kaganer, Philipp John, Oliver Brandt, and Jonas Lähnemann — Paul-Drude-Institut für Festkörperelektronik, Berlin, Germany

Threading dislocations in group-III nitrides are omnipresent and are a challenge especially in heteroepitaxial growth for device applications. However, the correlation of individual dislocations with each other and the resulting screening of the strain is often disregarded although it is a necessity to describe elastic energies in an extended crystal.

In this study, two GaN epitaxial layers with threading dislocation densities (TDD) of 5×10^8 cm^{-2} and 1.8×10^{10} cm^{-2} are investigated by x-ray diffraction (XRD) and high-resolution electron backscatter diffraction (HR-EBSD), complemented by Monte Carlo simulations to model and interpret the experimental results.

While the XRD measurement directly gives quantitative results about the average strain in the illuminated area, a cross-correlation analysis of Kikuchi patterns results in spatially-resolved maps for the components of the strain and rotation tensors. Through an analysis of the strain-strain correlation functions for the measured and simulated maps, it is found that the spatial resolution in the HR-EBSD maps is highly anisotropic. Furthermore, we discover that the strain is significantly underestimated for higher dislocation densities. As main result, the screening distances for dislocations were determined as 2 μm and 0.3 μm for the sample with the lower and higher TDD, respectively.

KFM 15.9 Thu 12:00 H9

Multiscale modeling of intergranular corrosion in iron — •Vahid Jamebozorgi[1], Karsten Rasim[2], and Christian Schröder[3] — [1]Bielefeld Institute for Applied Materials Research, Bielefeld University of Applied Sciences and Arts, Interaktion 1, 33619 Bielefeld, Germany — [2]Faculty of Physics, Bielefeld University, Universitätsstraße 4, 33615 Bielefeld, Germany — [3]Bielefeld Institute for Applied Materials Research, Bielefeld University of Applied Sciences and Arts, Interaktion 1, 33619 Bielefeld, Germany

Localized corrosion, particularly intergranular corrosion, causes a significant economical and structural challenge across various industries. An accurate predictive intergranular corrosion modeling should incorporate atomic scale details, including crystallographic aspects of grain boundaries, and their evolution by time increment. However, the size and scale limitations imposed by atomistic methods hinder the development of realistic models. To overcome these limitations, we propose a novel multiscale modeling approach that combines the detailed atomistic insights provided by reactive molecular dynamics with the computationally tractable finite element method. This multiscale strategy not only ensures the preservation of crucial atomistic details but also enables the simulation of larger spatial and temporal scales, thereby offering a comprehensive view on the microstructure*s evolution during the intergranular corrosion process.

KFM 15.10 Thu 12:30 H9

Landau Theory for Quasicrystals at the Mesoscale — •Marcello De Donno[1], Luiza Angheluta[2], Ken R. Elder[3], and Marco Salvalaglio[1,4] — [1]Institute of Scientific Computing, TU Dresden, 01062 Dresden, Germany — [2]Njord Centre, Department of Physics, University of Oslo, 0371 Oslo, Norway — [3]Department of Physics, Oakland University, Rochester, Michigan 48309, USA — [4]Dresden Center for Computational Materials Science (DCMS), TU Dresden, 01062 Dresden, Germany

Quasicrystals challenge traditional concepts of crystallinity by exhibiting ordered yet aperiodic atomic structures. Their peculiar atomic arrangements give rise to exceptional physical properties, including high hardness, low friction, and remarkable wear resistance, making them worth exploring for high-performance engineering applications. Additionally, their slow dislocation creep leads to high-temperature strength and stability in plastic regimes. We present a mesoscale field theory that unifies the modeling of growth, elasticity, and dislocations in quasicrystals. Using the amplitude formulation of the density-wave representation, our approach models the dynamics of quasicrystals through a free energy functional for complex amplitudes, with non-conserved dissipative dynamics describing their evolution. By specifying only the lattice structure in reciprocal space, our theory self-consistently captures elasticity-including phononic and phasonic deformations-along with defect nucleation and motion. Predictions include the kinematics of dislocations and the formation of semi-coherent interfaces, offering new insights into the mechanics of quasicrystals.

KFM 15.11 Thu 12:45 H9

An all-order phonon approach to thermal diffuse scattering — •Benjamin Fahl and Arkadiy Simonov — ETH,Zurich,Switzerland

Phonons play a role in various phenomena, from superconductivity through phonon-electron coupling and spintronics via phonon-spin interactions, to dynamical stability of solids, and are fundamental to elastic properties. They can be probed by measuring Thermal Diffuse Scattering (TDS) from single crystals. However, modelling of the TDS, is a computational challenge due to the number of intensities in the experiment. With existing software, like AB2TDS, the full experiment can be calculated only in one- or two-phonon approximations. Approximations of higher order are possible, but are computationally expensive and can be performed only on small portions of reciprocal space. In this work, we propose a new method for modeling and fitting TDS signals using joint atomic displacement parameters in YELL. This approach uses the crystal's dynamical matrix as input, which is derived by various methods including universal potentials, DFT, or approximated from elastic constants. By using a Fast-Fourier Transform, our method can quickly calculate large volumes of TDS in infinite phonon approximation. This development will enhance the 3D-ΔPDF suite, enabling extraction of elastic constants from various materials and extending to the analysis of high-amplitude soft phonons, which are relevant in negative thermal expansion materials like ScF_3. The softwares capability to handle higher-order phonon contributions makes it particularly valuable for systems where these effects are significant, addressing a current gap in available tools.

KFM 15.12 Thu 13:00 H9

Solving the phase problem: retrieving complex structure factors using Large-Angle Rocking-Beam Electron Diffraction — •Sam Fairman[1], Grigory Kornilov[2], Benedikt Haas[2], Zbignew Galazka[3], Adnan Hammud[4], Niklas Delby[5], and Christoph T. Koch[2] — [1]Physikalisch Technische Bundesanstalt, Berlin, Germany — [2]Humboldt Universität zu Berlin, Berlin, Germany — [3]Leibniz-Institut für Kristallzüchtung, Berlin, Germany — [4]Fritz-Haber-Institut, Berlin, Germany — [5]Nion Company, Kirkland, WA, USA

X-ray crystallography phasing methods have previously been successfully applied to electron diffraction experiments. However, dynamical scattering, caused by the electron's much larger scattering cross section, is normally viewed as a hindrance to structural determination and is mitigated, e.g. by continuous rotation or precession. Presented here is an ab-initio method that makes use of dynamical scattering to solve the phase problem directly from experimental data. A custom weighting scheme is combined with the ADAM optimizer to directly fit the complex structure factors in the Bloch-wave formalism to Large-Angle Rocking-Beam Electron Diffraction data. Our method allows for an approximate 5−fold increase in spatial resolution compared to the largest spatial frequency directly measured. This recovery of resolution is ideal for beam sensitive materials where high order diffraction data is impossible to measure. Simulated and experimental results are presented for non-centrosymmetric GaN and centrosymmetric $\beta - Ga_2O_3$.

KFM 18: Materials Research in Polar Oxides: Perspectives for Optics & Electronics

The focus session is dedicated to bridge the gap between materials research in polar oxides and research fields that apply those materials, such as nonlinear and quantum optics, electronics or sensoring. The goal is to improve the mutual understanding of each other research goals and necessities. Examples for topics could be improved or novel techniques for domain engineering, which are relevant for (nonlinear) optical applications, the growth of novel polar oxides with improved properties over traditional materials, such as higher temperature stability or improved nonlinear characteristics, or the discussion of novel emergent properties in this context, like conductive domain walls in opto-electronical applications.

Invited Talk KFM 18.1 Thu 15:30 H9

Domain gratings of sub-micrometer period for quantum technologies — •Carlota Canalias — KTH-Royal Institute of Technology, Stockholm Sweden

This talk explores the challenges and advancements in developing sub-micron ferroelectric domain gratings, which are vital for nonlinear optical devices capable of generating counter-propagating photons. Conventional materials and poling methods have proven insufficient to support these cutting-edge optical interactions, thereby constraining their applications in both classical and quantum technologies. The presentation showcases a breakthrough in periodic poling techniques for KTP isomorphs, enabling the fabrication of bulk structures with domain sizes as small as 200 nm. This achievement leverages coercive-field gratings formed via ion exchange, which play a pivotal role in domain formation. Our results demonstrate that the creation of sub-micron domains is governed by the characteristics of the ion-exchanged region, rather than the poling period, opening new possibilities for designing smaller and more intricate domain-engineered devices.

KFM 18.2 Thu 16:00 H9

Gray tracks in $KTiOPO_4$ from DFT calculations — •Adriana Bocchini, Uwe Gerstmann, and Wolf Gero Schmidt — Department Physik, Universität Paderborn, 33095 Paderborn, Germany

Ferroelectric $KTiOPO_4$ (KTP) is commonly applied in (nonlinear) optical devices. However, the irradiation with high-intensity laser light or the application of strong electric fields triggers the formation of detrimental gray tracks [1], the microscopic origin of which is usually attributed to Ti^{3+} centers (i.e., reduced titanium atoms) charge compensating for oxygen vacancies [2]. In this study, we use DFT routines to further clarify the gray-tracking mechanisms by systematically model oxygen-vacancy related Ti^{3+} centers in application-relevant environments, i.e., potassium vacancies and rubidium dopants. We find that the only thermally stable [2] Ti^{3+} center forms close, but not adjacent the oxygen vacancy itself. In addition, displaced potassium ions provide the stabilizing forces, whereas potassium interstitials rather than oxygen vacancies alone appear to be directly related to gray tracks. For this we suggest that the current gray-tracking model has to be partially revised. [3]

Interaction between small electron-polaron and neutral domain wall in $PbTiO_3$: A DFT+U study — •Mohammad Amirabbasi, Jochen Rohrer, and Karsten Albe — Technical University of Darmstadt, Materials Modelling Division, Otto-Berndt-Straße 3, Darmstadt D-64287, Germany

$PbTiO_3$ is a widely studied ferroelectric material that often requires doping to tailor its electronic structure for specific applications. Understanding charge compensation mechanisms, particularly those mediated by local lattice distortions such as small polarons, is crucial for optimizing these modifications. This research investigates the formation and stability of a small electron polaron in $PbTiO_3$, focusing on its interaction with the neutral 180° Pb-centered domain wall using density functional theory with Hubbard corrections (DFT+U). We begin by calculating the formation energy of the 180° Pb-centered domain wall. Next, we determine the Born effective charges for various ions and compute the polarization profile across the domain wall. Our results show that the polarization in the bulk region reaches a saturation value, which is in good agreement with experimental measurements. Finally, we calculate the trapping energy of a small electron polaron at Ti centers in both bulk and domain wall regions. The results reveal that the trapping energy is negative in both cases, indicating that small electron polaron formation is energetically favorable. Furthermore, the similarity in trapping energy values suggests that the 180° Pb-centered domain wall in $PbTiO_3$ has a minimal impact on this type of small electron polaron formation.

15 min. break

KFM 18.4 Thu 16:45 H9

Atomistic Modelling of Ferroelectric Bonded Structures — •Nils Andre Schäfer and Simone Sanna — Institute for Theoretical Physics, Justus Liebig University Giessen, Germany

Direct bonding in ferroelectric materials, such as lithium niobate (LN), provides a method to create both head-to-head (H2H) and tail-to-tail (T2T) domain walls (DWs). These DW configurations are particularly interesting due to their ability to exhibit (semi-)metallic behavior by the formation of a two-dimensional electron or hole gas. This phenomenon enables the creation of localized conducting areas within an otherwise wide-gap semiconductor material.

In this work, we model H2H and T2T bonded structures within DFT. Therefore, we start with the thermodynamically stable z-cut surfaces of LN. Simulations were conducted on slabs with varying film thickness to minimize the surface interactions before constructing the bonded structures. The energy landscape of the interface was mapped by systematically translating the films relative to each other and analyzing various quantities, such as free charge carrier densities, the film distance, and the surface energy. In conclusion, H2H and T2T bonded structures exhibit distinct morphological and electronic interfaces, resulting in variations in their expected conductivities.

KFM 18.5 Thu 17:00 H9

Influence of different organic molecules on dielectric response in halide perovskites — •Doru Lupascu[1], Youn Un Jin[1], Witchitaya Arpavate[1], Andre Karabanov[1], Lars Leander Schaberg[1], Niels Benson[1], Bernd Marler[2], and Andre Salak[3] — [1]Universität Duisburg-Essen — [2]Ruhr-Universität Bochum — [3]Universidade de Aveiro

The charge carrier mobility in halid perovskites is still not fully understood. We have been discussing dielectric effects as one fundamental piece in the explanation of the large screening of defects and the polaron mobility. In this presentation we compare different organic molecules for their influence on the dielectric response. The interrelation of molecule mobility and dielectric screening will be discussed.

KFM 18.6 Thu 17:15 H9

Piezoresponse force microscopy study of local polarization dynamics in uniaxial relaxors — •Vladimir Shvartsman[1], Boris Slautin[1], Jan Dec[2], Sergei Kalinin[3], and Doru Lupascu[1] — [1]Institute for Materials Science, University Duisburg-Essen, Essen, Germany — [2]University of Silesia, Katowice, Poland — [3]University of Tennessee-Knoxville, USA

The unusual properties of relaxor ferroelectrics are related to their particular polar structure. In these materials, the polarization is correlated only on the nanometer scale within the so called polar nanoregions (PNRs). The dynamics of PNRs strongly affects the dielectric properties of relaxors. Here, we report about piezoresponse force microscopy study of local polarization dynamics in SrxBa1-xNb2O6 single crystals. In these materials having uniaxial polarization, the cross-over from ferroelectric to relaxor behavior occurs with increasing Sr content making SBN a good model system. We use time-resolved piezoresponse force spectroscopy. This technique measures temporal decay of the piezoresponse induced by a locally applied electric field over a dense spatial grid. The analysis of the time dependences of the piezoresponse allows to estimate the local relaxation time. Spatial maps of relaxation parameters are constructed, giving information on the spatial heterogeneity of polarization dynamics for different compositions and temperatures. Temperature dependences of local relaxation time are analyzed.

KFM 18.7 Thu 17:30 H9

Surface-near domain engineering in multi-domain x-cut lithium niobate tantalate mixed crystals — Laura Bollmers[1,2], Tobias Babai-Hemati[2], Boris Koppitz[3], Christof Eigner[1], Laura Padberg[1,2], •Michael Rüsing[1,2], Lukas M. Eng[3,4], and Christine Silberhorn[1,2] — [1]Paderborn University, Institute for Photonic Quantum Systems (PhoQS), 33098 Paderborn, Germany — [2]Paderborn University, Integrated Quantum Optics, 33098 Paderborn, Germany — [3]Institut für Angewandte Physik, Technische Universität Dresden, 01062 Dresden, Germany — [4]ct.qmat: Dresden-Würzburg Cluster of Excellence|EXC 2147, TU Dresden, 01062 Dresden, Germany

Lithium niobate tantalate mixed crystals present a novel material plattform, which offer new possibilities over pure lithium niobate or lithium tantalate, such as improved thermal stability or the possibility to tune the birefringence. A key requisite for application in nonlinear optics, electronics and piezotronic is the possibility of domain engineering. So far, this proved difficult for mixed crystals due to stoichiometric inhomogeneities, which stabilizes the random as-grown domain structure. In this work, we investigate surface-near periodic poling of x-cut mixed crystals and demonstrate microscopically how the random domain structure in the as-grown crystals can inhibit large scale poling. If monodomain areas are poled, however, periodic poling becomes possible. Our work lays the foundation for future applications of lithium niobate tantalate mixed crystals.

KFM 19: Members' Assembly

We will elect our spokespersons, plan the programme for the next years, and award the poster prize.

Sessions

– Invited Talks, Topical Talks, Tutorials, Contributed Talks, and Posters –

MA 1: Into the Third (and Fourth) Dimension: Imaging Methods for 3D Nanomagnetism (joint session MA/TUT)

Nanostructured magnetic materials have found several applications in everyday objects, such as data storage devices, sensors, and biomedical devices. When one brings these materials to the third dimension, a variety of new physics, and opportunities for applications appear. However, until recently, the vast majority of experimental investigations have primarily been focused on 2D planar geometries, as 3D systems provide a set of experimental challenges that still needs to be overcome. This tutorial seeks to provide a comprehensive overview for both experts and non-experts in the field of 3D imaging to gain a deeper understanding of the recent advances and experimental challenges connected to the investigation of 3D magnetic systems.

Organized by Claire Donnelly (MPI-CPFS, Dresden, Germany) and Simone Finizio (Paul Scherrer Institut, Villigen, Switzerland).

Time: Sunday 16:00–18:15 Location: H4

Tutorial MA 1.1 Sun 16:00 H4

3D Magnetic Imaging: Utilizing Synchrotron X-Ray Coherence for Nanometric Resolution in Thick Samples — •Marisel Di Pietro Martinez — Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany — International Institute for Sustainability with Knotted Chiral Meta Matter (WPI-SKCM2)

In recent years, there has been a growing interest from the magnetism community in expanding to three-dimensional magnetic systems - from exploring new geometries to revealing complex magnetic textures arising in micrometer-thick samples. A key aspect of this exploration is the ability to visualize the magnetization vector field at the nanoscale throughout the entire sample, made possible by the development of 3D magnetic imaging. This technique can achieve nanometric spatial resolution in micrometer-thick samples by leveraging the penetration depth and coherence of synchrotron X-rays. Furthermore, the coherence of the X-ray beam provides magnetic contrast not only in the absorption of the transmitted wave, but also in the phase. This phase contrast enables the investigation of micron-sizes magnets, even with soft X-rays, while minimizing the sample damage. In this tutorial, I will introduce how to exploit these advantages using coherence-based techniques, such as Fourier transform holography and ptychography, to perform 3D magnetic imaging. Visualizing the magnetization vector field with nanometer spatial resolution in micrometer thick samples opens the door to studying magnetic textures in higher dimensions, offering insights into fundamental physical phenomena as well as promising new applications in information storage and processing.

Tutorial MA 1.2 Sun 16:45 H4

Nanoscale Mapping of Magnetic Textures in 3D Using Vector Field Electron Tomography — •Axel Lubk[1,2] and Daniel Wolf[1] — [1]Leibniz Institute for Solid State and Materials Research, Dresden, Germany — [2]Institute of Solid State and Materials Physics, TU Dresden, Germany

Vector field Electron Tomography (VFET) combines Electron Holography and Electron Tomography in the Transmission Electron Microscope (TEM) to reconstruct magnetic induction vector fields in 3D down to several nanometer resolution. In this tutorial we discuss the foundations of the technique, the practical workflow including pitfalls, and application to topical examples in nanomagnetism including domain walls in nanowires and skyrmion strings.

Tutorial MA 1.3 Sun 17:30 H4

3D magnetic imaging: an experimental window to study 3D magnetization at the nanoscale — •Aurelio Hierro-Rodriguez — Department of Physics, University of Oviedo,33007, Oviedo, Spain — CINN (CSIC-University of Oviedo) , 33940, El Entrego, Spain

The synergetic confluence of technological and scientific developments in nanofabrication and characterization techniques is paving the way towards the advance in Three-Dimensional Nanomagnetism, fuelled by the richness of phenomena and technological potential of the exploitation of the magnetization vector field in their natural dimensionality: three dimensions. In this lecture, a broad picture of the importance of the topic, in the framework of the novel physics that can be explored and exploited will be given, with a brief description of the methods that allow to fabricate almost any 3D magnetic geometry with nanometer resolution. The core of the lecture will deal with the advanced magnetic imaging techniques, which are opening a window towards the characterization of the full three-dimensional magnetization vector. Specifically, X-ray based magnetic vector tomography will be described and exemplified, showing the capabilities of the technique to volume resolve the magnetization vector field in arbitrary systems with nanometer resolution. These developments in vector magnetic imaging are making possible a change in the actual paradigm on how magnetization is characterized and studied at the nanoscale, by bringing a direct experimental probe to realize experimental micromagnetism.

MA 2: Multiferroics and Magnetoelectric Coupling (joint session MA/KFM)

Time: Monday 9:30–12:15 Location: H16

MA 2.1 Mon 9:30 H16

Trilinear coupling and toroidicity in multiferroics — Andrea Urru[1] and •Vincenzo Fiorentini[2,3] — [1]Dept. of Physics, Rutgers University, USA — [2]Chair of Materials Science and Nanotech, TU Dresden — [3]Dept. Physics, University of Cagliary, Italy

We discuss the properties of the triple-order-parameter (ferromagnet, ferroelectric, ferrotoroid) layered-perovskite metal Bi5Mn5O17, as predicted from first-principles calculations, in the light of a Landau expansion with trilinear coupling, with particular reference to its multiple degenerate ground states with mutually orthogonal vector order parameters, giant cross-coupling magnetoelectricity, and magnetotoroidic effects.

MA 2.2 Mon 9:45 H16

Engineering magnetic domain wall energies in $BiFeO_3$ via epitaxial strain: A route to assess skyrmionic stabilities in multiferroics from first principles — •Sebastian Meyer[1,2], Bin Xu[3,4], Laurent Bellaiche[4], and Bertrand Dupé[1,2] — [1]Université de Liège, Belgium — [2]Fonds de la Recherche Scientifique, Belgium — [3]Soochow University, China — [4]University of Arkansas, USA

Epitaxial strain has emerged as a powerful tool to tune magnetic and ferroelectric properties in functional materials such as in multiferroic perovskite oxides. Here, we use first-principles calculations to explore the evolution of magnetic interactions in the antiferromagnetic multiferroic $BiFeO_3$ (BFO), one of the most promising multiferroics for future technology [1]. The epitaxial strain in BFO is varied between $\varepsilon \in [-2\%, +2\%]$. We find that both strengths of the exchange interaction and Dzyaloshinskii-Moriya interaction decrease linearly from compressive to tensile strain whereas the uniaxial magnetocrystalline anisotropy lifts the energy degeneracy of the (111) easy plane of bulk BFO. From the trends of magnetic interactions we can explain the destruction of cycloidal order in compressive strain as observed in experiments due to the increasing anisotropy energy. For tensile strain, we predict that the ground state remains unchanged as a function of strain. By using the domain wall energy, we envision a region where isolated chiral magnetic textures might occur as a function of strain [2].

MA 2.3 Mon 10:00 H16

Hidden order in Cr_2O_3 and α-Fe_2O_3 as a predictor for (anti-)magnetoelectricity — •Xanthe Verbeek[1,2], Andrea Urru[2,3], and Nicola Spaldin[2] — [1]Insitut für Physik, Johannes Gutenberg-Universität Mainz, D-55099 Mainz, Germany — [2]Materials Department, ETH Zurich, 8093 Zürich, Switzerland — [3]Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA

With first-principles calculations of Cr_2O_3 and α-Fe_2O_3, we show that the different magnetoelectric effects in these materials result from the ordering of hidden magnetic multipoles. We reveal for the first time anti-ferroically ordered magnetic multipoles in both Cr_2O_3, and isostructural α-Fe_2O_3, in which the global inversion symmetry is preserved by the different magnetic dipolar ordering. We can relate each of these multipoles and their ordering to linear, quadratic, and cubic (anti-) magnetoelectric effects, where in an anti-magnetoelectric effect the induced moments are ordered antiferromagnetically in the unit cell. We confirm the predicted induced moments using first-principles calculations, showing the lowest response in α-Fe_2O_3 a centrosymmetric magnetic material, to be a linear anti-magnetoelectric effect, revealing the presence of the magnetoelectric coupling despite the preserved global inversion symmetry. Our results demonstrate the existence of hidden magnetic multipoles leading to local linear magnetoelectric responses, even in centrosymmetric magnetic materials, and broaden the definition of magnetoelectric materials by including those showing such local magnetoelectric responses.

MA 2.4 Mon 10:15 H16

Non-trivial Spin Structures and Multiferroic Properties of the DMI-Compound $Ba_2CuGe_2O_7$ — •Peter Wild[1], Korbinian Fellner[1], Michał Dembski-Villalta[1], Markus Garst[2], Eric Ressouche[5], Tommy Kotte[3], Bertrand Roessli[4], Alexandra Turrini[4], and Sebastian Mühlbauer[1] — [1]Heinz Maier-Leibnitz Zentrum (MLZ), Technische Universität München, Garching, Germany — [2]Karlsruhe Institute of Technology, (KIT), Karlsruhe, Deutschland — [3]Helmholtz-Zentrum Dresden-Rossendorf (HZDR), Dresden, Germany — [4]Paul Scherrer Institut (PSI), Villigen, Switzerland — [5]Institut Laue-Langevin (ILL), Grenoble, France

Antiferromagnetic $Ba_2CuGe_2O_7$, characterized by a quasi-2D structure with Dzyaloshinskii-Moriya interactions (DMI), is a non-centrosymmetric insulator that exhibits spiral spin structures with potential non-trivial topology and a variety of unconventional magnetic phase transitions. Below the Néel temperature T_N = 3.05K, the DMI term leads to a long-range incommensurate, almost AF cycloidal spin spiral in the ground state. Recently, a new phase with a vortex-antivortex magnetic structure has been theoretically described and experimentally confirmed in a pocket in the phase diagram at around 2.4K and an external field along the crystalline c-axis of around 2.2T. A lack of evidence for a thermodynamic phase transition towards the paramagnet in specific heat measurements and a finite linewidth in E and Q of the incommensurate peaks in neutron scattering, as opposed to the cycloidal ground state, seem to mark the vortex phase as a slowly fluctuating structure at the verge of ordering.

MA 2.5 Mon 10:30 H16

A comparison of Γ-point symmetries and phonon selection rules of spin-space and magnetic point group in $Co_2Mo_3O_8$ — •Onur Ercem[1], Felix Schilberth[1,2], Lilian Prodan[1], Vladimir Tsurkan[1], Alexander Tsirlin[3], István Kézsmárki[1], and Joachim Deisenhofer[1] — [1]Experimental Physics V, Center for Electronic Correlations and Magnetism, Institute for Physics, University of Augsburg, D-86135 Augsburg, Germany — [2]Department of Physics, Budapest University of Technology and Economics, 1111 Budapest, Hungary — [3]Felix Bloch Institute for Solid-State Physics, Leipzig University, 04103 Leipzig, Germany

$Co_2Mo_3O_8$, which has recently come into the focus of research, as different magnetically ordered ground states can be formed and tuned by external magnetic fields or doping. $Co_2Mo_3O_8$ has a hexagonal structure, the polarization along the c-axis, and a collinear antiferromagnetic order below T_N = 40 K. Reflectivity measurements were performed using the FTIR spectrometer, in the frequency range from 100 to 8000 cm^{-1}, and the temperature range from 10 to 300 K could be covered. A preliminary analysis of the infrared-active modes for $E \parallel c$ reveals that 8 out of the 9 predicted A_1 modes are observed at the expected eigenfrequencies and the emergence of the mode at around 300 cm^{-1} below T_N. In $E \perp c$ at room temperature 10 modes were observed. Below T_N two new modes at 301 cm^{-1} and at 362 cm^{-1} observed. Comparison was made with lattice dynamical calculations.

MA 2.6 Mon 10:45 H16

Ferroelectric hafnium oxide-based multiferroic bilayers for magnetoelectric spin-orbit devices — •Maximilian Lederer, Johannes Hertel, Christoph Durner, Tatiana Gurieva, and Benjamin Lilienthal-Uhlig — Fraunhofer IPMS, Center Nanoelectronic Technologies, Dresden, Germany

This study investigates multiferroic heterostructures comprising $Hf_{0.5}Zr_{0.5}O_2$ (HZO) with Co/Pt top and TiN bottom electrodes on Si substrates. Using advanced deposition techniques, sub-nanometric thin films were fabricated. The research highlights achieving both ferroelectricity and perpendicular magnetic anisotropy simultaneously through a two-step annealing process. These properties are crucial for magnetoelectric spin-orbit (MESO) devices, which offer significant advantages such as lower power consumption and enhanced data storage capabilities. Insights into crystallization and diffusion processes were gained through various structural investigation methods. Additionally, the study demonstrates the manipulation of magnetic and ferroelectric domains using different microscopy techniques, underscoring the potential of MESO devices in next-generation electronic applications.

15 min. break

MA 2.7 Mon 11:15 H16

Internal fields at the V-sites and magnetic structure of the lacunar spinel GeV_4S_8 — •Thomas Gimpel[1], Norbert Büttgen[1], Hiroyuki Nakamura[2], Vladimir Tsurkan[1], and István Kézsmárki[1] — [1]University of Augsburg — [2]Graduate School of Engineering, Kyoto

GeV_4S_8 is a multiferroic lacunar spinel that undergoes both structural (T_{JT}=30 K) and magnetic (T_N=13 K) transitions upon which the four V-sites of the V_4 tetrahedra that are equivalent in the cubic phase transform into three distinct sets of V-sites with zero-field ^{51}V NMR frequencies of 21.7, 53.6 and 65.6 MHz. This indicates that only two V-sites have the same internal magnetic field, while the other two have different ones. Based on the angular dependence of the resonance field upon the rotation of the field, we conclude that the direction of the internal field is common for the four V-sites and is parallel to one of the cubic [110]-type axes, which indicates that the magnetic space group is $Pmn2_1$.

MA 2.8 Mon 11:30 H16

Fast control of antiferromagnetic domains via pulsed electric fields in Co_3O_4 — •Isabel Täuber, Maximilian Winkler, Somnath Ghara, Lilian Prodan, and Istvan Kezsmarki — Universität Augsburg, Deutschland

Co_3O_4 shows the linear magnetoelectric effect below the Neel-temperature of 30K, with a large magnetoelectric coefficient of 14 ps/m. Besides the typical control of the AFM state by colling with electric and magnetic fields across TN, the domains can be switched by voltage pulses as short as a few ns far below the transition temperature. To improve the application ability, we focus on switching of thin films of Co_3O_4 single crystals, paving the way for the next generation of spintronics.

MA 2.9 Mon 11:45 H16

Anomalously strong magnetoelectric coupling in hexaferrite films — •Jakub Vít[1], Kwang-Tak Kim[2], Hyunju Hwang[2], Radomír Kužel[3], Milan Dopita[3], Darina Smržová[4], Kee Hoon Kim[2], and Josef Buršík[4] — [1]Institute of Physics, Czech Academy of Sciences, Czechia — [2]Center for Novel States of Complex Materials Research, Seoul National University, Korea — [3]Faculty of Mathematics and Physics, Charles University, Czechia — [4]Institute of Inorganic Chemistry, Czech Academy of Sciences, Czechia

Bulk hexaferrites are well known to exhibit strong magnetoelectric (ME) effects, often extending up to room temperature. In contrast, ME properties of hexaferrite films have been investigated only in a single recent study: In Z-hexaferrite films, the ME effect was found significantly stronger than in a crystal. [1] We continued this research by studying Y-hexaferrite films $Ba_{2-x}Sr_xCo_2Fe_{11.1}Al_{0.9}O_{22}$ on $SrTiO_3$ (111), grown by chemical solution deposition. For x=1, the magnetic-field-induced polarization reached 6.5 mC/m^2 at 10 K , i.e. 10x more than in the Z-hexaferrite films [1] and 50x more than in Y-hexaferrite crystals. [2] To elucidate these intriguing observations, microstructure of the films was studied in detail by real (SEM, TEM) and reciprocal (XRD) space techniques. Possible influence of the substrate on ME measurements was also taken into account.

[1] K. Shin et al., *Adv. Electron. Mater.* 2101294, (2022) [2] C. B. Park, et al., *Phys. Rev. Mater.* **5**, 034412 (2021)

MA 2.10 Mon 12:00 H16

Higher-order Magnetizations of Non-centrosymmetric Antiferromagnets — •Michael Paulsen[1], Silvia Knappe-Grüneberg[1], Jens Voigt[1], Allard Schnabel[1], Rainer Körber[1], Michael Fechner[2], Ivan Ushakov[3], and Dennis Meier[3] — [1]Physikalisch-Technische Bundesanstalt, Berlin, Germany — [2]Max Planck Institute for the Structure and Dynamics of Matter, CFEL, Hamburg, Germany — [3]NTNU Norwegian University of Science and Technology, Trondheim, Norway

Antiferromagnetic materials lack macroscopic magnetic dipole fields, due to their compensated magnetic spin texture. In his seminal work, Dzyaloshinskii predicted that higher-order magnetization contributions arise in non-centrosymmetric antiferromagnets, in particular quadrupolar magnetic field contributions, and first experimental data suggested the presence of such fields in the antiferromagnetic model system Cr_2O_3. Here, we present calculations and measurements gained at cryogenic and room temperature using Superconducting Quantum Interference Devices (SQUIDs) and Optically Pumped Magne-

tometers (OPMs) setups, respectively, in ultra-low magnetic field environments. The results demonstrate the existence of quadrupolar far-fields and characteristic signatures in different classes of antiferromagnets. Importantly, our SQUID-based approaches are universal and can be applied to a wide range of systems, establishing new methods for characterizing materials with ultra-small magnetic remanence in general.

MA 3: Magnonics I

Time: Monday 9:30–13:00 Location: H18

MA 3.1 Mon 9:30 H18

Floquet Magnons in a Periodically-Driven Magnetic Vortex — •Christopher Heins[1,2], Luaks Körber[1,2,3], Joo-Von Kim[4], Thibaut Devolder[4], Johan Mentink[3], Attila Kákay[1], Katirn Schultheiss[1], Jürgen Fassbender[1,2], and Helmut Schultheiss[2] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Institut für Ionenstrahlphysik und Materialforschung, Dresden, Germany — [2]Technische Universität Dresden, Dresden, Germany — [3]Radboud University, Institute of Molecules and Materials, Nijmegen, The Netherlands — [4]Centre de Nanosciences et de Nanotechnologies, CNRS, Université Paris-Saclay, Palaiseau, France

Magnetic vortices are prominent examples of topology in magnetism with a rich set of dynamic properties. They exhibit an intricate magnon spectrum and show an eigen-resonance of the vortex texture itself, the gyration of the vortex core. The fundamental modes of both excitation types are separated in their resonance frequencies. While the vortex typically gyrates at a few hundred MHz, the magnon modes typically have frequencies in the lower GHz range. Under the influence of a periodic driving field, Floquet states emerge due to a temporal periodicity imposed on the system's ground state by the gyration, much like the formation of Bloch states in the periodic potential of a crystal lattice. While Bloch states are shifted in momentum space, Floquet states are shifted in energy by multiples of the drive frequency.

MA 3.2 Mon 9:45 H18

Nanoscale YIG-Based Magnonic Crystals — •Khrystyna Levchenko[1], Kristýna Davídková[1], Mathieu Moalic[2], Carsten Dubs[3], Michal Urbánek[4], Qi Wang[5], Maciej Krawczyk[2], and Andrii Chumak[1] — [1]University of Vienna, Austria — [2]A. Mickiewicz University, Poland — [3]INNOVENT, Germany — [4]CEITEC Nano, Czech Republic — [5]Huazhong University, China

Magnonic crystals (MCs) are a spin-wave (SW) based class of artificial magnetic materials characterised by a spatially periodic variation of their properties. The combination of design flexibility and SW intrinsic advantages makes MCs promising candidates for RF applications, although multi-mode SW propagation disturbs the operating characteristics. To overcome this, it is necessary to work with nanostructures in the single-mode regime. Leveraging recent progress in materials science and fabrication techniques, we have realised 1D MCs from 100 nm thick epitaxial yttrium iron garnet (YIG) films. The MCs were developed using electron beam lithography, ion etching and evaporation, with periodicities of 1 μm and optimised notches (100-250 nm depth) or antidots (100-150 nm diameter). Microstrip antennae were used for SW excitation and detection. Experimental characterisation using micro-focused Brillouin light scattering and propagating spin-wave spectroscopy, supported by simulations (TetraX), confirmed efficient single-mode SW transport over a distance of 10 μm and bandgap formation. These results pave the way for further advances, such as 2D arrays with magnon guidance and topologically protected magnon transport - a milestone yet to be achieved experimentally.

MA 3.3 Mon 10:00 H18

The impact of local exchange bias on the dyanmics in chiral antiferromagnetic Mn_3Ir heterostructures with a $Ni_{80}Fe_{20}$ — •Rouven Dreyer[1], James M. Taylor[1], Stuart Parkin[2], and Georg Woltersdorf[1,2] — [1]Martin Luther University Halle-Wittenberg, 06120 Halle, Germany — [2]Max Planck Institute for Microstructure Physics, 06120 Halle, Germany

Non-collinear antiferromagnets (AFs) have been found to exhibit the intrinsic spin Hall effect (SHE) and to provide exchange bias (EB) in multilayer system, rendering these AFs interesting candidates for spintronic applications. However, the role of the chiral domain structure in this process and the transmission of the resulting spin current across interfaces with ferromagnets (FMs), remain open questions. Using a combination of integrative spin-torque ferromagnetic resonance (ST-FMR) and super-Nyquist-sampling magneto-optical Kerr effect (SNS-MOKE) measurements, we investigate the impact of the non-collinear spin texture of the Mn_3Ir on the magnetization dynamics in heterostructures with $Ni_{80}Fe_{20}$. Here, we show a strong discrepancy between local and integrative techniques due to interfacial exchange coupling between the AF and the FM. As a result of this, only SNS-MOKE studies allow for a local detection of the SHE. Furthermore, we obtain modifications of the magnetization dynamics strongly depending on the direction of applied EB. Moreover, we demonstrate that a combination of small bias fields and current-induced heating acts as an efficient control mechanism for setting of the exchange bias und thus for changing the magnetization dynamics during the measurements.

MA 3.4 Mon 10:15 H18

Evoution of coherence in magnonic BECs — •Malte Koster[1], Matthias R. Schweizer[1], Vitaliy Vasyuchka[1], Dmytro Bozhko[2], Burkard Hillebrands[1], Mathias Weiler[1], Alexander A. Serga[1], and Georg von Freymann[1,3] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Department of Physics and Energy Science, University of Colorado Colorado Springs, CO 80918 USA — [3]Fraunhofer Institute for Industrial Mathematics ITWM, 67663 Kaiserslautern, Germany

The process of formation of a coherent magnon-Bose-Einstein condensate (BEC) in an over-populated, hot magnon gas has recently been intensively studied. We have already demonstrated an electromagnetic detection scheme that allows direct evaluation of the phase correlation in the BEC. We have now extended the setup to study the evolution of the phase coherence during and after the formation of a homogeneous excitation of the magnon system - a BEC. In our experiments we use a perpendicularly magnetized yttirumiron-garnet film, which is parametrically pumped. This allows us to further demonstrate that coherence arises even though the magnon gas is still heated by the pumping. Furthermore, due to the phase sensitivity of our technique, we observe the spontaneous emergence of a random phase of the BEC without any influence of external factors.

This research was funded by the Deutsche Forschungsgemeinschaft in frame of TRR 173/2*268565370 Spin+X (Project B04).

MA 3.5 Mon 10:30 H18

Ultra-long magnon lifetime in the quantum limit — •Rostyslav O. Serha[1], Kaitlin H. McAllister[2], Fabian Majcen[1], Sebastian Knauer[1], Timmy Reimann[3], Carsten Dubs[3], Gennadii A. Melkov[4], Alexander A. Serga[5], Vasyl S. Tyberkevych[6], Dmytro A. Bozhko[2], and Andrii V. Chumak[1] — [1]University of Vienna, Vienna, Austria — [2]University of Colorado, Colorado Springs, USA — [3]INNOVENT e. V. technology development, Jena, Germany — [4]National Taras Shevchenko University, Kyiv, Ukraine — [5]RPTU, Kaiserslautern, Germany — [6]Oakland University, Rochester, USA

Quantum magnonics seeks to harness the quantum mechanical properties of magnons for quantum information technologies. A major bottleneck in this field is the limited magnon lifetime, which constrains the performance of quantum magnonic systems. In this study, we investigated yttrium iron garnet (YIG) spheres with varying impurity levels using ferromagnetic resonance (FMR) spectroscopy to examine magnon lifetimes at millikelvin temperatures. For k=0 magnon modes, lifetimes of up to one microsecond were observed. Remarkably, a specialized three-magnon splitting experiment revealed lifetimes of short-wavelength dipole magnons to be up to an order of magnitude longer than their k=0 counterparts. We report a maximum magnon lifetime of 18 microseconds at a frequency of 1.6 GHz. These findings offer crucial insights into the mechanisms influencing magnon lifetimes and pave the way for quantum magnonic devices featuring long-lived propagating magnons.

MA 3.6 Mon 10:45 H18

Exotic Magnon Spectra from Strong Dipolar Interactions and Anisotropy — •Konrad Scharff — KIT, Karlsruhe, Deutschland

Magnetic dipole-dipole interactions on lattices have been known to be the source of non-analytical behaviour of associated spin wave dispersions at and around the Brillouin zone center [1,2]. We investigate the consequences and predicted signatures of said non-analyticity in a 3D hexagonal lattice model that additionally hosts magnetic exchange interaction, as well as an easy-plane on-site anisotropy. Dynamical susceptibilities are theoretically evaluated and compared to available experimental data.

Machine learning tool for inelastic neutron scattering: The case of CrSBr — •Nihad Abuawwad[1], Yixuan Zhang[2], Hongbin Zhang[2], and Samir Lounis[1,3] — [1]Peter Grünberg Institut, Forschungszentrum Jülich, Jülich, Germany — [2]Institute of Materials Science, Technical University Darmstadt, Darmstadt , Germany — [3]Institute of Physics, University of Halle, Halle, Germany

Spin waves, or magnons, are fundamental excitations in magnetic materials that provide insights into their dynamic properties and interactions. Magnons are the

building blocks of magnonics, which offer promising perspectives for data storage, and quantum computing. These excitations are typically measured through Inelastic Neutron Scattering (INS) techniques, which involve heavy and time-consuming measurements, data processing, and analysis based on various theoretical models. Here, we introduce a machine learning algorithm that integrates adaptive noise reduction and active learning sampling, which enables the restoration from minimal INS point data of spin wave information and the accurate extraction of magnetic parameters, including hidden interactions. Our findings, benchmarked against the magnon spectra of CrSBr, significantly enhance the efficiency and accuracy in addressing complex and noisy experimental measurements. This advancement offers a powerful machine-learning tool for research in magnonics and spintronics, which can also be extended to other characterization techniques at large facilities[1].

Thermally Induced Demagnetizing Fields: Effective Potentials for Magnon Bose–Einstein Condensates — •Matthias R. Schweizer[1], Franziska Kühn[1], Victor S. L'vov[2], Anna Pomyalov[2,3], Georg von Freymann[1,4], Burkard Hillebrands[1], and Alexander A. Serga[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern — [2]Department of Complex Systems, Weizmann Institute of Science, Rehovot 76100, Israel — [3]Department of Chemical and Biological Physics, Weizmann Institute of Science, Rehovot 76100, Israel — [4]Fraunhofer Institute for Industrial Mathematics ITWM, Fraunhofer-Platz 1, 67663 Kaiserslautern

We investigate the control of magnon Bose–Einstein condensates (mBEC) by means of reconfigurable potentials. It is shown that the localized decrease of the saturation magnetization leads to strong demagnetizing fields which elevate the resonance frequency of magnons in the mBEC state at the bottom of the spin-wave spectrum. Consequently, spatially varying magnetization and field profiles act as space-modulated potentials, determining the dynamics of the mBEC. For the experimental observation, we create reconfigurable microscopic magnetization profiles using laser heating controlled by optical wavefront modulation. Electromagnetic parametric pumping is used to increase the magnon gas density and Brillouin light scattering spectroscopy is employed to detect the mBEC dynamics. This research was supported by the DFG–TRR 173-268565370 Spin+X (Project B04).

MA 3.9 Mon 11:45 H18

Fluctuations of the inverted magnetic state and how to sense them — •Anna-Luisa Römling[1], Artim Bassant[2], and Rembert Duine[2] — [1]Condensed Matter Physics Center (IFIMAC) and Departamento de Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, Madrid, Spain — [2]Institute for Theoretical Physics, Utrecht University, Utrecht, The Netherlands

Magnons are the low-energy exciations of magnetically ordered materials. While the magnetic moment of a ferromagnet below Curie tempertature aligns with an applied magnetic field, recent theoretical work has demonstrated that the magnetic order can be inverted by pumping spin orbit torque into the magnet. This results in an energetically unstable but dynamically stabilized state where the magnetic moment is antiparallel to an applied magnetic field. The excitations on such a state have negative energy and are called antimagnons, the antiparticle of the magnon. Here, we theoretically study the quantum and classical fluctuations of the inverted magnetic state and their sigatures in experimental set-ups. Our results advance the understanding of fundamental properties of antimagnons as well as experimental data related to the inverted magnetic state. They pave the way for exciting applications in spintronics and magnonics.

MA 3.10 Mon 12:00 H18

Inductive noise spectroscopy of thermally excited magnons — Luise Holder[1], Richard Schlitz[1], Jamal Ben Youssef[2], Christian Runge[1], Akashdeep Kamra[3,4], William Legrand[5], Hans Huebl[6,7,8], •Michaela Lammel[1], and Sebastian T.B. Goennenwein[1] — [1]Universität Konstanz, Konstanz — [2]LabSTICC-CNRS, Université Bretagne Occidentale, Brest — [3]RPTU Kaiserslautern-Landau, Kaiserslautern — [4]Universidad Autónoma de Madrid, Madrid — [5]CNRS, Institute Néel, Université Grenoble Alps, Grenoble — [6]Walther-Meißner-Institut, Garching — [7]Technische Universität München, Garching — [8]Munich Center for Quantum Science and Technology, Munich

For the identification of non-classical (squeezed) magnon states, quantitative knowledge about thermal or vacuum fluctuations of the magnetization is essential. We show that thermal magnetization fluctuations of a ferromagnetic thin film can be sensitively characterized using inductive magnon noise spectroscopy (iMNS). Our broadband approach based on a coplanar waveguide and a commercial spectrum analyzer allows to detect the microwave emission of the equilibrium magnetization fluctuations relative to a cold microwave background. Modeling the response of the whole microwave system and comparing it quantitatively with low-power broadband ferromagnetic resonance measurements in linear response yields excellent agreement, which verifies the equilibrium character of the iMNS. Thus, our work establishes a purely inductive broadband access to the equilibrium properties of magnetization fluctuations.

MA 3.11 Mon 12:15 H18

Threshold of parametric instability of magnons in different magnetization geometries under quasi-continuous pumping — •Tamara Azevedo[1], Rostyslav O. Serha[2], Matthias R. Schweizer[1], Vitaliy I. Vasyuchka[1], Burkard Hillebrands[1], and Alexander A. Serga[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Faculty of Physics, University of Vienna, 1090 Vienna, Austria

Parametric electromagnetic pumping of magnons is a key method for exciting and amplifying spin waves. Measuring the threshold of parametric instability, where energy input overcomes magnon damping, is crucial. Using a sensitive, automated technique with a quasi-continuous wave generated by a vector network analyzer, we measured this threshold in tangentially magnetized yttrium iron garnet films. Two geometries were studied: a microstrip pumping resonator aligned parallel and perpendicular to the external magnetization field $\mathbf{H}_0$. The threshold power as a function of $\mathbf{H}_0$ shows a sawtooth structure, likely caused by wave vector quantization of parametric magnons. In the perpendicular geometry, threshold power peaks suggest magnon-phonon hybridization with longitudinal, transverse, and surface acoustic modes. These results underline the role of magnetization geometry in determining parametric instability thresholds, providing guidance for optimizing spintronic and magnonic devices. This research was funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation)*TRR 173*268565370 Spin+X (Project B04).

MA 3.12 Mon 12:30 H18

Non-reciprocal phonon-magnon interaction in yttrium-iron-garnet/zinc oxide heterostructures — •Yannik Kunz[1], Julian Schüler[1], Kevin Künstle[1], Finlay Ryburn[2], Yangzhan Zhang[2], Katharina Lasinger[1,2], Philipp Pirro[1], John Gregg[2], and Mathias Weiler[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU in Kaiserslautern, Germany — [2]University of Oxford, United Kingdom

Magnon-based devices provide a promising approach for energy-efficient computation due to low intrinsic losses in materials such as yttrium-iron-garnet (YIG). Here we show that surface acoustic waves (SAWs) can be used for the excitation of spin waves in hybrid ferrimagnetic/piezoelectric devices. The SAW thereby couples to magnons under conservation of energy and momentum [1,2]. We studied the excitation and propagation behavior of surface acoustic waves in GGG/YIG/ZnO-heterostructures [3] by electrical and micro-focused optical techniques. The phonon-magnon coupling in YIG is investigated by performing SAW transmission measurement as a function of the magnetic field and orientation. The observed magnetoelastic coupling of phonons and magnons is non-reciprocal and highly dependent on the angle between the propagation direction of the SAW and the applied magnetic field.

Spatial control of hybridization-induced spin-wave transmission stop band — •Franz Vilsmeier[1,2], Christian Riedel[1], and Christian Back[1] — [1]Technische Universität München — [2]Universität Wien

Spin-wave (SW) propagation close to the hybridization-induced transmission stop band is investigated within a trapezoid-shaped 200 nm thick yttrium iron garnet film using time-resolved magneto-optic Kerr effect microscopy. The gradual reduction of the effective field within the structure leads to local variations of the SW dispersion relation and results in a SW hybridization at a fixed position in the trapezoid, where the propagation vanishes since the SW group velocity approaches zero. By tuning the external field or frequency, spatial control of the spatial stop band position and spin-wave propagation is demonstrated.

Tunable Half-Metallicity and Ferromagnetism in Gated single layer g-C3N4 via Nitrogen Lone Pair Depletion. — •Pietro Nicolò Brangi, Francesca Martini, Pier Luigi Cudazzo, and Matteo Calandra — Department of Physics, University of Trento, Via Sommarive 14, 38123 Povo, Italy

Graphitic carbon nitride (g-C3N4) is a promising catalyst for water splitting and hydrogen production, with nitrogen lone pairs arising from broken carbon-nitrogen bonds in its heptazine structure. These strongly localized and weakly hybridized lone pairs form ultraflat bands potentially leading to correlated states when doped.

Using first-principles calculations, we show that field-effect hole-doping in single-layer g-C3N4 depletes these lone pairs, generating ultraflat bands at the Fermi level and unveiling a rich phase diagram. At low hole concentrations, a half-metallic state emerges with tunable magnetization, increasing linearly with carrier density and reaching up to 1 Bohr magneton /3 f.u.. At an integer filling of one hole per cell, a band-insulating ferromagnetic state is stabilized, followed by an interplay of metallic and half-magnetic phases with further doping, ultimately leading to a second ferromagnetic insulating state.

Our work highlights nitrogen-based lone-pair systems as a novel platform for strongly correlated states, with implications for magnetism even at small electric fields, hinting at unexplored potential in photocatalysis.

MA 4.2 Mon 9:45 H19

Investigation of crystalline environment for Fe oxides using XAS and XPS:A DFT+MLFT approach — •Hamza Zerdoumi, Ruiwen Xie, and Hongbin Zhang — Institute of Materials Science, TU Darmstadt,Germany

Fe oxides are versatile materials with applications spanning catalysis, memory storage, and photoelectrochemical decomposition of seawater for clean hydrogen production. Taking Fe_2O_3 as an example, there exist five distinct phases, i.e., α-Fe_2O_3, β-Fe_2O_3, γ-Fe_2O_3, ϵ-Fe_2O_3, and ζ-Fe_2O_3, each exhibiting unique properties. Therefore, it is intriguing to clarify how the local crystalline environment can shape the electronic structure and hence tailor the corresponding functionalities. In this study, we simulate X-ray photoelectron spectroscopy (XPS) and X-ray absorption spectroscopy (XAS) spectra using a combination of density functional theory (DFT) and multiplet ligand field theory (MLFT). By analyzing individual spectral bands corresponding to iron sites in various crystal structures, we examine the correlation between local symmetry and the simulated spectra. Our work highlights how variations in local environments influence the spectroscopic features of iron oxide polymorphs, offering valuable insights into their diverse properties.

MA 4.3 Mon 10:00 H19

Domain wall engineering in distorted Kagome magnet — •Avdhesh Kumar Sharma[1], Premakumar Yanda[1], Samuel Harrison Moody[2], Chandra Shekhar[1], and Claudia Felser[1] — [1]Max Planck Institute for chemical physics of solids, 01187 Dresden, Germany — [2]Laboratory for Neutron Scattering and Imaging, Paul Scherrer Institute, CH-5232 Villigen, Switzerland

In condensed matter, Kagome material can host interplay of nontrivial topology, correlations, and magnetism due to their unique lattice and band structure. Recently, RTX series with ZrNiAl structure have gained attention due to possessing kagome lattice continuously breaking translation symmetry i.e., distorted kagome lattice. Intriguingly, HoAgGe has been predicted to have a kagome spin ice state and break the the reversal like symmetry and show two degenerate states in anomalous Hall effect. Along this line, we have synthesized single crystals of TbAgGe to investigate the magnetic and electrical transport properties in detail. It crystallizes in a hexagonal crystal structure with space group P-62m. It exhibits long-range AFM ordering of Tb3+ ions at Néel temperatures 29K, 25K and 20K. Further, it shows metamagnetic transitions when H || c, which might result in a non-coplanar spin structure in the system and goes to ferromagnetic (FM) state at high fields. Moreover, it shows significant anomalous Hall effect near the metamagnetic transitions, which is attributed to originating from the magnetic domain walls. Our findings suggest that RTX family with distorted kagome lattice can be an excellent platform to study the interplay of domain wall magnetism and topology.

MA 4.4 Mon 10:15 H19

Magnetic-circular dichroism on low-lying excitations in antiferromagnetic Fe2Mo3O8 — •Kirill Vasin[1], Istvan Kézsmárki[1], Sándor Bordács[2], and Joachim Deisenhofer[1] — [1]University of Augsburg, Augsburg, Germany — [2]Budapest University of Technology and Economics, Budapest, Hungary

We report the observation of a strong magnetic circular dichroism (MCD) and Faraday effect in the polar honeycomb antiferromagnet $Fe_2Mo_3O_8$ in the terahertz (THz) range. Using a common linear detection scheme with polarizers on both the emitter and detector set to the same angle, we observe seemingly thickness-dependent features and broadening in the transmission spectrum near narrow resonances in the Faraday configuration. These features are absent in the Voigt geometry with the same static magnetic field configuration, confirming that they arise from Faraday rotation (or MCD). By analyzing the zero-field spectrum and fitting Lorentz oscillators in the time-domain, we resolved oscillators parameters of the observed strong and narrow THz excitations with high accuracy. Using these parameters, we successfully reconstructed our field- and thickness-dependent transmission spectra, highlighting the role of Faraday rotation in the observed phenomena.

Our findings demonstrate the importance of considering detection schemes in Time-Domain THz spectroscopy and provide insights into methods of measuring MCD and Faraday rotation without ellipsometry techniques in «single-shot» transmission measurements for aniferromagnets.

MA 4.5 Mon 10:30 H19

Pressure-induced effects on the electronic band topology, magnetic order, and transport properties in FeSn — •Artem Chmeruk[1], Lilian Prodan[2], and Liviu Chioncel[3] — [1]University of Augbusrg — [2]University of Augbusrg — [3]University of Augbusrg

The family of kagome metals offers a fruitful platform for investigating the interplay between electronic band structure topology and various properties such as magnetism, electrical and optical response, etc. A rather promising topic of research is to control the positions of various topological features such as band (anti-) crossings of different dimensions (nodal points, lines, etc.) by some external parameters. For example, applying an external magnetic field could lead to band reconsctruction and therefore move the band crossings to different locations in the BZ. In a similar fashion, external pressure provides an opportunity to control these topological features both in terms of their location in the momentum space and on the energy scale. The possibility of moving such crossings closer to the Fermi level would immediately have an effect on the various observable quantities such as anomalous Hall conductivity. In this work, we study the effect of pressure on the magnetic order and the electronic band structure in FeSn up to 10 GPa. Furthermore, we investigate changes in the Berry curvature and its influence on the transport properties.

MA 4.6 Mon 10:45 H19

Emergent Majorana Metal from a Chiral Spin Liquid — •Shi Feng[1,2], Penghao Zhu[2], Kang Wang[3], Tao Xiang[3], and Nandini Trivedi[2] — [1]Technical University of Munich, Garching, Germany — [2]The Ohio State University, Columbus, USA — [3]Institute of Physics, Chinese Academy of Sciences, China

We propose a novel mechanism to explain the emergence of an intermediate gapless spin liquid phase (IGP) in the antiferromagnetic Kitaev model in an externally applied magnetic field, sandwiched between the well-known gapped chiral spin liquid (CSL) and the gapped partially polarized (PP) phase. We propose in moderate fields π-fluxes nucleate in the ground state and trap Majorana zero modes. As these fluxes proliferate with increasing field, the Majorana zero modes overlap creating an emergent Z_2 Majorana metallic state with a 'Fermi surface' at zero energy. We further show that the Majorana spectral function captures the dynamical spin and dimer correlations obtained by the infinite Projected Entangled Pair States (iPEPS) method thereby validating our variational approach. The emergence of the IGP as a Majorana metal at zero temperature indicates a new class of gapless QSLs alongside the commonly recognized Dirac spin liquids and $U(1)$ spinon Fermi surfaces in prevailing theories, bringing new insights into the nature of various candidate QSL phases of matter stabilized by moderate magnetic fields.

MA 4.7 Mon 11:00 H19

Tuning the order of a deconfined quantum critical point — Anika Goetz[2], •Natanael C. Costa[1], and Fakher Assaad[2] — [1]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil — [2]Institut für Theoretische Physik und Astrophysik, Universitat Würzburg, Würzburg, Germany

We consider a Su-Schrieffer-Heeger model in the assisted hopping limit where direct electron hopping is subdominant. At fixed electron-phonon coupling and in the absence of Coulomb interactions the model shows a deconfined quantum critical point between a $(0, \pi)$ valence bond solid in the adiabatic limit and a quantum antiferromagnetic (AFM) at high phonon frequencies. Here we show that by adding terms to the model that reinforce the AFM phase, thereby lowering the critical phonon frequency, the quantum phase transition becomes strongly first order. Our results does not depend on the symmetry of the model. In fact by adding a Hubbard-U term to the model lowers the $O(4)$ symmetry to SU(2), such that the DQCP we observe has the same UV symmetries as other models that account for the same quantum phase transitions.

MA 4.8 Mon 11:15 H19

The Laughlin vortex crystal in ideal Chern bands — •Saranyo Moitra and Inti Sodemann — Leipzig University, Leipzig, Germany

We have uncovered a novel phase transition of the celebrated Laughlin Fractional quantum Hall wave-function from its topologically ordered fluid phase onto a power-law-correlated vortex crystal in flat Chern bands with ideal quantum geometry. We will present a theory of ground state correlations and collective modes of these states across this transition and discuss their potential relevance to anomalous fractional quantum Hall phenomena in platforms such as moiré MoTe2, twisted bilayer graphene and pentalayer graphene.

MA 4.9 Mon 11:30 H19

Forestalled Phase Separation as the Precursor to Stripe Order — •Aritra Sinha and Alexander Wietek — Max Planck Institute for the Physics of Complex Systems, Nothnitzer Strasse 38, Dresden 01187, Germany

Stripe order is a prominent feature in the phase diagram of the high-temperature cuprate superconductors and has been confirmed as the ground state of the two-dimensional Fermi Hubbard model in certain parameter regimes. Upon increasing the temperature, stripes and the superconducting state give way to the enigmatic strange metal and pseudogap regime, whose precise nature poses long-standing, unresolved puzzles. Using modern tensor network techniques, we discover a crucial aspect of these regimes. Infinite projected entangled pair state (iPEPS) simulations in the fully two-dimensional limit reveal a maximum in the charge susceptibility at temperatures above the stripe phase. This maximum is located around hole-doping p=1/8 and intensifies upon cooling. Using minimally entangled typical thermal states (METTS) simulations on finite cylinders, we attribute the enhanced charge susceptibility to the formation of charge clusters, reminiscent of phase separation where the system is partitioned into hole-rich and hole-depleted regions. In contrast to genuine phase separation, the charge cluster sizes fluctuate statistically without a divergent charge susceptibility. Hence, while this precursor state features clustering of charge carriers, true phase separation is ultimately forestalled at lower temperatures by the onset of stripe order.

MA 5: Focus Session: Magnetic Phenomena from Phonon Chirality and Angular Momentum I (joint session MA/TT)

The magnetic moment of the electron lies at the heart of magnetism and spintronics. However, recent research has unveiled the angular momentum and magnetic moment of chiral phonons as fundamental quantities in their own right. These chiral phonons give rise to a plethora of novel lattice phenomena analogous to electronic effects, such as the phonon Hall and phonon Zeeman effects. Moreover, they play a critical role in angular momentum transfer on ultrafast timescales, as seen in the Einstein-de Haas effect. Chiral phonons can also generate effective magnetic fields reaching the tesla scale, inducing magnetization in antiferromagnetic, paramagnetic, and even nonmagnetic materials - a phenomenon reminiscent of the Barnett effect. These advancements showcase phonon chirality and angular momentum as powerful emerging tools for generating and controlling magnetism. This focus session aims to highlight the latest breakthroughs in chiral-phonon magnetism and foster connections between the rapidly evolving field of chiral phononics and the broader magnetism research community.

Driving Coherent Phonon-Phonon Angular Momentum Transfer via Lattice Anharmonicity — •Sebastian Maehrlein — Fritz Haber Institute of the Max Planck Society — Helmholtz Zentrum Dresden Rossendorf — TU Dresden

The discrete rotational symmetry of crystal structures leads to the conservation of quantized angular momentum in solids. Whereas the exchange of energy and linear momentum between lattice vibrations (phonons) via anharmonic coupling is a cornerstone of solid-state physics, conservation and transfer of angular momentum within the lattice remained a postulate, yet. Recently, phonon angular momentum, often in the form of chiral phonons, was linked to gigantic magnetic fields, dynamical ferroelectricity, ultrafast demagnetization, or magnetic switching. However, the fundamental process of phonon to phonon angular momentum transfer required for demagnetization and other spin-related relaxation phenomena remained elusive.

Here we drive coherent phonon-phonon angular momentum transfer by establishing helical nonlinear phononics. Thereby, we directly observe phonon helicity-switching dictated by (pseudo) angular momentum conservation and the discrete rotational symmetry of the lattice. Ab-initio modeling in conjunction with classical equations of motion confirm the experimentally observed anharmonic phonon-phonon coupling as the dominating lattice angular momentum transfer channel. Our results thus open the field of helical or chiral nonlinear phononics, turning lattice angular momentum into the long missing tuning knob for ultrafast material control.

Invited Talk MA 5.2 Mon 10:00 H20

Chiral phonons, phono-magnetism, and spin-rotation coupling — •Matthias Geilhufe — Department of Physics, Chalmers University of Technology, 412 96 Göteborg, Sweden

High-intensity THz lasers enable the coherent excitation of individual phonon modes. The ultrafast control of emergent magnetism through phonons and phonon angular momentum opens new avenues for tuning functional materials. Recent experiments suggest a substantial magnetization in various materials [1,2], presenting a challenge for theoretical modeling. I will provide an introduction to magnetization induced by phonon angular momentum via the phonon inverse Faraday effect [3]. Additionally, I will discuss a coupling mechanism based on inertial effects, which facilitates the interaction between rotational degrees of freedom and electron spin [4].

Geometry of temporal chiral structures and photoinduced chirality-spin coupling — •Olga Smirnova[1,2,3], Philip Flores[1], Aycke Roos[1], David Ayuso[4], Piero Decleva[5], Stefanos Carlstroem[1], Serguei Patchkovskii[1], and Andres Ordonez[4] — [1]Max-Born Institute, Berlin — [2]Technische Universität Berin — [3]Technion - Israeli Institute of Technology, Haifa, Israel — [4]Imperial College London, UK — [5]CNR IOM and Dipartimento di Scienze Chimiche e Farmaceutiche, Universita degli Studi di Trieste, Italy

In non-relativistic physics the concepts of geometry and topology are usually applied to characterize spatial structures, or structures in momentum space. We introduce the concept of temporal geometry [1], which encompasses geometric and topological properties of temporal shapes, e.g. trajectories traced by a tip of a time-dependent vector on sub-cycle time scale, and apply it to light-driven ultrafast electron currents in chiral molecules. The geometric concepts: curvature and connection emerge as ubiquitous features of photoexcited chiral electron dynamics. To demonstrate the link between the geometric fields and spin, we extend the concept of curvature to spin-resolved photoionization, and show that it is responsible for enantio-sensitive locking of the cation orientation to the photoelectron spin. This translates into chirality induced spin selectivity in photoionization of oriented chiral molecules both in one photon and two-photon processes.

Phonon thermal Hall effect — •Kamran Behnia — Ecole Supérieure de Physique et de Chimie Industrielles, Paris, France

In insulating solids and liquids, heat is carried by phonons. The phonon scattering time is close to the so-called Planckian time near the melting temperature. It increases with cooling, as phonon-phonon Umklapp scattering events rarefy. A rigorous determination of thermal conductivity of insulators from first principles has been a major accomplishment of the quantum theory of solids. In contrast, our understanding of momentum and energy exchange between phonons at low temperatures is imperfect. In this context, the experimental detection of

phonon thermal Hall effect in a growing number of insulators is a challenge to the condensed matter theory. The list now includes elmental insulators, such as black phosphorus, silicon and germanium, in which the spin degree of freedom is irrelevant and the atomic bonds are covalent. We will examine how magnetic field can influence anharmonicity.

Invited Talk MA 5.5 Mon 11:45 H20

Giant effective magnetic moment of chiral phonons — •Swati Chaudhary[1,3], Dominik Juraschek[2], Martin Rodriguez-Vega[3], and Gregory A Fiete[4] — [1]The Institute for Solid State Physics, The University of Tokyo, Japan — [2]Eindhoven University of Technology, Eindhoven, Netherlands — [3]The University of Texas at Austin, Austin, USA — [4]Northeastern University, Boston, USA

Chiral phonons carry angular momentum and lead to magnetic responses in applied magnetic fields or when resonantly driven with ultrashort laser pulses. On the basis of purely circular ionic motion, these phonons are expected to carry a magnetic moment of the order of a few nuclear magnetons. However, some recent experiments have demonstrated a phonon magnetic moment of the order of a few Bohr magnetons. This kind of giant magnetic response points towards the electronic contribution to the magnetic moment of phonons. Many diverse mechanisms have been discovered for this enhanced magnetic response of chiral phonons. The orbital-lattice coupling is one such mechanism where low-energy electronic excitations on a magnetic ion hybridize with phonons and endow a large magnetic moment to phonons. In this talk, I'll present a microscopic model for the effective magnetic moments of chiral phonons based on this mechanism. We apply our model to two types of materials: rare-earth halide paramagnets and transition-metal oxide magnets. In both cases, we find that chiral phonons can carry giant effective magnetic moments of the order of a Bohr magneton, orders of magnitude larger than previous predictions.

MA 5.6 Mon 12:15 H20

Extrinsic Phonon Thermal Hall Effect — •Dimos Chatzichrysafis[1], Robin Richard Neumann[1,2], and Alexander Mook[1] — [1]Johannes Gutenberg-Universität, Mainz, Germany — [2]Martin-Luther-Universität Halle-Wittenberg, Germany

The thermal Hall effect is a developing tool to investigate charge-neutral excitations, exposing the quantum many-body ground state of correlated materials. Since a sense of chirality for the energy carriers is necessary for the generation of a thermal Hall effect, it is natural to expect that quasiparticles of magnetic excitations are responsible for the Hall transport. This conventional wisdom has been recently challenged in experiments [1] which revealed a universal character of the thermal Hall effect independent on the magnetic texture and the lattice structure, even in systems where magnetism is completely absent. This finding asks for the re-investigation of the role of phonons in the thermal Hall effect.

Here, we develop a theory for a phononic thermal Hall effect where the source of chirality is given by the presence of the molecular Berry phase. As a toy model we study a non-magnetic system on a Bravais square lattice. We go beyond the intrinsic mechanism [2] usually studied in literature and consider the contribution of different possible extrinsic sources of phonon Hall transport. Our results demonstrate that phonon thermal Hall effects can be native to very generic systems.

Signatures of chiral phonons in $MnPS_3$ — •Banhi Chatterjee and Peter Kratzer — Faculty of Physics, University of Duisburg-Essen, Lotharstr. 1, 47057, Duisburg, Germany

Chiral phonons can exist in two-dimensional transition metal dichalcogenide (TMDC) monolayers without inversion symmetry. They can be observed in the non-equilibrium state triggered by optical excitations using circularly polarized light. In existing literature a detailed theoretical calculation of the circular phonons production rate has already been done for the TMDC MoS_2. We investigate the antiferromagnetic semiconductor $MnPS_3$ with a similar hexagonal crystal structure and band-structure like MoS_2 but a larger unit cell as a novel candidate material that may allow for excitation of circular phonons. In $MnPS_3$, although the total magnetic moment is zero in the ground state, exciting the system using circularly polarized light induces a net magnetic moment. The damping of the magnons observed experimentally points to the transfer of orbital angular moment to combined phonon-magnon excitations. Using DFT+U and density functional perturbation theory (DFPT) we obtain in-plane chiral phonon modes at the valley-points of a monolayer $MnPS_3$ and for these modes the S atoms make circular motions. We further study the electron-phonon coupling between these chiral phonon modes and the excited electronic states carrying orbital angular momentum, particularly the dominant d-electrons, in order to theoretically investigate the experimentally observed damping of magnons.

MA 5.8 Mon 12:45 H20

Elliptically polarized coherent phonons in a degenerate mode — Arne Ungeheuer, Mashood T. Mir, Ahmed Hassanien, Lukas Nöding, Thomas Baumert, and •Arne Senftleben — Institut für Physik, Universität Kassel

Controlled excitation of phonons in crystalline solids is an emerging way to alter the property of a material to create phenomena such as transient magnetic polarization [1,2]. Here, we want to focus on controlling the polarization properties of coherent optical phonons that can be launched by ultrashort laser pulses. we demonstrate the excitation of elliptically polarized coherent optical phonons of the E_{2g} shearing mode in graphite. This is achieved by exciting the superposition of two orthogonally polarized phonon modes using a tailored pair of time-delayed optical pulses with tilted polarization. The elliptically polarized coherent phonons are detected by ultrafast electron diffraction [3], where we determine the amount of ellipticity and the sense of rotation.

Magnetization dynamics of chiral helimagnetic insulators — •Aisha Aqeel — University of Augsburg, Augsburg, Germany — Technical University of Munich, Munich, Germany — Munich Center for Quantum Science and Technology (MCQST), Munich, Germany

Nature reveals fascinating patterns, often arising from intricate interactions among individual components. In magnets, remarkable patterns can emerge even in the absence of inversion symmetry. Chiral helimagnets, characterized by their twisted magnetic structures, whether topologically trivial or non-trivial, exhibit collective magnetic excitations ranging from GHz to THz. These exceptional properties make helimagnets highly attractive for spintronic technologies and unconventional computing [1]. However, realizing their full potential demands ultraclean magnetic systems with minimal dissipation and a deep understanding of their magnetization dynamics. In this talk, I will delve into the fundamental properties of chiral helimagnets and their dynamic magnetization behavior, focusing on the insulating material Cu2OSeO3. Our studies reveal evidence for a rare magnetic state in Cu2OSeO3 crystals - elongated skyrmions - observed through magnetic resonance experiments [2]. Additionally, utilizing a surface-sensitive electrical probe - spin Hall magnetoresistance - we discovered that the magnetic configurations at the surfaces of chiral magnets deviate significantly from those in the bulk [3].

MA 6.2 Mon 15:30 H16

Skyrmion dynamics in Ta/CoFeB/MgO at room temperature — •Hauke Lars Heyen[1], Malte Römer-Stumm[2], Michael Vogel[2], Florian Gossing[2], Jakob Walowski[1], Ethan Andrew Mullen[3], Christian Denker[1], Karin Dahmen[3], Jeffrey McCord[2], and Markus Münzenberg[1] — [1]Institute of Physics, University Greifswald, Germany — [2]Institute of Materials Science, Nanoscale Magnetic Materials and Magnetic Domains, CAU Kiel, Germany — [3]Department of Physics, The Grainger College of Engineering, University of Illinois Urbana-Champaign, USA

Applications in future storage devices, like the conceptual skyrmion race-track memory, require fundamental control over the skyrmion dynamics. We use Ta/CoFeB/MgO layer stacks to generate skyrmions at room temperature. The skyrmions are moved by applying nanosecond electric current pulses with current densities of around $5 \cdot 10^{10} A/m^2$ and are imaged with the magneto optical Kerr effect (MOKE). With a tracking algorithm the trajectories are determined and they hint at two diffusion types and the skyrmion-Hall effect. The latter occurs simultaneously with the topological Hall-effect that can be measured electrically. Combining the electrical measurements with MOKE allows us to separate the anomalous and the weak topological Hall effect. This allows for a differentiation between topological and non-topological stabilized magnetic structures.

MA 6.3 Mon 15:45 H16

Skyrmion Screws: A Novel 3D Topological Spin Texture — •Thorsten Hesjedal[1,2], Gerrit van der Laan[2], Haonan Jin[3,4], Jingyi Chen[3,4], and Shilei Zhang[3,4] — [1]Department of Physics, Clarendon Laboratory, Univer-

sity of Oxford, Oxford OX1 3PU, UK — [2]Diamond Light Source, Harwell Science and Innovation Campus, Didcot OX11 0DE, UK — [3]School of Physical Science and Technology, ShanghaiTech University, Shanghai 201210, China — [4]ShanghaiTech Laboratory for Topological Physics, ShanghaiTech University, Shanghai 201210, China

Three-dimensional (3D) magnetic skyrmions have attracted increasing interest as topological spin textures capable of hosting emergent electromagnetic properties and unique spin dynamics. In this study, we present the first direct experimental observation of skyrmion screws — a 3D spin crystal featuring modulations along the z-axis. Using state-of-the-art soft x-ray ptycho-tomography, we fully visualize the skyrmion screw lattice in a $Co_8Zn_{10}Mn_2$ thin lamella, fabricated to induce boundary confinement effects. Ferromagnetic resonance spectroscopy and micromagnetic simulations reveal a distinct low-frequency resonance mode, establishing skyrmion screws as a fundamentally new phase. These findings open avenues for studying 3D topological magnetism and its applications in magnonics and spintronics.

MA 6.4 Mon 16:00 H16

Skyrmion bags embedded in the skyrmion lattice — •Nikolai S. Kiselev — Peter Grünberg Institute, Forschungszentrum Jülich, 52425 Jülich, Germany

The micromagnetic model of 2D chiral magnets predicts the existence of skyrmion bags – solitons with arbitrary topological charge [1]. Recent experiments have confirmed the stability of skyrmion bags with positive topological charges [2,3]. Using Lorentz TEM on thin plates of B20-type FeGe, we demonstrate the remarkable stability of skyrmion bags with negative charges embedded within a skyrmion lattice [4]. We outline a robust protocol for nucleating these embedded skyrmion bags, which remain stable even in zero or inverted external magnetic fields. Our findings are in excellent agreement with micromagnetic simulations.

Skyrmion at finite temperature — •Thorben Pürling[1,2] and Stefan Blügel[1,2] — [1]Peter Grünberg Institut, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — [2]Physics Department, RWTH Aachen University, 52062 Aachen, Germany

In the past decade magnetic skyrmions have been under intense scientific scrutiny. Key properties of magnetic skyrmions such as the radius have been shown to exhibit highly nonlinear behavior as a function of the microscopic interaction parameters representing Heisenberg exchange, Dyzaloshinskii-Moriya interaction (DMI) and magnetic anisotropy [1]. Due to thermal fluctuations in both spin and lattice degrees of freedom, these interaction strengths carry an effective temperature dependence. Hence, temperature should demonstrate a strong effect on quantities like the skyrmion radius. Surprisingly little work has been done in this direction, particularly when it comes to taking lattice vibrations into account. Here we present our first attempts at investigating the role of the lattice dynamics on relevant interaction parameters.

We acknowledge funding from the ERC grant 856538 (project "3D MAGIC") and DFG through SFB-1238 (project C1).

MA 6.6 Mon 16:30 H16

Skyrmion lattices emerging from magnetic dipolar interactions — Elizabeth M Jefremovas[1], •Kilian Leutner[1], Miriam G. Fischer[1], Jorge Marqués-Marchán[2], Thomas B. Winkler[1], Agustina Asenjo[2], Jairo Sinova[1,3], Robert Frömter[1], and Mathias Kläui[1,4] — [1]Institute of Physics, Johannes Gutenberg University Mainz, 55128 Mainz, Germany — [2]Institute of Material Science of Madrid – CSIC, 28049 Madrid, Spain — [3]Department of Physics, Texas A&M University, College Station, Texas, USA — [4]Center for Quantum Spintronics, Norwegian University of Science and Technology, 7491 Trondheim, Norway

Magnetic skyrmions are well-studied two-dimensional topological spin textures. Surprisingly, little is known about the mutual interactions of dipolar-stabilized skyrmions. By engineering a magnetic multilayer stack, we stabilize for 1 to 30 repetitions skyrmion lattices at room temperature and zero field. Using Kerr microscopy and Magnetic Force Microscopy we observe a drastic decrease in skyrmion size as the number of repetitions is increased. We present an analytical model to describe the skyrmion radius and periodicity from the single-layer to the thick-film limit and complement this with micromagnetic simulations. Additionally, we identify the critical role of the nucleation process in forming the skyrmion lattice. Our work provides a comprehensive understanding of skyrmion-skyrmion interactions, which are driven by dipolar interactions as the multi-layer stack thickness increases.

Skyrmion size manipulation by external force — Klaus Raab, Kilian Leutner, •Leonie-Charlotte Dany, Simon Fröhlich, Grischa Beneke, Duc Minh Tranh, Sachin Krishnia, Robert Frömter, Peter Virnau, and Mathias Kläui — Institut für Physik, Johannes Gutenberg-Universität Mainz, Staudingerweg 7, 55128 Mainz, Germany

Magnetic skyrmions, spin textures with quasi-particle like properties, exhibit highly promising potential as information carriers in applications like storage or non-conventional computing.[1,2]

We experimentally investigate how the size of skyrmions is influenced by a combination of spin-orbit torques and repulsion from a structural barrier in a Ta/CoFeB/MgO based magnetic thin film. By employing Ga^+ ion implantation to modify the effective anisotropy of the magnetic layer, we create artificial barriers that serve as additional tools for manipulating skyrmions. Furthermore, the resulting changes in the formation of skyrmions lattice is characterized.

Based on the experimental finding, we then develop a new theoretical model within the framework of Thiele equation approach to describe the change in the skyrmions' size and their trajectories. Thiele equation accounts for the skyrmion size and skyrmion-skyrmion distance of an ensemble of skyrmions to an external stimulus, such as spin-orbit torques.

MA 6.8 Mon 17:15 H16

Eigenmode following for direct entropy calculation — •Stephan von Malottki[4], Moritz A. Goerzen[1], Hendrik Schrautzer[1,2], Pavel F. Bessarab[2,3], and Stefan Heinze[1] — [1]Institute of Theoretical Physics and Astrophysics, University of Kiel, Leibnizstrasse 15, 24098 Kiel, Germany — [2]cience Institute, University of Iceland, 107 Reykjavík, Iceland — [3]Department of Physics and Electrical Engineering, Linnaeus University, SE-39231 Kalmar, Sweden — [4]MODL, Insititute of Condensed Matter and Nanosciences, UC Louvain, Belgium

We present an eigenmode following method (EMF) to numerically calculate entropy contributions beyond harmonic approximation. In the framework of transition state theory, this increases the accuracy and applicability of transition rate calculations. In EMF, the potential energy landscape is explored along the investigated eigenvectors by iteratively updating a partial Hessian matrix along the way. Numerical integration of the Boltzmann factor over the obtained energy curve yields the contribution of the eigenmode to the partition function and entropy of the analysed state. The EMF method can be combined with other methods such as the harmonic approximation, making it a feasible method to improve the description of individual eigenmodes. The application of the method will be shown on the example of the Chimera skyrmion collapse mechanism and anti-skyrmion rotation modes.

MA 6.9 Mon 17:30 H16

Topological magnetism in diluted artificial adatom lattices — •Amal Aldarawsheh[1,2] and Samir Lounis[1,2] — [1]Peter Grünberg Institut and Institute for Advanced Simulations, Forschungszentrum Jülich & JARA, 52425 Jülich, Germany — [2]aculty of Physics, University of Duisburg-Essen and CENIDE, 47053 Duisburg, Germany

The ability to control matter at the atomic scale has revolutionized our understanding of the physical world, opening doors to unprecedented technological advancements. Quantum technology, which harnesses the unique principles of quantum mechanics, enables us to construct and manipulate atomic structures with extraordinary precision. Here[1], we propose a bottom-up approach to create topological magnetic textures in diluted adatom lattices on the Nb(110) surface. By fine-tuning adatom spacing, previously inaccessible magnetic phases can emerge. Our findings reveal that interactions between magnetic adatoms, mediated by the Nb substrate, foster the formation of unique topological spin textures, such as skyrmions and anti-skyrmions, both ferromagnetic and antiferromagnetic. Since Nb can be superconducting, our findings present a novel platform with valuable insights into the interplay between topological magnetism and superconductivity, paving the way for broader exploration of topological superconductivity in conjunction with spintronics applications.

The impact of magnetic anisotropy on the stability of antiskyrmions in schreibersite magnets — •Mamoun Hemmida[1], Jan Masell[2,3], Kosuke Karube[3], Dieter Ehlers[1], Hans-Albrecht Krug von Nidda[1], Vladimir Tsurkan[1,4], Yoshinori Tokura[3,5,6], Yasujiro Taguchi[3], and Istvan Kezsmarki[1] — [1]Experimental Physics V, Center for Electronic Correlations and Magnetism, Institute for Physics, University of Augsburg, Germany — [2]Institute of Theoretical Solid State Physics, Karlsruhe Institute of Technology, Germany — [3]RIKEN Center for Emergent Matter Science, Japan — [4]Institute of Applied Physics, Academy of Sciences of Moldova, Republic of Moldova —

[5]Department of Applied Physics and Quantum-Phase Electronics Center, University of Tokyo, Japan — [6]Tokyo College, University of Tokyo, Japan

Magnetic anisotropy is a fundamental property of magnetic materials that plays an essential role in the stability of magnetic domains and skyrmions. In this ferromagnetic resonance (FMR) study we report the evolution of magnetic anisotropy by substituting various 4*d* metals in the easy-plane schreibersite magnet $(Fe,Ni)_3P$ with S_4 tetragonal symmetry,Hemmida2024. Starting from easy-plane anisotropy, Pd doping turns $(Fe,Ni)_3P$ to an easy-axis-type magnet. As a consequence, antiskyrmions are created. FMR study of the planar anisotropy proofs a fourfold symmetry as expected for the tetragonal crystal structure. The corresponding planar anisotropy parameter is an order of magnitude smaller than the uniaxial one. Hemmida2024 M. Hemmida, *et al.*, Phys. Rev. B 110, 054416 (2024).

MA 6.11 Mon 18:00 H16

The impact of the non-chiral magnetic fan state on the transformation of chiral textures in $Mn_{1.4}PtSn$ — M. Winter[1,2], A. Pignedoli[3], M.C. Rahn[4], A.S. Sukuhanov[4], A. Tahn[2], S. Schneider[2], D. Pohl[2], M. Azhar[3], K. Everschor-Sitte[3], J. Geck[4], G. van der Laan[5], T. Hesjedal[5,6], P. Vir[1], C. Felser[1], and •B. Rellinghaus[2] — [1]MPI CPfS, Dresden, Germany — [2]DCN, TU Dresden, Germany — [3]Univ. Duisburg-Essen, Germany — [4]IFMP, TU Dresden, Germany — [5]Diamond Light Source, UK — [6]Univ. Oxford, UK

The Heusler compound $Mn_{1.4}PtSn$ is a chiral magnet that exhibits a rich of variety non-topological and topologically protected chiral magnetic textures at room temperature. We have used Lorentz transmission electron microscopy (LTEM) supported by resonant elastic x-ray scattering (REXS) and micromagnetic simulations to characterize the emerging magnetic structures as function of the magnitude and orientation of an external magnetic field. We find that in out-of-plane fields, chiral soliton lattices emerge, while in-plane fields promote the formation of non-chiral magnetic fan domains. At fields in the stability range of the latter, the nucleation of non-topological bubbles (ntB's) occurs. Intriguingly, ntB's show combined characteristics of chiral solitons and the fan-type structure and may consequently be interpreted as hybrid structures of the latter. Following a distinct field protocol, ordered lattices of these ntB's then successively transform into anti-skyrmion lattices. Financial support by DFG through SPP 2137, project no. 403503416, is gratefully acknowledged.

MA 6.12 Mon 18:15 H16

Emergence of polar skyrmions in 2D Janus CrInX3 (X=Se, Te) magnets — •Duo Wang[1], Fengyi Zhou[1], Monirul Shaikh[2], and Biplab Sanyal[3] — [1]Macao Polytechnic University — [2]University of Nebraska, Kearney — [3]Uppsala University

In the realm of multiferroicity in 2D magnets, whether magnetic and polar skyrmions can coexist within a single topological entity has emerged as an important question. Here, we study Janus 2D magnets CrInX3 (X=Se, Te) for a comprehensive investigation of the magnetic ground state, magnetic excited state, and corresponding ferroelectric polarization by first-principles electronic structure calculations and Monte Carlo simulations. Specifically, we have thoroughly elucidated the magnetic exchange mechanisms, and have fully exemplified the magnetic field dependence of the magnon spectrum. More importantly, our study reveals a previously unrecognized, remarkably large spin-spiral-induced ferroelectric polarization (up to 194.9 μC/m2) in both compounds. We propose an approach to identify polar skyrmions within magnetic skyrmions, based on the observed direct correlation between spin texture and polarization density. Elucidating this correlation not only deepens our understanding of magnetic skyrmions but also paves the way for innovative research in the realm of multiferroic skyrmions.

MA 7: INNOMAG e.V. Prizes 2025 (Diplom-/Master and Ph.D. Thesis)

Die Arbeitsgemeinschaft Magnetismus der DPG hat einen Dissertationspreis und einen Diplom-/Masterpreis ausgeschrieben, welche auf der Tagung der DPG 2025 in Regensburg vergeben werden. Ziel der Preise ist die Anerkennung herausragender Forschung im Rahmen einer Diplom-/Masterarbeit beziehungsweise einer Promotion und deren exzellente Vermittlung in Wort und Schrift. Im Rahmen dieser Sitzung tragen die besten der für ihre an der Hochschule eines Mitgliedslands der European Physical Society durchgeführten Diplom-/Masterarbeit beziehungsweise Dissertation Nominierten vor. Im direkten Anschluss entscheidet das Preiskomitee über den Gewinner bzw. die Gewinnerin des INNOMAG e.V. Diplom/Master-Preises und des Dissertationspreises 2025. Talks will be given in English!

Time: Monday 15:00–18:00 Location: H18

Invited Talk MA 7.1 Mon 15:00 H18

Realizing Reservoir Computing with skyrmions in geometrical confinements tuned by ion irradiation — •Grischa Beneke — Institut für Physik, Johannes Gutenberg-Universität Mainz, 55128 Mainz, Germany

Physical reservoir computing (RC) is a beyond von-Neumann computing paradigm that harnesses complex physical systems' dynamics for efficient information processing. Magnetic skyrmions, topological spin textures, show promise for RC systems due to their non-linear interactions and low-power manipulation capabilities. Previous spin-based RC implementations either focused on static detection or required rescaling of real-world data to match intrinsic magnetization dynamics timescales. In this thesis, we demonstrate time-multiplexed skyrmion RC by adjusting the reservoir's intrinsic timescales to match real-world temporal patterns [1]. Using hand gestures recorded via range-Doppler radar in collaboration with industry, we show that our hardware solution outperforms conventional software-based neural networks while consuming less energy. The system's ability to directly integrate sensor data without temporal conversion enables real-time applications. To structure the geometrical confinement, we investigate how high-energy ion irradiation influences magnetic properties in skyrmion-hosting multilayers. By locally modifying the perpendicular magnetic anisotropy, we create attractive and repulsive regions that enable controlled skyrmion nucleation, manipulation and confinement, enabling novel devices and, enhancing device functionality. [1] G. Beneke et al., Nat. Commun. 15, 8103 (2024).

Invited Talk MA 7.2 Mon 15:20 H18

Low-energy spin excitations of the Kitaev candidate material $Na_2Co_2TeO_6$ probed by high-field/high-frequency electron spin resonance spectroscopy — •Luca Bischof[1], Jan Arneth[1], Kwang-Yong Choi[2], Raju Kalaivanan[3], Raman Sankar[3], and Rüdiger Klingeler[1] — [1]Kirchhoff Institute for Physics, Heidelberg University, Germany — [2]Department of Physics, Sungkyunkwan University, Republic of Korea — [3]Institute of Physics, Academia Sinica, Taiwan

The realization of a Kitaev spin liquid state in the Co-based honeycomb magnet $Na_2Co_2TeO_6$ is circumvented by magnetic ordering due to Heisenberg and off-diagonal interactions. The nature of these interactions and the magnetic ground state in $Na_2Co_2TeO_6$ are still under debate. We report high-frequency/high-field electron spin resonance (ESR) measurements of single-crystal $Na_2Co_2TeO_6$ probing the low-energy spin excitations of the ordered phase below $T_N \simeq 27$ K. A complex magnon spectrum for in-plane magnetic fields $B \parallel a^*$ indicates field-induced phase transitions. For out-of-plane magnetic fields $B \parallel c$, we observe one softening and two hardening magnon modes. They share a magnon excitation gap of $\Delta = 219(13)$ GHz. We performed spin wave calculations for the extended Heisenberg-Kitaev model to compare the observed magnon modes to the low-energy excitations expected for zigzag and triple-q ground states in an applied magnetic field.

Invited Talk MA 7.3 Mon 15:40 H18

Tailoring the first-order magnetostructural phase transition in Ni-Mn-Sn for caloric applications by microstructure — •Johannes Puy, Enrico Bruder, Oliver Gutfleisch, and Franziska Scheibel — TU Darmstadt, Darmstadt, Germany

Ni-Mn-Sn Heusler alloys show a large inverse magnetocaloric (MCE) and conventional elastocaloric effect (ECE), making them a promising candidate for multicaloric cooling. The caloric effects arise from a first-order magnetostructural phase transition (FOMST) from high-magnetic austenite to low-magnetic martensite, driven by a nucleation and growth process. Optimizing the multicaloric performance of these materials requires tailoring the FOMST, which implies a comprehensive understanding of the role of microstructure and coupling factors, such as atomic, magnetostatic, and stress coupling. In this study, the influence of microstructure and defects (grain boundaries, pores, sintering necks) on the temperature-driven FOMST is investigated in single- and polycrystalline particles, as well as in spark-plasma-sintered Ni-Mn-Sn. By adjusting the relative density, the effect of porosity on the FOMST is studied. Temperature-dependent magnetometry reveals that an increase of the relative density from 88 % to 99 % narrows the transition ranges from 18 K to 9 K and decreases

the transition temperature from 263 K to 254 K. Temperature-dependent in-situ optical and in-situ scanning electron microscopy reveal preferential martensite nucleation at free particle surfaces in powder and sintered, 88% dense Ni-Mn-Sn, while nucleation in 99 % dense Ni-Mn-Sn is favored at sintering necks. We thank the CRC/TRR 270 'HoMMage' for funding.

Invited Talk MA 7.4 Mon 16:15 H18

Tuning the properties of two-dimensional magnetic heterostructures via interface engineering with molecular and inorganic van der Waals crystals. — •Carla Boix-Constant[1], Samuel Mañas-Valero[2], and Eugenio Coronado[1] — [1]Institute of Molecular Science, 46980 Paterna (Valencia), Spain. — [2]Kavli Institute of Nanoscience - TU Delft, Delft 2628 CJ, The Netherlands.

Two-dimensional (2D) materials offer unprecedented opportunities for fundamental and applied research in several condensed matter physics areas. For this purpose, state-of-the-art techniques were employed in this thesis (divided in two blocks) to fabricate van der Waals heterostructures based on mainly 2D magnets (both inorganic and molecular systems) and to characterize the resulting devices by magneto-transport techniques. On the one hand, new chemically designed molecular building blocks were combined with 2D materials to afford hybrid devices offering a new playground for exploiting the potential of spin transition molecular systems to control the properties of the 2D material. On the other hand, we focused on purely 2D magnetic materials: the quantum spin liquid candidate 1T-TaS2 - where our results throw some light in the debate about the exotic behaviour of the material - and the metamagnet CrSBr - results that afford a new generation of van der Waals heterostructures with programmable properties.

Invited Talk MA 7.5 Mon 16:40 H18

Theoretical Prediction for Probing Magnon Topology — •Robin R. Neumann — Johannes Gutenberg University Mainz — Martin Luther University Halle-Wittenberg

Magnons, the bosonic quasiparticles of collective spin excitations, hold potential as information and energy carriers in spintronic devices. Although the magnonic counterpart of the electronic quantum Hall states was predicted over a decade ago [1, 2], experimental evidence remains absent because established methods fail to probe them [3].

In my thesis I have studied the signatures of topological magnons in transport and spectroscopic observables. While I demonstrated that the thermal Hall effect can be sensitive to topological phase transitions in the magnon band structure [4], magnon-phonon hybridization may obscure their contributions [5]. I present a specific proposal for using electrical probes to detect topological magnons [6]. Despite their charge neutrality, magnetoelectric effects grant magnons an electrical dipole moment. Consequently, edge magnons give rise to an electric polarization at the edges driven by thermal spin fluctuations. Furthermore, magnons are predicted to interact with alternating electric fields, opening up the possibility of resonantly exciting topological magnons. The resulting absorption spectrum encodes footprints of topological magnons that might assist in their detection.

Invited Talk MA 7.6 Mon 17:05 H18

Multiphysics-Multiscale Simulation of Additively Manufactured Functional Materials — •Yangyiwei Yang — Technische Universität Darmstadt, Darmstadt, Germany

The progress of additive manufacturing (AM) technologies has led to a growing interest in AM-produced magnetic functional materials with tailored properties, including magnetic coercivity, remanence and saturation magnetization. However, the lack of comprehensive research on the process-microstructure-property (PMP) relationship poses a significant challenge to the production of magnetic materials with designed properties by AM. In this work, a multiphysics-multiscale simulation framework has been developed to thoroughly investigate the PMP relationships in magnetic functional materials and to further facilitate simulation-driven property tailoring. The framework is methodically structured to ensure clarity and depth, with emphasis on key concepts with corresponding physical backgrounds. By employing the established framework, phenomenological relationships between AM processing parameters and the resulting material properties are obtained, notably magnetic hysteresis. The sensitivity of the local magnetic coercivity to residual stress states in AM-produced Fe-Ni permalloy is also revealed. In particular, the relationship between the average residual stress and the magnetic coercivity within the melt zone are shown to obey an exponential growth law, suggesting a strategy for tailoring the magnetic coercivity by controlling the residual stress within an AM-produced permalloy.

30 min. discussion break and bestowal of INNOMAG e.V. Diplom-/Master Prize and Ph.D. Thesis Prize

MA 8: Spin-Dependent Phenomena in 2D (joint session MA/HL)

Time: Monday 15:00–17:15 Location: H19

MA 8.1 Mon 15:00 H19

Magnetoelectric behavior of breathing kagomé monolayers of Nb3(Cl,Br,I)8 from first-principles calculations — •John Mangeri — Technical University of Denmark, Kongens Lyngby, Denmark

We apply density functional theory to explore the magnetoelectric (ME) properties of two-dimensional Nb3(Cl,Br,I)8. These compounds have recently been proposed to exhibit coupled ferroelectric and ferromagnetic order leading to a switchable anomalous valley Hall effect (AVHE). Using both spin-spiral and self-consistent spin-orbit coupled calculations, we predict an in-plane 120 degree cycloid of trimerized spins as the ground state for Nb3Cl8. For Nb3Br8 and Nb3I8 we find long period incommensurate helical order. We calculate a number of magnetic properties such as the exchange constants, orbital magnetization, and Weiss temperatures. It is then shown that, despite having both broken inversion and time-reversal symmetry, the proposed AVHE and linear ME response are forbidden by the presence of helical order in the ground state. In addition, the computed switching trajectory demonstrates that it is unlikely that the polar state of the monolayers can be switched with a homogeneous electric field due to an unusual equation of state of the out-of-plane dipole moment. Nevertheless, we highlight that in the presence of a strong electric field, the trimerized spins in Nb3Cl8 will exhibit a magnetic phase transition from the 120 degree cycloid to out-of-plane ferromagnetic order, which restores the symmetry required for both AVHE and linear ME effects.

MA 8.2 Mon 15:15 H19

Ab-initio Investigation of two-dimensional Fe-Sn Kagome lattice with Nb doping — •Gérald Kämmerer[1,2] and Sinéad Griffin[2] — [1]Faculty of Physics, University of Duisburg-Essen — [2]Lawrence Berkeley National Laboratory (LBNL), Berkeley

This research investigates Fe-Sn-based kagome compounds for green energy applications, focusing on their magnetic and electronic properties, particularly in spintronics and phononics. We are investigating tunable properties in Fe_3Sn. We aim to control spin states in 2D magnetic systems by studying doped variants (Nb) in Kagome lattices to uncover topological electronic states, including Dirac fermions and flat bands.

Using first-principles calculations, we analyse impurity interactions in 2D lattices using VASP. By comparing experimental data with our computational results, this study aims to provide insights into dopant-controlled quantum states and improve material performance in electronic applications.

The financial support of the DFG within the SFB 1242 and the computational time on the LBNL supercomputer system are gratefully acknowledged.

MA 8.3 Mon 15:30 H19

Spin polarization of the two-dimensional electron gas at the EuO/$SrTiO_3$ interface — •Paul Rosenberger[1,2], Andri Darmawan[3], Olena Fedchenko[1], Olena Tkach[1], Serhii V. Chernov[4], Dmitro Kutnyakhov[4], Moritz Hoesch[4], Markus Scholz[4], Kai Rossnagel[4,5], Rossitza Pentcheva[3], Gerd Schönhense[1], Hans-Joachim Elmers[1], and Martina Müller[2] — [1]JGU Mainz, Germany — [2]Uni Konstanz, Germany — [3]UDE, Duisburg, Germany — [4]DESY, Hamburg, Germany — [5]CAU Kiel, Germany

Spin-polarized two-dimensional electron gases (2DEGs) are of particular interest for functional oxide electronics applications. Here, we use magnetic circular dichroism in the angular distribution (MCDAD) of photoemitted electrons to investigate whether and how the induced spin polarization of the redox-created 2DEG at the EuO/$SrTiO_3$ (001) interface depends on the dimensionality of the strongly ferromagnetic (7 $\mu_B/f.u.$) EuO layer [1]. Samples with EuO thicknesses ranging from one to four monolayers were studied. We show that the EuO/STO interfacial 2DEG becomes spin-polarized starting from a threshold EuO thickness of only two monolayers. Experimental data are complemented by DFT+U calculations. Our results, and the potential to enhance the magnetic order of EuO by other proximity effects [2], indicate that the EuO/STO interface is an ideal template for creating functional spin-polarized 2DEGs for application in oxide electronics.

MA 8.4 Mon 15:45 H19

***Ab initio* calculation of Spin-Orbit torques in 2D magnets** — •Gusthavo Brizolla and Jaroslav Fabian — Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany

The interplay of spin-orbit coupling and magnetism in two-dimensional materials and their heterostructures presents exciting opportunities for advancing next-generation spintronic devices. In this work, we investigate the role of proximity effects in generating spin-orbit torques (SOTs) in Fe_3GeTe_2 (FGT) and FGT-based van der Waals heterostructures. Using a tight-binding Hamiltonian derived from first-principles calculations via the Wannierization procedure, we evaluate the torkances within the linear response regime using the Kubo formalism. Our results reveal key mechanisms underlying the generation of torques driven by spin accumulation, elucidating the fundamental physics of SOTs in these systems.

This research has been supported by 2D SPIN-TECH.

MA 8.5 Mon 16:00 H19

Unveiling Long-range Magnetic Textures in Twisted Moiré Antiferromagnets — •King Cho Wong[1], Ruoming Peng[1], Xiaodong Xu[3], Elton Santo[2], Adam Wei Tsen[4], Rainer Stoehr[1], and Joerg Wrachtrup[1] — [1]3rd Physics Institute, University of Stuttgart, Stuttgart, Germany — [2]University of Edinburgh, United Kingdom — [3]University of Washington, USA — [4]University of Waterloo, Canada

Stacking two-dimensional (2D) materials offers a controllable and versatile platform to engineer interlayer interactions, unveiling numerous intriguing correlated and topological states. Recent progresses in twisted 2D magnets have revealed periodic ferromagnetic domains due to the local Moiré stacking. In this study, we employed scanning quantum microscopy to investigate local magnetic responses of twisted double bilayer chromium triiodide (tDB CrI3). We observed unexpected antiferromagnetic textures with periods more than 300 nm at the 1.1° twisted devices, which are significantly exceeding the corresponded Moiré size of about 30 nm. These periodic magnetic textures are setting atop randomly distributed ferromagnetic domains with net two-layer magnetization of 30 uB/nm^2 and antiferromagnetic domains with magnetization of 0 uB/nm^2. Our findings suggest that strong magnetic competition at small twisted angles (<2°) can extend magnetic textures beyond the Moiré size, leading to the emergence of Néel skyrmions after field cooling.

MA 8.6 Mon 16:15 H19

Spin model of graphene triangulenes embedded in hexagonal boron nitride — •Dániel Tibor Pozsár[1,3,4,5], László Oroszlány[1,2,3], and Viktor Ivády[1,4,5,6] — [1]Department of Physics of Complex Systems, Eötvös Loránd University, Egyetem tér 1-3, H-1053 Budapest, Hungary — [2]Wigner Research Centre for Physics, Konkoly-Thege M. út 29-33, H-1121 Budapest, Hungary — [3]TRILMAX Consortium, Twinning, Horizon Europe, Budapest, Hungary — [4]QUEST projec, Twinning, Horizon Europe, Budapest, Hungary — [5]MTA*ELTE Lendület "Momentum" NewQubit Research Group, Pázmány Péter, Sétány 1/A, 1117 Budapest, Hungary — [6]Department of Physics, Chemistry and Biology, Linköping University, SE-581 83 Linköping, Sweden

We are investigating triangulene shaped substitutional defects in hexagonal boron nitride filled with carbon atoms. We show how the triangulene shaped defects encompass magnetic moments and with ab initio methods we build Heisenberg like classical spin models representing their interactions. We show how different lattice terminations and sizes impact the magnetic properties of the system.

MA 8.7 Mon 16:30 H19

Realizing Spin-3/2 AKLT State for Quantum Computation with Tetrapod Architectures — •Claire Benjamin[1], László Oroszlány[1,2], Dániel Varjas[3], and Gábor Széchenyi[1] — [1]Department of Physics of Complex Systems, Eötvös University, Pázmány Péter sétány 1/A, H-1117 Budapest, Hungary — [2]Wigner Research Centre for Physics, Konkoly-Thege M. út 29-33, H-1121 Budapest, Hungary — [3]Department of Theoretical Physics, Institute of Physics, Budapest University of Technology and Economics, Muegyetem rkp. 3., H-1111 Budapest, Hungary

Using a novel tetrapod (5-site cluster) architecture, we implement spin-3/2 degrees of freedom in a semiconductor quantum bit platform. This framework enables us to construct a tunable artificial spin system that can realize the two-dimensional Affleck-Kennedy-Lieb-Tasaki (AKLT) state on a honeycomb lattice, known to be a universal resource for measurement-based quantum computation. We assess the model's robustness and feasibility for measurement based quantum computing using semi-analytic perturbation theory and numerical calculations.

MA 8.8 Mon 16:45 H19

Anomalous quantum oscillations from boson-mediated interband scattering — •Léo Mangeolle[1,2] and Johannes Knolle[1,2,3] — [1]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 München, Germany — [3]Blackett Laboratory, Imperial College London, London SW7 2AZ, United Kingdom

Quantum oscillations (QO) in metals refer to the periodic variation of thermodynamic and transport properties as a function of inverse applied magnetic field. QO frequencies are normally associated with semi-classical trajectories of Fermi surface orbits but recent experiments challenge the canonical description. We develop a theory of composite frequency quantum oscillations (CFQO) in two-dimensional Fermi liquids with several Fermi surfaces and interband scattering mediated by a dynamical boson, e.g. phonons or spin fluctuations. Specifically, we show that CFQO arise from oscillations in the fermionic self-energy with anomalous frequency splitting and distinct strongly non-Lifshitz-Kosevich temperature dependencies. Our theory goes beyond the framework of semi-classical Fermi surface trajectories highlighting the role of many-body effects. We provide experimental predictions and discuss the effect of non-equilibrium boson occupation in driven systems.

MA 8.9 Mon 17:00 H19

Identifying the Origin of Thermal Modulation of Exchange Bias in $Fe_3GeTe_2/MnPS_3$ van der Waals Heterostructures — Aravind Puthirath Balan[1], •Aditya Kumar[1], Patrick Reiser[2], Joseph Vimal Vas[3], Thibaud Denneulin[3], Rafal E. Dunin-Borkowski[3], Patrick Maletinsky[2], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg University Mainz, Staudinger Weg 7, 55128 Mainz, Germany — [2]Department of Physics, University of Basel, Klingelbergstrasse 82, 4056 Basel, Switzerland — [3]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons and Peter Grünberg Institute, Forschungszentrum Jülich, 52425 Jülich, Germany

This study investigates the origin of exchange bias in $Fe_3GeTe_2/MnPS_3$ vdW heterostructures. A substantial 170 mT exchange bias is observed at 5 K, one of the largest values reported for vdW heterostructures, despite the compensated interfacial spin configuration of $MnPS_3$. This exchange bias is linked to unexpected weak ferromagnetic ordering in $MnPS_3$ below 40 K that we reveal by NV center imaging. A 1000% variation in the magnitude of exchange bias is obtained through thermal cycling linked to changes in the vdW gap during field cooling. Detailed interface analysis reveals atom migration between layers, forming amorphous regions on either side of the vdW gap. These findings underscore the robust and tunable nature of exchange bias in vdW heterostructures but also challenge the often assumed pristine nature of vdW interfaces calling for in-depth interface characterization.

MA 9: Altermagnets I

Time: Monday 15:00–18:30 Location: H20

MA 9.1 Mon 15:00 H20

Tuning the Octupolar Degrees of Freedom in the Altermagnetic Candidate MnF_2 by Strain and Magnetic Field — •Rahel Ohlendorf[1,2], Hilary M. L. Noad[1], Jörg Schmalian[3], Elena Hassinger[2], Andrew P. Mackenzie[1,4], and Elena Gati[1] — [1]Max-Planck-Institute for Chemical Physics of Solids, Dresden, Germany — [2]Technical University, Dresden, Germany — [3]Karlsruhe Institute of Technology, Karlsruhe, Germany — [4]University of St Andrews, UK

Altermagnetism can unambiguously be differentiated from the known ferro- and antiferromagnetic phases within the framework of spin-group symmetry [1]. In centrosymmetric altermagnets the ordered state can be described in terms of ferroically ordered magnetic octupoles [2]. The experimental conjugate field that is predicted to couple to this order parameter is a combination of strain and magnetic field. Consequently the application of strain and magnetic field should enable the exploration of the physics near the ferrooctupolar critical point, including its associated crossover lines.

We discuss experimental phase diagrams on the centrosymmetric altermagnetic candidate MnF_2 in magnetic field and strain, mapped out by means of elastocaloric measurements and compare our results to theoretical predictions based on a Landau free energy [3].

*Work is supported by the DFG through TRR288 (Elasto-Q-Mat).

MA 9.2 Mon 15:15 H20

Tuning the magnetic anisotropy of the altermagnet CrSb — •Miriam Fischer[1], Lukas Odenbreit[1], Sonka Reimers[1], Toni Helm[2], Mathias Kläui[1], and Martin Jourdan[1] — [1]Johannes Gutenberg Universität, Mainz — [2]Helmholtz-Zentrum Dresden-Rossendorf

CrSb is an altermagnetic compound, whose band structure we recently investigated by SX-ARPES [Rei24]. For the utilization of this compound in spintronics, a rotation of the magnetic easy axis is required. Thus, we study the tunability of the magnetic anisotropy of CrSb and related compounds by measurements of the spin-flop field.

[Rei24] S. Reimers et al., Nat Commun. 15, 2116 (2024)

MA 9.3 Mon 15:30 H20

Local signatures of altermagnetic order — •Jannik Gondolf[1], Andreas Kreisel[1], Mercè Roig[1], Daniel F. Agterberg[2], and Brian M. Andersen[1] — [1]Niels Bohr Institute, University of Copenhagen, DK-2200 Copenhagen, Denmark — [2]Department of Physics, University of Wisconsin-Milwaukee, Milwaukee, Wisconsin 53201, USA

Altermagnets are known to share properties of ferromagnets and antiferromagnets. They feature time-reversal symmetry breaking, non-relativistic anisotropic band splitting and compensated net magnetization. Fundamental properties of altermagnetism include the anomalous Hall effect, a spin-polarized band structure in angle-resolved photoemission spectroscopy and spin-polarized currents. We employ a minimal model to investigate the local signatures of altermagnetism in the vicinity of impurities using T-matrix theory and exact diagonalization. Our findings suggest that the altermagnetic symmetry breaking is directly imprinted in the local density of states. These signatures can be quantified by scanning tunnel microscopy, offering a new approach for identifying and characterizing potential altermagnetic materials experimentally. Further, we explore potential interplay between altermagnetism and superconductivity.

MA 9.4 Mon 15:45 H20

Spin-wave theory and magnon transport properties of altermagnetic hematite (α-Fe2O3) — •Rhea Hoyer[1], P. Peter Stavropoulos[2], Libor Šmejkal[1,3,4], and Alexander Mook[1] — [1]Department of Physics, Johannes Gutenberg University Mainz, 55128 Mainz, Germany — [2]Institut für Theoretische Physik, Goethe-Universität Frankfurt, 60438 Frankfurt am Main, Germany — [3]Max Planck Institute for the Physics of Complex Systems, Nothnitzer Str. 38, 01187 Dresden, Germany — [4]Institute of Physics, Czech Academy of Sciences, Cukrovarnická 10, 162 00 Praha 6, Czech Republic

We develop a four-sublattice spin-wave theory for the g-wave altermagnet hematite (α-Fe2O3) in its two magnetic phases: the easy-axis phase below, and the weak ferromagnetic phase above the Morin temperature. We estimate the Morin temperature with a free energy calculation. The relativistic magnon dispersion relation in the easy-axis phase shows the spin (or chirality) splitting typical of altermagnets. We investigate magnon transport properties with a particular focus on the crystal thermal Hall effect.

MA 9.5 Mon 16:00 H20

Giant spatial anisotropy of magnon lifetime in altermagnets — •António Costa[1,2], João Henriques[1,3], and Joaquín Fernández-Rossier[1] — [1]International Iberian Nanotechnology Laboratory, Braga, Portugal — [2]Physics Center of Minho and Porto Universities (CF-UM-UP), Braga, Portugal — [3]Universidade de Santiago de Compostela, Santiago de Compostela, Spain

Altermagnets are a new class of magnetic materials with zero net magnetization (like antiferromagnets) but spin-split electronic bands (like ferromagnets) over a fraction of reciprocal space. As in antiferromagnets, magnons in altermagnets come in two flavours, that either add one or remove one unit of spin to the $S = 0$ ground state. However, in altermagnets these two magnon modes are non-degenerate along some directions in reciprocal space. Here we show that the lifetime of altermagnetic magnons has a very strong dependence on both flavour and direction. Strikingly, coupling to Stoner modes leads to a complete suppression of magnon propagation along selected spatial directions. This giant anisotropy will impact electronic, spin, and energy transport properties and may be exploited in spintronic applications.

MA 9.6 Mon 16:15 H20

Chiral spin-flip magnons in metallic altermagnets from many-body perturbation theory — •Wejdan Beida[1], Ersoy Sasioglu[2], Gustav Bihlmayer[1], Christoph Friedrich[1], Yuiry Mokrousov[1], Ingrid Mertig[2], and Stefan Blügel[1] — [1]Peter Grünberg Institut, Forschungszentrum Jülich, 52425 Jülich Germany — [2]Institute of Physics, Martin Luther University Halle-Wittenberg, 06120 Halle, Germany

Altermagnets represent a novel class of magnetic materials that bridge the gap between conventional ferro- and antiferromagnets. A unique feature of altermagnets is the lifting of degeneracy of their spin-wave modes (magnons) along the same crystallographic directions in which electronic bands also exhibit spin splitting. This non-degeneracy leads to chirality and directional anisotropy in spin-wave dispersions. In this presentation, we present the spin splitting of electronic bands and chiral spin-wave excitations in a series of metallic altermagnets, which have NiAs-type crystal structure, using DFT and many-body perturbation theory [1]. Our findings reveal a pronounced anisotropic splitting in chiral magnon bands, a small chiral asymmetry in the magnon lifetime, and demonstrate that magnon damping due to Stoner excitations is minimal. This results in long-lived magnons with efficient propagation, underscoring the potential of altermagnets for advanced spintronic and magnonic applications.

MA 9.7 Mon 16:30 H20

Fingerprints of altermagnetism in the optical properties of MnTe — •Luca Felipe Haag[1], Marius Weber[1,2], Jairo Sinova[2], and Hans Christian Schneider[1] — [1]Department of Physics and Research Center OPTIMAS, University of Kaiserslautern-Landau, Germany — [2]Institut für Physik, Johannes Gutenberg University Mainz, Germany

It has recently been demonstrated by magneto-optical Kerr effect (MOKE) measurements that the spin system in planar d-wave altermagnets can be controlled by linearly polarized optical excitation [2] as one can selectively address spin-up or spin-down electrons by choosing the polarization of the optical pulse. The objective of this study is to investigate whether similar optical effects can be observed in bulk g-wave altermagnets. To this end, we focus on MnTe, which has been demonstrated to be altermagnetic by ARPES measurements [3]. Using ab-initio techniques together with a time-dependent calculation of the absorption process, we study theoretically the optically induced spin polarization for all polarization angles. Our results show an intriguing interplay between the complex nodal-plane structure in bulk g-wave altermagnets and the anisotropic excitation due to the polarized pulses, causing planar d-wave or g-wave signatures depending on the laser's incident direction.

MA 9.8 Mon 17:00 H20

Optical Excitation of Spin Polarization in the Altermagnet RuO_2 — •Marius Weber[1], Stephan Wust[1], Luca Haag[1], Akashdeep Akashdeep[2], Kai Leckron[1], Christin Schmitt[2], Rafael Ramos[3], Takashi Kikkawa[4], Eiji Saitoh[4], Mathias Kläui[2], Libor Šmejkal[2], Jairo Sinova[2], Martin Aeschlimann[1], Gerhard Jakob[2], Benjamin Stadtmüller[5], and Hans Christian Schneider[1] — [1]University of Kaiserslautern-Landau, Germany — [2]Johannes Gutenberg University Mainz, Germany — [3]CIQUS, Universidade de Santiago de Compostela, Spain — [4]The University of Tokyo, Japan — [5]Augsburg University, Germany

We explore the ultrafast response of altermagnetic materials after optical excitation with femtosecond light pulses. For the case of RuO_2, we employ ab-initio based dynamical calculations to predict the spin polarization of the optically excited carriers. Our theoretical results are confirmed by time-resolved MOKE experiments[1], which demonstrate that highly spin-polarized carrier distributions can be generated in ultrathin, strained RuO_2 by tuning the excitation conditions, in particular the orientation of the light polarization vector.

MA 9.9 Mon 17:15 H20

Magnetotransport in altermagnetic CrSb — •Christoph Müller — FZU Prague

Altermagnets (AMs) constitute a recently established category of magnetically ordered materials distinguished by an antiparallel alignment of identical magnetic moments, however with an alternating spin polarization in the electronic band structure. This unique attribute has ignited considerable interest in exploring novel applications within the realm of spintronics. Furthermore, AMs host transport and optical effects, associated with spin-polarized currents and strongly spin-split bands otherwise only observed in ferromagnets. Chromium Antimonide (CrSb) is due to its crystal symmetry and its compensated order classified as an altermagnet. CrSb exhibits a sizable spin splitting of 1.2 eV which is enabled by the non-relativistic crystal field origin. In my work I investigated the magnetotransport properties of the material in bulk and thin films. The bulk samples were also measured in a high field laboratory in search for a spin-flop transition or the anomalous Hall effect.

MA 9.10 Mon 17:30 H20

Altermagnetic spin wave dispersion in atomistic spin models — •Tobias Dannegger[1], Levente Rózsa[2,3], László Szunyogh[3], and Ulrich Nowak[1] — [1]Fachbereich Physik, Universität Konstanz, Konstanz, Germany — [2]Department of Theoretical Solid State Physics, Institute for Solid State Physics and Optics, HUN-REN Wigner Research Centre for Physics, Budapest, Hungary — [3]Department of Theoretical Physics, Institute of Physics, Budapest University of Technology and Economics, Budapest, Hungary

Altermagnets have a broken symmetry reflected in the shape of the spin density around the magnetic atoms. Using an ab initio parametrised atomistic spin model of hematite (α-Fe_2O_3), we show that this altermagnetic symmetry breaking induces a remarkably high splitting of 2.8 meV in the isotropic exchange couplings between the Fe spins for equidistant neighbours within the thirteenth coordination shell. We further study the resulting spin-wave dispersion relation and find that, in addition to the relativistic band splitting on the order of 10 GHz present almost throughout the entire Brillouin zone, the altermagnetic asymmetry of the isotropic interactions causes a much larger band splitting of the order of 1 THz, but only along low-symmetry directions in the Brillouin zone.

MA 9.11 Mon 17:45 H20

First-principles calculations of Luttinger ferrimagnets — •Jan Priessnitz[1], Igor Mazin[2], and Libor Šmejkal[1] — [1]Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Straße 38, 01187 Dresden, Germany — [2]Department of Physics and Astronomy, and Quantum Science and Engineering Center, George Mason University, Fairfax, VA, USA

The discovery of altermagnets demonstrated that it is possible to have a material with zero net magnetization, but broken Kramers' spin degeneracy and large spin-splitting, even without considering relativistic effects (spin-orbit coupling) [1]. The altermagnetic spin polarization promises applications in the field of spintronics.

Apart from altermagnets, there are several other classes of magnets showing such properties, such as the Luttinger compensated ferrimagnets. These are materials containing two or more magnetic sublattices which are not connected by symmetry, but which perfectly compensate each other by the virtue of Luttinger's theorem [2].

In this talk, we will give a brief introduction into Luttinger compensated ferrimagnets and present first-principle calculations of several candidate materials and unconventional properties not seen in conventional magnetic materials.

[2] Mazin, I. (2022). Editorial, Physical Review X, 12(4).

MA 9.12 Mon 18:00 H20

Magnetic domain features in the altermagnetic Mn_5Si_3 — •Gregor Skobjin[1], Javier Rial[2], Sebastian Beckert[3], Helena Reichlová[3,4], Andy Thomas[3,5], Vincent Baltz[2], Lisa Michez[6], Richard Schlitz[1], Michaela Lammel[1], and Sebastian T.B. Goennenwein[1] — [1]Department of Physics, University of Konstanz, Germany — [2]Université Grenoble Alpes, CNRS, CEA, IRIG-Spintec, France — [3]IFMP, TU Dresden, Germany — [4]Institute of Physics ASCR, Czech Republic — [5]Aix-Marseille Université, CNRS, CINaM, France — [6]IFW Dresden, Germany

Altermagnets are an intriguing novel class of magnetic materials. We exploit the anomalous Hall effect response of micropatterned Mn_5Si_3 thin films to investigate their magnetization relaxation behavior. In experiments at T < 200 K i.e., in the altermagnetic phase, and for magnetic fields for which the samples exhibit large magnetic susceptibility, we observe a strong magnetic aftereffect as well as Barkhausen-like steps in the time-dependent Hall voltage evolution. More specifically, we recorded the evolution of the Hall voltage in micropatterned Hall bars with widths of 10 microns down to 0.1 microns at a series of different magnetic field magnitudes to gain insights into potential domain effects in the altermagnetic phase of Mn_5Si_3. We critically analyze our experimental results and discuss implications for the micromagnetic structure of altermagnetic thin films.

MA 9.13 Mon 18:15 H20

Altermagnetism in twisted magnetic bilayers — •Venkata Krishna Bharadwaj[1], Libor Šmejkal[1,2], and Jairo Sinova[1] — [1]Institut für Physik, Johannes Gutenberg Universität Mainz, Germany — [2]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

A recent development in the field of magnetism has introduced a new category of magnetic materials known as altermagnets [1]. These materials form a distinct class of magnetic compounds, characterized by magnetic compensation and the breaking of time-reversal symmetry, leading to a spin-split band structure. This unique band structure exhibits alternating spin polarization in both real and reciprocal spaces. The spin splitting originates from variations in local crystal field anisotropies across different magnetic sublattices. In this study, we introduce a novel approach to achieve altermagnetism in two-dimensional van der Waals materials by twisting bilayers. Furthermore, we explore the physical properties of altermagnets arising in these twisted bilayer structures. Our results lay the groundwork for exploring new possibilities in altermagnetic materials.

MA 10: Focus Session: Magnetic Phenomena from Phonon Chirality and Angular Momentum II (joint session MA/TT)

The magnetic moment of the electron lies at the heart of magnetism and spintronics. However, recent research has unveiled the angular momentum and magnetic moment of chiral phonons as fundamental quantities in their own right. These chiral phonons give rise to a plethora of novel lattice phenomena analogous to electronic effects, such as the phonon Hall and phonon Zeeman effects. Moreover, they play a critical role in angular momentum transfer on ultrafast timescales, as seen in the Einstein-de Haas effect. Chiral phonons can also generate effective magnetic fields reaching the tesla scale, inducing magnetization in antiferromagnetic, paramagnetic, and even nonmagnetic materials - a phenomenon reminiscent of the Barnett effect. These advancements showcase phonon chirality and angular momentum as powerful emerging tools for generating and controlling magnetism. This focus session aims to highlight the latest breakthroughs in chiral-phonon magnetism and foster connections between the rapidly evolving field of chiral phononics and the broader magnetism research community.

MA 10.1 Tue 9:30 H16

Continuous-wave terahertz spectroscopy on chiral phonons — •Ji Eun Lee, Luca Eisele, Artem Pronin, and Martin Dressel — 1. Physikalisches Institut, Universität Stuttgart, Germany

We apply continuous-wave frequency-domain terahertz spectroscopy to study chiral phonons at low frequencies. As samples, we use thin films of materials with soft phonon modes, such as SrTiO3 and (doped) PbTe. Our experimental method utilizes both, measurements of transmission with circular-polarized light and Faraday-rotation experiments. In the talk, our approach to the measurements and preliminary results will be summarized.

MA 10.2 Tue 9:45 H16

Spin-lattice coupling in multiscale modeling: from angular momentum transfer to chiral phonons — •Markus Weissenhofer[1,2], Philipp Rieger[1], Sergiy Mankovsky[3], Akashdeep Kamra[5], MS Mrudul[1], Hubert Ebert[3], Ulrich Nowak[4], and Peter M. Oppeneer[1] — [1]Uppsala University, Uppsala, Sweden — [2]Freie Universität Berlin, Berlin, Germany — [3]Ludwig Maximilian Universität, München, Germany — [4]Universität Konstanz, Konstanz, Germany — [5]Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, Kaiserslautern, Germany

Transfer and manipulation of angular momentum is a key aspect in spintronics. Recently, it has been shown that angular momentum transfer between spins and lattice is possible on ultrashort timescales [1]. To contribute to the understanding of this transfer, we have developed a theoretical multiscale framework for spin-lattice coupling, which is linked to ab-initio calculations on the one hand

and magnetoelastic continuum theory on the other [2], allowing for the study of a wide range of magnetomechanical phenomena. Here I will discuss how this framework can be used to calculate magnon-phonon coupling parameters, emphasizing the importance of a Dzyaloshinskii-Moriya type interaction for angular momentum transfer [2] and revealing the existence of chiral phonons in iron arising from a chirality-selective coupling [3]. MA 10.3 Tue 10:00 H16

Chiral phonon-induced magnetization reversal in 2D ferromagnets — •Daniel Bustamante Lopez[1] and Dominik Juraschek[2] — [1]Department of Physics, Boston University, Boston, Massachusetts 02215, USA — [2]Department of Applied Physics and Science Education, Eindhoven University of Technology, Eindhoven, Netherlands

In our previous work, we explored magnonic rectification, where a coherently excited chiral phonon generates an effective magnetic field capable of inducing quasistatic magnetization in antiferromagnetic materials. In this study, we extend this concept to ferromagnetic materials, demonstrating that phononic magnetic fields can achieve permanent magnetization reversal. We focus on two-dimensional chromium-based ferromagnetic crystals, including CrI3, CrGeTe3, and CrCl3, and investigate reversal mechanisms such as damping switching and precessional switching. Our findings reveal that phononic magnetic fields enable robust and permanent magnetization reversal within nanoseconds, highlighting their potential for ultrafast magnetic control.

MA 10.4 Tue 10:15 H16

Chiral phonons in coupled magnon-phonon band structure — •Yelyzaveta Borysenko, Daniel Schick, and Ulrich Nowak — University of Konstanz, Konstanz, Germany

Coupling of spin and lattice degrees of freedom in magnetic materials is a key aspect for angular momentum based information processing. During ultrafast demagnetization, spin angular momentum can be transferred into the lattice creating chiral phonons even in simple centrosymmetric materials [1]. Spin-lattice coupling mechanisms involved in such processes can be approached using first principles calculations, which allow to determine leading energy terms for angular momentum exchange for different materials [2, 3]. Coupled spin-lattice dynamics is then described constructing angular momentum-conserving Hamiltonian linked to ab initio calculated model parameters [4].

Here, we linearize the equations of motion and calculate coupled magnon-phonon dispersions. We discuss how different coupling terms, e.g., of anisotropy or Dzyaloshiskii-Moriya type, can modify magnon and phonon dispersions, open up energy gaps, lift the degeneracy of modes, and lead to avoided crossings in the band structure.

MA 10.5 Tue 10:30 H16

Phonon Inverse Faraday effect from electron-phonon coupling — •Natalia Shabala and Matthias Geilhufe — Department of Physics, Chalmers University of Technology, 412 96 Gothenburg, Sweden

The phonon inverse Faraday effect describes the emergence of a DC magnetization due to circularly polarized phonons. From time-dependent second order perturbation theory and electron-phonon coupling we develop a microscopic formalism for phonon inverse Faraday effect. We arrive at a general and material-independent equation [1]. Using this equation for ferroelectric soft mode in $SrTiO_3$ gives an estimate of effective magnetic field which is consistent with recent experiments [2]. Hence, our approach is promising for shedding light into the microscopic mechanism of angular momentum transfer between ionic and electronic angular momentum, which is expected to play a central role in the phononic manipulation of magnetism.

MA 10.6 Tue 10:45 H16

Temperature dependent magnon-phonon coupling in YIG/GGG heterostructures — •J. Weber[1,2], M. Cherkasskii[3], F. Engelhardt[3,4,5], S.T.B. Goennenwein[6], S.Viola Kusminskiy[3,5], S. Geprägs[1], R. Gross[1,2,7], M. Althammer[1,2], and H. Huebl[1,2,7] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]School of Natural Sciences, Technical University of Munich, Munich, Germany — [3]Institute for Theoretical Solid State Physics, RWTH Aachen University, Aachen, Germany — [4]Department of Physics, University Erlangen-Nuremberg, Erlangen, Germany — [5]Max Planck Institute for the Science of Light, Erlangen, Germany — [6]Department of Physics, University of Konstanz, Konstanz, Germany — [7]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany

Magnon-phonon coupling in heterostructures has recently gained interest in the context of angular momentum conversion and angular momentum transport via phonons. A typical experimental setting is a bilayer system, where the magnetization dynamics of a magnetic thin film interacts with the elastic standing wave excitations of a non-magnetic bulk crystal. So far, bulk acoustic wave resonators consisting of a ferrimagnetic yttrium iron garnet (YIG) film deposited on a crystalline gadolinium gallium garnet (GGG) substrate have been studied at room temperature due to the favorable magnetic damping properties of YIG [1]. We present a temperature dependent analysis of the magnon-phonon coupling of a YIG/GGG bulk acoustic wave resonator.

Modeling of the preparation and conservation of coherent phonon (pseudo) angular momentum — •Olga Minakova[1], Maximilian Frenzel[1], Carolina Paiva[2], Joanna M. Urban[1], Michael S. Spencer[1], Martin Wolf[1], Dominik M. Juraschek[2,3], and Sebastian F. Maehrlein[1,4,5] — [1]FHI Berlin — [2]Tel Aviv University — [3]Eindhoven University of Technology — [4]HZDR — [5]TU Dresden

The angular momentum of lattice vibrations - phonon angular momentum - is an underexplored degree of freedom in solid-state systems. Recent experiments have shown that circularly-polarized THz pulses can coherently excite degenerate phonon modes, enabling the preparation of phonon angular momentum states. THz-Kerr effect spectroscopy provides a means to monitor these states by directly measuring vectorial phonon trajectories. To interpret such experiments, it is essential to understand the symmetry properties of the phonon modes that influence the driving and probing processes, as well as the conservation of angular momentum in the crystal lattice. Here, we model the generation and detection of coherent phonon angular momentum, revealing how crystal symmetry dictates the selection rules in the lattice. We show that the form of the Raman tensors associated with the phonon explains the phonon helicity observed in experiments, linking the discrete rotational symmetry of the material to the conservation of pseudo angular momentum in lattice vibrations.

MA 10.8 Tue 11:30 H16

Spin-spin interaction via chiral phonons — •Daniel Schick[1], Markus Weissenhofer[2,3], Akashdeep Kamra[4], and Ulrich Nowak[1] — [1]University of Konstanz, Konstanz, Germany — [2]Uppsala University, Uppsala, Sweden — [3]Free University of Berlin, Berlin, Germany — [4]University of Kaiserslautern-Landau, Kaiserslautern, Germany

Coupling between the magnetic degrees of freedom and phonons has emerged as a topic of great importance for explaining various magnetic phenomena, like ultrafast demagnetization processes [1], and the possibility to affect magnetization dynamics via phonon pumping [2]. We develop a tool to study spin-lattice coupling in atomistic simulations, which conserves total angular momentum. This allows us to precisely retrace the transfer of angular momentum between the spin and lattice systems. We demonstrate the emergence of an effective spin-spin interaction mediated by chiral phonons. This effect can arise from thermal phonons as follows. A spin may precess after coupling to a phonon, with this precession producing chiral phonons, which in turn, affect other spins. A similar effect can be achieved by driving a spin to induce chiral phonons. We discuss the dependence of this interaction on the temperature and strength of the spin-lattice interaction and discuss our findings within the context of phonon-enhanced magnon transport phenomena.

MA 10.9 Tue 11:45 H16

Ultrafast generation of multicolor chiral phonons in magnetic and ferroelectric materials — •Omer Yaniv[1] and Dominik M. Juraschek[2] — [1]Tel Aviv University, Tel Aviv, Israel — [2]Eindhoven University of Technology, Eindhoven, Netherlands

Terahertz pulses are powerful tools capable of initiating coherent vibrational motions in solids. Circularly polarized pulses can further excite chiral phonons. Such phonons carry an angular momentum and are able to generate magnetic moments leading to a varying range of phenomena, including the phonon Hall, phonon Zeeman, and phonon inverse Faraday effects. Our study investigates the coherent driving of phonons using multicolor laser pulses, leading to Lissajous trajectories of the atoms. We demonstrate the generation of such multicolor chiral phonons in BaTiO3, a task that presents significant challenges due to the requirement of an exact 1:2 phonon frequency ratio. Achieving this precise ratio is crucial for the generation of closed atomic Lissajous loops. However, we overcome this challenge by creating phonon polaritons with shifted frequencies through the use of optical cavities. This approach allows us to surpass the limitations imposed by the strict phonon frequency ratio. By carefully tuning the cavity parameters, we demonstrate a new pathway for controlling lattice vibrations at ultrafast timescales. We also explore how multicolor phonons tune magnetic properties in monolayer CrI3, a 2D material with strong spin-orbit

coupling and ferromagnetism. By manipulating phonon dynamics, we examine the interaction between lattice vibrations and magnetic order.

MA 10.10 Tue 12:00 H16

Chiral Phonons induced by Magnon-Phonon Coupling — •Hannah Bendin[1], Alexander Mook[2], Ingrid Mertig[1], and Robin R. Neumann[1,2] — [1]Martin Luther University Halle-Wittenberg, Halle (Saale), Germany — [2]Johannes Gutenberg University, Mainz, Germany

Chiral phonons, the quasiparticles of circularly polarized lattice vibrations, have recently been investigated due to a range of emerging phenomena. Notably, chiral phonons carry nonzero angular momentum. However, the systems in which they occur still require extensive research. Chiral phonons may, for example, be found in lattices with broken inversion symmetry. Alternatively, they can be induced by the coupling to magnons, the quasiparticles of spin excitations, thereby lifting time-reversal symmetry.

Here, we analyze how magnetoelastic coupling gives rise to magnon-phonon hybridization, which, in turn, generates phonon angular momentum. Conversely, we show how the phonon angular momentum and the spin of the magnons affects their coupling strength. This interplay between magnons and chiral phonons allows for the tunability of the phonon angular momentum.

MA 10.11 Tue 12:15 H16

Ultrafast laser-induced carrier and magnetization dynamics in $SrTiO_3$ from real-time time-dependent DFT — •Andri Darmawan, Markus E. Gruner, and Rossitza Pentcheva — Department of Physics, University of Duisburg-Essen

Recent experimental studies indicate electric-field-driven ferroelectricity [1] and multiferroicity [2] in the paradigmatic nonmagnetic band insulator $SrTiO_3$ in the terahertz regime. Following a comprehensive study of the optical [3] and x-ray absorption [4] spectra including quasiparticle and excitonic effects, here we explore the response of $SrTiO_3$ to laser excitation. Using real-time time-dependent density functional theory (RT-TDDFT) as implemented in the Elk code, we investigate both linear and circular polarized laser pulses. A complex site- and orbital-dependent temporal dynamics is observed with opposite sign of fluctuations at O and Ti sites and charge transfer from O 2*p* to Ti 3*d* states for linearly polarized light, that breaks dynamically inversion symmetry. Notably, circularly polarized pulses induce a finite transient magnetic moment which is absent for linearly polarized pulses. Funding by DFG within CRC1242 (project C02) and computational time at magnitUDE, amplitUDE and the Leibniz Supercomputer Center (project pr87ro) are gratefully acknowledged.

Phonon pumping in ferromagnet/nonmagnetic insulator hybrid systems — •Richard Schlitz[1], Luise Holder[1], Johannes Weber[2,3], Mikhail Cherkasskii[4], Fabian Engelhardt[4], Julie Střihavková[5], Matthias Althammer[2,3], Silvia V. Kusminskiy[4,6], Hans Huebl[2,3,7], and Sebastian T. B. Goennenwein[1] — [1]Department of Physics, University of Konstanz, Konstanz, Germany — [2]Walther-Meißner-Institut, BAdW, Garching, Germany — [3]School of Natural Sciences, TUM, Garching, Germany — [4]Institute for Theoretical Solid State Physics, RWTH Aachen University, Aachen, Germany — [5]Faculty of Mathematics and Physics, Charles University, Prague — [6]Max Planck Institute for the Science of Light, Erlangen, Germany — [7]Munich Center for Quantum Science and Technology, München, Germany

In ferromagnetic thin films, magnetization dynamics, e.g., driven by ferromagnetic resonance, can coherently couple to phonons. If a ferromagnetic film is deposited on a crystalline substrate with polished parallel faces, the sample stack forms a bulk acoustic resonator, leading to characteristic modifications of the magnetic resonance signal.

In this work, we show that the magnetoelastic coupling can mediate the hybridization of the coherent magnetization dynamics with longitudinal and transverse phonons, with a particular dependence on the orientation of the magnetic field. We extract the magnetoelastic coupling parameters and compare them with theoretical expectations. Our results show that both longitudinal and transverse phonons can be efficiently excited, depending on the magnetic field orientation.

MA 11.1 Tue 9:30 H18

Topological orbital Hall effect caused by skyrmions and antiferromagnetic skyrmions — •Lennart Schimpf, Ingrid Mertig, and Börge Göbel — Institut für Physik, Martin-Luther-Universität Halle-Wittenberg

The topological Hall effect is a hallmark of topologically non-trivial magnetic textures such as magnetic skyrmions. It quantifies the transverse electric current once an electric field is applied and occurs as a consequence of the emergent magnetic field of the skyrmion. Likewise, an orbital magnetization is generated. Here we show that the charge currents are orbital polarized even though the conduction electrons couple to the skyrmion texture via their spin [1]. The topological Hall effect is accompanied by a topological orbital Hall effect even for *s* electrons without spin-orbit coupling. As we show, antiferromagnetic skyrmions and antiferromagnetic bimerons that have a compensated emergent field [2], exhibit a topological orbital Hall conductivity that is not accompanied by charge transport and can be orders of magnitude larger than the topological spin Hall conductivity.

Optimization of orbital torques in ferrimagnets and their relationship with Gilbert damping — •shilei ding, william legrand, hanchen wang, mingu kang, paul noel, and pietro gambardella — Department of Materials, ETH Zurich, 8093 Zurich, Switzerland

Application of an electric field can induce a non-equilibrium orbital angular momentum in conductive materials whose electronic bands have a k-dependent orbital character. This phenomenon can lead to the current-induced accumulation of orbital momenta in nonmagnetic layers, which can then diffuse into neighboring magnetic layers and interact with the local magnetization through spin-orbit coupling, giving rise to orbital torques. Conversely, the excitation of spin precession in a magnetic layer can give rise to an orbital current, resulting in orbital pumping and dissipation of angular momentum in the nonmagnetic layer. In the first part, I will present the efficacy of converting orbital to spin momenta in ferrimagnetic materials, specifically in the RE-TM ferrimagnet GdyCo100-y. This work underscores the mechanisms that facilitate orbital-to-spin conversion within a magnetic layer at the atomic level. In the second part, I will discuss how the Gilbert damping parameter correlates to spin and orbital torques in magnetic layers adjacent to Pt and CuOx layers, respectively. I will show that CoFe/CuOx bilayers exhibit a favorable combination of efficient orbital torque and minimal increase in Gilbert damping, which is promising for the implementation of orbital torque oscillators with reduced damping compared to spin torque oscillators.

MA 11.3 Tue 10:00 H18

Orbital magnetoresistance in insulating antiferromagnets — •Christin Schmitt[1], Sachin Krishnia[1], Edgar Galíndez Ruales[1], Takashi Kikkawa[2], Duc Tran[1], Timo Kuschel[1], Eiji Saitoh[2], Yuriy Mokrousov[1,3], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg-University Mainz, 55128 Mainz, Germany — [2]Department of Applied Physics, The University of Tokyo, Tokyo 113-8656, Japan — [3]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany

Insulating antiferromagnetic and ferrimagnetic materials are promising candidates for spintronic devices due to their intrinsic properties such as low damping [1]. Recently, orbital angular momentum (OAM) has emerged as a crucial concept in condensed-matter physics. Theoretical and experimental studies have highlighted that the orbital Hall effect (OHE) can enable orbital currents with efficiency orders of magnitude higher than that of spin Hall effects [2]. Here, we investigate magneto-resistance effects in magnetic systems [2,3]. We find that in TmIG the transverse magnetoresistance signal is increased significantly upon replacing Pt, a spin-current generator, by Cu*, a pure orbital-current generator. Further, we explore antiferromagnets with orbital magnetoresistance effects as pure orbital current is crucial for next generation pure orbitronics devices using abundant, cheap and environmentally friendly materials.

Non-reciprocity in magnon mediated charge-spin-orbital current interconversion — •Sachin Krishnia[1], Omar Ledesma-Martin[1], Edgar Galindez-Ruales[1], Felix Fuhrmann[1], Duc Tran[1], Rahul Gupta[1], Marcel Gasser[1,2], Dongwook Go[1,2], Gerhard Jakob[1], Yuriy Mokrousov[1], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg University Mainz, 55099

Mainz, Germany — [2]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany

In magnetic systems, angular momentum is carried by the spin and orbital degrees of freedom. Non-local devices can be used to study angular momentum transport. They consist of parallel heavy-metal nanowires placed on top of magnetic insulators like yttrium iron garnet (YIG), facilitating the transmission of information by magnons, generated by the accumulation of spin at the interface, created via the spin Hall effect (SHE) and detected via the inverse SHE (iSHE). It has been demonstrated that these processes have comparable efficiencies when the role of the detector and injector is reversed, which points to reciprocity of the processes. However, we show that by adding Ru as a source of direct and inverse orbital Hall effect (OHE), the system no longer exhibits this reciprocity. Specifically, the generation of magnons via the combination of SHE and OHE and detection via the iSHE is found to be about 35% more efficient than the inverse process for our system [1]. [1] O. Ledesma et al., arXiv:2411.07044 (2024).

MA 11.5 Tue 10:30 H18

Detection of dynamic x-ray magnetic linear dichroism in NiO — •Timo Kuschel[1], Johannes Demir[1], Olga Kuschel[2], Joachim Wollschläger[2], and Christoph Klewe[3] — [1]Bielefeld University, Germany — [2]Osnabrück University, Germany — [3]Advanced Light Source (ALS), Berkeley, USA

Spin transport through thin antiferromagnetic layers such as NiO has been studied by ferromagnetic resonance (FMR) spin pumping [1], spin Seebeck effect [2], non-local magnon spin transport [3] and x-ray detected FMR (XFMR) [4]. In all these experiments, the spin current has been identified in an adjacent Pt layer [1-3] or FeCo film [4] via inverse spin Hall effect or dynamic x-ray magnetic *circular* dichroism, respectively, after having the NiO layer already passed.

In this contribution, we study Fe_3O_4/NiO/Pt [5] by XFMR and present the identification of dynamic x-ray magnetic *linear* dichroism (XMLD) [6] at the Ni L edges directly in the NiO layer for FMR spin pumping in the adjacent Fe_3O_4 layer. We will analyze the XFMR response depending on the NiO thickness. Further, we will discuss coupling phenomena at the NiO-Fe_3O_4 interface vs. spin transport through the NiO layer as the origin of the dynamic XMLD response.

Manipulating the sign of the interlayer exchange coupling — •Nathan Walker — The Open University, Milton Keynes, UK

We demonstrate, using computer simulations and a non-equilibrium Greens function approach, that the sign of the out-of-equilibrium interlayer exchange coupling (ooeIEC) changes in the presence of an external bias. The system consists of a double barrier connected to an exchange coupled ferromagnetic trilayer. We find a strongly non-linear dependence of the spin current on voltage which results in the exchange coupled tri-layer switching between parallel and antiparallel configurations. Our results are in excellent agreement with earlier theoretical calculations, which predict an approximately 2π topological phase change of the (equilibrium) IEC. We believe that this could act as an energy efficient mechanism for magnetic switching which does not rely on spin-transfer torque (STT). There are potential applications to magnetoresistive random-access memory (MRAM), one of the principal contenders for a universal memory.

MA 11.7 Tue 11:00 H18

Harnessing Orbital Hall Effect in Spin-Orbit Torque MRAM — •J. Omar Ledesma Martin[1,2], Rahul Gupta[1], Chloé Bouard[2], Fabian Kammerbauer[1], Iryna Kononenko[1], Sylvain Martin[2], Gerhard Jakob[1,3], Marc Drouard[2], and Mathias Kläui[1,3] — [1]1 Institute of Physics, Johannes Gutenberg University Mainz, 55099, Mainz, Germany — [2]Staudingerweg 7 — [3]Department of Physics, Center for Quantum Spintronics, Norwegian University of Science and Technology, 7491, Trondheim, Norway

There is considerable potential in the Orbital Hall Effect (OHE) and the Spin Hall Effect (SHE) as electrical means for controlling the magnetization of spintronic devices. Here Ru stands out exhibiting an orbital Hall conductivity four times greater than the spin Hall conductivity of Pt. [1] This work assesses the efficiency of four distinct stacks in devices with perpendicular Magnetic Tunnel Junctions (MTJ). Following the formula Ta/OHE/Pt/[Co/Ni]x3/Co/MgO/CoFeB/Ta/Ru, where the OHE materials are Ru, Nb, and Cr. Additionally, a sample with Pt instead of OHE serves as a reference. The results demonstrate an improvement for the Ru samples, exhibiting higher damping-like torque and significantly lower switching current density compared to both the other samples and the Pt reference. These findings, including first-principle calculations, underscore the potential of Ru as an OHE material for enhancing the performance and power consumption of spintronic devices.

Spin and orbital Hall effect in metal systems: extrinsic vs. intrinsic contributions — •Sergiy Mankovsky and Hubert Ebert — LMU of Munich, 81377 Munich, Germany

Kubo's linear response formalism has been used to study the orbital Hall effect (OHE) for non-magnetic undoped and doped metallic systems, focusing on the impact of different types of disorder. Corresponding first-principles calculations of the orbital Hall conductivity (OHC) were performed making use of the KKR Green function method that allows in particular to monitor the impact of the vertex corrections on the OHC. The doping- and temperature-dependence of the OHC have been investigated and compared with corresponding results for the spin Hall conductivity (SHC). The temperature dependent properties of the OHC and SHC determined by thermally induced lattice vibrations (in non-magnetic materials) and spin fluctuations (in magnetic systems) have been accounted for making use of the alloy analogy model. For elemental systems at finite temperature a dominating role of the intrinsic contribution to the temperature-dependent OH and SH conductivities is found. In contrast, the OH and SH conductivities of doped systems at low temperatures are dominated by the SOC-driven extrinsic contributions strongly decreasing at higher temperatures due to the increasing impact of the electron-phonon scattering.

MA 11.9 Tue 11:45 H18

Simulations of spin transport in YIG — •Ben Schwanewedel, Moumita Kundu, and Ulrich Konstanz — Fachbereich Physik, Universität Konstanz, Konstanz, Germany

Being synthesized first in 1957, YIG has the lowest Gilbert damping among all known materials. This makes it interesting for spintronic applications and long-range spin transport. In YIG's complex unit cell Fe atoms occupy 20 sublattices leading to 20 magnon bands between 0 and 25 THz. We develop an atomistic spin model for YIG based on exchange interactions from Ref. [1], which were determined through neutron scattering. Further parameters were adapted from Ref. [2]. We varify our study through investigation of the magnon dispersion and comparing it to the results of Ref. [1].

We use atomistic spin dynamics simulations for the model above based on the stochastic Landau-Lifshitz-Gilbert equation to unravel its spin dynamics and spin transport properties. The spin transport is triggered by thermal gradients and and local magnetic fields and it is analyzed using an observable which is proportional to the magnon population. Also, magnon dispersions far from equilibrium are evaluated and discussed.

Orbital Hall effect accompanying quantum Hall effect — •Börge Göbel and Ingrid Mertig — Institut für Physik, Martin-Luther-Universität Halle-Wittenberg

The quantum Hall effect emerges when two-dimensional samples are subjected to strong magnetic fields at low temperatures: Topologically protected edge states cause a quantized Hall conductivity in multiples of e^2/h. Here we show that the quantum Hall effect is accompanied by an orbital Hall effect [1]. Our quantum mechanical calculations fit well the semiclassical interpretation in terms of "skipping orbits". The chiral edge states of a quantum Hall system are orbital polarized akin to an orbital version of the quantum anomalous Hall effect in magnetic systems. The orbital Hall resistivity scales quadratically with the magnetic field making it the dominant effect at high fields.

The discussion can be generalized to systems with effective magnetic fields: The topological Hall effect caused by the emergent field of topological spin textures, such as magnetic skyrmions, is accompanied by an orbital Hall effect, as well [2].

Large Spin Hall Angle in Mn-based Antiferromagnetic Alloys — •Nabil Menai[1], Martin Gradhand[2], and Derek Stewart[3] — [1]H. H. Wills Physics Laboratory, University of Bristol, Tyndall Ave, BS8-1TL, UK — [2]Institute of Physics, Johannes Gutenberg University Mainz, Staudingerweg 7, 55128 Mainz, Germany — [3]Western Digital Research Center, San Jose, California 95119, USA

Antiferromagnets (AFMs) have emerged as crucial materials for spintronic technologies for their ability to host spin-dependent transport phenomena, despite their zero net magnetization. Their robustness against external magnetic fields and ultrafast spin dynamics make them ideal for efficient spin-charge interconversion. In this theoretical study, we use density functional theory and Greens function methods to investigate the transport properties of Mn-based binary alloyed AFMs. Our focus is on the total spin Hall conductivity (SHC), account-

ing for both the intrinsic contributions from Berry curvature and the extrinsic effects from skew scattering and side-jump mechanisms. The objective is to identify AFM materials that exhibits a high spin Hall angle (SHA); with an efficient charge-to-spin Hall current conversion ratio. Our results reveal that doping MnPt with Ir significantly enhances the SHA, achieving a value of 8% at room temperature. In contrast, doping with Pd offers temperature stability with lower SHA values. Additionally, we examine the effects of substituting Mn atoms with magnetic transition metals such as Fe and Ni. These findings underscore the potential of antiferromagnetic alloys for efficient spin current generation.

MA 11.12 Tue 12:30 H18

Competing ordinary and Hanle magnetoresistance in Pt and Ti thin films — •Sebastian Sailler[1], Giacomo Sala[2], Denise Reustlen[1], Richard Schlitz[1], Min-Gu Kang[2], Pietro Gambardella[2], Sebastian T.B. Goennenwein[1], and Michaela Lammel[1] — [1]Department of Physics, University of Konstanz — [2]Department of Materials, ETH Zurich

One of the key elements in spintronics research is the spin Hall effect, allowing to generate spin currents from charge currents. A large spin Hall effect is observed in materials with strong spin orbit coupling, e.g. Pt. Recent research suggests the existence of an orbital Hall effect, the orbital analogue to the spin Hall effect, which also arises in weakly spin orbit coupled materials like Ti, Mn or Cr. In any of these materials, a magnetic field perpendicular to the spin or orbital accumulation leads to additional Hanle dephasing and thereby the Hanle magnetoresistance. Here, we studied the magnetoresistance (MR) of Pt thin films over a wide range of thicknesses. Careful evaluation shows that the MR of our textured samples is dominated by the so-called ordinary MR, while the Hanle effect does not play a significant role. Analyzing the intrinsic properties of Pt films deposited by different groups, we find that next to the resistivity, also the structural properties of the film influence which MR dominates. We further show that this correlation can also be found in orbital Hall active materials like Ti. We conclude that in all materials exhibiting a spin or orbital Hall effect, the Hanle MR and the ordinary MR coexist, and that the sample's purity and crystallinity determines which MR dominates.

MA 11.13 Tue 12:45 H18

Orbital Hanle magnetoresistance in Mn thin films — •Min-Gu Kang, Federica Nasr, Giacomo Sala, and Pietro Gambardella — Department of Materials, ETH Zurich, 8093 Zurich, Switzerland

Momentum-space orbital texture, or orbital character of electrons, enables the orbital Hall effect (OHE), a current-induced flow of nonequilibrium orbital angular momentum in centrosymmetric systems with negligible spin-orbit coupling. This orbital current, which can be orders of magnitude larger than its spin counterpart, offers transformative potential for spin-orbitronics, yet the mechanisms of orbital relaxation remain unclear. In this work, we present temperature-dependent orbital Hanle magnetoresistance and associated orbital relaxation mechanisms in Mn thin films. The results clearly show that the orbital Hanle magnetoresistance depends on the structure of the Mn thin films and can be associated with competing Dyakonov-Perel and Elliott-Yafet orbital relaxation effects. Our study highlights the critical role of orbital relaxation in determining the magnitude of current-induced orbital effects in 3d transition metal films.

MA 11.14 Tue 13:00 H18

Tuning of spin transport properties in 2D ferromagnet VSe_2 by structural polytypes of TaS_2 electrodes — •Biplab Sanyal and Masoumeh Davoudiniya — Department of Physics & Astronomy, Ångströmlaboratoriet, Uppsala University, Box-516, 75120 Uppsala, Sweden

2D magnets and their heterostructures are promising materials for future spintronic applications. Here, we present a study of spin transport through a ferromagnetic monolayer of 1T-VSe_2 with two structural polytypes of TaS_2 electrodes stacked in van der Waals heterostructures. Using density functional theory coupled with the nonequilibrium Green function framework, we explore the impact of TaS_2 electrode polytypes on the device's quantum transport properties. We observe that devices with 1T-TaS_2 electrodes exhibit higher spin-dependent transmission compared to 2H-TaS_2 electrodes. Incorporating MoS_2 as a tunnel barrier, anisotropic tunnel magnetoresistance enhances significantly, reaching 168% for the 1T-device and 1419% for the 2H-device. Spin-transfer torque (STT) analysis shows that its magnitude is highest at 90° (−702 μeV/V for 1T and −1561 μeV/V for 2H devices) and decreases towards 180°. The 1T-device shows superior performance with lower Gilbert damping, reduced critical current density and voltage for magnetization switching, compared to the 2H-device, which requires significantly higher current and voltage. Our predictions reveal the potential of 1T-VSe_2-based heterostructures for advanced spintronic applications.

MA 12: Magnetization Dynamics and Damping

Time: Tuesday 9:30–11:30 Location: H19

MA 12.1 Tue 9:30 H19

Oscillatory dynamics of strongly coupled magnetic domain walls in three-dimensional chiral nanostructures — •Pamela Morales Fernández[1,2], I. Konstantinos Douveas[3], S. Ruiz Gómez[4], E. Zhakina[1], L. Turnbull[1], M. König[1], A. Hierro Rodríguez[5], N. Leo[6], S. Finizio[7], S. Wintz[8], C. Abert[3], D. Suess[3], A. Fernández Pacheco[2], and C. Donnelly[1,9] — [1]MPI CPFS, Germany — [2]TU Viena, Austria — [3]University of Vienna, Austria — [4]ALBA Synchrotron, Spain — [5]Universidad de Oviedo, Spain — [6]Loughborough University, UK — [7]PSI, Switzerland — [8]BESSY II, Germany — [9]Hiroshima University, Japan.

The expansion of nanomagnetism into three dimensions opens opportunities for new topological textures, curvilinear effects, and exotic magnetization dynamics. Here, we investigate the magnetization dynamics in 3D double-helix nanostructures, which host strongly coupled domain wall pairs formed through the interplay of shape anisotropy, chirality, and inter-helix magnetostatic interactions. Using direct 3D nanofabrication techniques, cobalt nano double helices are grown on top of microwave antennas and exposed to GHz magnetic fields. Time-resolved scanning transmission X-ray microscopy reveals enhanced dynamics in the area of the coupled domain walls within the helical conduits. Observed dynamics depend on the geometrical parameters of the system and excitation frequency, matching with micromagnetic simulations that reveal additional higher-frequency modes beyond the reach of the experimental technique. This work provides insights into the physics of 3D nanomagnetism, advancing control for future technologies.

MA 12.2 Tue 9:45 H19

Anisotropic energy dissipation in model Kagome systems — Rajgowrav Cheenikundil[1], Zhiwei Lu[2], Ivan Miranda[3], Manuel Pereiro[4], and •Danny Thonig[1,4] — [1]Örebro University, Sweden — [2]KTH Royal Institute of Technology, Sweden — [3]Linnaeus University, Sweden — [4]University Uppsala, Sweden

Recent efforts have been directed towards understanding spin-orbit mediated phenomena such as the spin Hall effect [1], and energy dissipation phenomena [2], which are enhanced by non-collinear magnetism. Notably, the latter results in anisotropies in energy dissipation that have not been methodically investigated.

We employ the Kubo-Bastin formalism [3] of linear perturbation theory to calculate the non-local Gilbert damping tensor in a model Kagome system with Rashba spin-orbit coupling. This approach is implemented in the Cahmd code [4]. We vary the magnetic state according to different chiralities and phase differences.

Remarkably, the Bastin formalism connects the occurrence of anisotropic damping to a Fermi-sea contribution and, consequently, to spin-spin Berry curvature. Our systematic study examines the dependency of isotropic and anisotropic effective damping, as well as the full non-local damping, on electron lifetimes, Rashba parameters, and other factors. The results of this study pave the way for controlled dissipation in innovative spintronics applications.

MA 12.3 Tue 10:00 H19

propelling ferrimagnetic domain walls by dynamical frustration — •reza doostani — university of cologne, cologne, germany

In this work, we realize the concept of active matter in a solid state system. By sending a ferrimagnet out of equilibrium by an oscillating magnetic field, we activate rotational goldstone mode where spins start to rotate clockwise or anticlockwise depending on the ferromagnetic component. We see that in this setup, a domain wall moves actively to the left or right due to dynamical frustration. We further discuss the dynamics of these domain walls and the relation between domain wall motion and the external field amplitude, as well as their interaction and consequence of these on the whole system. Furthermore, we continue to study the effect of defects on the movement of domain walls.

MA 12.4 Tue 10:15 H19

Tunable magnetic easy axis orientation with ion irradiation — •Gabriel Gray[1], Kilian Lenz[1], Alexandra Lindner[1], Jürgen Lindner[1], Jürgen Fassbender[1], Fabian Ganss[1], Rodolfo Gallardo[2], and Pedro Landeros[2] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Ion Beam Physics and Material Research, Dresden, Germany — [2]Universidad Técnica Federico Santa María, Department of Physics, Valparaíso, Chile

Our research focuses on the ion-irradiation-induced changes in magneto-crystalline anisotropy and exchange coupling in epitaxially grown Fe thin films in the (110) orientation under ultra-high vacuum conditions on GaAs (110) single crystals. A Cr capping layer was deposited to prevent oxidation. The samples were irradiated with Cr ions at varying kinetic energies and fluences. Subsequent magnetic characterizations were performed using Ferromagnetic Resonance and Vibrating Sample Magnetometry techniques, while structural characterizations where perform using X-ray Diffractometry and Transmission Electron Microscopy.

Our results reveal a clear correlation between ion fluence and modifications in uniaxial magneto-crystalline anisotropy, while cubic anisotropy and the effective magnetization remain largely unaffected. Notably, the observed changes are sufficient to induce a reorientation of the easy axis of magnetization in the system.

MA 12.5 Tue 10:30 H19

Evidence of relativistic field-derivative torque in nonlinear THz response of magnetization dynamics — •Arpita Dutta[1], Christian Tzschaschel[2,3], Debankit Priyadarshi[3], Kouki Mikuni[4], Takuya Satoh[4,5], Ritwik Mondal[6], and Shovon Pal[1] — [1]NISER Bhubaneswar, HBNI, Jatni, India — [2]Max-Born Institute, Berlin, Germany — [3]ETH Zurich, Switzerland — [4]Institute of Science Tokyo, Japan — [5]Quantum Research Center for Chirality, Okazaki, Japan — [6]IIT (ISM) Dhanbad, India

The selective addressing of spins by terahertz (THz) electromagnetic fields via Zeeman torque is, by far, one of the most successful means of controlling magnetic excitations. Here, we show that the conventional Zeeman torque on the spin is not sufficient, rather an additional relativistic field derivative torque (FDT) is essential to realize the observed magnetization dynamics. We accomplish this by exploring the ultrafast nonlinear magnetization dynamics of a ferrimagnetic garnet when excited by two co-propagating THz pulses. Having identified the Kaplan-Kittel mode at 0.48 THz, resulting from the exchange interaction between the rare-earth and transition metal sublattices, we drive this mode to a nonlinear regime. We find that the observed nonlinear trace of the magnetic response cannot be mapped to the magnetization precession induced by the Zeeman torque, while the Zeeman torque supplemented by an additional FDT follows the experimental evidences.

MA 12.6 Tue 10:45 H19

Ferromagnetic resonance linewidth as a probe for investigating magnon-phonon interaction — •Gauravkumar Patel[1], Rodolfo Gallardo[2], Ruslan Salikhov[1], Sven Stienen[1], Kilian Lenz[1], Olav Hellwig[1,3], and Jürgen Lindner[1] — [1]Helmholtz-Zentrum Dresden–Rossendorf, Dresden, Germany — [2]Universidad Técnica Federico Santa María, Valpariso, Chille — [3]Chemnitz University of Technology, 09107 Chemnitz

The Ferromagnetic resonance (FMR) linewidth measurements provide information about dynamic energy losses present in magnetic materials. For materials with high magnetoelastic coupling strength, like Co, the uniform precession can excite the elastic vibrations in the underlying lattice. Using the FMR linewidth as a probe, we investigate this magnon-phonon interaction in Co thin films on Pt seed layers. This interaction results in a non-monotonic behavior of the linewidth as a function of frequency, showing multiple peaks at specific frequencies, in contrast to the typical Gilbert-like linear dependence. The magnon-phonon coupling is more pronounced in Co thin films with higher perpendicular anisotropy. Variation of the Co or Pt layer thickness shifts the linewidth peak position, indicating control over the frequency of the generated phonon.

MA 12.7 Tue 11:00 H19

Landau-Lifshitz damping from Lindbladian dissipation in quantum magnets — •Götz Uhrig — TU Dortmund University

As of now, the phenomenological classical Landau-Lifshitz (LL) damping of magnetic order is not linked to the established quantum theory of dissipation based on the Lindbladian master equation. This is an unsatisfactory conceptual caveat for the booming research on magnetic dynamics. Here, it is shown that LL dynamics can be systematically derived from Lindbladian dynamics using a local mean-field theory. Thereby, the successful LL approach is set on a firm quantum basis in the regime where the Lindblad approach is applicable. Furthermore, we extend the LL dynamics in a systematically controlled way to include not only changes of the orientation of the magnetization $\vec{m}$, but also of its length $|\vec{m}|$. The key aspect is that the Lindbladian relaxation must be adapted to the Hamiltonian $H(t)$ at each instant of time in time-dependent non-equilibrium systems. It is conjectured that this idea holds true well beyond the damping of magnetic dynamics given the appropriate hierarchy of time scales.

MA 12.8 Tue 11:15 H19

Dynamics of electronic phase separation at the laser-induced insulator/metal transition in LPCMO — •Maximilian Staabs, Tim Titze, Karen Stroh, Stefan Mathias, Vasily Moshnyaga, and Daniel Steil — I. Physikalisches Institut, Universität Göttingen, Göttingen, Deutschland

The closely related colossal magnetoresistive manganites LCMO and LPCMO exhibit surprising differences in their transient reflectivity dynamics after nanosecond pulsed laser excitation close to their metal-to-insulator transition (MIT). Transient resistance measurements reveal that both systems show transient metallization effects upon laser excitation in the vicinity of the static MIT. These are, however, weak and on the timescale of the laser pulse for LCMO, but much stronger and long-lived for LPCMO. We attribute the differences between these compounds to the presence of mesoscopic electronic phase separation in LPCMO in the MIT region, stabilized by Jahn-Teller polarons [1]. Laser excitation leads to the annihilation of Jahn-Teller distortions [2,3], thus enabling charge transfer between the formerly separated electronic phases. This process is observed as a collapse of the global electrical resistivity on the nanosecond timescale, whereas the recovery of the insulating phase separated state takes nearly 20 nanoseconds [4].

MA 13: Altermagnets II

Time: Tuesday 9:30–13:00 Location: H20

MA 13.1 Tue 9:30 H20

Dynamics of the altermagnetic candidate compound UCr_2Si_2C — Nikolaos Biniskos[1], •Manuel dos Santos Dias[2], Karin Schmalzl[3], Andrea Piovano[4], Ursula Bengaard Hansen[4], Michal Vališka[1], and Petr Čermák[1] — [1]Department of Condensed Matter Physics, Charles University, Praha, Czech Republic — [2]Scientific Computing Department, STFC Daresbury Laboratory, United Kingdom — [3]Jülich Centre for Neutron Science at ILL, Forschungszentrum Jülich, Grenoble, France — [4]Institut Laue-Langevin, Grenoble, France

Altermagnets are collinear antiferromagnets where spin degeneracy of the electronic bands or degeneracy of the magnon bands is not enforced by symmetry, potentially enabling diverse physical phenomena. However, it remains challenging to find materials that experimentally exhibit the hallmarks of altermagnetism. UCr_2Si_2C has been recently reported as a high-temperature antiferromagnet with a rare crystal structure that is compatible with altermagnetism [1]. This talk will report on our combined experimental and theoretical investigation of this compound. A large single crystal was successfully grown and experimentally investigated with bulk specific heat and magnetic susceptibility measurements, and through unpolarized and polarized inelastic neutron scattering. These experimental results have been interpreted with density functional theory calculations, providing a unified picture of UCr_2Si_2C and of its prospects as an altermagnet.

Theory of circular dichroism in resonant photoelectron diffraction of altermagnets — •Peter Krüger — Materials Science Dpt, Chiba University, Chiba 263-8522 Japan

Recently we have developed a computational method for resonant photoelectron diffraction (RPED) and its circular dichroism (CD) of magnetic surfaces, by combining ligand field multiplet and multiple scattering theory. The method was successfully tested for ferromagnetic Ni(111) [Phys. Rev. B 107, 075407 (2023)]. Here I apply the new method to the altermagnet MnTe. For a photon energy at the Mn L3-edge resonance and light incidence parallel to the magnetization axis, I show that there is a large, purely magnetic CD signal at the forward focusing peaks of the RPED pattern. This CD signal provides a direct probe of the staggered magnetization in altermagnets, which is closely related to the X-ray magnetic circular dichroism observed in ferromagnets.

MA 13.3 Tue 10:00 H20

New altermagnetic material candidates showing 4*f*-magnetism — •Franziska Walther[1], Johannes Fey[1], Michelle Ocker[1], Libor Šmejkal[2,3], Cornelius Krellner[1], and Kristin Kliemt[1] — [1]Physikalisches Institut, Goethe-Universität 60438 Frankfurt/Main — [2]Max Planck Institut für Physik komplexer Systeme, Nöthnitzer Str. 38, 01187 Dresden — [3]Institut für Physik, Johannes Gutenberg Universität Mainz, 55099 Mainz

Altermagnets are a novel class of collinear magnetic materials, which are characterised by a vanishing net magnetization while breaking the time-reversal symmetry in the electronic band structure with a unique alternating spin-momentum locking [1]. So far, altermagnetism has been proven for magnetic 3*d*-systems such as CrSb [2], MnTe [3] and Mn_5Si_3 [4] by the time-reversal breaking signature in the band structure or the observation of the anomalous Hall effect. In order to study the altermagnetism arising from local 4*f* moments, we have grown single crystals of lanthanoid-based intermetallic compounds and characterised their physical and chemical properties. We report on the crystal growth and measurements of magnetism, heat capacity and resistivity of the altermagnetic candidates.

MA 13.4 Tue 10:15 H20

Altermagnetic properties of hematite. — •Edgar Galindez-Ruales[1], Rafael Gonzales-Hernandez[1,2], Gerhard Jakob[1], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg University Mainz, Staudingerweg 7, 55128 Mainz, Germany. — [2]Grupo de Investigacíon en Física Aplicada, Departamento de Física,Universidad del Norte, Barranquilla, Colombia.

Hematite, a prototypical antiferromagnet, has emerged as a promising altermagnet due to its unique magnetic and electronic properties[1]. Unlike conventional antiferromagnets, altermagnets exhibit a nonzero anomalous Hall effect (AHE) due to symmetry-breaking electronic structures despite having no net magnetization. In hematite, we observe anisotropic magnetotransport with a strong crystal orientation dependence, including a striking sign inversion in the Hall effect[2]. Using advanced XMCD and XMLD imaging, we directly visualize and distinguish 180° domains, confirming the interplay between collinear antiferromagnetism and non-centrosymmetric atomic arrangements that drive the altermagnetic behavior. These findings provide robust experimental evidence of hematite*s altermagnetic nature, offering new mechanisms for identifying altermagnetic candidates and establishing hematite as a model system for exploring altermagnetic phenomena. This work paves the way for utilizing altermagnetic materials in spintronic applications, revolutionizing our understanding of magnetic material classification and transport phenomena.

MA 13.5 Tue 10:30 H20

Ferro-spinetic altermagnetic insulators from electronic correlations — •Toshihiro Sato[1,2], Ion Cosma Fulga[1,2], Fakher F. Assaad[3,2], and Jeroen van den Brink[1,2] — [1]Institute for Theoretical Solid State Physics, IFW Dresden, Germany — [2]Würzburg-Dresden Cluster of Excellence ct.qmat, Germany — [3]Institut für Theoretische Physik und Astrophysik, Universität Würzburg, Germany

While altermagnets are a class of fully compensated antiferromagnets lacking combined time-reversal and translational symmetry, their symmetry allows for unique polarization phenomena when inversion symmetry is broken. In this talk, we introduce an interacting fermion model with emergent ferro-spinetic polarizations in altermagnetic insulators - a spin analog to ferroelectricity. This model is grounded in a two-dimensional Hubbard framework incorporating inversion symmetry-breaking elements. Quantum Monte Carlo simulations demonstrate an altermagnetically ordered state with broken inversion symmetry driven by electron correlations, where spin-up and spin-down polarizations accumulate on opposite edges, with their directions reversibly controlled by the inversion symmetry-breaking factor. While the system retains electron-hole symmetry, resulting in zero ferroelectric charge polarization, breaking this symmetry induces the charge polarization orthogonal to the spin polarization.

MA 13.6 Tue 10:45 H20

Interplay of composition and magnetic properties in VxNbS2: An Altermagnetic candidate — •Sunil Wilfred Dsouza and Jan Minár — New Technologies Research Centre, University of West Bohemia, Univerzitní 8, CZ-306 14 Pilsen, Czech Republic

We investigate the interplay of chemical composition and electronic structure with respect to V atoms in an altermagnetic candidate VxNbS2 in the magnetically ordered state. The results from the first-principles calculations employing coherent potential approximation demonstrate that the electronic band structure exhibits valley-spin splitting induced by bulk magnetic order, which is only slightly affected by disorder and deficiency of V atoms, but an impact on the magnetic exchange coupling can be inferred. The results are interesting for the research on 3d-metal inserted transition-metal dichalcogenides and in a broader context for the understanding and design of Altermagnet- based spintronic materials.

MA 13.7 Tue 11:00 H20

Spin-transfer and topological Hall physics in d-wave altermagnets — •Ricardo Zarzuela — Johannes Gutenberg Universität Mainz, Mainz, Germany

Altermagnets, a novel magnetic phase of matter exhibiting zero net magnetization, anisotropic spin-split isoenergy surfaces and time reversal-symmetry-broken momentum-dependent spin splittings in the electronic band structure, have gained enormous momentum in the recent years due to their potential usage as active elements in Terahertz spintronic-based technologies [1]. In this talk, I will introduce an effective long-wavelength theory for charge carriers flowing within a d-wave altermagnet, from which the spin-splitter effect can be inferred as well as an unconventional spin-transfer response of the electron fluid. Reciprocally, the presence of altermagnetic textures induces the deflection of the electron trajectories. In this regard, I will also discuss how the d-wave nature of the altermagnet yields unconventional features to the topological Hall conductivity, which can be observed experimentally.

MA 13.8 Tue 11:30 H20

Crystal structure and absence of magnetic order in single crystalline RuO_2 — •Lara Kiefer[1], Felix Wirth[1], Alexandre Bertin[1], Petra Becker[2], Ladislav Bohatý[2], Karin Schmalzl[3], Anne Stunault[4], José Alberto Rodríguez-Velemazan[4], Oscar Fabelo[4], and Markus Braden[1] — [1]II. Physic. Inst., Univ. Cologne, Germany — [2]Inst. Geology a. Mineralogie, Univ. Cologne, Germany — [3]Fz Jülich, Grenoble, France — [4]ILL, Grenoble, France

The recent report of antiferromagnetic order above room temperature in RuO_2 and its identification as an altermagnetic state boosted research on the material [1,2]. However, muon and neutron experiments, along with DFT calculations, recently questioned the existence of magnetic order in RuO_2 and suggested that it only occurs in the presence of vacancies [3-4]. We conducted polarized and unpolarized neutron diffraction experiments on RuO_2 crystals, which were characterized by magnetization, EDX, electrical conductance, and XRD measurements [5]. We did not confirm the proposed structural distortion in our crystals down to 2K. Ruthenium vacancies were below a few percent in our crystals. Polarized neutron experiments did not show magnetic Bragg reflections for the proposed $\vec{k}$=(0,0,0) [2]. Even a smaller ordered moment would have yielded significant intensities. Thus, this antiferromagnetic order is ruled out in our stoichiometric crystals [5].

MA 13.9 Tue 11:45 H20

Ferroelectric Switchable Altermagnetism — Mingqiang Gu[1], Yuntian Liu[1], Haiyuan Zhu[1], Kunihiro Yananose[2], Xiaobing Chen[1], Yongkang Hu[1], •Alessandro Stroppa[3], and Qihang Liu[1] — [1]Department of Physics and Guangdong Basic Research Center of Excellence for Quantum Science, Southern University of Science and Technology, Shenzhen 518055, China — [2]Korea Institute for Advanced Study, Seoul 02455, Republic of Korea — [3]CNR-SPIN - Via Vetoio - 67100 - Coppito (AQ), Italy.

We propose a novel ferroelectric switchable altermagnetism effect, by synergistically correlating the switching of ferroelectric polarization and the altermagnetic spin splitting. We demonstrate the design principles for the ferroelectric altermagnets and the further symmetry constraints for switching the altermagnetic spin splitting through flipping the electric polarization based on the state-of-the-art spin-group symmetry techniques. 22 ferroelectric altermagnets are found by screening through the 2001 experimental reported magnetic structures in the MAGNDATA database and 2 of them are identified as ferroelectric switchable altermagnets. Using the hybrid improper ferroelectric material [C(NH2)3]Cr(HCOO)3 as an example, we show how the altermagnetic spin splitting is tightly coupled to the ferroelectric polarization, providing an ideal platform for designing electric-field-controllable multiferroic devices. Finally, we find that such manipulation of altermagnetism can be detected by monitoring the physical quantities that are related to the non-vanishing Berry curvature dipole, such as the linearly polarized photogalvanic spin current.

MA 13.10 Tue 12:00 H20

Growth and properties of sputter-deposited altermagnetic RuO_2 thin films — •Maik Gaerner, Martin Wortmann, Judith Bünte, Inga Ennen, Andreas Hütten, Jan Schmalhorst, Timo Kuschel, and Günter Reiss — Bielefeld University, Germany

Altermagnetic materials exhibit time-reversal symmetry breaking and non-relativistic, anisotropic spin splitting in their bandstructure. RuO_2 is widely regarded as such an altermagnetic material, since e.g. spin-torque generation in RuO_2 has been observed [1]. However, muon spin rotation experiments [2] and density functional theory calculations [3] hint at the fragility of the magnetic order in RuO_2.

Here, we report on the growth and characterisation of RuO_2 thin films, deposited on MgF_2-, TiO_2- and MgO-substrates using reactive magnetron sputtering. In contrast to MgF_2-substrates, the lattice mismatch between the commonly used TiO_2-substrates and RuO_2 induces a significant strain on the RuO_2 which can enhance the density of states near the Fermi level [4]. We compare the crystallographic and electronic transport properties of the RuO_2 films, deposited at varying growth conditions and on the different substrates, with regard to the detection of the altermagnetic phase.

Thermo-electric magnetotransport studies on altermagnetic CrSb — •Sajal Naduvile Thadathil[1,2], T. Kotte[1], C. Müller[3], D. Kriegner[4], J. Pospíšil[4], R. Firouzmandi[5], M. Uhlarz[1], M. C. Rahn[2], T. Speliotis[6], V. Kocsis[5], J. Wosnitza[1,2], H. Reichlova[3], and T. Helm[1] — [1]High Magnetic Field Laboratory Dresden, (HLD-EMFL), HZDR, Germany — [2]Institute of Solid State and Materials Physics, TU Dresden, Germany — [3]Institute of Physics, Academy of Science of the Czech Republic — [4]Charles University, Czech Republic — [5]Leibniz Institute for Solid State and Materials Research, Dresden, Germany — [6]Institute of Nanoscience and Nanotechnology, NCSR Demokritos

Recent observations of materials exhibiting properties of both ferromagnets and antiferromagnets, characterized by antiparallel magnetic ordering, have led to the classification of a third distinct magnetic phase known as "altermagnetism". In this study, we investigate the thermo-electric and magnetotransport properties of the altermagnetic candidate material CrSb, using bulk and micron-sized structures fabricated from single crystals. We performed measurements of thermal-transport, magnetoresistance (MR) and the Hall effect between 1.8 and 300 K under magnetic fields up to 14 T. Our results reveal a significant nonlinear field dependence of the Hall resistance, confirmed by similar nonlinear behavior in the thermal Hall effect, providing evidence for multiband physics in CrSb. Additionally, we observe a non-saturating MR up to 14 T. These findings provide new insights into the multiband electronic structure of CrSb.

MA 13.12 Tue 12:30 H20

SU(N) altermagnetism: Lattice models, magnon modes, and flavor-split bands — •Pedro Monteiro Cônsoli and Matthias Vojta — Institut für Theoretische Physik, TU Dresden

Altermagnets are magnetically ordered states which, much like antiferromagnets, have zero net magnetization, and yet resemble ferromagnets in that their band structure shows signs of broken time-reversal symmetry. They have stirred great interest lately not only due to their potential for spintronics applications, but also as gateways to unconventional phases of matter. In this talk, we will demonstrate that a generalized form of altermagnetism can occur in SU(N) magnets with $N > 2$. Guided by symmetry principles, we will present a recipe to construct simple Heisenberg models for such generalized altermagnets and apply it explicitly to two-dimensional examples with $N = 2$ and 3. We will then report a comparative analysis based on spin- and flavor-wave calculations which proves that both systems share the same characteristic behavior of insulating altermagnets, namely that their magnon bands are nondegenerate and carry different sets of magnetic quantum numbers. Finally, we will show that the analogy between the models persists when they are supplemented with charge carriers to become metallic.

MA 13.13 Tue 12:45 H20

Quasi-symmetry Constrained Spin Ferromagnetism in Altermagnets — Mercè Roig[1,2], Yue Yu[2], Rune C. Ekman[1], •Andreas Kreisel[1], Brian M. Andersen[1], and Daniel F. Agterberg[2] — [1]Niels Bohr Institute, University of Copenhagen, DK-2100 Copenhagen, Denmark — [2]Department of Physics, University of Wisconsin Milwaukee, Milwaukee, Wisconsin 53201, USA

Altermagnets break time-reversal symmetry and their spin-orbit coupling (SOC) allow for an anomalous Hall effect (AHE) that depends on the direction of the Néel ordering vector. AHE and ferromagnetic spin moment share the same symmetry and hence are usually proportional. However, density functional theory (DFT) calculations find that the AHE exists with negligible ferromagnetic spin moment for some compounds, whereas it reaches sizable values for other altermagnets. By examining realistic minimal models for altermagnetism in which the DFT phenomenology is captured, we uncover a general SOC-enabled quasi-symmetry that provides a natural explanation for the amplitude of the ferromagnetic spin moment across the vast range of different altermagnetic materials. Additionally, we derive analytic expressions for the magnetic anisotropy energy, providing a simple means to identify the preferred altermagnetic Néel vector orientation for altermagnets.

MA 14: Focus Session: Strongly Correlated Quantum States in Moire Heterostructures (joint session TT/HL/MA)

In recent years, significant progress has been made in realizing and exploring correlated quantum states in multilayer moiré heterostructures of graphene or transition metal dichalcogenides. These achievements have been made possible by the high level of control and tunability of these systems. Striking phenomena have been demonstrated experimentally, including unconventional superconductivity, fractional quantum anomalous Hall states, Mott-Wigner states and density waves, as well as kinetic ferromagnetism. Moreover, recently novel spectroscopic experimental techniques have been developed which allow for new ways to explore the dynamical response of these exotic states. This focus session will discuss recent experimental advancements as well as theoretical developments in the field of strongly correlated moiré heterostructures.

Organizers: Dmitri K. Efetov (LMU München), Michael Knap (TU München)

Time: Tuesday 9:30–13:15 Location: H36

See TT 18 for details of this session.

MA 15: Poster I

Time: Tuesday 10:00–12:30 Location: P1

MA 15.1 Tue 10:00 P1

Truly Chiral Phonons Arising From Chirality-Selective Magnon-Phonon Coupling — •Philipp Rieger[1], Markus Weissenhofer[1,2], Luca Mikadze[1], M. S. Mrudul[1], Ulrich Nowak[3], and Peter M. Oppeneer[1] — [1]Uppsala University, Uppsala, Sweden — [2]Freie Universität Berlin, Berlin, Germany — [3]Universität Konstanz, Konstanz, Germany

Growing attention has focused on the angular momentum of phonons, particularly in ultrafast magnetization dynamics. This arises from the circular or elliptical motion of atoms around equilibrium positions, forming collective modes known as chiral phonons.

Structural inversion symmetry (P) breaking is well known to give rise to chiral phonons. Here, we present an alternative mechanism for the generation of chi-

ral phonons, stemming from magnon-phonon coupling in P-symmetric crystal lattices with time-reversal symmetry breaking.

We investigate magnon-phonon coupling in bcc Fe using a first-principles framework. Our calculations reveal the hybridization of magnon and phonon modes, giving rise to magnon-polarons and an avoided crossing (energy gap) in the dispersion relations. Along specific high-symmetry lines in reciprocal space, we observe that magnon coupling transforms degenerate transverse phonon modes into chiral phonons, characterized by an energy splitting between left- and right-handed modes. Our findings challenge conventional magneto-elastic interpretations and reveal zero-point phonon angular momentum and anomalous Hall effects linked to finite (spin) Berry curvatures.

MA 15.2 Tue 10:00 P1

Polymer-free stacking and μ-ARPES of multiferroic $CuCrP_2S_6$ — •Niklas Leuth[1], Tim Jacobs[1], Jeff Strasdas[1], Wendong Wang[2], Roman Gorbachev[2], Elena Voloshina[3], Yuriy Dedkov[3], Marcus Liebmann[1], Vitaly Feyer[4], and Markus Morgenstern[1] — [1]II. Institute of Physics B, RWTH-Aachen University, Germany — [2]National Graphene Institute, University of Manchester, UK — [3]Department of Physics, Shanghai University, China — [4]PGI 6, Forschungszentrum Jülich, Germany

Transition-metal (Tm) phosphorus trisulfides are antiferromagnetic van-der-Waals materials with various magnetic orders, providing a platform for detailed studying and tuning of 2D magnetism [1,2]. The binary Tm compound $CuCrP_2S_6$ exhibits additional ferro-/ antiferroelectricity and magnetoelectric coupling enabling gate induced magnetic orders [2]. We present results on stacking of this material by a fully inorganic transfer process in a glovebox developed by the University of Manchester, leading to polymer-free inter- and surfaces [3]. These stacks are analysed by atomic force microscopy and x-ray photoelectron spectroscopy. After transfer in ultra-high vacuum, they are suitable for surface-sensitive angular-resolved photoelectron spectroscopy (ARPES) with micrometre focus. We tracked the band structure from 300 K to 40 K covering several known phase transitions and discuss changes of the band structure in comparison with density functional theory calculations and analyse the relevant photoelectron matrix elements. [1] J. Mater. Chem. A, 2021, 9, 2560-2591. [2] Nat. Comm., 2024, 15, 3029. [3] Nat. Electron., 2023, 6, 981-990.

MA 15.3 Tue 10:00 P1

Towards time-resolved cubic Magneto-optic Kerr effect measurements — •Farell Keiser, Wentao Zhang, Yuhao Meng, Maik Gaerner, Nicolas Beermann, Hassan Hafez, Savio Fabretti, Timo Kuschel, and Dmitry Turchinovich — Bielefeld University, Germany

The magneto-optic Kerr effect (MOKE) represents an alteration in the polarization of light when it is reflected from a magnetized surface. MOKE-based techniques are widely employed to characterize the magnetic properties of thin films. While many experiments focus on first- or second-order MOKE [1,2], a systematic investigation of the third order "cubic MOKE" (CMOKE) was only reported recently [3]. In this study, we present time-resolved MOKE measurements in Ni(111) thin films to investigate the dynamics of CMOKE. Specifically, we measure MOKE-curves for different sample orientations under strong optical pumping to observe the influence of demagnetization on the CMOKE. Time-resolved MOKE measurements were performed for different sample orientations and pump fluences.

[2] R. Silber et al., Phys. Rev. B 100, 064403 (2019)
[3] M. Gaerner et al., Phys. Rev. Applied 22, 024066 (2024)

MA 15.4 Tue 10:00 P1

Cubic magneto-optic Kerr effect in Ni(111) and Co(111) thin films depending on the angle of incidence — •Malte Schaeffer[1], Maik Gaerner[1], Robin Silber[2], Jaroslav Hamrle[3], Martin Wortmann[4], Andrea Ehrmann[4], and Timo Kuschel[1] — [1]Bielefeld University, Germany — [2]VSB-Technical University of Ostrava, Czechia — [3]Charles University Prague, Czechia — [4]Bielefeld University of Applied Science and Arts, Germany

The magneto-optic Kerr effect (MOKE) describes the change in polarization of linear polarized light when reflected from a magnetized sample. It can be utilized to investigate magnetic properties of thin films and microstructures. In most cases, only the linear dependence on the magnetization M and sometimes the quadratic contribution depending on M^2 (QMOKE) are studied [1,2]. The third-order MOKE, so-called cubic MOKE (CMOKE), has only been studied recently [3,4]. In order to separate the individual MOKE contributions, the eight-directional method is used by applying an external magnetic field in eight different in-plane directions. In this contribution, we measured QMOKE and CMOKE in ferromagnetic Ni(111) and Co(111) thin films for different angles of incidence ranging from 45° to normal. We compared the findings with theoretical predictions based on Yeh's matrix formalism.

MA 15.5 Tue 10:00 P1

Dynamical Mean Field Theory for Spin Systems at Finite Temperature — •Przemysław Bieniek, Timo Grässer, and Götz Uhrig — Technische Universität Dortmund, Fakultät Physik

In the recent years, a dynamical mean field theory approach for spin systems at infinite temperature (spinDMFT) was developed. It is an approximate technique in the limit of an infinite coordination number, reducing the full dynamics of a spin system to a problem of a single spin interacting with a dynamical environment field. This allows for very efficient computation of spin correlations, which shows good agreement with other computational techniques and excellently describes nuclear magnetic resonance (NMR) experiments.

However, the current version of spinDMFT applies only to systems at infinite temperature and two-site couplings. We aim at extending the technique. One goal is to address finite temperatures, but still above any ordering temperature. To this end, we modify the approach to dynamical Green's functions instead of spin correlations. The second goal is to deal with three-site couplings as they arise in experiments with magic angle spinning. We benchmark the developed techniques for various spin models by comparing the results with other numerical approaches and discuss possible applications.

MA 15.6 Tue 10:00 P1

Spin Textures and Surface State Sequences of a Prototypical Topological Insulator Revealed by Momentum Microscopy — •Wei-Sheng Chiu[1,2], Ina Marie Verzola[3], Ying-Jiun Chen[1,4], Rovi Angelo Beloya Villaos[3], Claus Michael Schneider[1,2], Feng-Chuan Chuang[3], and Christian Tusche[1,2] — [1]Forschungszentrum Jülich, Peter Grünberg Institut PGI-6, 52425 Jülich, Germany — [2]Fakultät für Physik, Universität Duisburg-Essen, 47057 Duisburg, Germany — [3]National Sun Yat-sen University, Department of Physics, 80424 Kaohsiung, Taiwan — [4]Forschungszentrum Jülich,Ernst Ruska-Centre ER-C-1, 52425 Jülich, Germany

As a hallmark of the prototypical topological insulator of Bi_2Se_3, its intriguing topological surface state (TSS) has been extensively studied. By using spin-resolving momentum microscopy (SPEMM) with an Au passivated Ir(100) imaging spin filter, we directly recorded the spin-resolved momentum maps (k_x, k_y) over entire surface Brillouin zone (SBZ) of Bi_2Se_3. In addition to the well-known Dirac cone at the Fermi level, our measurements reveal a sequence of several Dirac-like spin textures and crossings. Our first-principles calculations indicate that those overlooked bands are attributed to Bi_2Se_3 surface states spanning a wide binding energy up to 4 eV below the Fermi level.

MA 15.7 Tue 10:00 P1

A single crystal study of the kagome magnets *R*Mn6Sn6 — •Ana Kurtanidze[1,2], Shingo Yamamoto[1], Klara Uhlirova[3], Yurii Skourski[1], Sergei Zherlitsyn[1], Jeremy Sourd[1], and Joachim Wosnitza[1,2] — [1]Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, Dresden, Germany — [2]Institut für Festkörper- und Materialphysik, TU Dresden,Germany — [3]Materials Growth and Measurement Laboratory (MGML), Charles University, Prague, Czech Republic

The kagome magnets *R*Mn6Sn6 (*R* = Sc, Y, Gd-Lu) with hexagonal structure (P6/mmm) attract attention due to a possible correlation between the observed topological electronic properties and various magnetic phases. We synthesized high-quality single crystals of *R*Mn6Sn6 (*R* = Er and Tm) by a tin-flux method. We performed scanning electron microscopy, energy-dispersive x-ray spectroscopy, and wavelength dispersive x-ray fluorescence measurements to characterize the phase purity of the samples, which showed a composition close to the nominal stoichiometric ratio. We observed approximately 0.25 at.% aluminum impurity, which originated from the alumina crucibles used. In addition to the chemical characterization, we will discuss the magnetic properties from our preliminary magnetization results under magnetic fields applied along the principal crystallographic axes.

MA 15.8 Tue 10:00 P1

Static and dynamic magnetic properties in the Li-rich antiperovskite $(Li_2Fe)ChO$ (Ch = S, Se) — •F.L. Carstens[1], F. Seewald[2], T. Schulze[2,3], N. Grässler[3], M.A.A. Mohamed[3], S. Hampel[3], L. Singer[1], H.-H. Klauss[2], H.-J. Grafe[3], and R. Klingeler[1] — [1]Kirchhoff Institute for Physics, Heidelberg University, Germany — [2]Institut für Festkörperphysik, TU Dresden, Germany — [3]Leibniz Institute for Solid State and Materials Research IFW Dresden, Germany

The recently discovered class of lithium-rich antiperovskites crystallize in cubic antiperovskite crystal structure such that Li^+ and transition metal ions TM^{2+} are randomly distributed at the same atomic position. They octahedrally coordinate central O^{2-} ions while the chalcogens (S^{2-}/Se^{2-}) are at corners of the cubic crystallographic cell. Despite their compelling properties as high-capacity cathode materials, very little is known about their electronic and magnetic properties. Here, we report static magnetisation, Mössbauer, and NMR studies on Li-rich antiperovskite $(Li_2Fe)ChO$ (Ch = S, Se). Our data show a Pauli paramagnetic-like behaviour, a long-range antiferromagnetically ordered ground state and a regime of short-range magnetic order at least up to 100 K. Our results are con-

sistent with predominantly random Li-Fe distribution on the shared lattice position. In addition, the effect of Li-hopping is observed and discussed. Overall, our data elucidate magnetism in a disordered presumably semimetallic system with thermally induced ionic dynamics.

MA 15.9 Tue 10:00 P1

Manipulation of Surface Domains in an Ultrasoft van-der-Waals Ferromagnet — •Stephan Schmutzler[1], Yichen Jin[1], Guangyao Miao[2,3], Florian Kronast[4], Sergio Valencia[4], Zefang Li[5], Martin Weinelt[1], and Cornelius Gahl[1] — [1]Fachbereich Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany — [2]Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — [3]Department of Physics and CSMB, Humboldt-Universität zu Berlin, Berlin 12489, Germany — [4]Helmholtz-Zentrum Berlin, Albert-Einstein-Str. 15, 12489 Berlin, Germany — [5]School of Physics, Nankai University, Tianjin, China

The layered van-der-Waals material $Cr_2Ge_2Te_6$ (CGT) is a very soft ferromagnet at temperatures below 61 K. We show by X-ray magnetic circular dichroism in photoelectron emission microscopy (XMCD-PEEM) that the surface domain structure of a bulk CGT crystal can be reproducibly switched between topologically different phases by ultrashort laser pulse trains in combination with applying small magnetic fields. The effect is attributed to the transient temperature profile normal to the surface established by the interplay of absorption of light and the low interlayer heat conductivity of the material. The laser parameters accordingly allow for tayloring the sample depth of domain manipulation.

MA 15.10 Tue 10:00 P1

Sensing the Spin States of Individual Lanthanide Atoms on a surface — •Kyungju Noh[1,2,3], Gregory Czap[3], Jairo Velasco Jr.[3,4], Roger M. Macfarlane[3], Harald Brune[3,5], and Christopher P. Lutz[3] — [1]Center for Quantum 467 Nanoscience (QNS), Institute of Basic Science (IBS), Seoul 468 03760, Republic of Korea — [2]Department of Physics, Ewha 469 Womans University, Seoul 03760, Republic of Korea — [3]IBM Almaden Research Center, San Jose, 466 California 95120, United States — [4]Department of Physics, 472 University of California, Santa Cruz, California 95064, 473 United States — [5]Institute of Physics, Ecole 458 Polytechnique Fédérale de Lausanne (EPFL), Lausanne CH-459 1015, Switzerland

Research on single atoms and molecules of lanthanide elements has become a focal point in materials science due to their exceptional magnetic and electronic properties arising from the 4f shell electrons.

Here, we introduce the magnetic property of individual Samarium (Sm) and Europium (Eu) atoms, which has nearly half-filled and half-filled 4f shell each, adsorbed on various binding sites of a MgO thin film. Using electron spin resonance scanning tunneling microscopy (ESR-STM), we analyze the spin structures of Sm and Eu on different binding sites. Titanium (Ti), a well-established atom, serves as a spin sensor to detect interactions with the lanthanide atoms. Our comparison across binding sites reveals distinct spin characteristics of the lanthanides on a surface, which further opens a way to implement lanthanide atoms to quantum devices.

MA 15.11 Tue 10:00 P1

Applications of 3D Nano-Lithography in Magnetism — •Jana Kredl[1], Christian Denker[1], Cornelius Fendler[2], Julia Bethune[1], Nina Meyer[1], Theresa Brinker[1], Finn-F. Stiewe[1], Hauke Heyen[1], Chris Badenhorst[1], Alena Rong[1], Jakob Walowski[1], Robin Silber[3], Mark Doerr[1], Raghvendra Palankar[1], Uwe T. Bornscheuer[1], Marcel Kohlmann[1], Toni Hache[6], Michaela Lammel[4], Alexander Paarmann[5], Andy Thomas[4], Robert Blick[2], Mihaela Delcea[1], and Markus Münzenberg[1] — [1]University of Greifswald, Germany — [2]University of Hamburg, Germany — [3]VSB-Technical University of Ostrava, Czech Republic — [4]IFW Dresden, Germany — [5]Fritz Haber Institute of Max Planck Society, Berlin, Germany — [6]Helmholtz-Zentrum Dresden-Rossendorf, Germany

3D 2-Photon-Lithography, originally developed for 3D photonic crystals, opens a wide range of new possible applications in many fields, e.g. life sciences, micro-optics and mechanics. We will present our recent applications of 3D 2-Photon-lithography and show 3D evaporation masks for in-situ device fabrication using different deposition angles, infra-red laser light focusing lenses directly fabricated on optical fibers, tunnel structures for guiding growth of neurons [1], pillars for investigation of cell mechanics and master-mold fabrication for Polydimethylsiloxane (PDMS) micro-fluidic channels. Based on our experience we will discuss possible applications in magnetism. [1] C. Fendler et al., Adv. Biosys. 5 (2019) doi: 10.1002/adbi.201970054

MA 15.12 Tue 10:00 P1

Straining three-dimensional magnetic nanostructures — •José Claudio Corsaletti Filho, Mohammad Sedghi, Elina Zhakina, Markus König, Elena Gati, and Claire Donnelly — Max Planck Institute for Chemical Physics of Solids, Dresden, Germany

The study of nanoscale magnetic objects has led to fascinating discoveries over the past few decades. Three-dimensional magnetism offers new opportunities to develop compact energy storage devices and explore spin textures and novel domain walls, which could be crucial for energy-efficient computation. To improve our fundamental understanding and enable the development of new devices, it is important to be able to tune the magnetic properties of materials. One way to achieve the controlled manipulation of magnetic properties is through the application of strain. While the straining of materials is well established for both bulk, and thin film samples, applying strain to 3D magnetic nanostructures remains an open challenge. In this project we develop a protocol to strain three-dimensional cobalt nanostructures grown with focused electron beam induced deposition. By performing in-situ measurements as a function of applied strain, we explore first the mechanical properties of the 3D nanostructures under an electron microscope, and secondly, the evolution of the magnetic properties of the nanostructure with strain. The straining of magnetic nanostructures opens the door to control of magnetic textures in complex geometries, of key importance both to our fundamental understanding, and the development of new devices.

MA 15.13 Tue 10:00 P1

Micromagnetic Simulations of Domain Wall Dynamics in Chiral Nanostructures — •Iason-Konstantinos Douveas[1], Pamela Morales Fernandez[1,8], Sandra Ruiz- Gómez[3], Elina Zhakina[2], Sebastian Wintz[4], Markus König[2], Aurelio Hierro Rodríguez[5], Simone Finizio[6], Luke Turnbull[2], Naëmi Leo[7], Dieter Suess[1], Amalio Fernández-Pacheco[8], Claire Donnelly[2,9], and Claas Abert[1] — [1]Faculty of Physics, University of Vienna, Austria — [2]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [3]ALBALBA Synchrotron Light Source, CELLS, Spain — [4]Helmholtz Zentrum Berlin BESSY II, Germany — [5]CINN CSIC, University of Oviedo, Spain — [6]Paul Scherrer Institut, Swiss Light Source, Switzerland — [7]Loughborough University, United Kingdom — [8]Institute of Applied Physics, University of Vienna, Austria — [9]International Institute for Sustainability with Knotted Matter, Japan

We investigate domain wall (DW) eigenmodes in three-dimensional chiral magnetic nanostructures through micromagnetic simulations using the finite-element method. Our study focuses on double helices under external magnetic fields, examining the relationship between DW behavior and structural parameters. We employ two computational approaches: a small-scale model for extensive parameter space exploration and a larger structure matching experimental specimens. By implementing X-ray magnetic circular dichroism simulations, we provide direct comparison with experimental data, offering insights into DW mechanics in curved geometries.

MA 15.14 Tue 10:00 P1

Developing a two sublattice model for spin inertia and nutation — •Tarek Moussa[1], Ritwik Mondal[2], and Akashdeep Kamra[1] — [1]Department of Physics, RPTU Kaiserlautern-Landau, Kaiserslautern, Germany — [2]Department of Physics, Indian Institute of Technology (ISM) Dhanbad, India

Recent theoretical and experimental works on ultrafast magnetization dynamics suggest the existence of a finite spin inertia resulting in a nutation mode. Using the Landau-Lifshitz-Gilbert equation, we develop a two sublattice model for the description of spin inertia on the basis of an effective spin-orbit-coupling description and results for two sublattice ferrimagnets. We examine the conditions under which the two-sublattice model leads us to the magnetization dynamics description including spin inertia.

MA 15.15 Tue 10:00 P1

Flip-flop transport of magnetic cuboidal particles in dynamic potential energy landscapes for Lab-on-Chip applications — •Jonas Bugase, Christian Janzen, Arne Vereijken, Yahya Shubbak, Nikolai Weidt, Rico Huhnstock, and Arno Ehresmann — Institute of Physics , University of Kassel, 34132 Kassel

The unique possibility to transport magnetic particles using controlled magnetic forces have resulted in their increased use in bio-applications. We, therefore, present the remotely controlled transport mechanism for cubiodal particles, fabricated using two-photon polymerization (2PP) lithography above a magnetically patterned flat substrate. By sputtering a magnetic exchange bias thin film system on the surface of the polymeric particles, we fix the magnetic moment of the particles along the elongated axis. We characterized the magnetic properties of the custom-made particles and studied their exotic transport within a periodic magnetic stray field landscape, artificially created by parallel stripe domains fabricated via ion bombardment induced magnetic patterning [1]. The shape anisotropy contributions and the rotation dynamics of the particles in a quiescent liquid environment leading to the lateral walking and flipping modes of the particle transport are characterized using optical microscopy. This transport mechanism is promising for the detection of biomolecules in Lab-on-Chip devices [2] and for probing the effective field direction of dynamically transformed magnetic stray field landscapes.

MA 15.16 Tue 10:00 P1

Current status and outlooks in time-resolved scanning transmission X-ray microscopy imaging — Simone Finizio[1], Bart Olsthoorn[2], Joe Bailey[1], Claire Donnelly[3], Sina Mayr[1,4], Ales Hrabec[1,4], and •Jörg Raabe[1] — [1]Paul Scherrer Institut, Villigen PSI, Switzerland — [2]Nordita (KTH), Stockholm, Sweden — [3]MPI-CPFS, Dresden, Germany — [4]DMATL, ETH Zurich, Zurich, Switzerland

Time-resolved X-ray microscopy is a powerful imaging technique that has been extensively employed for the study of dynamical processes in condensed matter systems. In particular, time-resolved scanning transmission X-ray microscopy (TR-STXM) has been the workhorse in the experimental study of magneto-dynamical processes such as magnonics, switching, domain wall motion, and the dynamics of topological magnetic objects.

In this contribution, we will present the current status and outlooks of TR-STXM imaging at soft X-ray energies. The TR-STXM setup of the Swiss Light Source (SLS) will be presented, together with examples of 3D TR-STXM imaging, of periodogram-based imaging, and of how to overcome the limitations given by the X-ray pulse width.

In addition, we will present the planned future developments of the technique in view of the significant increase of coherent photon flux that will be offered by the upgrade of the SLS to a diffraction limited storage ring.

MA 15.17 Tue 10:00 P1

Micro-Hall magnetometry on magnetic grains and nanostructures — •Bereket Ghebretinsae and Jens Müller — Institute of Physics, Goethe University Frankfurt, 60438 Frankfurt (M), Germany

Micro-Hall magnetometry is a highly versatile and extremely sensitive magnetic measurement technique which allows for stray field measurements on micro- to nanosized samples with nanotesla sensitivity. The magnetometer is a Hall sensor based upon an AlGaAs/GaAs heterostructure which hosts a 2DEG whose unparalleled electron mobility in measurements directly translates into an ultrahigh stray-field resolution. Micro-Hall sensors have previously been used for diverse purposes such as resolving the discrete lattice potential inside a YIG thin film [1], pinpointing the onset of the formation of magnetic polarons inside ferromagnetic EuB_6 [2] as well as investigating the magnetostatics and the magnetization dynamics of two- and three-dimensional artificial spin ice systems [3]. Here we outline a (PhD) thesis project which intends to exploit the capabilities and the versatility of micro-Hall magnetometry to investigate a variety of magnetic systems of current scientific interest. We explain how micro-Hall measurements on specially prepared micron-sized YIG flakes, exchange-biased ferromagnetic bricks, and most of all, three-dimensional Co_3Fe nanotetrapod lattices serve to elucidate their characteristic properties and add upon our current understanding of the magnetism in these systems.

MA 15.18 Tue 10:00 P1

Impact of sample dimensions on the anomalous Hall effect response — •Dominik Vogel, Denise Reustlen, Sebastian Sailler, Gregor Skobjin, Michaela Lammel, Richard Schlitz, and Sebastian T. B. Goennenwein — Fachbereich Physik, Universität Konstanz, Konstanz, Germany

The anomalous Hall effect (AHE) enables an electrical detection of the magnetization in ferromagnetic conductors. In typical AHE measurements, the voltage transverse to both the applied charge current and magnetic field is detected. Recording this voltage as a function of magnetic field strength and polarity allows one to infer the magnetic hysteresis loop of a given magnetic microstructure. However, the absolute magnitude of the AHE voltage characteristically scales with the sample dimensions. In particular, the smaller the width w of the respective studied Hall bar microstructure, the smaller the Hall voltage signal for constant current density. In order to establish the minimal sample dimensions required for a detectable AHE signal, we have systematically varied the dimensions of Hall bar microstructures patterned into thin Co/Pt multilayers with perpendicular magnetic anisotropy and measured their Hall response as a function of field magnitude and current density. We critically discuss the scaling of the Hall voltage with sample dimensions observed and its implications for Hall effect-based experiments in magnetic nanostructures.

MA 15.19 Tue 10:00 P1

Bright days ahead - Soft X-ray scanning microscopy at 4th generation light-sources — •Simone Finizio[1], Tim Butcher[1,2], Lars Heller[1], Benjamin Watts[1], Blagoj Sarafimov[1], Mirko Holler[1], and Jörg Raabe[1] — [1]Paul Scherrer Institut, Villigen PSI, Switzerland — [2]Max-Born-Institut, Berlin, Germany

Diffraction limited synchrotron (DLSR), or 4th generation, light sources are now delivering an increase in the coherent photon flux of several orders of magnitude compared to the current 3rd generation storage ring design, revolutionizing synchtrotron-based experiments.

For scanning transmission X-ray microscopy (STXM), the increase in coherent photon flux will allow us to routinely perform high-resolution imaging, as it will tackle all the issues occurring for high-resolution X-ray optics. In addition, the combined increase in coherent photon flux, in the available (GPU) computational power, and in the performances of 2D soft X-ray detectors will also enable for the routine performing of high-resolution soft X-ray ptychographic imaging.

In this presentation, we will show the current status of the commissioning of a new combined STXM and soft X-ray ptychography endstation at the SoftiMAX beamline of the MaxIV DLSR, and the first results in the ptychographic imaging of the magneto-electric coupling between ferroelectric domains and spin cycloid in freestanding BiFeO3 thin films, which fully exploit the sub-5nm spatial resolutions achievable with the technique.

MA 15.20 Tue 10:00 P1

Theory of Magnetization Dynamics Control by Phonons — •Meritxell Valls Boix and Alexander Mook — Johannes Gutenberg University, Mainz

Spin-lattice coupling plays a crucial role in facilitating angular momentum exchange between the lattice and magnetic subsystems. In this work, we explore how this coupling can be harnessed to enhance the lifetime of magnons in ferromagnetic materials. Specifically, we focus on the interaction between propagating surface acoustic waves and a proximate magnetic system, where these waves generate a torque on the spins. Using perturbation theory, we derive the effective field arising from magneto-rotational coupling and subsequently define the resulting torque. In particular, we investigate whether a damping-like component of the torque can emerge, which could act as an anti-damping mechanism to counteract the intrinsic magnon damping.

Prospects of spin dynamic mean-field theory for nuclear magnetic resonance — •Timo Gräßer and Götz S. Uhrig — Condensed Matter Physics, TU Dortmund University, Germany

The recently developed dynamic mean-field theory for spins at infinite temperature (spinDMFT) [1] is perfectly tailored to simulate NMR experiments. The underlying idea of spinDMFT is to couple a spin to a dynamic Gaussian mean-field with second moments that are self-consistently linked to the spin's autocorrelations. The approach can be straight-forwardly improved by considering clusters of spins quantum-mechanically in a mean-field background [2,3]. As such, the extension to a non-local spinDMFT (nl-spinDMFT) has been successfully benchmarked for calcium fluoride (CaF_2) and adamantane ($C_{10}H_{16}$) [3]. Due to the low computational requirements and the high flexibility of the method, it can be applied to various scenarios in NMR such as magic angle spinning (MAS) or spin diffusion.

Micromagnetic simulation of an X-shaped crossing controlled by the orientation of an external bias magnetic field — •Sven Niehues, Robert Schmidt, Jannis Bensmann, Steffen Michaelis de Vasconcellos, and Rudolf Bratschitsch — Institute of Physics, University of Münster, Germany

Magnonics is a well-known research field in solid-state physics, which studies magnetic phenomena and the propagation of spin waves and their respective quanta, called magnons. The possibility of steering the propagation direction of spin waves in magnetic insulators such as yttrium iron garnet (YIG) is of crucial importance for the realization of magnonic logic devices. By changing the orientation of the external bias magnetic field relative to the propagation direction, the propagation of spin waves can be manipulated. In this work, numeric simulations of an X-shaped YIG crossing are presented, which allows the steering of spin waves from one input arm into all three output arms at selected frequencies by rotation of the magnetic bias field.

MA 15.23 Tue 10:00 P1

Coupled dynamic modes of a skyrmion chain in a synthetic antiferromagnet (SAF) — •Kauser Zulfiqar[1,2,3], Samuel Holt[1,3], Martin Lang[1,3], Swapneel Amit Pathak[1,3], and Hans Fangohr[1,3,4] — [1]Max Planck Institute for the Structure and Dynamics of the Matter, Hamburg, Germany. — [2]University of Hamburg, Hamburg, Germany. — [3]Center for Free Electron Laser, Hamburg, Hamburg, Germany. — [4]University of Southampton, Southampton, United Kingdom.

Synthetic antiferromagnets (SAFs) are multilayer structures with ferromagnetic layers coupled via RKKY interaction [1]. Skyrmions in SAFs are smaller than in ferromagnetic systems, and studying their modes provides insights into their dynamics and stability, enhancing their potential for spintronic devices [2].

In this work, we expand on previous studies of skyrmion dynamics in circular geometries [3] by exploring a chain of Néel-type skyrmions in a rectangular strip using finite-difference micromagnetic simulations [4]. We use the ringdown method to excite the system with a sinc pulse. Through Fourier analysis, we identify individual modes and observe hybrid and coupled breathing modes among layers.

This work is funded by Marie Skłodowska-Curie (grant 101152613), MaMMoS (Horizon Europe, grant 101135546), and HEC-DAAD (ID 57630247).

MA 15.24 Tue 10:00 P1

Spin dynamics in ferrimagnetic heterostructures — •Felix Fuhrmann[1], Akashdeep Akashdeep[1], Sven Becker[1], Mathias Weiler[3], Gerhard Jakob[1,2], and Mathias Kläui[1,2,4] — [1]Institute of Physics, University of Mainz, Germany — [2]Graduate School of Excellence "Materials Science in Mainz" (MAINZ), Germany — [3]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische UniversitätKaiserslautern-Landau, 67663 Kaiserslautern, Germany — [4]Center for Quantum Spintronics, Norwegian University of Science and Technology, Trondheim, Norway

Magnons emerge as promising information carriers for energy-efficient technology. To advance magnon-based devices, crucial materials requirements must be addressed. Yttrium Iron Garnet (YIG, $Y_3Fe_5O_{12}$) and related garnets, like Gadolinium Iron Garnet (GdIG, $Gd_3Fe_5O_{12}$), stand out due to low damping and large magnon propagation lengths. Using pulsed laser deposition, we fabricated YIG/GIG heterostructures and simulated their magnetic properties. Our findings reveal ferromagnetic coupling between Fe sublattices, leading to complex magnetic response and nontrivial temperature dependence [1]. Experiments on spin current generation via spin Seebeck effect and spin pumping at ferromagnetic resonance align with our micromagnetic simulations [2]. These results provide insights for magnon-based devices and highlight YIG/GIG heterostructures' potential in spintronics applications. [1] S. Becker et al., Phys. Rev. Appl., 16, 014047 (2021). Magnetization fluctuations probed via the anomalous Hall effect — •Nadine Nabben[1], Giacomo Sala[2], Ulrich Nowak[1], Matthias Krüger[3], and Sebastian T. B. Goennenwein[1] — [1]Universität Konstanz — [2]ETH Zürich — [3]Universität Göttingen

Fluctuation phenomena inherently limit the precision of physical measurements, making it essential to understand the underlying mechanisms for improving measurement accuracy. In particular, analyzing magnetic fluctuations provides valuable insights into magnetization behavior and domain wall dynamics. We employ the anomalous Hall effect to electrically investigate low-frequency magnetization fluctuations in thin ferromagnetic layer stacks with perpendicular magnetic anisotropy. By examining the anomalous Hall effect noise at different points in the hysteresis loop, we probe the distinct types of magnetic noise associated with different magnetization states. Our results show that Barkhausen noise, exhibiting a characteristic $1/f^2$ frequency dependence, dominates as long as magnetic relaxation processes occur. In contrast, quasi-stationary magnetization fluctuations generate noise that obeys a $1/f$ frequency dependence. We discuss how these findings offer new perspectives on magnetic fluctuation mechanisms and their implications for both fundamental understanding and technical applications.

MA 15.26 Tue 10:00 P1

Micromagnetic Mumax3 simulations of spin-waves under the influence of stray field landscapes — •Fabian Samad[1,2], Attila Kákay[2], and Olav Hellwig[1,2] — [1]University of Technology Chemnitz, Chemnitz, Germany — [2]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

In most spin-wave application concepts the capability of manipulating and confining the spin-waves is pivotal. One promising way is the usage of hybrid systems [1,2], where the spin-wave transport layer is not directly manipulated, e.g. by patterning, but instead is influenced by a "programming" layer. In our study, we choose for the programming layer a synthetic antiferromagnet (SAF) with perpendicular magnetic anisotropy (PMA) [3], which acts on a spin-wave transport layer via its stray field. The SAF can exhibit a variety of magnetic states depending on the energy parameters and the applied magnetic field, making it – and thus the hybrid system – field-reconfigurable. By performing Mumax3 simulations, we investigate the influence of the stray field of various magnetic patterns in the SAF on the spin-wave dispersion in a layer with YIG-type properties. Particularly, we focus on regular and periodic magnetic domains in the SAF, which can be stabilised e.g. by means of focussed ion beam irradiation and manipulated with external magnetic fields [4].

MA 15.27 Tue 10:00 P1

Quantum spin liquid mimicry in correlated proton disorder double hydroxide perovskite $CuSn(OD)_6$ — •Anton Kulbakov[1], Ellen Haeussler[2], Aswathi Mannathanath Chakkingal[1], Nikolai Pavlovskii[1], Kaushick Parui[1], Sergey Granovsky[1], Sebastian Gass[3], Laura Teresa Corredor Bohorquez[3], Anja Wolter[3,4], Vladimir Pomjakushin[5], Darren Peets[1], Thomas Doert[2], and Dmytro Inosov[1,4] — [1]IFMP, TUD, Dresden, Germany — [2]Faekultaet fuer Chemie und Lebensmittelchemie, TUD, Dresden,Germany — [3]IFW, Dresden, Germany — [4]Wuerzburg-Dresden ct.qmat, TUD, Dresden, Germany — [5]PSI, Villigen, Switzerland

In a magnetic double perovskite hydroxide $CuSn(OD)_6$, the frustration of the proton network coexists with magnetic frustration on the distorted fcc sublattice. Structural distortions, which are most pronounced in the Cu^{2+} compounds due to the Jahn-Teller effect, partially alleviate both frustrations. On the other hand, the quantum spin $S = \frac{1}{2}$ promotes quantum fluctuations that lower the ordering temperature. Proton disorder is also expected to suppress long-range order tendencies from most general considerations, as it should lead to variations in the exchange constants, which can effectively be described as bond disorder in the spin model. In certain scenarios, these can destroy long-range order in favor of spin-liquid-mimicry.

Observation of the spiral spin liquid in a triangular-lattice material — •Nikita Andriushin[1], Stanislav Nikitin[2], Oystein Fjellvag[2,3], John White[2], Andrey Podlesnyak[4], Dmytro Inosov[1], Marein Rahn[6,1], Marcus Schmidt[5], Michael Baenitz[5], and Aleksandr Sukhanov[6,1] — [1]TU Dresden, Germany — [2]PSI, Switzerland — [3]IFE, Norway — [4]ORNL, USA — [5]MPI CPfS, Dresden, Germany — [6]Augsburg University, Germany

The spiral spin liquid (SSL) is a highly degenerate state characterized by a continuous contour or surface in reciprocal space spanned by a spiral propagation vector. Although the SSL state has been predicted in a number of various theoretical models, very few materials are so far experimentally identified to host such a state. Via combined single-crystal wide-angle and small-angle neutron scattering, we report observation of the SSL in the quasi-two-dimensional delafossite-like $AgCrSe_2$ [1]. We show that it is a very close realization of the ideal Heisenberg J_1–J_2–J_3 frustrated model on the triangular lattice. By supplementing our experimental results with microscopic spin-dynamics simulations, we demonstrate how such exotic magnetic states are driven by thermal fluctuations and exchange frustration.

Magnetism in i-Tb-Cd quasicrystals — •Andreas Kreyssig — Institute for Experimental Physics 4, Ruhr-Universität Bochum, 44801 Bochum, Germany

i-Tb-Cd orders as icoshedral quasicrystal with the magnetic Tb3+ ions arranged in Tsai-type clusters. We studied the magnetic correlations and excitations by elastic and inelastic neutron scattering on single-grain isotopically enriched samples. The measurements of the crystalline electric field excitations demonstrated that the Tb3+ moments are directed along the local fivefold axes of the Tsai-type clusters. By using a simple Ising-type model for the moment configurations on a single Tb3+ icosahedron, we calculated the magnetic diffuse scattering for the low-energy configurations and identified the most likely moment configuration in a single cluster by comparison with our diffuse neutron scattering signals. We further studied the role of intercluster interactions for magnetic frustration and the magnetic scattering.

This work was supported by the U. S. DOE, BES, DMSE, under Contract DE-AC02-07CH11358. This research used resources at HFIR and SNS, U. S. DOE Office of Science User Facilities operated by the Oak Ridge National Laboratory.

Frustrated magnetism in hydrogenated hexagonal Boron Nitride — •Maksim Ulybyshev, Manish Verma, and Giorgio Sangiovanni — Institut für Theoretische Physik und Astrophysik, Universität Würzburg, 97074 Würzburg, Germany

We study monolayer hexagonal boron nitride (h-BN) with hydrogen adatoms arranged in a regular triangular lattice. Extensive density functional theory (DFT) calculations reveal a flat band formed by electronic states localized near the adatoms, situated within the band gap of h-BN. Based on these results, we construct a tight-binding model that captures the essential features of this band structure and derive an effective Hamiltonian for electrons in the flat band. This effective Hamiltonian incorporates the effects of long-range Coulomb interactions projected onto the flat band using a technique previously validated by Quantum Monte Carlo simulations of similar systems. We demonstrate that the lack of particle-hole symmetry in this system causes the projected long-range Coulomb interactions to induce frustrated spin couplings between electrons localized near neighboring adatoms. Depending on the spatial configuration of the adatoms, this frustration can give rise to various nontrivial magnetic states.

Geometrical frustration mediated unconventional magnetism in a Kondo lattice Ce3ZrBi5 — •Saswata Halder, Arumugam Thamizhavel, and Kalobaran Maiti — Tata Institute of Fundamental Physics, Mumbai, India

Kondo lattice materials with geometric frustration offer fertile ground for exploring exotic new physics with a field-induced fractional magnetization platform. In this work, we investigate hexagonal Ce3ZrBi5 with 1D Bi chains and a frustrated Ce-kagome network to understand its magnetic properties. Density functional theory (DFT) calculations reveal the presence of a non-trivial electronic structure, that changes significantly in the presence of SOC. The temperature dependent magnetization for Ce3ZrBi5 show the presence of two antiferromagnetic (AFM) transitions below TN = 4.9 K; highlighting a complex and highly anisotropic magnetic landscape. The magnetization shows a peculiar nature where the moments align along the CEF hard axis; contrary to conventional antiferromagnets. The unconventional magnetization can be attributed to multiple observables: geometric frustration, presence of competing Kondo and RKKY nergy scales and strong spin- orbit coupling (SOC). Field-induced metamagnetic transitions are observed in the isothermal magnetization data which follows the one-third magnetization rule observed in frustrated Kagome lattices. Specific heat and transport measurements highlight inherent Kondo-lattice characteristics in Ce3ZrBi5. Our work establishes Ce3ZrBi5 and related materials as a unique platform for exploring low-dimensional quantum fluctuations in frustrated antiferromagnets.

MA 15.33 Tue 10:00 P1

Flat bands and megnetoelectric effect in XX sawtooth chain with three-spin interactions — •Karen Baghdasaryan[1], Vadim Ohanyan[2,3], Ostap Baran[4], and Oleg Derzhko[4] — [1]Ludwig-Maximilians-Universität, München, Germany — [2]Yerevan State University, Yerevan, Armenia — [3]CANDLE Synchrotron Research Institute, Yerevan, Armenia — [4]Institute for Condensed Matter Physics, Lviv, Ukraine

We present an exact analysis of the XX sawtooth chain with three-spin interactions and the Katsura-Nagaosa-Balatsky (KNB) mechanism. Using Jordan-Wigner fermionization, we identify all zero-temperature phases of the model and observe the emergence of a flat band in the free-fermion spectrum. These flat bands result in jumps in observables such as magnetization and dielectric polarization as functions of both magnetic and electric fields.

MA 15.34 Tue 10:00 P1

Two-dimensional coherent spectroscopy as a probe for spin-1 single ion bound states — •Sagar Ramchandani[1], Yoshito Watanabe[1], Simon Trebst[1], and Ciarán Hickey[2,3] — [1]Institute for Theoretical Physics, University of Cologne, 50937 Cologne, Germany — [2]School of Physics, University College Dublin, Belfield, Dublin 4, Ireland — [3]Centre for Quantum Engineering, Science, and Technology, University College Dublin, Dublin 4, Ireland

Nonlinear spectroscopy has emerged as a powerful prospect to probe quantum magnets by extracting information from higher-order responses. In this work, we report on the implementation of 2-dimensional coherent spectroscopy (2DCS) in the context of the Su(n)ny Julia package for modelling atomic-scale magnetism. We employ this code (and its semi-classical approach) to study the properties of spin-1 single ion bound states (SIBS), motivated in part by recent experiments on FeI_2.

MA 15.35 Tue 10:00 P1

Theoretical study on in-plane, out-of-plane, and transverse anisotropic magnetoresistance effects for ferromagnetic films — •Satoshi Kokado[1] and Masakiyo Tsunoda[2] — [1]Shizuoka University, Hamamatsu, Japan — [2]Tohoku University, Sendai, Japan

We theoretically study the in-plane [1], out-of-plane [2], and transverse anisotropic magnetoresistance (AMR) effects [3] for a strong ferromagnet, Fe_4N. We here use the electron scattering theory with an extrinsic mechanism, in which the conduction electron is scattered into the conduction state and the localized d states by impurities and so on [4]. The in-plane and out-of-plane AMR effects exhibit the negative AMR ratio with the twofold symmetry, while the transverse AMR effect shows the positive AMR ratio with the fourfold symmetry. The calculation results agree qualitatively well with the respective experimental results [1,2,3] for Fe_4N. In addition, the peak structures of the AMR ratios reflect the probability densities of the current direction of the single atomic d states.

MA 15.36 Tue 10:00 P1

Preparation and characterization of $Co_{20}Fe_{80}Si_x$ thin films — •Florian Knossalla, Maik Gaerner, Luca Kempe, Karsten Rott, Jan Schmalhorst, and Günter Reiss — Bielefeld University, Germany

In spintronics, materials with favorable magnetic properties, such as large magnetic polarization and a high Curie temperature are essential. By means of machine learning, different Fe-Co-Si compounds were identified as promising [1]. This study focuses on the investigation of alloys with the composition $Co_{20}Fe_{80}Si_x$.

The samples were fabricated using DC and RF magnetron co-sputtering. Subsequently, temperature-dependent resistance measurements, investigations of the ordinary and the anomalous Hall effect were performed alongside with measurements of the anisotropic magneto-resistance.

The magnetic polarization decreased with increasing silicon content, from approximately 2 T for $Co_{20}Fe_{80}$ to about 0.5 T for $Co_{20}Fe_{80}Si_{100}$. In the latter, a phase transition at 60K was observed, which coincides with the appearance of a linear nonsaturating magnetoresistance. Interestingly, $Co_{20}Fe_{80}Si_{50}$ exhibited a higher magnetic polarization than $Co_{20}Fe_{80}Si_{25}$, as well as twice the charge carrier density compared to $Co_{20}Fe_{80}$.

Real-time in-situ giant magnetoresistance measurements in Co/Cu multilayers during sputter deposition — Michael Mattern, •Luca Kempe, Jan Schmalhorst, and Günter Reiss — Bielefeld University, Faculty of Physics, Germany

Magnetoresistive sensors generate important input information that is further processed in complex microelectronic systems in a wide range of applications. For optimization purposes or the investigation of new material combinations, a permanent analysis of the influence of deposition conditions on the magnetoresistive performance is necessary. Today, research and development in the field of magnetic sensor technology is slowed down due to slow feedback from results of ex-situ characterization of samples into modelling and production. This study presents an experimental technique for real-time in-situ measurements of magnetoresistive effects, such as giant magnetoresistance (GMR), during the sputtering process. As an example, an oscillating in-plane magnetic field with an amplitude of 420 Oe and a frequency of 10 Hz was applied to samples of cobalt/copper multilayers during film growth. By employing advanced instrumentation with a sampling rate of 20 kS/s and the implementation of real-time GMR amplitude calculation, we were able to obtain and analyze complete R versus H curves within 100 milliseconds. Correlations between the magnetic response of these samples and structural changes at different stages of film deposition are shown.

MA 15.38 Tue 10:00 P1

Quantitative study of the spin Hall magnetoresistance in a yttrium iron garnet/Pt heterostructure — •Denise Reustlen, Sebastian Sailler, Davina Schmidt, Richard Schlitz, Michaela Lammel, and Sebastian T. B. Goennenwein — Department of Physics, University of Konstanz, 78457 Konstanz

The spin Hall magnetoresistance (SMR) is a well-known and extensively studied phenomenon in the field of spintronics. The SMR is most commonly observed in heterostructures consisting of a ferromagnetic insulator and a normal metal with a large spin orbit interaction. In this study, we use yttrium iron garnet as the ferrimagnetic insulator and platinum as the normal metal due to its relatively large spin Hall angle. While the SMR is usually measured locally, on a single Hallbar structure, the data obtained often are used to gauge the magnetic quality of the underlying magnetic insulator or of the magnet/metal interface. Interestingly, however, up to now little is known about the SMR statistics in one Hallbar and the scatter of the SMR magnitude across several Hallbars on a single sample. Given that the SMR is a local effect, it is relevant to ascertain the significance of a single measurement as a representative measure for the entire sample. We thus have patterned more than 200 nominally identical SMR microstructures into a single YIG/Pt bilayer and studied the statistical distribution of the SMR as a function of position across the entire sample. Our results demonstrate that the SMR amplitude is robust and provide the basis for a consistent comparison of the SMR.

MA 15.39 Tue 10:00 P1

Spin Textures Stability in Exfoliated Fe3GaTe2 Two-Dimensional Magnets — •Kai Litzius[1], Yara Mahboub[2], Krishnanjana Puzhekadavil Joy[2], Steffen Wittrock[1], Lilian Prodan[1], István Kézsmárki[1], and Felix Büttner[1,2] — [1]University of Augsburg, Augsburg, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany

Two-dimensional (2D) van der Waals magnets have emerged as an exciting area of research, providing unique opportunities to study magnetism in reduced dimensions. Among these materials, Fe3GaTe2 is particularly notable for its exceptionally high Curie temperature [1], which enables investigations and device applications at room temperature. Moreover, its structural and compositional similarity to Fe3GeTe2, one of the most extensively studied 2D magnets, suggests significant potential for tuning its magnetic properties [2,3], making it a promising candidate for both fundamental research and spintronic device applications. In this study, we explore the spin texture stability of Fe3GaTe2 thin flakes, prepared through mechanical exfoliation, using magnetic force microscopy (MFM). We also assess their resistance to oxidation [4] and degradation under ambient conditions, confirming their robust performance. These results highlight Fe3GaTe2 as a high-TC, stable 2D magnet, well-suited to advancing research in 2D magnetism and enabling next-generation spintronic technologies. References: [1] H. Electrical detection of spin currents in magnetic insulators — •Ankita Nayak[1], Matthias Kronseder[2], Nynke Vlietstra[3], Hans Huebl[3,4,5], Jeroen A. Heuver[6], Beatriz Noheda[6], Maxim Mostovoy[6], Christian Back[3,4], and Aisha Aqeel[1,3,4] — [1]University of Augsburg, 86135, Augsburg, Germany — [2]Department of Physics, Regensburg University, 93053, Regensburg, Germany — [3]Department of Physics, Technical University Munich, 85748 Garching b. München, Germany. — [4]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, D-80799, München, Germany. — [5]Walther -Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748, Garching, Germany, — [6]Zernika Institute for Advanced Materials, University of Groningen, Nijenborgh 4, 9747 AG, Groningen, The Netherlands.

We investigate the spin current-induced phenomena, such as spin Hall magnetoresistance and the spin Seebeck effect within Pt films deposited on a non-collinear magnet [1], CoCr2O4 (CCO). CCO is a spinel with a collinear ferrimagnetic state below Tc = 94 K and non-collinear magnetic phases at lower temperatures [2]. We investigated the SMR and the SSE at different temperatures (5K-300K) [2]. The temperature-dependent behavior of both SMR and SSE signals exhibits a noticeable variation correlated with different magnetic phases of CCO. This study offers insights into spin-current-driven phenomena, paving the way for potential spintronic applications. [1]. A. Aqeel, et al., Phys. Rev. B 103 (10), L100410 (2021). [2]. A. Aqeel, Phys. Rev. B 92 (22), 224410 (2015).

First principle study of Spin and charge transport properties in CrO2/CrI3/Td-WTe2/CrO2 based device heterostructures — •Nivedita Pandey and Oscar Granas — Department of Physics and Astronomy, Uppsala University, SE-751 20 Uppsala, Sweden

Van der Waals heterostructures are attractive for spintronic applications due to tunability of electronic, and magnetic properties. Herein, we show that precise control over spin injection and filtering can be achieved by interfacing magnetic and non-magnetic 2D layers, and these properties are robust to electrode attachment. We study a bilayer of CrI3/WTe2, using electrode CrO2 to design a promising spintronic device. We use density functional theory, capturing charge transport and thermal properties through the use of the non-equilibrium Green function. Integration of ferromagnetic CrI3 with either metallic or semiconducting phase of WTe2 results in substantially different properties of the interface. Further, the coupling between magnetism, and charge/spin transport has been studied in detail for both parallel magnetization and anti-parallel magnetization case. The spin polarized current with variation in the electrode temperature has been calculated for the designed CrO2/CrI3/WTe2/CrO2 device, further the spin filtration efficiency is extracted to understand the effect of temperature on spin filtration. The proposed device shows a spin filtration efficiency of around 100% at the studied temperatures. In addition, a high thermal magnetoresistance has been obtained for the designed device.

Workflow for Robust Code and Data Management exemplified for the numerical calculation of the Hopf index — •Jonas Nothhelfer, Ross Knapman, and Karin Everschor-Sitte — Universität Duisburg-Essen

Structured workflows for code and data management are essential in scientific projects to ensure reproducibility and quality. We will discuss these workflows from a system administrator's perspective, emphasizing the infrastructure and tools needed to support scientific computing. Using a recent scientific project as a case study, we present an example workflow that makes the projects numerical methods for calculating the three-dimensional topological Hopf index accessible [1]. Not only do we offer Python scripts, but we also develop extensions for the standard micromagnetic software tool, Mumax3 [2]. Code management is handled through GitLab, ensuring access to the most current versions of code [3], while Zenodo is used to provide persistent identifiers for released versions [4].

Angle-resolved calculation of magnetocrystalline anisotropy using symmetry-adapted Wannier functions — •Hiroto Saito and Takashi Koretsune — Tohoku University, Sendai, Japan

Magnetocrystalline anisotropy is one of the most fundamental physical quantities that determine the properties of magnetic materials. However, since its value is often very small, dense k-mesh is needed to accurately calculate it using first-principles calculations. We have previously developed a method to calculate magnetocrystalline anisotropy with high precision and low computational cost by constructing a Wannier tight-binding model that incorporates both crystal and spin symmetries, and by using the time-reversal-symmetry operation to separate the magnetization and spin-orbit interaction [1, 2].

Recently, a systematic approach for generating a complete set of symmetry-adapted multipole bases has been developed to describe the electronic degrees of freedom in crystals [3]. In this study, we apply this method to demonstrate that symmetry-adapted Wannier Hamiltonians for magnetic materials can be expanded using multipole bases. This finding highlights the feasibility of constructing symmetry-based effective models directly from first-principles calculations. As a practical application, we report the calculation results of the magnetic anisotropy of anomalous Hall conductivity.

Discretization Anisotropy In Micromagnetics — Samuel Holt[1,2], •Andrea Petrocchi[1,2], Martin Lang[1,2], Swapneel Pathak[1,2], and Hans Fangohr[1,2,3] — [1]Max Planck Institute for the Structure and Dynamics of Matter, Luruper Chaussee 149, 22761 Hamburg, Germany — [2]Center for Free-Electron Laser Science, Luruper Chaussee 149, 22761 Hamburg, Germany — [3]Faculty of Engineering and Physical Sciences, University of Southampton, Southampton SO17 1BJ, United Kingdom

Micromagnetics models the physics of magnetic systems using partial differential equations to express quantities such as the magnetization, energy density, and effective field. The discretization of these equation onto a regular lattice produces anisotropy. Its impact is extensive and includes phenomena such as the energy-minimizing rotation of magnetic structures, preferred directions, and creating artificial magnetization structures.

Despite this, the consequences of discretization anisotropy and how to mitigate against it are rarely discussed in the context of micromagnetics. A thorough understanding of these effects is important for the accurate interpretation of simulation results and for enhancing the overall fidelity of micromagnetic modeling. In this work we focus on these errors introduced by using finite difference approximations in micromagnetic simulations.

Magnetization Reconstruction from Magnetic Field Measurements Using Physics-Informed Inverse Problems — •Alexander Setescak, Florian Bruckner, and Claas Abert — University of Vienna, Austria

Understanding the magnetization of topological spin textures is crucial for advancing spintronic applications. This work covers a physics-informed framework for reconstructing magnetization from high-resolution magnetic field measurements, such as those obtained via nitrogen-vacancy (NV) magnetometry. The approach leverages the micromagnetic equilibrium condition as a critical constraint in the inverse problem, ensuring the reconstructed magnetization satisfies the fundamental energy minimization principles.

The reconstruction process is formulated as an optimization problem, where a loss functional is designed to minimize discrepancies between measured and computed magnetic fields while imposing physical and regularization constraints. Efficient gradient computation is achieved through a combination of backpropagation algorithms and the adjoint method, enabling accurate and robust parameter optimization.

Preliminary results reveal detailed magnetization structures consistent with theoretical predictions and experimental observations. This demonstrates the potential of the proposed framework to investigate tailored magnetic configurations on the nanoscale, thereby laying the groundwork for future advancements in spintronic device engineering.

MA 15.46 Tue 10:00 P1

Synthetic Data Training Strategies for Magnetic Phase Classification — •Marcelo Arlego[1,2], Agustín Medina[1], and Carlos Lamas[1] — [1]Instituto de Física La Plata, La Plata, Argentina. — [2]Institute for Theoretical Physics TU-BS

In this work, we explore the potential of artificial neural networks trained with a synthetic catalogue of spin patterns, examining their ability to generalize and classify phases in complex models beyond the simplified training context.

Specifically, we investigate the transition from order to disorder in a diluted Ising model, a problem for which no exact solution exists, and where most current analytical and numerical techniques face significant difficulties.

Despite these obstacles, we used direct methods to achieve consistency in determining percolation densities and transition temperatures.

Our results suggest that a simple yet strategic training approach for neural networks can help in understanding complex physical phenomena, with potential applications beyond condensed matter physics.

MA 15.47 Tue 10:00 P1

Simulation of magnetoelastic mode filters for surface acoustic waves — •Bernhard Emhofer[1], Michael Karl Steinbauer[1], Peter Flauger[1], Matthias Volz[3], Matthias Küss[2], Stephan Glamsch[2], Manfred Albrecht[2], Hubert Krenner[3], and Claas Abert[1] — [1]University of Vienna — [2]University of Augsburg — [3]University of Münster

Surface acoustic wave (SAW) propagation critically depends on the waveguide geometry, with a key challenge being the independent excitation of specific mode types such as Rayleigh and shear modes.

In this study, we employ micromagnetic simulations, specifically the python library magnum.np [1], to explore a novel approach for selectively absorbing specific acoustic modes via magnetoelastic coupling. This coupling occurs through the excitation of spin waves in a thin magnetic film, layered on top of the waveguide. To achieve controlled mode filtering, the equilibrium magnetization is manipulated by varying the angle and strength of an external magnetic field. The distinct resonance configurations for Rayleigh and shear modes observed experimentally [2], enable their selective attenuation.

Simulations performed for a $LiNbO_3$ substrate with a 108 nm thick Ni film show that SAWs experience significant attenuation, with the maximum displacement at the surface reduced by around 70% after 13 wavelengths. These results demonstrate the potential of magnetoelastic interactions for precise mode filtering.

Revealing rich magnetic phases and novel spin-wave spectra in Orthorhombic perovskite TbCrO3: a frsfprinciples study — •Fengyi Zhou — Faculty of Applied Sciences, Macao Polytechnic University, Macao SAR, 999078, China

The experimental measurements have revealed the orthohombic perovskite $TbCrO_3$ crystal exhibits rich magnetic structures with temperature variation. Specifically, a long-range canted AFM state of Cr^{3+} ions is formed below T_N^{Cr} = 157.9 K. At a lower temperature (below T_N^{Tb} ~ 7.7 K), the Tb^{3+} ions exists a long-range antiferromagnetic (AFM) order. Furthermore, a weak competition between the FM and AFM interactions within the Cr^{3+} ions is observed at 15 K. Importantly, a strong coupling between the spin orders of the Cr^{3+} and Tb^{3+} ions is observed at 1.8 K. As the temperature decreases, the magnetic moment of Tb disappears first. Currently, in-depth theoretic research is appealing and urgently needed to explore these complex magnetic interactions, magnetic phase transition and spin wave spectra of $TbCrO_3$.

Based on the first-principles study, this study presents the entire magnetic landscape of $TbCrO_3$ including the magnetic ground state, equilibrium state, and excited state. Meanwhile, we clarified the detailed magnetic exchange mechanisms including the isotropic Heisenberg exchange and the antisymmetric Dzyaloshinskii-Moriya interaction, as well as single ion anisotropy. Finally, the spin wave spectrum considered adiabatic and temperature-dependent relationships is also evaluated.

Topological Hall effects on two-dimensional Archimedean lattices — •L.V. Duc Pham[1,2], Nicki F. Hinsche[2], and Ingrid Mertig[2] — [1]Fakultät für Chemie und Lebensmittelchemie, Technische Universität Dresden, Bergstraße 66c, 01062 Dresden, Germany — [2]Institut für Physik, Martin-Luther-Universität Halle-Wittenberg, D-06099 Halle (Saale), Germany

Archimedean lattices are a family of tilings in which the two-dimensional plane is filled with different regular polygons while maintaining the vertices configuration. Kagome, the most famous member of the Archimedean lattices familiy, was studied extensively in a wide variety of theoretical works. Another lattice of this type, the snub square lattice, was also used as an approximant for quasi crystals [1]. The rich geometry of these systems gives rise to various unconventional nano ribbon edge configurations and therewith various possible topological edge states. In this work, we calculate the band structures of all 8 pure Archimedean lattices using a tight-binding method including s and p orbitals and study topological properties of these lattices, such as topological edge states, the $\mathbb{Z}_2$ invariance and the quantum spin Hall conductivity within the Kubo formalism [2].

MA 16.2 Tue 14:15 H16

Spin topology, spin-orbit coupling and entanglement — •Gunnar Felix Lange[1], Wojciech Jankowski[2] und Robert-Jan Slager[2,3] — [1]Department of Physics, University of Oslo, Norway — [2]TCM Group, Cavendish Laboratory, University of Cambridge, UK — [3]Theoretical Physics Group, University of Manchester, UK

Topological systems with time-reversal symmetry are of great theoretical and practical interest. Theoretically, such phases often rely on studying the topology in each spin sector separately, as in the spin Hall effect.

This requires identifying the spin degree of freedom in the band structure, which is not always straightforward in the presence of spin-orbit coupling. This field has received renewed interest in recent years, leading to the concept of spin topology.

In this talk, we will discuss some recent results on spin topological phases, with a particular focus on spin-orbit coupling and its interplay with entanglement.

MA 16.3 Tue 14:30 H16

Fractionally Charged Vortices at Quantum Hall/Superconductor Interfaces — •Enderalp Yakaboylu and Thomas Schmidt — Department of Physics and Materials Science, University of Luxembourg, L-1511 Luxembourg

We investigate interface states between a type-II *s*-wave superconductor (SC) and a Chern insulator describing an integer quantum Hall (QH) system. We find that an effective pairing interaction at this boundary gives rise to two emergent Abelian Higgs fields, representing the two paired electrons at the SC/QH interface, coupled to a gauge field that incorporates both Chern-Simons and Maxwell terms. We use this model to investigate the effect of magnetic flux vortices in the SC on the QH system. In particular, we find vortex solutions in which the Cooper pairs give rise to topological fractionally-charged vortices localized at the interface.

MA 16.4 Tue 14:45 H16

Local and Global Topological Characteristics of Local Magnetic Moments Coupled to Chern Insulators — •Devesh Vaish and Michael Potthoff — I. Institute of Theoretical Physics, Department of Physics, University of Hamburg

A magnetic impurity, modelled as a classical spin and locally exchange coupled to a Chern insulator may cause in-gap bound states. Their nature can be very different depending on the (k-space) topological phase of the Chern insulator. Here we study several impurity spins coupled to a QWZ model and analyze, for different k-space topological phases, the additional "local" topological properties on the manifold of impurity-spin configurations (S-space). In case of $R > 1$ spins, the R-th spin-Chern number serves as a topological invariant on S-space. Varying the local exchange-coupling strength, we find local topological phase transitions and relate them to Fermi-energy crossings of in-gap states. In addition, we compute the first spin-Chern number for various physically motivated closed two-dimensional sub-manifolds of the full configuration space and relate those to the R-th spin-Chern number.

MA 16.5 Tue 15:00 H16

Non-relativistic linear Edelstein effect in noncollinear EuIn2As2 — •Adriana Nayra Alvarez Pari[1], Rodrigo Jaeschke Ubiergo[1], Atasi Chakraborty[1], Jairo Sinova[1,5], and Libor Smejkal[1,2,3,4] — [1]Institut für Physik, Johannes Gutenberg Universität, Mainz, Germany — [2]Max Plank Institute for the Physics of Complex Systems, Dresden, Germany — [3]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [4]Institute of Physics, Academy of Sciences of the Czech Republic, Praha, Czech Republic — [5]Department of Physics, Texas A & M University, Texas, USA

Motivated by the ongoing interest in understanding the actual magnetic ground state of the promising axion insulator candidate EuIn2As2, we present here a spin symmetry analysis and *ab-initio* calculations, aiming to identify specific exchange-dominated physics that could offer insights into the current debate. We investigate two non-collinear coplanar magnetic orders reported in this compound: the *helical* and *broken-helical* phases [1]. Our symmetry analysis shows that magnetic-exchange alone results in the formation of an out-of-plane odd-wave order in momentum space in both phases. Additionally, we identify an in-plane g-wave order that emerges exclusively in the *broken-helical* phase, providing a distinguishing feature for this phase. Furthermore, we report a non-relativistic Edelstein effect with a distinct out-of-plane polarized spin density that dominates over spin-orbit coupling effects.

MA 17: Micro- and Nanostructured Magnetic Materials

Time: Tuesday 14:00–15:00 Location: H18

MA 17.1 Tue 14:00 H18

Thin films of a dinuclear Fe^{2+} complex on HOPG: Spin-crossover studies using X-ray absorption spectroscopy — •Marcel Walter[1], Sebastien Elie Hadjadj[1], Clara Trommer[2], Jorge Torres[1], Jendrik Gördes[1], David Swerev[1], Christian Lotze[1], Chen Luo[3], Florin Radu[3], Felix Tuczek[2], Sangeeta Thakur[1], and Wolfgang Kuch[1] — [1]Institut für Experimentalphysik, Freie Universität Berlin — [2]Institut für Anorganische Chemie, Christian-Albrechts Universität zu Kiel — [3]Helmholtz Zentrum Berlin for Materialien und Energie

The spin-crossover (SCO) properties of the dinuclear complex $[\{Fe(H_2B(pz)_2)_2\}_2\mu - (ac(bipy)_2)]$ deposited as (sub)-monolayer and thin film by an ultra-high-vacuum liquid-jet deposition technique on highly oriented pyrolytic graphite (HOPG) were studied by X-ray absorption spectroscopy. A comparison of the SCO properties of thin films and a dropcast sample indicates that the spin-switching capability of the thin films is lower due to substrate*molecule interactions. The similar switching properties of the dropcast sample as of a bulk powder sample confirm that the SCO properties are not affected by the presence of solvent necessary for deposition. The soft-X-ray-induced excited spin-state trapping (SOXIESST) effect is pronounced in all samples, although the light-induced high-spin (HS) fractions of the dropcast and the thin-film samples on HOPG are higher as compared to the HS fraction attained by SOXIESST, which confirms the sensitivity of the complex to light.

MA 17.2 Tue 14:15 H18

Magnetic Characterization of Antidot Arrays in NiFe Thin Films: Insights from Ferromagnetic Resonance and Micromagnetic Simulations — •Zeynep Reyhan Ozturk[1] and Fikret Yildiz[2] — [1]SESAME, Amman, Jordan — [2]Gebze Technical University, Kocaeli, Türkiye

Antidot arrays, patterned magnetic films with regular nonmagnetic holes, are gaining attention for their unique behaviors and applications in data storage and sensors [1]. These arrays modify magnetic properties by introducing stray field energy, enabling control over magnetic anisotropy and magnetization reversal [2].

Optimizing antidot size, spacing, and lattice symmetry allows precise control of switching fields, magnetoresistance, and spin-wave modes, making them ideal for advanced technologies [3]. Their dynamic behavior, particularly localized spin-wave modes, sets them apart from continuous films.

This study combines ferromagnetic resonance (FMR) and micromagnetic simulations to reveal the influence of antidot geometry on magnetic performance. Insights gained optimize thin-film properties for next-generation devices.

Effect of Ag addition on structure, morphology and magnetism of CoCrFeMnNi micro powders prepared by HEBM — •Emmanouil Kasotakis, Ivan Tarasov, Tatiana Smoliarova, Michael Farle, and Natalia Shkodich — Faculty of Physics and Center of Nanointegration (CENIDE), University of Duisburg-Essen, Duisburg, 47057 Germany

We fabricated (CoCrFeMnNi)-Agx (x=0; 2; 5; 10 wt.%) high entropy alloy nanocrystalline (~10 nm) microparticles which are paramagnetic at room temperature (Tc = 80 K) by a two-step high energy ball milling (HEBM) [1] process in Argon at 700/1400 rpm. An elemental powder blend of Co, Cr, Fe, Mn, Ni was milled for 60 min to produce single phase FCC Cantor alloy with a homogeneous distribution of the principal elements, followed by 10 min of HEBM with the addition of Ag. By varying the Ag concentration, we modified the morphology. For 2 and 5 wt.% Ag (Cantor + Ag) we find flake-like core shell particles, and for 10 wt.% Ag, we obtain round homogeneous particles, with a lattice expansion of the FCC phase. Annealing cycles up to 700 K in a magnetic field of 1 T magnetic field increased M at 9 T up to 2.5-fold (14 Am^2/kg) for homogeneous particles (x = 10 wt.%) and Hc up to 5-fold (41 kA/m) for core shell particles (x = 2 wt.%) at 310 K. We acknowledge DFG financial support (project ID: FA209/27-1).

MA 17.4 Tue 14:45 H18

Fabrication and characterization of freestanding magnetic nanostructures for microwave to photon transduction — •Matthias Grammer[1,2], Jonny Qiu[3], Sebastian Sailler[4], Sebastian T. B. Goennenwein[4], Matthias Althammer[1,2], Stephan Geprägs[1,2], Michaela Lammel[4], Eva Weig[3], and Hans Huebl[1,2] — [1]Walther-Meißner-Institut, BAdW, Garching, Germany — [2]School of Natural Sciences, TUM, Garching, Germany — [3]School of Computation, Information and Technology, TUM, Garching, Germany — [4]Department of Physics, University of Konstanz, Konstanz, Germany

Efficient transduction between microwave and optical photons is critical for quantum network applications. Engelhard et al. [1] proposed a trasduction scheme based on collective magnetic and elastic excitations as mediators between the microwave and the optical regime. Implementing this concept requires co-localization of microwave, magnetic and elastic excitations within a suspended microstructure resembling an optomechanical crystal (OMC). In this presentation we present our progress towards the fabrication of a OMC based on the ferrimagnetic insulator yttrium iron garnet (YIG). To realize freely suspendend structures we explore two fabrication strategies: (i) the structuring of grown YIG/SiO_x/GGG heterostructures and (ii) the integration of YIG on semiconductor substrates. We will report on fabrication aspects and the characterization of the resulting devices using e.g. scanning electron microscopy and magneto-optical Kerr effect measurements.

MA 18: Functional Antiferromagnetism

Time: Tuesday 14:00–15:30 Location: H19

MA 18.1 Tue 14:00 H19

Switching of magnetic domains in a noncollinear antiferromagnet at the nanoscale — •Atul Pandey[1,2], Prajwal Rigvedi[1], Edouard Edouard[3], Jitul Deka[1], Jiho Yoon[1], Wolfgang Hoppe[2], James M. Taylor[2], Stuart S. P. Parkin[1], and Georg Woltersdorf[1,2] — [1]Max Planck Institute of Microstructure Physics, Weinberg 2, 06120 Halle, Germany — [2]Institute of Physics, Martin Luther University Halle Wittenberg, Von Danckelmann Platz 3, 06120 Halle, Germany — [3]Max Planck Institute for Chemical Physics of Solids, Nothnitzer Straße 40, 01187 Dresden, Germany

Antiferromagnets that display very small stray magnetic field are ideal for spintronic applications. Of particular interest are non-collinear, chiral antiferromagnets of the type Mn_3X (X=Sn, Ge), which display a large magnetotransport response that is correlated with their antiferromagnetic ordering. The ability to read out and manipulate this ordering is crucial for their integration into spintronic devices. These materials exhibit a tiny unbalanced magnetic moment such that a large external magnetic field can, in principle, be used to set the material into a single antiferromagnetic domain. However, in thin films of Mn_3Sn, we find that such fields induce only a partial magnetic ordering. By detecting two orthogonal in-plane components of the magnetic order vector, we find that the non-switchable fraction has a unidirectional anisotropy. This also enables us to visualize switching along multiple easy axes in Mn_3Sn. Studying the switching at the nanoscale allows us to correlate the pining behavior to crystal grain boundaries in the Mn3Sn nanowire structures.

MA 18.2 Tue 14:15 H19

Understanding the role of spin non-conserving on magnon excitation — •Hebatalla Elnaggar — Sorbonne University, Paris, France

Conventional wisdom suggests that one photon that carries one unit of angular momentum (1h) can change the spin angular momentum of a magnetic site with one unit (*M* = *1h) at most following the selection rules. This implies that a two-photon process such as 2*3* resonant inelastic X-ray scattering (RIXS) can change the spin angular momentum of a magnetic system with a maximum of two units (*M* = * 2h). Herein we describe a triple-magnon excitation in *-Fe2O3 and various perovskite thin films, which contradicts this conventional wisdom that only 1- and 2-magnon excitations are possible in a resonant inelastic X-ray scattering experiment [1].

We observe an excitation at exactly three times the magnon energy, along with additional excitations at four and five times the magnon energy, suggesting quadruple and quintuple magnons as well. Guided by theoretical calculations, we reveal how a two-photon scattering process can create exotic higher-rank magnons due to spin non-conserving interactions.

MA 18.3 Tue 14:30 H19

Domain wall patterns in granular Cr_2O_3 thin films — •Igor Veremchuk[1], Oleksandr V. Pylypovskyi[1], Peter Rickhaus[2], Natascha Hedrich[3], Artem V. Tomilo[1], Tobias Kosub[1], Kai Wagner[3], Brendan Shields[3], Gediminas Seniutinas[2], Vicent Borras[2], Paul Lehmann[3], Liza Žaper[2], Paulina J. Prusik[1], Pavlo Makushko[1], René Hübner[1], Jüren Fassbender[1], Denis D. Sheka[4], Patrick Maletinsky[3], and Denys Makarov[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf e.V.,01328 Dresden, Germany — [2]Qnami AG, CH-4132 Muttenz, Switzerland — [3]University of Basel, Basel CH-4056, Switzerland — [4]Taras Shevchenko National University of Kyiv, 01601 Kyiv, Ukraine

Cr_2O_3 provides possibility to control its magnetic order parameter by an external electric field rendering it a prospective material for spintronic applications. We developed a material model for granular thin Cr_2O_3 films. The coupling between the grains influences the equilibrium domain pattern due to pinning of antiferromagnetic domain walls at the grain boundaries. By the characterization of the experimentally measured domain patterns via fractal dimension, we determine the inter-grain exchange coupling [1]. In contrast to extended films, finite-size samples can be set into a single-domain state even via a zero-field cooling procedure. Such a sample should be small enough for the propagation of thermally driven domain walls through the energy landscape formed by grain boundaries [2].

Domain walls properties and spin-flop transition in Cr_2O_3 — •Paulina J. Prusik[1,2], Igor Veremchuk[1], Florin Radu[3], Andrey N. Anisimov[1], Pavlo Makushko[1], Georgy V. Astakhov[1], Sophie F. Weber[4], René Hübner[1], Nicola A. Spaldin[4], Kirill D. Belashchenko[5], Jürgen Fassbender[1,2], Denys Makarov[1], and Oleksandr V. Pylypovskyi[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf e.V. — [2]Dresden University of Technology, 01062 Dresden, Germany — [3]Helmholtz-Zentrum Berlin für Materialien und Energie, 14109 Berlin, Germany — [4]ETH Zürich, 8093 Zürich, Switzerland — [5]University of Nebraska-Lincoln, Lincoln, NE 68588, USA

A room-temperature magnetoelectric uniaxial antiferromagnet Cr_2O_3 is a prospective material for spintronics and fundamental research [1,2]. We derive a σ-model for Cr_2O_3 and show the presence of a symmetry-breaking term relevant for non-collinear magnetic textures. It couples the magnetic field with a gradient of the Néel vector. Analyzing quantum magnetometry images of antiferromagnetic domain walls, we can properly describe the material parameters of Cr_2O_3. Furthermore, this term results in lowering of the spin-flop field for thin films of Cr_2O_3 by a factor of two comparing with single crystals. This finding is confirmed by X-ray magnetic linear dichroism measurements.

MA 18.6 Tue 15:15 H19

Amplifying the antiferromagnetic spin Seebeck effect through topological magnons — Feodor Svetlanov Konomaev and •Kjetil Magne Dørheim Hals — Department of Engineering Sciences, University of Agder, 4879 Grimstad, Norway

Topological magnons emerge as topologically protected spin wave states at the edges of magnets. Here, we theoretically explore how these surface states can be harnessed to amplify the spin Seebeck effect (SSE) in antiferromagnets (AFMs) interfaced with normal metals (NMs). Based on a microscopic model of a kagome AFM, we demonstrate that broken mirror symmetry, combined with the Dzyaloshinskii-Moriya interaction (DMI), drives the system into a topological phase hosting spin-polarized magnons at the boundaries. Notably, linear response calculations reveal that in AFM/NM heterostructures, the topological magnons exhibit strong coupling to the metals charge carriers, resulting in a substantial enhancement of the SSE. The relative contribution of the topological magnons is found to be 4-5 times greater than that of the trivial magnon bands. Moreover, our results show that this enhancement is highly sensitive to the strength of the DMI.

Green synthesis of R-type hexagonal ferrite magnetic nanoparticles and their electrochemical sensor for levofloxacin — •SAJJAD HUSSAIN — Centre of Excellence in Solid State Physics, University of the Punjab, Lahore

The usage of Levofloxacin (LEV) has increased in recent years for the treatment of bacterial infections in both human and veterinary fields. In this context, there has been a significant demand for the development of a highly sensitive and cost-effective approach to LEV quantification. In this study, R-type hexagonal ferrite nanoparticles (SrSn2Fe4O11-NPs) were prepared by an auto-ignition methodology and various analytical techniques were used for the material characterization, including X-ray diffraction (XRD), Field emission scanning electron microscopy (FE-SEM), X-ray photoelectron spectroscopy (XPS), Brunauer Emmett and Teller (BET) analysis, dynamic light scattering (DLS), and vibrating sample magnetometer (VSM) analysis. The characterization confirmed that the prepared material has a crystalline structure single-phase with a crystalline size of 35.02 nm. The R-type hexagonal ferrite nanoparticles were immobilized on a glassy carbon electrode (GCE) by a simple drop-casting approach to developing an efficient electrochemical sensor (SrSn2Fe4O11-NPs) for sensitive and selective LEV detection through an extended concentration range (0.06 * 10*6 to 170 * 10*6 M) and a low detection limit of (41.5nM). The developed sensor was applied successfully to quantitatively determine LEV in clinical samples and pharmaceutical preparations with excellent recoveries from 95.2 to 102.5 %.

MA 19.2 Tue 14:15 H20

Signatures of Berezinskii-Kosterlitz-Thouless transitions in magnetic films in Nitrogen Vacancy Magnetometry — •Mark Potts and Shu Zhang — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

Nitrogen vacancy magnetometry provides sensitive measurements of the correlation functions of magnetic degrees of freedom in a material. Recent experiments have applied this technique in the study of two dimensional thin films, candidates for realising the topological Berezinskii-Kosterlitz-Thouless phase transition. We present calculations of frequency dependent relaxation rates for nitrogen vacancy centres coupled to an XY-type magnetic film, and identify features characteristic of the transition to quasi-long ranged order, and show that algebraic spin correlations are inherited by the relaxation rate as a temperature dependent power-law at low frequencies.

MA 19.3 Tue 14:30 H20

Development of an Ultra High Vacuum and Low Temperature Scanning NV Magnetometer — •Sandip Maity[1], Ricardo Javier Peña Román[1], Dinesh Pinto[1,3], Klaus Kern[1,3], and Aparajita Singha[2,1] — [1]Max Planck Institute for Solid State Research, Stuttgart, German — [2]Technische Universität Dresden, Dresden, Germany — [3]Institut de Physique, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

The nanoscale spatial resolution and calibration-free quantifiable magnetic field measurement capabilities of nitrogen-vacancy (NV) centers have enabled us to investigate the properties of magnetic spin textures with high magnetic sensitivity through scanning probe microscopy across a wide range of temperatures and pressure. I will be discussing the development of a scanning probe magnetometer capable of imaging magnetic nanostructures under ultra-high vacuum and low temperature. Moreover, we have integrated commercial NV tips with a home-built tip holder equipped with an AFM amplifier and microwave excitation on the tip (not on the sample), allowing us to have a magnetic image of any sample region without restriction. To exploit the quantifying nature of NV magnetometry using Optically Detected Magnetic Resonance, a coherent microwave (MW) delivery to the probe is mandatory. I will also discuss different means of delivering MW to the NV probes through different designs of the tip holders and how effective they are in coherently manipulating the NV spin states.

MA 19.4 Tue 14:45 H20

On-surface Spin Characterization using Shallow NV Centers in Diamond — •Olga Shevtsova[1,2], Atharva Paranjape[2], Lisa Ebo[2,3], Bernhard Putz[4], Ulrich Ziener[4], Marvin Grünhagen[5], Rainer Herges[5], and Aparajita Singha[1,2] — [1]Technische Universität Dresden, Dresden, Germany — [2]Max-Planck-Institut für Festkörperforschung, Stuttgart, Germany — [3]Universität Konstanz, Konstanz, Germany — [4]Universität Ulm, Ulm, Germany — [5]Christian-Albrechts-Universität zu Kiel, Kiel, Germany

As interest in quantum systems surges due to their potential applications in quantum computing, information storage, and sensing, molecular spins emerge as promising candidates for these technologies. Unlike conventional systems such as superconducting qubits and trapped ions, molecular spins offer unique advantages in stability, tunability, and scalability. However, key challenges remain in assessing their coherent properties, which are crucial for practical application. Existing techniques face limitations in terms of environmental requirements, complexity, and invasiveness. In this context, Nitrogen-Vacancy (NV) centers in diamonds emerge as a highly suitable solution, as they can operate at a wide range of temperatures and provide non-invasive optical readout. This study aims to leverage on the capabilities of NV-center-based sensors to probe the coherent properties of molecular spins, thus providing insights into their viability as stable and controllable components for future quantum technologies.

MA 19.5 Tue 15:00 H20

Imaging magnetic vortices in a van der Waals magnet at room temperature with scanning NV magnetometry — •Carolin Schrader[1], Elias Sfeir[1], Mário Ribeiro[2], Giulio Gentile[2], Alain Marty[2], Céline Vergnaud[2], Frédéric Bonell[2], Isabelle Robert-Philip[1], Matthieu Jamet[2], Vincent Jacques[1], and Aurore Finco[1] — [1]Laboratoire Charles Coulomb, Université de Montpellier, CNRS, Montpellier, France — [2]Université Grenoble Alpes, CEA, CNRS, IRIG-SPINTEC, Grenoble, France

Two-dimensional van der Waals (vdW) magnets have gained significant attention for their potential application in spintronics, however, this would require room temperature magnetism and large-scale fabrication. Recently, ferromagnetic order at room temperature has been demonstrated in thin Fe_5GeTe_2 grown by Molecular Beam Epitaxy (MBE). Here, we employ scanning NV magnetometry to quantitatively image the magnetic texture in MBE-grown Fe_5GeTe_2 at the nanoscale. We use the single spin of the nitrogen-vacancy (NV) defect in diamond to investigate the effect of patterning on the magnetic order and demonstrate the stabilisation of magnetic vortices in various micron-sized structures at room temperature. Upon application of an external magnetic field of a few mT we obtain a single ferromagnetic domain in these structures, which allows us to extract a saturation magnetisation of about 160 kA/m. Our results show the role of confinement for the stabilisation of complex magnetic structures in 2D magnets and highlight the potential of the room temperature vdW magnet Fe_5GeTe_2 for applications in spintronics.

MA 20.1 Wed 9:30 H16

Wavenumber-dependent magnetic losses in YIG-GGG heterostructures at millikelvin temperatures — •David Schmoll[1], Andrey A. Voronov[1], Rostyslav O. Serha[1], Denys Slobodianiuk[2], Khrystyna Levchenko[1], Claas Abert[1], Sebastian Knauer[1], Dieter Suess[1], Roman Verba[2], and Andrii V. Chumak[1] — [1]University of Vienna, Vienna, Austria — [2]V.G. Baryakhtar Institute of Magnetism of the NAS of Ukraine, Kyiv, Ukraine

With its low magnetic damping, the ferrimagnet yttrium iron garnet (YIG), grown on gadolinium gallium garnet (GGG), is the most promising material for magnon based quantum technologies, wich demand long decoherence times. While such samples are already well established at room temperature, further knowledge needs to be acquired at millikelvin temperatures, due to the paramagnetic character of the GGG substrate. We report on propagating spin-wave spectroscopy studies at temperatures between 4 K to 26 mK and the recorded change of the dissipation rate. Additionally, we compute the dispersion and the dissipation rate of the layered YIG-GGG magnetic system quasi- analytically and with micromagnetic simulations, allowing us to investigate the magnon losses with respect to wavenumber. Contrary to room temperature, we observe a significant increase of the magnetic losses with k at cryogenic temperatures, introduced by the dipolar coupling between the ferrimagnetic YIG film and the partially magnetized GGG substrate. Our theoretical calculations predict a steady decrease of the dissipation for short-wavelength exchange magnons.

MA 20.2 Wed 9:45 H16

Exchange enhanced switching in quantum antiferromagnets with dephasing and relaxation — •Asliddin Khudoyberdiev and Götz S. Uhrig — Condensed Matter Theory, TU Dortmund University, Otto-Hahn-Straße 4, 44221 Dortmund, Germany

One requirement for ultrafast storage devices is that they can be operated in the terahertz (THz) regime. Suitable candidates are antiferromagnets because of their characteristic frequencies range. The efficient control of their order is the focus of a plethora of current studies. Recently, we established a quantum approach, time-dependent Schwinger boson mean-field theory, to reverse the sublattice magnetization in anisotropic quantum antiferromagnets by means of external static and oscillating magnetic fields [1,2]. We also showed that the exchange enhancement for staggered control fields persists on the quantum level so that significantly lower fields are sufficient to switch the order [3]. Our quantum theory incorporates dephasing, i.e., the destructive interference of the contributions of all spin modes at their respective frequencies, which results in a slow, non-exponential decrease of the oscillations after the switching [2,3]. This must be distinguished from spin-lattice relaxation which induces faster decay of oscillations. Our methodological progress including Lindblad dissipators allows us to address the differences between dephasing and spin-lattice relaxation in the switching processes. [1] K. Bolsmann, A. Khudoyberdiev, and G. S. Uhrig, PRX Quantum 4, 030332 (2023) [2] A. Khudoyberdiev and G. S. Uhrig, Phys. Rev. B 109, 174419 (2024) [3] A. Khudoyberdiev and G. S. Uhrig, arXiv:2407.00472.

MA 20.3 Wed 10:00 H16

Non-linear processes in YIG based spin-wave transducers — •Matthias Wagner, Felix Kohl, Björn Heinz, and Philipp Pirro — Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany

Spin waves are considered as promising candidates for the realization of future signal processing devices. Due to their fundamental equation of motion, spin-wave dynamics are inherently non-linear. For the practical application of spin-wave based devices, this non-linear nature can either be a perspective or a challenge, depending on the desired use case. Therefore, a systematic study on the impact of non-linear dynamics on a potential spin-wave based device is instructive. For this purpose, spin-wave transducers patterned on yttrium iron garnet (YIG) films are investigated. Using micro-focused and time-resolved Brillouin light scattering spectroscopy, the power-limiting non-linear processes as well as their scattering dynamics are analysed. The characterization is complemented by propagating spin-wave spectroscopy measurements to study the corresponding impact of the non-linear processes on the output of the spin-wave transducers. The results of this work provide an important foundation to develop new concepts of signal processing devices using spin waves. This research is funded by the European Union within HORIZON-CL4-2021-DIGITAL-EMERGING-01 (No. 101070536,MandMEMS).

MA 20.4 Wed 10:15 H16

Higher Order Resonances in Periodically Driven Magnon Systems — •Jan Mathis Giesen, Alexandre Abbass Hamadeh, Philipp Pirro, Imke Schneider, and Sebastian Eggert — RPTU, Kaiserslautern, Germany

We analyze resonant excitations of ferromagnetic magnons via microwave pumping below the threshold frequency using Floquet theory. A special feature of parameteric resonance is the possibility to create magnons with higher energy

than the driving frequency, which allows for new tuning possibilities. We develop a theoretical framework that analytically predicts the region of resonances and resonance thresholds in thin films of ferro- and ferri-magnetic materials as a function of damping, amplitude and frequency. The results are compared with micomagnetic simulations.

MA 20.5 Wed 10:30 H16

SAW-Induced Spin Wave Excitation in Ferromagnetic Epitaxial Thin Films — •Alfons Georg Schuck, Sebastian Kölsch, and Michael Huth — Institute of Physics, Goethe University, Max-von-Laue-Str. 1, 60438 Frankfurt am Main, Germany

Surface acoustic wave (SAW) excitation of spin waves in ferromagnetic thin films has recently gained significance due to the potential for the realization of novel microwave devices and applications in magnonics. So far, SAW excitation has commonly been accomplished by use of piezoelectric substrate materials, such as $LiNbO_3$, on top of which the ferromagnetic thin film is deposited [1]. This approach has severe limitations with regard to studying SAW-spin wave coupling effects in epitaxial magnetic thin films. For epitaxy to occur, selected substrate materials and crystal orientations have to be used; and these substrate materials tend not to be piezoelectric.

Here we show how textured piezoelectric AlN thin film transducer structures can be fabricated on different substrate materials by means of reactive RF sputtering. By proper selection of the material for the interdigital transducer electrode structures and standard UV lithography, the frequency range up to about 3 GHz becomes available for spin wave excitation. Selected examples of SAW-induced spin wave excitation in epitaxial magnetic thin films are presented and compared to results obtained on Nickel thin films as commonly used reference material. Complementary simulations of the SAW attenuation are shown and the influence of the magnetic anisotropy is described.

MA 20.6 Wed 10:45 H16

Integrated hybrid magnonic-spintronic system for tunable broadband signal filtering and microwave generation — •Abbas Koujok[1], Abbass Hamadeh[1,2], Leandro Martins[3], Felix Kohl[1], Björn Heinz[1], Ricardo Ferreira[4], Alex Jenkins[4], Ursula Ebels[3], and Philipp Pirro[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Université Paris-Saclay, Centre de Nanosciences et de Nanotechnologies, CNRS, 91120, Palaiseau, France — [3]Univ. Grenoble Alpes, CEA, CNRS, Grenoble INP, IRIG, Spintec, Grenoble, France — [4]International Iberian Nanotechnology Laboratory (INL), 4715-31 Braga, Portugal

Non-conventional beyond-the-state-of-the-art signal processing schemes require parallelism, scalability, robustness and energy efficiency to meet the demands of complex data-driven applications. Magnonic and spintronic circuits are potential candidates that can aid in fulfilling these requirements. Hereby, an experimental proof-of-concept for a novel hybrid magnonic-spintronic device is proposed. Using spintronic auto-oscillations, this device can generate a broad, GHz-wide RF signal and filter this signal in a selective and tunable manner using a magnonic circuit. This research is funded by the European Research Council within the Starting Grant No. 101042439 "CoSpiN" and by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) - TRR 173-268565370 (project B01). MA 20.7 Wed 11:00 H16

Spatially Resolved Investigation of Spin Wave frequency Multiplication — •Roméo Beignon[1], Chris Körner[2], Rouven Dreyer[2], Georg Woltersdorf[2], Vincent Jacques[1], and Aurore Finco[1] — [1]Laboratoire Charles Coulomb, Université de Montpellier, CNRS, Montpellier, France — [2]Martin Luther University Halle-Wittenberg, Halle, Germany

Interactions between spin waves and magnetic textures offer promising tools for designing magnonic devices. Among new developments, a frequency multiplication phenomenon has been observed in permalloy microstructures [1]. This generation of a high harmonic frequency has been observed using magnetic resonance measurements on NV center ensembles.

Here, we use scanning NV-center microscopy to investigate this phenomenon further. Our aim is to obtain maps of the harmonic generation with a spatial resolution of about 50 nm, and to correlate them with the magnetic state of the Py microstructures (edges, domain walls, ...).

Our results show that we can detect the spin wave frequency comb with a single NV center in a scanning probe tip. Furthermore, we are able to spatially map the effect of each harmonic on the NV center separately, revealing a non-trivial behavior. These measurements are a first step towards the understanding of the interplay between the non-linear process that generates the harmonics and the magnetic texture.

Tayloring spin-wave transducers for integrated RF application — •Felix Kohl, Björn Heinz, Matthias Wagner, and Philipp Pirro — Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany

Current advances in magnonics are increasingly targeted at improving the functional applicability of integrated magnonic devices. Despite the widespread use of transducers based on dynamic Oersted field excitation, there are still inefficiencies due in part to a discrepancy between the scientific understanding of magnetic responses and the technical requirements for practical implementation. Using propagating spin-wave spectroscopy, we investigated spin-wave transducers patterned on yttrium-iron-garnet (YIG) films, demonstrating the capability to tailor transducer characteristics, such as non-reciprocity towards a desired use case. Supported by a modelling approach, our measurements provide a useful framework for designing efficient, application-specific transducers and pave the way for integrated and standalone RF devices such as isolators and filters. This work is an important step towards scalable, energy-efficient magnonic application and demonstrates the potential of magnonics to become a future technology. This research is funded by the European Union within HORIZON-CL4-2021-DIGITAL-EMERGING-01 (No. 101070536,MandMEMS).

MA 20.9 Wed 11:45 H16

Investigation of parallel parametric signal amplification in YIG nanostructures — •Akira Lentfert, Björn Heinz, David Breitbach, Burkard Hillebrands, and Philipp Pirro — Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany

In the pursuit of advanced information processing beyond traditional CMOS technologies, various magnonic circuits and devices such as magnon transistors, majority gates, and half adders have been developed. However, for an extended magnonic network, a phase-conserving and sensitive amplification of spin waves is required. One of the candidates is the use of the parallel parametric pumping process. A phase-conserving signal amplification in microscopic metallic waveguides has already been demonstrated in previous works. In this work, we focus on the phase dependence of the parallel parametric amplification processes in Damon-Eschbach (DE) geometry in yttrium iron garnet (YIG) nanowaveguides for propagating spin waves. Due to the low spin-wave damping in YIG, other damping mechanisms such as radiative losses have a significant impact on the pumping processes. Time-resolved micro-focused Brillouin light scattering spectroscopy is used to study the phase-dependent amplification of short spin-wave pulses. This project has been supported by the EU Horizon research and innovation program within the SPIDER project (No. 101070417) and by DFG (TRR 173-268565370: Spin+X).

MA 20.10 Wed 12:00 H16

Nanoscaled Spin-Wave Frequency Selective Limiter (FSL) for 5G Technology — •Kristýna Davídková[1], Khrystyna Levchenko[1], Florian Bruckner[1], Roman Verba[2], Fabian Majcen[1], Qi Wang[3], Carsten Dubs[4], Vincent Vlaminck[5], Jan Klíma[6], Michal Urbánek[6], Dieter Suess[1], and Andrii Chumak[1] — [1]University of Vienna, Austria. — [2]Institute of Magnetism, Ukraine. — [3]School of Physics, China. — [4]INNOVENT e. V. Technologieentwicklung, Germany. — [5]IMT Atlantique, France — [6]CEITEC BUT, Czech Republic

Power limiters are essential devices in radio frequency communications systems to protect the input channels from large incoming signals. Nowadays-used semiconductor limiters suffer from high electronic noise and switching delays when approaching the GHz range, which is crucial for the modern generation of 5G communication technologies aiming to operate at the EU 5G high band (24.25-27.5 GHz). The proposed solution is to use ferrite-based Frequency Selective Limiters (FSLs), which maintain their efficiency at high GHz frequencies, although they have only been studied at the macroscale so far. We demonstrate a proof of concept of nanoscale FSLs based on spin-wave transmission affected by four-magnon scattering phenomena in a 97-nm-thin YIG film. Spin waves were excited and detected using coplanar waveguide transducers of the smallest feature size of 250 nm. The FSLs are tested in the frequency range up to 25 GHz, and the key parameters are extracted (power threshold, power limiting level, insertion losses, bandwidth) for different SW modes and transducer lengths.

MA 20.11 Wed 12:15 H16

Uniaxial strain response of antiferromagnetic magnons — •Manuel Knauft, Arthur von U.-S. Schwark, Yiran Liu, Lichen Wang, Sajna Hameed, Matteo Minola, and Bernhard Keimer — Max Planck Institute for Solid State Research, Stuttgart, Germany

With the suggested paradigm shift away from conventional transistors towards lower loss devices, magnonics has attracted considerable attention in recent years. Generation, manipulation and detection of magnons are prerequisites for successful integration into microstructured chips. We will present ideas and results of using uniaxial strain to control magnon behavior in perovskite antiferromagnets. In particular, recent work on iridates has shown that the magnon energy can be varied by as much as 40 % with small uniaxial strain of about

0.1 % [1]. Building on those findings, we discuss alternative approaches. Furthermore, through spatially inhomogeneous strain environments, we will also demonstrate ideas of guiding magnons as investigated using finite element simulation and confocal Raman scattering.

MA 20.12 Wed 12:30 H16

cavity-enhanced optical manipulation of Antiferromagnetic magnon-pairs — •Tahereh Parvini — Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Walther-Meißner-Str.8, 85748 Garching, Germany

The optical manipulation of magnon states in antiferromagnets (AFMs) holds the potential for advancing AFM-based computing devices. In particular, two-magnon Raman scattering processes are known to generate entangled magnon-pairs with opposite momenta. We propose to harness the dynamical backaction of a driven optical cavity coupled to these processes, to obtain steady states of squeezed magnon-pairs, represented by squeezed Perelomov coherent states. The system's dynamics can be controlled by the strength and detuning of the optical drive and by the cavity losses. In the limit of a fast (or lossy) cavity, we obtain an effective equation of motion in the Perelomov representation, in terms of a light-induced frequency shift and a collective induced dissipation which sign can be controlled by the detuning of the drive. In the red-detuned regime, a critical power threshold defines a region where magnon-pair operators exhibit squeezing, a resource for quantum information, marked by distinct attractor points. Beyond this threshold, the system evolves to limit cycles of magnon-pairs. In contrast, for resonant and blue detuning regimes, the magnon-pair dynamics exhibit limit cycles and chaotic phases, respectively, for low and high pump powers. Observing strongly squeezed states, auto-oscillating limit cycles, and chaos in this platform presents opportunities for future quantum technologies.

MA 20.13 Wed 12:45 H16

Predicting the future with magnons — •Zeling Xiong[1,2], Christopher Heins[1,2], Katrin Schultheiss[1], Helmut Schultheiss[1], Thibaut Devolder[3], and Joo-Von Kim[3] — [1]Helmholtz-Zentrum Dresden Rossendorf, Germany — [2]Technische Universität Dresden, Germany — [3]Centre de Nanosciences et de Nanotechnologies, CIderNRS, Université Paris-Saclay, France

The Mackey-Glass (MG) time series data describes how density of mature circulating cells change over time using time delayed differential equations. This is a standard problem to test the performance of physical reservoirs. Here, we used different magnon reservoir systems to carry out such time series prediction task. By connecting several reservoirs together we increase the reservoir depth which yielded very accurate long-time future prediction.

MA 20.14 Wed 13:00 H16

Dynamic Control of Spin-Wave Propagation for Advanced Computing Applications — •Dmitrii Raskhodchikov[1], Kirill Nikolaev[2], Jannis Bensmann[1], Rudolf Bratschitsch[1], Vladislav Demidov[2], Sergey Demokritov[2], and Wolfram Pernice[1,3] — [1]Institute of Physics and Center for Nanotechnology (CeNTech), Muenster, Germany — [2]Institute of Applied Physics, Muenster, Germany — [3]Kirchhoff-Institute for Physics, Heidelberg, Germany

Spin waves, collective excitations of electron spins in magnetic materials, have attracted significant interest for spin-wave and neuromorphic computing applications. A key challenge in utilizing spin waves for these technologies is achieving precise control over their propagation. This study investigates methods to regulate spin-wave dynamics by manipulating parameters like the external magnetic field, excitation frequency, and the integration of external memory elements, including phase-change materials.

Our results show that varying the external magnetic field influences the dispersion relation of spin waves, allowing for tunable propagation velocities and wavelengths. Adjusting the excitation frequency enables selective excitation of spin-wave modes with desired properties. Furthermore, incorporating phase-change materials allows for dynamic modulation of spin-wave propagation through localized changes in magnetic anisotropy or damping. This approach provides a foundation for adaptive control mechanisms essential for spin-wave-based information processing.

MA 21: Frustrated Magnets I

Time: Wednesday 9:30–12:45 Location: H18

MA 21.1 Wed 9:30 H18

Ab-initio exploration of complex magnetism of frustrated Mn and Cr films on hexagonal metallic surfaces — •Selcuk Sözeri[1,2] and Samir Lounis[2,1] — [1]Faculty of Physics, University of Duisburg-Essen and CENIDE, 47053 Duisburg, Germany — [2]Peter Grünberg Institut, Forschungszentrum Jülich & JARA, 52425 Jülich, Germany

We employ ab initio first-principles simulations to explore the complex magnetic behavior in antiferromagnetic (AFM) systems. Specifically, we investigate Mn films on an Ag(111) substrate, where spin-polarized STM experiments established Néel order as the ground state for a single Mn layer [1,2] in contrast to previous predictions. Our focus extends to the interplay of Heisenberg exchange interactions, leading to magnetic frustration, and higher-order magnetic interactions when increasing the thickness of Mn films, which can host complex three-dimensional AFM spin-textures. Additionally, we examine the magnetic properties of multiple AFM Cr layers deposited on a PdFe bilayer supported by an fcc Ir(111) substrate. Instead of being in a Néel state, a single Cr layer prefers a row-wise AFM state, which hosts single and catenated intrinsic AFM skyrmions [3]. For thicker Cr films, we monitor the emergence of new topological magnetic objects.

– Project funded by DFG (SPP 2137: LO 1659/8-1).

MA 21.2 Wed 9:45 H18

Dilatometry studies on the spin supersolid candidate materials $K_2Co(SeO_3)_2$ and $Rb_2Co(SeO_3)_2$ — •Erik Walendy[1], Kwangwoo Shin[2], Jae-Ho Chung[2], Kwang-Yong Choi[2], and Rüdiger Klingeler[1] — [1]Kirchhoff Institute for Physics, Heidelberg University, Germany — [2]Department of Physics, Korea University, Seoul 02841, Korea

The layered triangular lattice material $K_2Co(SeO_3)_2$ has recently attracted attention due to the presence of a high-field spin supersolid phase between 18 and 21 T, at 2 K [1]. We report high-resolution capacitance dilatometric studies on single crystals of $K_2Co(SeO_3)_2$ and $Rb_2Co(SeO_3)_2$. Pronounced anomalies in thermal expansion and magnetostriction measurements at the phase boundaries imply significant magnetoelastic coupling. We obtain the uniaxial strain dependencies of the field-induced phases and construct the magneto-elastic phase diagrams.

[1] T. Chen et al. arXiv:2402.15869 (2024).

MA 21.3 Wed 10:00 H18

NMR Study of the $S = 1/2$ 1D Heisenberg Antiferromagnetic Chain $Cu(C_6H_8N_2)ClBr$ — •Marlis Schuller[5], Monika Jawale[1], Avinash Mahajan[1], Sanjay Bachhar[1], Saikat Nandi[1], Rahul Kumar[2], Athinarayanan Sundaresan[2], John Wilkinson[3], Rabindranath Bag[4], Sara Haravifard[4], Norbert Büttgen[5], Thomas Gimpel[5], and István Kézsmárki[5] — [1]Department of Physics, IIT Bombay, IN — [2]CPMU, JNCASR, IN — [3]ISIS Facility, STFC Rutherford Appleton Laboratory, GB — [4]Department of Physics, Duke University, US — [5]EPV, Institute of Physics, University of Augsburg, DE

$Cu(C_6H_8N_2)ClBr$ is a possible candidate for realising the frustration-induced quantum spin-liquid phase, as proposed in a recent theoretical study by Uematsu *et al.* (JPSJ **90**, 124703 (2021)) on the random-bond $S = 1/2$ Heisenberg antiferromagnet on the zigzag chain. Based on μSR and bulk susceptibility data, it does not display any long-range order down to 88 mK. Mixing chlorine and bromine may generate randomness in the nearest-neighbour exchange necessary to satisfy the criteria from the aforementioned proposal. We investigated this compound by ^{1}H-NMR, and determined the spin-lattice relaxation rate $1/T_1(T)$ to probe low-energy excitations. Our study revealed a discontinuity in the relaxation rate at a characteristic temperature of approximately 2.5 K, where anomalies were observed in the specific heat and μSR experiments. These experimental results imply the emergence of a dimerised ground state.

MA 21.4 Wed 10:15 H18

Geometric design of frustrated magnetic textures in ferrotoroidal spin chains — •Oleksandr V. Pylypovskyi[1], Enrico Di Benedetto[2], Carmine Ortix[3], and Denys Makarov[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf e.V., 01328 Dresden, Germany — [2]Università degli Studi di Palermo, 90123 Palermo, Italy — [3]Università di Salerno, IT-84084 Fisciano (SA), Italy

Design of geometric shapes in magnetic nanosystems provides a possibility to tune their magnetic responses [1] and even enable multiferroicity by a finite geometry-driven toroidal moment [2]. Here, we consider the effects of ring-like geometries with a constant torsion on properties of 3D ferro- (FM) and anti-

ferromagnetic (AFM) spin chains. Their magnetic state is primarily determined by the knots in geometry with a high curvature, which corresponds to a localized geometry-driven Dzyaloshinskii–Moriya interaction (DMI). This DMI favors the twist of the order parameter at the knot. For the AFM chains with even and odd number of spins, the number of knots in their geometry allows designing the ground-state magnetic texture characteristic either for the spin system with or without geometric frustration. While the FM chains with the easy tangential axis of magnetization host a large toroidal moment for the whole sample, AFM hard-axis chains split into toroidal domains by geometric knots. To conclude, the localized geometry-driven DMI offers a possibility to design frustrated magnetic textures in spin chains.

[1] D. Makarov et al., Adv. Mater. 34, 2101758 (2022). [2] C. Ortix, J. van den Brink, Phys. Rev. Research, 5, L022063 (2023).

MA 21.5 Wed 10:30 H18

High-temperature expansion of dynamical spin correlator: Dyn-HTE — •Ruben Burkard[1], Benedikt Schneider[2,3], and Björn Sbierski[1] — [1]Institut für Theoretische Physik, Universität Tübingen, Auf der Morgenstelle 14, 72076 Tübingen, Germany — [2]Department of Physics and Arnold Sommerfeld Center for Theoretical Physics, Ludwig-Maximilians-Universität München, Theresienstr. 37, 80333 Munich, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany

Currently, there is a scarcity of theoretical methods to calculate dynamical correlation functions at finite temperatures in frustrated spin systems. To address this challenge, we extend the well-established method of high-temperature expansion to the dynamical two-point Matsubara Green's function, which we calculate to high order in perturbation theory. We consider Heisenberg models with one coupling constant J, arbitrary spin length, and without external magnetic field. We use resummation techniques to extrapolate our results to temperatures down to about $T \approx 0.2J$. Our method also gives an analytical expression for the frequency dependence, enabling analytical continuation to real frequencies. Using the dynamical information of the Matsubara correlator, we aim to study spin-liquid phases with this approach in the future.

MA 21.6 Wed 10:45 H18

Pseudo-Majorana Functional Renormalization for Frustrated XXZ-Z Spin-1/2 Models — Ruben Burkard[1], Benedikt Schneider[2], and •Björn Sbierski[1] — [1]Universität Tübingen — [2]LMU München

The numerical study of high-dimensional frustrated quantum magnets remains a challenging problem. Here we present an extension of the pseudo-Majorana functional renormalization group to spin-1/2 XXZ type Hamiltonians with field or magnetization along spin-Z direction at finite temperature. We consider a U(1) symmetry-adapted fermionic spin representation and derive the diagrammatic framework and its renormalization group flow equations. We discuss benchmark results and application to two anti-ferromagnetic triangular lattice materials recently studied in experiments with applied magnetic fields: First, we numerically reproduce the magnetization data measured for CeMgAl11O19 confirming model parameters previously estimated from inelastic neutron spectrum in high fields. Second, we showcase the accuracy of our method by studying the thermal phase transition into the spin solid up-up-down phase of Na2BaCo(PO4)2 in good agreement with experiment.

MA 21.7 Wed 11:15 H18

NMR study of the field-induced magnetic states in Cu-based mineral $Cu_2(OH)_3NO_3$ — •Yoshihiko Ihara[1], Issei Niwata[1], Aswathi M. Chakkingal[2], Dmytro Inosov[2], and Darren Peets[2] — [1]Hokkaido University, Sapporo, Japan — [2]TU Dresden, Dresden, Germany

Magnetic ground states are stabilized at low temperature by minimizing the energy costs for magnetic moments interacting with each other. When the interactions compete by geometrical frustration in the case of a non-bipartite lattice or by the bond-dependent sign of interactions, the magnetic ground state cannot be easily selected and the perturbation by external fields can modify the ground state introducing a nontrivial magnetic state with intriguing properties. Here, we focus on the Cu-based mineral rouaite, $Cu_2(OH)_3NO_3$, in which $S = 1/2$ Cu^{2+} spins construct both ferromagnetic (FM) and antiferromagnetic (AFM) chains in a unit cell. Competing FM and AFM interactions result in complicated field-temperature phase diagram with at least three different magnetic states. We study the magnetic structure and the low-energy magnetic excitations by measuring the NMR spectra and the nuclear spin-lattice relaxation rate. The low-field magnetic structure is identified and compared with the results of neutron diffraction measurements. We will also discuss the external magnetic field effect on the magnetic ground state from the results of NMR measurements at higher magnetic fields.

MA 21.8 Wed 11:30 H18

Magnetic Properties of the Frustrated Cu-based Quantum Magnets Posnjakite, Kobyashevite, and Ktenasite — Kaushick K. Parui[1], Anton A. Kulbakov[1], Roman Gumeniuk[2], Sergey Granovsky[1], Dmytro S. Inosov[1], and •Darren C. Peets[1] — [1]IFMP, TU Dresden, Germany — [2]IEP, TU Bergakademie Freiberg, Germany

Posnjakite, kobyashevite, and ktenasite are copper hydroxide sulphates in which the magnetic copper sites are arranged in distorted-triangular planes. Such a magnetic sublattice is expected to lead to strong geometric frustration, which can produce exotic magnetic order. We report the synthesis of all three materials and the results of our investigations into their low temperature magnetic properties by magnetization, specific heat, and diffraction. All three compounds indeed exhibit low magnetic transition temperatures with high frustration factors, confirming that frustration plays a key role in selecting their magnetic ground states.

MA 21.9 Wed 11:45 H18

The role of quantum fluctuations in rare-earth pyrochlore oxides — •Lasse Gresista[1], Daniel Lozano-Gómez[2], Simon Trebst[1], and Yasir Iqbal[3] — [1]Institute for Theoretical Physics, University of Cologne — [2]Institut fur Theoretische Physik and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universitat Dresden — [3]Department of Physics and Quantum Center for Diamond and Emergent Materials (QuCenDiEM), Indian Institute of Technology Madras, Chennai, India

Rare-earth pyrochlore oxides provide a rich platform for exploring exotic magnetic phenomena, ranging from the highly degenerate spin-ice states governed by emergent gauge theories in $Dy_2Ti_2O_7$ and $Ho_2Ti_2O_7$, to order-by-disorder effects in $Er_2Ti_2O_7$, multi-phase magnetism in $Yb_2Ti_2O_7$, and the ongoing quest to realize a quantum spin liquid state in experiment. Many of these materials are well described by localized spin-$\frac{1}{2}$ moments on a pyrochlore lattice coupled via anisotropic interactions. While the classical limit of this model has been extensively studied, a full quantum mechanical treatment remains challenging. In this work, we investigate the general spin-$\frac{1}{2}$ Hamiltonian using a pseudo-fermion functional renormalization group approach, which incorporates quantum fluctuations beyond mean-field theory. Our results reveal a significant shift in phase boundaries compared to the classical model, alongside the emergence of disordered regions without conventional magnetic order. This highlights the importance of quantum fluctuations when interpreting experimental observations in pyrochlore magnets.

MA 21.10 Wed 12:00 H18

Dynamical response of the Kitaev quantum spin liquid in the $KJ\Gamma$-model under external magnetic field — •Peng Rao[1], Roderich Moessner[2], and Johannes Knolle[1,3,4] — [1]Physics Department, Technical University of Munich, TUM School of Natural Sciences, 85748 Garching, Germany — [2]Max Planck Institute for the Physics of Complex Systems, 01187 Dresden, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 München, Germany — [4]Blackett Laboratory, Imperial College London, London SW7 2AZ, United Kingdom

We study the dynamical structure factor of the Kitaev quantum spin liquid (KQSL) generally, i.e. away from the solvable Kitaev limit, in the $KJ\Gamma$-model with external magnetic field. Using Majorana mean field theory, we compute spin susceptibility by including Majorana interactions in the random phase approximation (RPA). At zero field for the pure Kitaev model, RPA reproduces qualitatively spin susceptibility in the adiabatic approximation, which is close to the exact result. Small non -Kitaev couplings J and Γ induce sharp low-energy magnon modes as Majorana bound states. Larger couplings or finite field generally tend to weaken the KQSL and cause the sharp modes to condense, whence the system becomes magnetically ordered. However in specific paramter regimes, magnetic field may destroy the zero-field magnetic order and stabilize KQSL at intermediate field values, thus exemplifying the proposed 'field-induced KQSL'.

MA 21.11 Wed 12:15 H18

Short-range spin correlations in the 3D face-centred frustrated spin-$\frac{5}{2}$ system $MnSn(OH)_6$ — •Kaushick K. Parui[1], Anton A. Kulbakov[1], Ellen Häussler[2], Nikolai S. Pavlovskii[1], Roman Gumeniuk[3], Thomas Doert[2], Maxim Avdeev[4], Dmytro S. Inosov[1], and Darren C. Peets[1] — [1]IFMP, TU Dresden, Germany — [2]AC II, TU Dresden, Germany — [3]IEP, TU Bergakademie Freiberg, Germany — [4]ANSTO, Australia

Manganese tin hydroxide, $MnSn(OH)_6$, is an A-site-vacant double perovskite with magnetic Mn^{2+} ions on a face-centred sublattice, creating frustration that may lead to exotic magnetism. Combined x-ray and neutron diffraction data analysis reveals tetragonal $P4_2/n$ symmetry with precise H/D positions. Despite dominant antiferromagnetic interactions among Mn^{2+} moments, evidenced by a negative Curie-Weiss temperature, the lack of a sharp thermodynamic transition down to 350 mK implies the absence of long-range magnetic order. This suppression of the magnetic order hints towards a large frustration factor >10. Low-temperature neutron diffraction performed at 20 mK shows the absence of sharp magnetic Bragg peaks but reveals broad diffuse peaks, indicating 3D anti-

ferromagnetic short-range interactions with a correlation length of roughly three unit cells.

MA 21.12 Wed 12:30 H18

Understanding the Hamiltonian of α-$RuCl_3$ through Nonlinear Spin-Wave Analysis — •Jonas Habel[1,2], Roderich Moessner[3] und Johannes Knolle[1,2,4] — [1]Technical University of Munich, Germany — [2]Munich Center for Quantum Science and Technology, Germany — [3]Max-Planck-Institut für Physik komplexer Systeme, Dresden, Germany — [4]Blackett Laboratory London, UK

The precise values of the magnetic exchange couplings in α-$RuCl_3$ are of significant interest to understand the proposed Kitaev spin-liquid phase. A common method for extracting them involves fully field-polarizing the magnetic moments, performing an inelastic neutron scattering (INS) experiment, and fitting a non-interacting (linear) spin-wave theory to the data. However, due to magnetic frustration, magnon many-body interactions are strong in α-$RuCl_3$ and cannot be neglected, even at high fields. We present a procedure for fitting an interacting (nonlinear) spin-wave theory to INS data, explicitly accounting for these many-body interactions. This reveals a significant renormalization of the exchange couplings compared to linear spin-wave estimates.

MA 22: Caloric Effects in Ferromagnetic Materials

Time: Wednesday 9:30–11:30 Location: H19

MA 22.1 Wed 9:30 H19

Utilizing frustration in Gd- and Yb-based oxides for milli-Kelvin adiabatic demagnetization refrigeration — •Tim Treu[1], Prachi Telang[1], Marvin Klinger[1], Alexander Tsirlin[2], Anton Jesche[1], and Philipp Gegenwart[1] — [1]Experimental Physics VI, Center for Electronic Correlations and Magnetism, University of Augsburg — [2]Felix Bloch Institute for Solid-State Physics, University of Leipzig

Gadolinium- and Ytterbium-oxide based frustrated magnets have recently been characterised as excellent millikelvin adiabatic demagnetization refrigerants [1]. They offer several advantages over conventional paramagnetic hydrated salts, such as higher entropy density at similar minimum temperatures, chemical stability and UHV compatibility. We present a comprehensive study of the structural, magnetic and thermodynamic properties as well as the adiabatic demagnetisation refrigeration performance of several different Gd- and Yb-based oxides (including [1-2] and further unpublished results). For the temperature range between 0.03 and 2 K, a systematic comparison of the field-induced entropy density change and the refrigerant capacity is provided, demonstrating the advantages of frustrated magnets for low-temperature ADR.

Work supported by the German Research Foundation through the project 514162746 (GE 1640/11-1).

MA 22.2 Wed 9:45 H19

High-throughput design of all-d-metal Heusler alloys for transverse thermoelectric applications — •Fu Li, Hao Wang, Ruiwen Xie, and Hongbin Zhang — Technical University of Darmstadt, 64287 Darmstadt, Germany

Magnetic materials with prominent topological transport properties have been attracting significant attention due to the underlying intriguing physics and great potentials in various applications. Among these, Heusler alloys are particularly interesting because of their compositional flexibility which enables tunability of their physical properties via chemical doping. In this work, we perform high-throughput density functional theory calculations to evaluate the effects of chemical doping on the intrinsic anomalous Hall conductivity (AHC) and anomalous Nernst conductivity (ANC) in all-d-metal Heusler compounds, where chemical alloying with neighboring elements is considered using the virtual crystal approximation. The AHC and ANC are computed using the tight-binding Hamiltonian by automatically constructing the maximally localized Wannier functions. It is observed that rigid band model does not apply in all cases, because not only the Fermi energy has been shifted, but also the band structure has modified significantly. For (Pt0.7Ir0.3)2RhFe, detailed analysis reveals that the significant AHC and ANC are originated from the Weyl points close to the Fermi energy. These findings highlight the critical importance of chemical doping in the development of high-performance materials.

MA 22.3 Wed 10:00 H19

Electronic structure of all-*d*-metal Ni(-Co)-Mn-Ti vs. *p-d* Ni_2MnSn: DFT and XAS insights — •Olga Miroshkina[1], Johanna Lill[1], Benedikt Eggert[1], Benedikt Beckmann[2], David Koch[2], Franziska Scheibel[2], Katharina Ollefs[1], Wolfgang Donner[2], Oliver Gutfleisch[2], Heiko Wende[1], and Markus Gruner[1] — [1]University of Duisburg-Essen, Duisburg, Germany — [2]Technical University of Darmstadt, Darmstadt, Germany

All-*d*-metal Heusler alloys are a new class of promising caloric materials for energy efficient solid-state refrigeration [1]. We investigate the peculiar differences of the electronic structure between *d-d* Ni(-Co)-Mn-Ti and *p-d* Ni_2MnSn by combining density functional theory and x-ray absorption spectroscopy (XAS). To retrieve the distinctive characteristics of *d-d* orbital hybridization in K- and $L_{2,3}$-edges spectra, we correlate the features in the electronic densities of states (DOS) and XAS. The comparison of *d-d* Ni(-Co)-Mn-Ti with the conventional *p-d* Ni_2MnSn enables us to reveal the impact of the third *d*-element on magnetic and vibrational properties. The correlation of the calculated and measured XAS shows the presence of (partial) disorder not only in all-*d*-metal systems, but also in *p-d* Ni_2MnSn sample. This is consistent with our earlier findings of the traces of atomic disorder in the vibrational DOS [2]. Therefore, the interatomic hybridization in all-*d*-metal Heusler compounds can be utilized as an intrinsic control parameter for designing high-performance caloric materials.

MA 22.4 Wed 10:15 H19

Magnetocrystalline anisotropy of magnetocaloric Fe_2AlB_2 single crystals — •Nicolas Josten[1], Ralf Meckenstock[1], Anna Semisalova[1], Benedikt Beckmann[2], Konstantin Skokov[2], Oliver Gutfleisch[2], Hanna Pazniak[3], Thierry Ouisse[3], Michael Farle[1], and Ulf Wiedwald[1] — [1]Faculty of Physics and Center for Nanointegration (CENIDE), University Duisburg Essen, Germany — [2]Functional Materials, Institute of Materials Science, Technical University of Darmstadt, Germany — [3]LMGP, Grenoble INP, CNRS, Université Grenoble Alpes, France

Fe_2AlB_2 is a low-cost, low weight and easily synthesized material composed of abundant elements for magnetocaloric applications near room temperature [1]. It is a ferromagnetic MAB phase with an orthorhombic crystal structure and a Curie-temperature T_C = 274 K [2]. The low crystal symmetry of Fe_2AlB_2 leads to a significant magnetocrystalline anisotropy up to around 1 MJ·m^{-3} at 10 K. We determined the temperature-dependent magnetocrystalline anisotropy constants of a bulk Fe_2AlB_2 single crystal using the Sucksmith-Thomson method and broadband ferromagnetic resonance measured along principal crystallographic directions. Both methods show perfect quantitative agreement.

MA 22.5 Wed 10:30 H19

Effect of boron doping on the magnetocaloric properties in $La(Fe, Si)_{13}$ — •M. Strassheim[1,2], C. Salazar-Mejía[1], J. Wosnitza[1,2], and T. Gottschall[1] — [1]Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, Dresden, Germany — [2]TU Dresden, Dresden, Germany

Traditional refrigeration methods rely on gases and toxic refrigerants, contributing to environmental degradation and energy inefficiencies. In contrast, magnetocaloric materials offer a promising alternative, with the ability to produce large, reversible thermal changes when exposed to magnetic fields. Among these, $La(Fe,Si)_{13}$-based compounds stand out due to their excellent magnetocaloric effect at near-room temperatures, relatively high transition temperatures, and comparatively low cost of the base elements, making them ideal candidates for practical applications. The influence of elements such as hydrogen and carbon on interstitial sites of the $La(Fe,Si)_{13}$ lattice is already well understood, but boron doping is not. We present a study of the latter in regard of magnetization and transition temperature with a perspective of both room-temperature and cryogenic applications.

MA 22.6 Wed 10:45 H19

Direct measurements of the adiabatic temperature change of a dysprosium single crystal — •E. Bykov[1], T. Gottschall[1], J. Wosnitza[1,2], C. Salazar Mejia[1], M. D. Kuz'min[3], Y. Mudryk[4], and D. L. Schlagel[4] — [1]Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, Dresden, Germany — [2]Technische Universität Dresden, Dresden, Germany — [3]Aix-Marseille Université, IM2NP, Marseille, France — [4]Ames Laboratory, U.S. Department of Energy, Iowa State University, Ames, USA

Heavy rare-earth elements in the Gd-Tm series have unique magnetic properties due to their electronic structure. The exchange between $4f$ electrons occurs via RKKY interactions and, therefore, is extremely sensitive to the ionic radii of the elements, exhibits anisotropy, and shows pronounced magnetoelastic coupling. This leads to various magnetic phase diagrams with different helicoidal magnetic structures despite similar chemical and physical properties of the $4f$ elements.

The high total angular momentum enables significant magnetocaloric effects, which is relevant for magnetic refrigeration applications. Gadolinium, for instance, exhibits a notable magnetocaloric effect at room temperature, serving as a comparative standard. Prior research at the Dresden High Magnetic Field Laboratory demonstrated record magnetocaloric effects in terbium. Holmium's broad plateau in ΔT_{ad} at 5 T suggests potential in cryogenic applications, such as for hydrogen liquefaction. Continuing our study of the magnetocaloric effect of the $4f$ elements, we present our recent results for a dysprosium single crystal.

MA 22.7 Wed 11:00 H19

Estimation of the inverse giant barocaloric effect in Fe_2P — •Sven Wiesekopsieker[1,2], Tapas Samanta[1], Chris Taake[1], Judith Bünte[1], Andreas Hütten[1], and Luana Caron[1,2] — [1]Faculty of Physics, Bielefeld University, Bielefeld 33501, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin 12489, Germany

The Fe_2P system has so far been explored with respect to the magnetocaloric effect, linked to it's first-order magnetostructural transition between a ferromagnetic high volume phase at low T and a paramagnetic low volume phase at high T. Both phases show a hexagonal structure ($P\bar{6}2m$ space group) [1]. This transition also gives rise to the barocaloric effect (BCE), which we studied by means of an indirect method, consisting of magnetization measurements under pressure and ambient pressure differential scanning calorimetry [2]. Application of pressure shifts the transition by −45.8(1.0) K/GPa. It is accompanied by a transition entropy change of $|\Delta S_{tr}| = 1.06(0.16)$ J/(kg K), similar to that reported by Hudl et al. Under application of 0.74 GPa a moderate adiabatic temperature change of -0.65 K is observed.

MA 22.8 Wed 11:15 H19

Towards the hydrogenation of DyCo2 for cryogenic magnetocaloric liquefaction applications — •Allan Döring, Imants Dirba, Fernando Maccari, Konstantin Skokov, and Oliver Gutfleisch — TU Darmstadt, Darmstadt, Germany

Hydrogen can play an important role in the carbon-neutral society. Liquid H2 stands out for its higher volume-to-energy ratio. However, the current liquefaction method sums up to 34% of the costs to liquefy H. The magnetocaloric cooling could be one alternative to improve the efficiency of this process. Hence, research for materials with intense magnetocaloric effect (MCE) between 20 K and 77 K is needed. Those materials exhibit the peak of the MCE at transition temperatures, such as the Curie temperature (TC). Further, the MCE is stronger in heavy rare-earth (Re) based compounds, such as ReCo2. However, some of the ReCo2 materials exhibit giant MCE in temperatures above 77 K, and one way to shift down TC of such compounds is by introducing H as interstitial atoms. The TC of DyCo2 was shifted down by 120 K through the hydrogenation processK. Further, partially hydrogenated samples showed two distinct TCs. By X-ray diffraction analysis a crystalline state was confirmed with distorted lattices. The magnetic entropy changes were measured in non-hydrogenates, partially and fully hydrogenated samples, revealing a peak of entropy change at 25 K after hydrogenation. The reversibility of hydrogenation and its microstrutuctre was also investigated. We acknowledge the HyLICAL project through grant 101101461.

MA 23: Focus Session: Magneto-Transport and Magneto-Optics of Higher Orders in Magnetization I

Magneto-transport and magneto-optic effects linear in the magnetization M (e.g. anomalous Hall effect (AHE), Faraday effect or magneto-optic Kerr effect (MOKE)) are important magnetic phenomena in spintronics and magneto-optics for the characterization of magnetic samples by vectorial magnetometry, microscopy, spectroscopy and pump probe experiments. However, already some time ago, it has been shown that the angular dependence of the anisotropic magnetoresistance and of magneto-optic effects contains higher-order-in-M terms. In the last decade, these effects beyond the linear dependence on M, e.g. quadratic effects proportional to M^2, have been mainly utilized to investigate antiferromagnetic materials.

Recently, the third-order MOKE proportional to M^3, so-called cubic MOKE, was reported to be sensitive to the structural domain twinning in thin-film samples of (111) orientation. By investigating AHE and MOKE of higher orders in M, the multipolar structure of the Berry curvature in magnetization space can be probed. These additional higher-order contributions in standard Hall or polar MOKE setup geometries are able to trace the in-plane magnetization while the linear effect keeps sensitive to the out-of-plane magnetic moment. This can be utilized, for example, to detect spin-orbit torques magneto-optically.

This Focus Session introduces the main magneto-transport and magneto-optic effects of higher orders in magnetization, draws connections between both research fields, distinguishes between already known and new higher-order effects and presents first applications beyond the study of antiferromagnets by quadratic effects.

Invited Talk MA 23.1 Wed 9:30 H20

Magneto-transport effects in crystalline magnetic films — •Sebastian T. B. Goennenwein — Fachbereich Physik, Universität Konstanz, Konstanz, Germany

The magneto-transport response of magnetically ordered materials – such as the anisotropic magneto-resistance (AMR), or the anomalous Hall effect (AHE) – has been extensively studied in the last decades. While the magneto-transport response of amorphous or polycrystalline samples can often be described by comparatively simple expressions, the implications of crystal symmetry lead to a much richer and more complex response in single-crystalline specimens [1]. In particular, higher-order terms with a seemingly 'unconventional' dependence on the magnetization can be allowed by symmetry, and indeed also be detected in experiment [2].

In the presentation, I will first review the implications imposed onto the magneto-transport response by crystal symmetry, and then discuss typical experimental results, focusing on crystalline (Ga,Mn)As films as a prototypical and well-studied example [3,4]. If time permits, I will furthermore touch upon the impact of crystalline symmetry onto the magneto-thermopower response.

Cubic magneto-optic Kerr effect in thin films depending on structural domain twinning and crystal orientation — •Robin Silber[1], Maik Gaerner[2], Jaroslav Hamrle[3], and Timo Kuschel[2] — [1]VSB - Technical University of Ostrava, Czechia — [2]Bielefeld University, Germany — [3]Charles University, Czechia

Many of the second-order effects in magnetization in magneto-transport and magneto-optics are of practical importance in research and applications today. In the case of magneto-optic Kerr effect (MOKE), the second-order effect (quadratic MOKE) has been utilized to e.g. study antiferromagnetics [1] or to investigate spin-orbit torques in insulating structures [2], while the third-order effect (cubic MOKE, CMOKE) has only been discussed rarely so far [3, 4]. Here we provide a solid theoretical background for the phenomenological description of CMOKE for (111)- and (001)-oriented cubic crystal structures and compare the results with the experimental data collected on Ni(111) and Ni(001) thin film samples. CMOKE manifests as a three-fold angular dependence in Ni(111) thin films while for Ni(001) a four-fold angular dependence of CMOKE is predicted. The dependence on the incidence angle is changing from one to the other crystal orientation. Furthermore, the strength of the CMOKE is also sensitive to the

degree of twinning of the Ni(111) thin film [4].

MA 23.3 Wed 10:30 H20

Unconventional Magneto-Optical Effects — •Rudolf Schäfer and Ivan Soldatov — Leibniz Institute for Solid State and Materials Research (IFW), Dresden, Germany

Numerous magneto-optical reflection effects will be discussed that have hardly been considered in the past and that lead to intensity-based domain contrast in the absence of analyser and compensator in a wide-field magneto-optical microscope: (i) The transverse Kerr effect can be applied for in-plane magnetized material. (ii) In- and out-of-plane magnetized material can be imaged by circularly polarized light, leading to domain contrasts with different symmetry as the conventional Kerr contrast. (iii) Plane-polarized light at a specific angle can be employed for both in-plane and perpendicular media (Oppeneer effect). (iv) Perpendicular light incidence leads to a contrast on in-plane materials that is quadratic in the magnetization and to a domain boundary contrast. In case (iii), the contrast is generated by magnetic circular dichroism, while magnetic linear dichroism is responsible for the contrast in case (iv). The latter, being due to the diagonal elements in the quadratic dielectric magneto-optical tensor has a different symmetry as the conventional linear birefringence (Voigt) effect which is due to the off-diagonal elements. The domain*boundary contrast is caused by the magneto-optical gradient effect, which also exists as birefringence and dichroic effect. Reference: R. Schäfer, et al., Appl. Phys. Rev. 8, 031402 (2021)

MA 23.4 Wed 10:45 H20

Multipolar anisotropy in anomalous Hall effect from spin-group symmetry breaking — •Zheng Liu — University of Science and Technology of China, Hefei, China

Traditional view of the anomalous Hall effect (AHE) in ferromagnets is that it arises from the magnetization perpendicular to the measurement plane and that there is a linear dependence on the latter. However, this view is squarely challenged by a number of experiments recently, urging for a thorough theoretical investigation on the fundamental level. We find that for strong magnets, it is more appropriate and fruitful to regard the AHE as a spin-group symmetry breaking phenomenon where the critical parameter is the spin-orbit interaction strength, which involves a much smaller energy scale. Born out of our framework is a rich multi-polar relationship between the anomalous Hall conductivity and the magnetization direction, with each pole being expanded progressively in powers of the spin-orbit coupling strength. For the leading order contribution, i.e., the dipole, its isotropic part corresponds to the traditional view, and its anisotropic part can lead to the in-plane AHE where the magnetization lies within the measurement plane. Beyond the dipolar one, the octupolar structure offers the leading order source of nonlinearity and hence introduces unique anisotropy where the dipolar structure cannot. The dipolar and octupolar structure offers a unified explanation for the in-plane AHE recently observed in various ferromagnets. Our theory lays the ground for decoding the coupling between various transport and optical phenomena and the magnetic orders.

15 min. break

Invited Talk MA 23.5 Wed 11:15 H20

electrical and optical detection of the multipolar structure in the magnetization space — •Dazhi Hou — University of Science and Technology of China, Hefei, China

The anomalous Hall effect (AHE) in ferromagnetic materials has traditionally been understood to originate from a dipolar magnetization, with the effect typically showing sensitivity to out-of-plane magnetization. In contrast, we present compelling evidence that the AHE fundamentally arises from multipolar contributions to the magnetization. This discovery enables the observation of AHE under in-plane magnetization in cubic ferromagnets such as iron and nickel, challenging the conventional view. The magnitudes of these multipoles align with theoretical predictions from our recently proposed multipolar structure of Berry curvature in magnetization space. Notably, the octupole term can dominate the AHE in certain conditions, as observed in a van der Waals ferromagnet. Furthermore, we introduce a novel MOKE geometry that detects both the magnitude and direction of the perpendicular magnetization component, enabled by the multipolar structure of Berry curvature. This orthogonal MOKE geometry reveals unique angle-dependent behaviors, providing a direct probe of the magnetization multipoles at optical frequency. Our findings offer new insights into the quantum geometry of magnetization and open new avenues for probing magnetic orders across both electrical and optical domains, offering a unified framework for the study of multipolar magnetization in the context of Berry curvature.

MA 23.6 Wed 11:45 H20

Polarization variation method for investigation of magnetic and magneto-optical anisotropies — •Tomáš Ostatnický, Zeynab Sadeghi, Jozef Kimák, Peter Kubaščík, Eva Schmoranzerová, Lukáš Nádvorník, František Trojánek, and Petr Němec — Charles University, Faculty of Mathematics and Physics, Prague, Czech Republic

We present a newly developed method for all-in-one measurement of both magnetic anisotropy and anisotropy of magneto-optical (MO) coupling in magnetic materials. It fully relies on the quadratic MO response (in magnetization) of a sample. The method works in both the reflection and transmission at near-normal incidence, it is not limited by presence of components with linear MO response in setup and it does not require sample rotation during the experiment; it therefore allows measurements with a sample placed inside a cryostat. Measurement scheme is based on a scanning of the probe beam polarization change upon rotation of external magnetic field for several linear polarization of the probe laser. Numerical analysis of the full set of data allows us to recover magnitude and anisotropy of the MO coupling coefficient and we further determine the magnetic anisotropy of the sample by a fitting procedure. We demonstrate the precision of the method by characterizing several GaMnAs ferromagnetic samples with different Mn contents. Reliability of the method is confirmed by a perfect fit of the MO coupling constants with the predictions based on the G-tensor formalism and by a mutual agreement of magnetic anisotropic constants, determined from data acquired at different wavelengths.

MA 23.7 Wed 12:00 H20

Magnetic polymorphism in 2D layered antiferromagnets — •Shiwei Wu — Department of Physics, Fudan University

Polymorphism, commonly denoting the variety of molecular or crystal structures, is a vital element in many natural science disciplines. In van der Waals layered antiferromagnets, a new type of magnetic polymorphism is allowed by having multiple layer-selective magnetic structures with the same total magnetization. However, resolving and manipulating such magnetic polymorphs remain a great challenge. In this talk, I will report the use of phase-resolved magnetic second-harmonic generation microscopy to elucidate such magnetic polymorphism in the 2D semiconducting layered antiferromagnet CrSBr, and demonstrate how the magnetic polymorphs can be deterministically switched in an unprecedented layer-selective manner. With the nonlinear magneto-optical technique unveiling the magnetic symmetry information through the amplitude and phase of light, we could unambiguously resolve the polymorphic spin-flip transitions in CrSBr bilayers and tetralayers. Remarkably, the deterministic routing of polymorphic transitions originates from the breaking of energy degeneracy via a magnetic layer-sharing effect: the spin-flip transitions in a tetralayer are governed by the laterally extended bilayer, which acts as a *control bit*. We envision such controllable magnetic polymorphism to be ubiquitous for van der Waals layered antiferromagnets, and could lead to conceptually new design and construction of spintronic and opto-spintronic devices for probabilistic computation and neuromorphic engineering.

MA 23.8 Wed 12:15 H20

Anisotropy of the contributions to the orbital magnetization — •Milan Vrána[1,2] and Jaroslav Hamrle[1,2] — [1]Charles University, Prague, Czech Republic — [2]Czech Technical University, Prague, Czech Republic

The general definition of orbital magnetization is the change in the grand canonical potential, Ω, with respect to the external magnetic field: $\mathbf{m}_{\mathrm{orb}} = -\partial\Omega/\partial\mathbf{B}$. The orbital magnetization consists of two distinct contributions [1]. The first term originates from the orbital motion of electrons and is given by $\mathbf{m}_{\mathrm{dip}} = -\frac{e}{2}\langle\psi|\mathbf{r}\times\mathbf{v}|\psi\rangle$. The second term, $\mathbf{m}_{\mathrm{kden}}$, has been reinterpreted as arising from changes in the density of $\mathbf{k}$-points in phase space due to the concurrent presence of both the magnetic field and the Berry curvature, Ω [2]. This violates Liouville's theorem, leading to an expansion or contraction of the phase space volume by a factor of $(1 + \frac{e}{\hbar}\mathbf{B}\cdot\Omega)$. In the model material bcc Fe, we demonstrate that $\mathbf{m}_{\mathrm{kden}}$ is negligible in the [100] magnetization direction, whereas $\mathbf{m}_{\mathrm{dip}}$ is negligible in the [111] direction. It demonstrates different nature of the orbital magnetization for different magnetization directions. However, the magnitude of the total orbital magnetization, $\mathbf{m}_{\mathrm{orb}} = \mathbf{m}_{\mathrm{dip}} + \mathbf{m}_{\mathrm{kden}}$, remains nearly independent of the magnetization direction.

Invited Talk MA 23.9 Wed 12:30 H20

Ultrafast Néel order dynamics detected by time-resolved magneto-optical Voigt effect — •Haibin Zhao — Fudan University, Shanghai, China

The time-resolved magneto-optical (MO) Voigt effect can be principally utilized to study the Néel order dynamics in antiferromagnetic (AFM) materials. In this talk, I will present the quench of AFM order by ultrafast laser pulses in both collinear and noncollinear AFM spin configurations in antiferromagnets with

negligible net magnetization probed by the time-resolved MO Voigt effect. For CoO with collinear spin configuration, the quench time of Néel order slows down pronouncedly near the Néel temperature (TN). In contrast, for Mn3Sn with an inverse triangular spin structure, The AFM order quench time shows negligible change with increasing temperature approaching the TN. This atypical behavior can be explained by the influence of weakened Dzyaloshinskii-Moriya interaction rather than the smaller exchange splitting on the diminished AFM order near TN. The temperature-insensitive ultrafast spin manipulation can pave the way for high-speed spintronic devices either working at a wide range of temperature or demanding spin switching near TN. The modulated Voigt angle in Mn3Sn is significantly larger than the polarization rotation due to the crystal-structure related linear dichroism effect and the modulated MO Kerr angle arising from the ferroic ordering of cluster magnetic octupole.

MA 24: Focus Session: Nonlinear Spectroscopy of Collective Excitations in Quantum Magnets (joint session TT/MA)

In recent years, significant progress has been made in understanding strongly correlated quantum magnets, with a particular focus on fractionalized states of matter such as quantum spin liquids. These achievements in understanding have been made possible by remarkable developments in both materials science and experimental techniques. In particular, improvements in both traditional experimental tools (e.g., inelastic neutron scattering, Raman scattering, resonant X-ray scattering, etc.) and the introduction of innovative techniques such as 2D coherent THz spectroscopy and sophisticated noise experiments have advanced studies of quantum matter to qualitatively new levels of insight. This focus session will discuss these recent advancements in nonlinear spectroscopy techniques along with theoretical inroads in describing the nonlinear spectroscopic signatures of complex quantum magnets.

Organizers: Simon Trebst (Universität zu Köln), Johannes Knolle (TU München)

Time: Wednesday 9:30–12:45 Location: H36

See TT 27 for details of this session.

MA 25: Focus Session: Physics of the van der Waals Magnetic Semiconductor CrSBr I (joint session HL/MA)

The session is the first part of the focus session on the physics of the van der Waals magnetic semiconductor CrSBr, with a main session on Friday morning. The focus session is jointly organized by HL and MA.

Time: Wednesday 15:00–15:30 Location: H15

See HL 37 for details of this session.

MA 26: Ultrafast Magnetization Effects I

Time: Wednesday 15:00–18:45 Location: H16

MA 26.1 Wed 15:00 H16

Terahertz field assisted magneto-optical effects in nonmagnetic substrates — •Sergey Kovalev[1], Igor Ilyakov[2], Anneke Reinold[1], Patrick Pilch[1], Ahmed Ghalgaoui[1], Ruslan Salikhov[2], Jürgen Lindner[2], Cong Li[3], Jianbing Zhang[3], Pu Yu[3], and Zhe wang[1] — [1]Fakultät Physik, Technische Universität Dortmund, Dortmund, Germany — [2]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [3]Tsinghua University, China

Coherent control of matter on ultrafast timescales is attracting much attention due to numerous applications in advanced technologies. Strong terahertz (THz) fields are highly demanded in many of these studies, which focus on the control of carrier flow, spin dynamics, orbital polarisation and various aspects of nonlinear electron dynamics. For these studies it is very important to understand and disentangle different THz field induced processes occurring in the investigated systems and their substrates. In this contribution, we present two effects that occur in fused silica [1] and in LaAlO3 driven by strong THz field, resulting in rotation of laser pulse polarisation. These observations are due to the magneto-optical effect in amorphous systems or the Kerr electro-optical effect in anisotropic systems. Our results show that in general these effects should be carefully considered in the studies of ultrafast THz magnetisation dynamics by ultrafast pump-probe approaches. [1] S. Kovalev et al., Optics Letters 49, 4749 (2024)

MA 26.2 Wed 15:15 H16

Photoinduced spectral manipulation of coherent magnonics in ultrathin iron garnets — •Volker Wiechert[1], Moritz Cimander[1], Hanchen Wang[2], William Legrand[3], Pietro Gambardella[2], and Davide Bossini[1] — [1]Department of Physics, University of Konstanz, D-78457 Konstanz, Germany — [2]Department of Materials, ETH Zürich, Hönggerbergring 64, CH-8093 Zürich, Switzerland — [3]Unité Mixte de Physique, CNRS, Université Paris-Saclay, Palaiseau 91767, France

Iron garnets, particularly Bi:YIG thin films, are promising materials for magnonics and magnetotransport due to their low damping and tunable magnetic properties through doping or external magnetic fields [1]. Recent advances demonstrate the ability of ultrashort laser pulses to excite, control, and even switch magnetization with minimal heating [2-4]. In this study, we investigate Bi:YIG single crystals in quasi-2D ultrathin form (~20 nm), using a femtosecond, balanced-detection scheme to capture simultaneous optical and magneto-optical responses. Our findings reveal two pathways for modifying magnetic resonance eigenfrequency: an impulsive femtosecond modification of magneto-crystalline anisotropy and a nanosecond lattice-mediated heating effect. This dual effect is quantitatively identified in time-resolved experiments, with potential applications in other quasi-2D ultrathin magnetic systems exhibiting temperature-dependent phase transitions.

MA 26.3 Wed 15:30 H16

Ultrafast Entropy Production in Non-Equilibrium Magnets — •Finja Tietjen and R. Matthias Geilhufe — Chalmers University of Technology, Gothenburg, Sweden

We present an ultrafast thermodynamics framework to model heat generation and entropy production in laser-driven ferromagnetic systems. By establishing a connection between the magnetic field strength of the laser pulse and magnetization dynamics we model time-dependent entropy production rates and deduce the associated heat dissipation in epitaxial and polycrystalline FeNi and CoFeB thin films. Our theoretical predictions are validated by comparison to experimental magnetization dynamics data, shedding light on thermodynamic processes on picosecond timescales.

Crucially, we incorporate recently observed inertial spin dynamics, to describe their impact on heat generation in pump-probe experiments. As such, this formalism provides novel insights into controlling heat production in magnetic systems, and contributes to advancing the understanding of non-equilibrium

thermodynamics in magnetic systems, with implications for future experimental protocols in spintronics and nanotechnology.

MA 26.4 Wed 15:45 H16

Spin-lattice modeling of elastic waves generated by ultrafast demagnetization in fcc Ni — •Ievgeniia Korniienko[1], Pablo Nieves[2], Alberto Fraile[3], Roberto Iglesias[2], and Dominik Legut[1] — [1]IT4Innovations, VSB-TU Ostrava, Ostrava, Czech Republic — [2]University of Oviedo, Oviedo, Spain — [3]Catalan Institute of Nanoscience and Nanotechnology (ICN2), Barcelona, Spain

Picosecond ultrasonics is a fast growing and advanced research field with broad application to the imaging and characterization of nanostructured materials as well as at a fundamental level. Experiments that provide direct, layer-specific, and quantitative information on the picosecond strain response [1], however, face comparably limited theoretical descriptions and modeling. In our work we propose a 3D model on the base of atomistic spin-lattice simulations [2] for laser-induced elastic response. As an example for testing our modeling approach we use ferromagnetic fcc Ni. Such choice allows us not only to calculate the lattice elastic response including ultrafast thermal expansion, but also to characterize the magnetic contribution to stress in this material [3]. The theoretical approach presented in our work [3] can be useful for further interpretations of experiments in the picosecond ultrasonics, as well as for providing other required parameters (like ultrafast thermal expansion coefficient) in micromagnetic models, e.g. within a multiscale approach. MA 26.5 Wed 16:00 H16

Ultrafast orbital Hall effect in metallic nanoribbons — •Oliver Busch, Franziska Ziolkowski, Börge Göbel, Ingrid Mertig, and Jürgen Henk — Institut für Physik, Martin-Luther-Universität, D-06099 Halle

The orbital Hall effect can generate currents of angular momentum more efficiently than the spin Hall effect in most metals. However, so far, it has only been understood as a steady-state phenomenon [1]. In this theoretical study, the orbital Hall effect is extended into the time domain [2]. We investigate the orbital angular momenta and their currents induced by a femtosecond laser pulse in a Cu nanoribbon.

Our numerical simulations provide detailed insights into the laser-driven electron dynamics on ultrashort timescales with atomic resolution. As we show, the ultrafast orbital Hall effect described here is consistent with the familiar pictorial representation of the static orbital Hall effect, but we also find pronounced differences between physical quantities that carry orbital angular momentum and those that carry charge. For example, there are deviations in the time series of the respective currents. This work lays the foundations for investigating ultrafast Hall effects in confined metallic systems.

MA 26.6 Wed 16:15 H16

Ultrafast magnetization dynamics of magnetic garnet thin films — •Paul Herrgen[1], Christian Holzmann[2], Manfred Albrecht[2], Benjamin Stadtmüller[2], and Martin Aeschlimann[1] — [1]Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Institute of Physics, University of Augsburg, 86159 Augsburg, Germany

The rare-earth iron garnets (REIG) are a class of magnetic oxide materials, known for their excellent magneto-optical properties, high magnetic permeability, and applications in photonics and spintronics. [1]

In our work we investigate the ultrafast magnetization dynamics of a gadolinium iron garnet (GdIG) thin film after an excitation with an ultrashort laser pulse. Our static characterization of the magnetic properties revealed hysteresis loops with opposite sign of the saturation magnetization for equal field directions depending on the probe photon energy. This points to a photon energy dependent magnetic response of both sublattices and allows us to disentangle their ultrafast response after optical excitation. We observe an ultrafast demagnetization of both sublattices within the first few hundred fs, after excitation with photon energies larger than the material's band gap. We find a different quenching for the signals of both sublattices despite the otherwise very similar demagnetization time. On longer timescales, we find another different behavior for the sublattices, with the iron sublattice starting to remagnetize much earlier than the gadolinium one.

MA 26.7 Wed 16:30 H16

Accelerated ultrafast demagnetization of an interlayer-exchange-coupled Co/Mn/Co trilayer — •Jendrik Gördes[1], Ivar Kumberg[1], Chowdhury S. Awsaf[1], Marcel Walter[1], Tauqir Shinwari[1], Sangeeta Thakur[1], Sangeeta Sharma[2], Christian Schüssler-Langeheine[3], Niko Pontius[3], and Wolfgang Kuch[1] — [1]Institut für Experimentalphysik, Freie Universität Berlin, Berlin — [2]Max Born Institute for Nonlinear Optics and Short Pulse Spectroscopy, Berlin — [3]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin

We studied the influence of the spin structure of an antiferromagnetic (AFM) layer at the interface to a ferromagnetic (FM) layer on the FM magnetization dynamics in epitaxial Co/Mn/Co/Cu(001) trilayers. The two FM layers are coupled indirectly by the Ruderman-Kittel-Kasuya-Yosida (RKKY) interaction and directly by exchange through the AFM spin structure [1]. Deposition of Mn in a wedge allowed for access to different coupling regimes on the same sample. Magnetization dynamics were probed after excitation with 800 nm fs laser pulses by X-ray magnetic circular dichroism in reflectivity. A difference in demagnetization time between the two regimes for parallel and antiparallel alignment of FM is observed. We explain this by differences in the AFM spin structure leading to presence or absence of optically induced intersite spin transfer [2] between Mn and Co. [1] B. Zhang *et al.*, J. Appl. Phys. 115, 233915 (2014). [2] J. K. Dewhurst *et al.*, Nano Letters 18, 1842 (2018)

15 min. break

MA 26.8 Wed 17:00 H16

Development of planar micro optics for ultrafast in-situ measurements in the TEM — •Max Herzog[1], Johannes Schultz[1], and Axel Lubk[1,2] — [1]IFF, IFW Dresden, Helmholtzstraße 20, 01069 Dresden — [2]IFMP, TU Dresden, Haeckelstraße 3, 01069 Dresden

The miniaturization of magnetic electron optics has been a goal for at least the past decade, because it will not only allow for smaller and easier to build electron optics, but will also result in other favorable scaling effects. Namely, the small scale allows for magnetic flux densities in the hundreds of millitesla with a significantly reduced power consumption and lower overall complexity regarding vacuum, cooling and power supply. More important for this work, however, is the small inductance that follows from the small size, which in turn allows the optics to be switched with radio frequencies (RF). The aim of this work is to lithographically produce planar micro optics (e.g. deflectors, focusing quadrupoles, vector magnets, etc.), that are capable of utilizing this RF switching to image ns-scale processes (e.g. the movement of magnetic domain walls) stroboscopically in a transmission electron microscope. The optics were characterized using differential phase contrast (DPC) to determine the spatial distribution of the magnetic field and by measuring the optical power (e.g. deflection, focusing behaviour) at varying switching frequencies. Using an acceleration voltage of 80 kV, the optics show a promising performance with a deflection power of up to 330 μrad at an excitation frequency of 7.5 MHz and still 120 μrad at 2 GHz with a very homogeneous magnetic field as determined by DPC.

MA 26.9 Wed 17:15 H16

Ultrafast energy-resolved spin dynamics in nickel — Christopher Seibel, Tobias Held, Markus Uehlein, •Sebastian T. Weber, and Baerbel Rethfeld — Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern-Landau

Magneto-optical methods were used when ultrafast magnetization dynamics were discovered and are still used intensively. Recent experiments show a strongly energy-dependent magneto-optic response and indicate spin transfer processes on the timescale of the pulse duration in a pure metallic ferromagnet [1].

We investigate the non-equilibrium spin dynamics on these early timescales by full spin-resolved Boltzmann collision integrals [2]. We trace the temporal evolution of the individual distribution functions of up and down electrons, where spin-flips due to electron-electron and electron-phonon collisions are taken into account.

From the dynamics of the distributions, we extract the spin-resolved densities of both, electrons and holes, at various energies. The energy-resolved spin polarization can vary significantly depending on the considered energy range. It can deviate from the overall magnetization dynamics, both in terms of the qualitative behavior and the timescales involved. Additionally, we present results on the non-equilibrium magneto-optic response calculated from the distribution functions.

MA 26.10 Wed 17:30 H16

Differentiating mechanisms that drive ultrafast magnetization precession — •Fried-Conrad Weber[1,2], Maximilian Mattern[3], Jasmin Jarecki[3], Marwan Deb[1], Dieter Engel[3], Daniel Schick[3], Alexander von Reppert[1] und Matias Bargheer[1,2] — [1]Universität Potsdam — [2]Helmholtz-Zentrum für Materialien und Energie, Berlin — [3]Max-Born-Institut, Berlin

We use the time-resolved polar magneto-optical Kerr effect to measure the laser-induced magnetization precession of a 20 nm and 200 nm thin nickel film for different external magnetic field angles. We identify the role of quasi-static strain,

strain pulses, and demagnetization for driving the precession in these samples. The magnetization response is modeled using the udkm1Dsim toolbox, which calculates the temperature, strain, and subsequent magnetization response with a modified Landau-Lifshitz-Gilbert equation that incorporates demagnetization. Contributions from the demagnetization-induced change in anisotropy, quasi-static strain, and propagating strain pulses are included in the time-dependent effective field. In the case of nickel, the quasi-static strain drives the effective field in the opposite direction to the demagnetization-induced change in anisotropy. For the samples and fluences measured, we identify the laser-induced strain and the subsequent change in the magnetoelastic field as the dominant mechanism controlling the precession. In a subsequent double-pulse excitation experiment, we balance the effect of the demagnetizationinduced change in anisotropy and the magnetoelastic contribution in a non-conventional coherent control scheme.

MA 26.11 Wed 17:45 H16

Temperature and Magnetic Field Dependence of Ultrafast Magnetization Dynamics — •Leon Seidel[1], Clemens von Korff Schmising[2], Tino Noll[2], Wolfgang-Dietrich Engel[2], Simon Gaebel[2], Daniel Metternich[2], and Stefan Eisebitt[1,2] — [1]Technische Universität Berlin — [2]Max-Born-Institut für Nichtlineare Optik und Kurzzeitspektroskopie

In this work, we present a wide-field optical microscope designed to study the temperature and magnetic field dependence of ultrafast magnetization dynamics with femtosecond temporal and micrometer spatial resolution. The compact device integrates xyz, yaw and tilt adjustments as well as a motorized sample manipulation. The sample temperature is controlled by a continuous flow cryostat in a temperature range between 20 K / 80 K and 500 K using either LN2 or LHe. An inbuilt electromagnet provides an external magnetic field of up to one Tesla. We show first results of ultrafast all-optical magnetization switching (AOS) in ferrimagnetic rare earth-transition metal alloys. We characterize two CoTbGd films with different stochiometries and systematically examine the role of the magnetization and angular momentum compensation for AOS.

MA 26.12 Wed 18:00 H16

Heterogenity of the laser-induced magneto-structural phase transition in FeRh revealed by ultrafast x-ray diffraction — •Maximilian Mattern[1], Jan-Etinne Pudell[2], Vojtech Uhlir[3], Jon Ander Arregi[3], Angel Rodriguez-Fernandez[2], Roman Shayduk[2], Wonhyuk Jo[2], Anders Madsen[2], and Daniel Schick[1] — [1]Max-Born-Institut, Germany — [2]European XFEL, Germany — [3]CEITEC BUT, Czech Republic

Laser-induced heterogeneities play an important role for ultrafast dynamics especially of first-order phase transitions due to the phase co-existence during nucleation. However, their probing on picosecond time and nanometer length scales is challenging.

We use time-resolved x-ray diffraction to reveal the transient nanoscale heterogeneity of the laser-induced first-order antiferromagnetic (AFM) to ferromagnetic (FM) phase transition in FeRh that is accompanied by a lattice expansion. Utilizing the good reciprocal space and femtosecond time-resolution of the MID instrument at the European X-ray Free-electron laser, we individually track the picosecond shifts of the structural AFM and FM Bragg peak. The integral of the latter quantifies the transient fraction of the FeRh layer that is in the FM phase, and the signatures of the propagating picosecond strain pulses in the shift of both Bragg peaks reveal its spatial distribution. Our results can distinguish between different nucleation scenarios and reveal that the FM phase nucleates as laterally separated columns through the photoexcited near-surface region, finally forming a closed FM layer at the surface of the inhomogeneously excited FeRh film.

MA 26.13 Wed 18:15 H16

Ultrafast electron dynamics in altermagnetic materials — Marius Weber[1,2], •Kai Leckron[1], Luca Haag[1], Libor Šmejkal[2], Jairo Sinova[2], and Hans Christian Schneider[1] — [1]Department of Physics, University of Kaiserslautern-Landau, Germany — [2]Institut für Physik, Johannes Gutenberg University Mainz, Germany

One of the intriguing properties of altermagnetic materials is that a linearly polarized optical pulse can induce a spin polarization of the electrons depending on the direction of the linear polarization [1]. This contribution investigates the impact of the polarization direction and fluence of the optical excitation on the ultrafast magnetization dynamics in the prototypical altermagnetic band structure of KRu4O8. We explicitly consider electron-electron scattering and electron-phonon scattering contributions to the light-driven carrier dynamics. The optical excitation is computed using ab initio dipole transition rates in the whole Brillouin zone. Our momentum-dependent calculation of the subsequent scattering dynamics fully includes the anisotropies of the altermagnet, which leads to unique k-resolved electron dynamics at ultrashort times and a long-lived spin polarization [2]. We present a numerical study of the influence of the excitation conditions on the lifetime of this spin polarization.

MA 26.14 Wed 18:30 H16

The dynamics of a memory-enhanced LLG equation — •Felix Hartmann[1] and Janet Anders[1,2] — [1]University of Potsdam, Institute of Physics and Astronomy, Karl-Liebknecht-Str. 24-25, 14476 Potsdam, Germany — [2]Department of Physics and Astronomy, University of Exeter, Stocker Road, Exeter EX4 4QL, UK

Recently, Anders et al. [1] have proposed a stochastic Landau-Lifshitz-Gilbert (LLG) equation which takes into account memory effects and colored thermal fluctuations, with either a classical, semi-classical or quantum thermostat. In this talk we will present some recent results that characterize the spin dynamics in different parameter regimes. We show how the proposed stochastic LLG equation has a well-described white-noise and Markovian limit of the spin dynamics. Further, going beyond the white-noise and Markovian limit, we present numerical results that show strong ultrafast and inertial effects in the spin dynamics, such as a faster relaxation and the appearance of nutation oscillations.

[1] J. Anders et al., New J. Phys. 24 033020 (2022)

MA 27: Focus Session: Magneto-Transport and Magneto-Optics of Higher Orders in Magnetization II

Magneto-transport and magneto-optic effects linear in the magnetization M (e.g. anomalous Hall effect (AHE), Faraday effect or magneto-optic Kerr effect (MOKE)) are important magnetic phenomena in spintronics and magneto-optics for the characterization of magnetic samples by vectorial magnetometry, microscopy, spectroscopy and pump probe experiments. However, already some time ago, it has been shown that the angular dependence of the anisotropic magnetoresistance and of magneto-optic effects contains higher-order-in-M terms. In the last decade, these effects beyond the linear dependence on M, e.g. quadratic effects proportional to M^2, have been mainly utilized to investigate antiferromagnetic materials.

Recently, the third-order MOKE proportional to M^3, so-called cubic MOKE, was reported to be sensitive to the structural domain twinning in thin-film samples of (111) orientation. By investigating AHE and MOKE of higher orders in M, the multipolar structure of the Berry curvature in magnetization space can be probed. These additional higher-order contributions in standard Hall or polar MOKE setup geometries are able to trace the in-plane magnetization while the linear effect keeps sensitive to the out-of-plane magnetic moment. This can be utilized, for example, to detect spin-orbit torques magneto-optically.

This Focus Session introduces the main magneto-transport and magneto-optic effects of higher orders in magnetization, draws connections between both research fields, distinguishes between already known and new higher-order effects and presents first applications beyond the study of antiferromagnets by quadratic effects.

Quantifying magnetization multipole of Berry curvature in ferromagnets — •Wenzhi Peng, Zheng Liu, Bin Xiang, Qian Niu, Yang Gao, and Dazhi Hou — University of Science and Technology of China

The anomalous Hall effect, originating from the Berry curvature in momentum space, typically manifests as a dipole behavior in magnetization. This implies that the anomalous Hall conductivity is parallel to the magnetization in most transport measurements. However, even in iron, the in-plane magnetization can also induce the anomalous Hall effect, which contradicts the predictions of the dipole term in a cubic lattice. This behavior can be understood within the framework of the Berry curvature multipole structure in magnetization space. In this work, we propose a paradigm to quantify the coefficients of the Berry curvature multipole by examining the angular dependence of the Hall resistivity, which matches well with first-principles calculations. Under certain conditions, the contribution of the magnetization multipole can even surpass that of the dipole term, dominating the AHE.

MA 27.2 Wed 15:15 H18

Orthogonal faraday effect in garnet — •Haolin Pan[1], Han Li[2], Qinhui Yang[2], and Dazhi Hou[1] — [1]University of Science and Technology of China, Hefei, China. — [2]University of Electronic Science and Technology of China, Chengdu, China.

Faraday effect, a transmissive magneto-optical phenomenon with a long history and diverse applications, has been be confined within parallel configuration between light and magnetization in experiments. This routine originates from the common assumption that the asymmetric components of dielectric tensor is in linear response to magnetization. However, our experiments in garnet materials reveal the nonlinear nature of Faraday effect with respect to magnetization orientation, which allows the orthogonal geometry between light and magnetization. The lattice angular dependence and spectroscopy results are in good agreement with theory of multipole structures of Berry curvatures in magnetization space. The observation of orthogonal Faraday effect provides new opportunities for magneto-optical studies and applications.

MA 27.3 Wed 15:30 H18

Strong anisotropy of quadratic magneto-optical Kerr effect in FeRh — •zeynab sadeghi, vladislav wohlrath, jozef kimák, peter kubaščík, eva schmoranzerová, tomas ostatnický, and petr němec — faculty of mathematics and physics, charles university, prauge, 121 16, czech republic

recently, we developed a technique that enables to measure magnetic anisotropy and anisotropy of quadratic magneto-optical Kerr effect (QMOKE) [1]. This technique is based on measurement of magneto-optical response in rotating magnetic field using series of incident light linear polarizations at normal incidence on the sample with a fixed position and, therefore, it can be applied also for samples placed in a cryostat. In this contribution, we report on measurements in FeRh, which is an interesting material with an antiferromagnetic (AFM) ordering at room temperature and a ferromagnetic (FM) phase at temperatures above 400 K. We show that in the FM phase QMOKE has a very strong wavelength-dependent anisotropy in the investigated spectral range from 460 nm to 1600 nm. We also discuss the possibility of investigation of the FeRh AFM phase using this technique. [1] wohlrath, w., sadeghi, z. et al. "quadratic magneto-optical Kerr effect spectroscopy: Polarization variation method for investigation of magnetic and magneto-optical anisotropies." arXiv:2409.20205 (2024).

MA 28: Cooperative Phenomena: Spin Structures and Magnetic Phase Transitions

Time: Wednesday 15:00–17:30 Location: H19

MA 28.1 Wed 15:00 H19

Correlations of short-range environment and hyperfine parameters in disordered FeV thin-films — •Simon Rauls[1], Benedikt Eggert[1], Jürgen Fasbender[2], Kay Potzger[2], Rantej Bali[2], and Heiko Wende[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen — [2]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf

The binary alloy $Fe_{1-x}V_x$ shows a variety of interesting properties, ranging from antiparallel coupling of induced V magnetic moments up to 1 μ_B per V atom to the positive vibrational entropy in the disorder/order transition from the A2 to the B2 bcc-crystalline phase. Furthermore, around equiatomic composition, the structurally complex σ-phase might develop. To understand these effects, the local atomic environment as well as both structural and chemical disorder need to be considered. Using Mössbauer spectroscopy, the local environment of ^{57}Fe atoms and different aspects of disorder can be investigated through careful analysis of the distribution of hyperfine parameters, i.e.. the hyperfine field splitting and the isomer shift. In this talk, the conversion electron Mössbauer spectra of the entire concentration range of $Fe_{1-x}V_x$ thin film samples are presentedd. Enrichment with 95% ^{57}Fe results in a very high signal to noise ratio, which allows for comparison of Hesse-Rübartsch fits with a model, in which the hyperfine parameters are described by a binomial distribution of the first three nearest-neighbor shells. We acknowledge funding by the DFG through project No. 322462997.

Simulating magnetostriction in skyrmion-hosting $MnSc_2S_4$ — •Justus Grumbach[1], Mahmood Deeb[1], Sergey Granovsky[1], Lilian Prodan[2], Vladimir Tsurkan[2], Martin Rotter[3], and Mathias Doerr[1] — [1]Institut für Festkörper- und Materialphysik, TU Dresden, 01062 Dresden — [2]Experimentalphysik V, Universität Augsburg, 86135 Augsburg — [3]*McPhase* Projekt, 01159 Dresden

Measurements of neutron scattering on $MnSc_2S_4$ explored an antiferromagnetic skyrmion state [1]. We measured the magnetostriction and found curves with characteristic anomalies. To find out which is linked to skyrmions, we performed mean field Monte Carlo simulations with the *McPhase* program package using the hamiltonian introduced earlier [1].

We could resemble main properties of the experimental outcome. The exact location of the skyrmionic state in the phase diagram and the discovery of a new $2\boldsymbol{q}$ structure between the skyrmion state and saturation in field were new informations gained by these simulations.

Simulations and experimental results introduce a link of magnetostriction and skyrmions by a plateau-like non-distorted region, which could also be found in other compounds.

MA 28.3 Wed 15:30 H19

Tilted spin state near the spin reorientation of the topological kagome magnet Fe_3Sn_2 — •Lilian Prodan[1], Donald M. Evans[1,2], Aleksandr S. Sukhanov[1], Stanislav E. Nikitin[3], Alexander A. Tsirlin[4], Lukas Puntingam[1], Marein C. Rahn[1], Liviu Chioncel[1], Vladimir Tsurkan[1,5], and Istvan Kezsmarki[1] — [1]University of Augsburg, Augsburg, Germany — [2]Department of Sustainable Energy Technology, SINTEF Industry, Oslo, Norway — [3]Paul Scherrer Institut, Switzerland — [4]Leipzig University, Germany — [5]Moldova State University, Chisinau, Moldova

Spin reorientation due to competing magnetic anisotropies can have drastic effects on various physical properties in itinerant magnets with topologically nontrivial band structure. Therefore, understanding the mechanism of spin reorientation provides an efficient tool for engineering the properties of topological magnets [1]. Our target material is the topological kagome ferromagnet Fe_3Sn_2 [2], where we investigated the temperature-driven spin reorientation using a number of experimental techniques and numerical modeling. We reveal that the crossover from the high-temperature state with uniaxial easy-axis anisotropy to the low-temperature state with easy-plane anisotropy take place at ~120 K through an intermediate tilted easy-cone state. Our MFM study highlights significant changes in the magnetic patterns emerging on the mesoscale across all three states, including the formation of magnetic bubbles on the surface of bulk centrosymmetric Fe_3Sn_2 crystals. [1] A. Kimel et.al, Nature 429, 850-853 (2004). [2] F. Schilberth et al., Phys. Rev. B 106, 144404 (2022).

MA 28.4 Wed 15:45 H19

High-field/high-frequency Ferromagnetic Resonance Studies on the van-der-Waals ferromagnet Fe_3GeTe_2 — •Birte Beier[1], Martin Jonak[1], Eva Brücher[2], Reinhard K. Kremer[2], and Rüdiger Klingeler[1] — [1]Kichhoff Institute for Physics, Heidelberg University, Germany — [2]Max Planck Institute for Solid State Research, Stuttgart, Germany

Long-range ferromagnetic order develops down to the monolayer in Fe_3GeTe_2 and is particularly robust both in the monolayer and in the bulk as compared to other van-der-Waals ferromagnets. In the bulk, T_C amounts to about 220 K as compared to, e.g., 61 K in CrI_3 and 65 K in $Cr_2Ge_2Te_6$. In order to elucidate the origin of robust long-range ferromagnetism, we have investigated low-energy magnon excitations in Fe_3GeTe_2 by high-field/high-frequency ferromagnetic resonance studies. Our data reveal the size and temperature dependence of the anisotropy gap and also show the evolution of short-range magnetic order well above T_C. The frequency- and field-dependence of magnon excitation is discussed and compared with our recent findings on CrI_3 [1].

MA 28.5 Wed 16:00 H19

Derivation of spin-orbit generated relativistic symmetric and antisymmetric exchange interactions — •Hiroshi Katsumoto[1], Yuriy Mokrousov[1,2], and Stefan Blügel[1] — [1]Peter Grünberg Institut, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Germany

It has become clear that the higher-order exchange interactions beyond the Heisenberg interaction can promote very complex magnetic structures. Moriya derived the Dyzaloshinskii-Moriya interaction (DMI) for spin-1/2 systems, including spin-orbit coupling (SOC). We derived an expression that generates the DMI according to a systematic algorithm for any higher-order antisymmetric exchange interaction. Applying this expression to particular spin models consistently provides all recently suggested DMIs extended to higher-order exchange interactions [1]. In addition, it is found that in the second-order perturbation of SOC, not only the antisymmetric higher-order terms but also the symmetric spin-nematic term is obtained. The spin-nematic term is known to produce electromagnetic effects [2], and in this study, its microscopic derivation is given. We acknowledge funding from the ERC grant 856538 (project "3D MAGIC") and DFG through SPP-2137 and SFB-1238 (project C1).

MA 28.6 Wed 16:15 H19

magnetism and electronic dynamics in CuCr1-xSnxS4 — •Elaheh Sadrollahi[1], Cynthia P. C. Medrano[2], Magno A.V. Herling[2], Elisa M. Baggio Saitovitch[2], Lilian Prodan[3,4], Vladimir Tsurkan[3,4], and F. Jochen Litterst[5] — [1]IFMP, TU Dresden, 01069 Dresden, Germany — [2]CBPF, Rio de Janeiro, 22290-180, Brazil — [3]EKM, Inst. of Physics, University Augsburg, 86135 Augsburg, Germany — [4]IAP, Moldova State University, MD 2028, Chisinau, Republic of Moldova — [5]IPKM, TU Braunschweig, 38106 Braunschweig, Germany

Magnetization, muon spin rotation and relaxation(muSR), and 119Sn Mössbauer spectroscopy have been performed on the metallic ferromagnetic CuCr1-xSnxS4 (x=0.03-0.08) cubic spinel (Tc=360 K-343 K). Magnetization and muSR results reveal the same low-temperature magnetic transitions around 80 K and 40 K as found for the undoped material with a magnetic ground state deviating from a simple collinear ferromagnet [1] and proposed charge ordering [2]. The changes in Mössbauer hyperfine spectra are less pronounced and are discussed in view of the different positions of the local probes mu+ and 119Sn and their different magnetic coupling to the magnetic Cr lattice. Above 70 K, both muSR and Mössbauer spectra show temperature-dependent inhomogeneous broadening either due to structural or charge disorder and changing spin and charge dynamics that can be related to a precursor magnetic phase above the well-defined static low-temperature phase.

Ground state magnetization in superstable graphs — •Fabio Pablo Miguel Méndez-Córdoba[1,2,3], Joseph Tindall[4], Dieter Jaksch[1,2,5], and Frank Schlawin[1,2,3] — [1]Universität Hamburg, Luruper Chaussee 149, Gebäude 69, D-22761 Hamburg, Germany — [2]The Hamburg Centre for Ultrafast Imaging, Luruper Chaussee 149, Hamburg D-22761, Germany — [3]Max Planck Institute for the Structure and Dynamics of Matter, Luruper Chaussee 149, 22761 Hamburg, Germany — [4]Center for Computational Quantum Physics, Flatiron Institute, 162 5th Avenue, New York, NY 10010 — [5]Clarendon Laboratory, University of Oxford, Parks Road, Oxford OX1 3PU, UK

Much of our understanding of ground state magnetic properties rests on analytical results on bipartite lattices. However, few exact results are known in non-bipartite graphs with frustrated couplings. We determine the ground state magnetization of strongly correlated systems on non-bipartite graphs displaying superstability. Superstability allows reinterpreting non-bipartite graphs as a collection of bipartite-connected components, providing magnetic properties of important lattices, such as the triangular ladder. Numerical evidence suggests further generalizations are feasible.

MA 28.8 Wed 17:00 H19

Magneto-optical spectroscopy on cubic noncollinear antiferromagnet HoCu — •Felix Schilberth[1,2], Marein Rahn[3], Andreas Bauer[4], Christian Pfleiderer[4], Sándor Bordács[2], and István Kézsmárki[1] — [1]Lst. für Experimentalphysik V, Universität Augsburg — [2]Dept. of Physics, BME Budapest — [3]Lst. für Experimentalphysik VI, Universität Augsburg — [4]Lst. für Experimentalphysik zur Topologie korrelierter Systeme, TU München

Giant anomalous Hall effect (AHE) and magneto-optical Kerr-effect (MOKE) can emerge in magnets with topologically non-trivial electronic bands. Besides extrinsic contributions from scattering of electrons by impurities, two intrinsic contributions are considered. In momentum space, the Berry curvature generated by non-trivial band features like Weyl points or nodal lines can produce resonances in the optical conductivity, leading to AHE in the static limit. On the other hand, noncollinear magnetic texture in the real space can induce topological Hall effect (THE). The separation of all three contributions is a remarkable experimental challenge which typically cannot be solved by magnetotransport experiments alone. Here, we address this question in the itinerant cubic antiferromagnet HoCu where a remarkably large AHE on the order of $10^6\ \Omega^{-1}\mathrm{cm}^{-1}$ was observed. By measuring reflectivity and MOKE, we determine the optical Hall effect spectrum, the finite frequency analog of the AHE. In this quantity, the energy scales provided by the scattering rate or the energy of band degeneracies allow to disentangle the AHE contributions by free carriers from interband resonances, decomposing this remarkable transport response.

MA 28.9 Wed 17:15 H19

Investigating the soft X-ray-induced spin-state switching in the room temperature regime of a Fe(II) spin-crossover complex — •Lea Kämmerer[1], Carolin Schmitz-Antoniak[2,3], Tobias Lojewski[1], Damian Günzing[1], Torsten Kachel[4], Florin Radu[4], Radu Abrudan[4], Katharina Ollefs[1], Senthil K. Kuppusamy[5], Mario Ruben[5,6], and Heiko Wende[1] — [1]University of Duisburg-Essen and CENIDE — [2]Forschungszentrum Jülich — [3]University of Applied Sciences Wildau, — [4]Helmholtz-Zentrum Berlin — [5]Karlsruhe Institute for Technology — [6]Institut de Science et d'Ingénierie Supramoléculaires

Spin-crossover complexes exhibit two distinct spin-states, designated as low-spin and high-spin, which are contingent upon the ligand field surrounding the central metal ion. It is possible to induce a switching of the spin state in these complexes through the use of soft X-rays. The complex $Fe(1-bpp-COOC_2H_5)_2(BF_4)_2CH_3CN$ exhibits an abrupt spin-state switching with an open thermal hysteresis around room temperature. Static X-ray absorption spectroscopy was performed at the synchrotron BESSY II, which allows for the analysis of the two spin states at the Fe $L_{2,3}$ absorption edges due to the presence of different fine structures. We gained insight into the cooperative mechanism that occurs during the soft X-ray-induced spin-state switching at room temperature. It was observed that once the effect was initiated in a thin film, a chain reaction led to further switching, even in the absence of soft X-rays. We thank the Deutsche Forschungsgemeinschaft for their financial support of the SFB 1242.

MA 29.1 Wed 15:00 H20

Emergent electromagnetic inductance of interface skyrmions in $SrRuO_3/SrIrO_3$ bilayers — •Ludwig Scheuchenpflug[1], Sebastian Esser[2], Robert Gruhl[1], Max Hirschberger[2,3], and Philipp Gegenwart[1] — [1]Universität Augsburg, Lehrstuhl für Experimentalphysik VI — [2]Department of Applied Physics, University of Tokyo, Japan — [3]RIKEN Center for Emergent Matter Science, Japan

Emergent electromagnetic induction (EEMI) by current-driven spin dynamics was proposed and observed in the spin helix magnet $Gd_3Ru_4Al_{12}$ [1], where the (current-nonlinear) imaginary impedance at kHz frequency was associated with the motion of helical spin structures. To explore the possibility of EEMI arising from current-driven skyrmion dynamics, we fabricated and microstructured epitaxial thin film bilayers of ferromagnetic $SrRuO_3$ and paramagnetic $SrIrO_3$ on $SrTiO_3$. This bilayer system is known to host DMI-stabilized Néel-skyrmions, indicated by the topological Hall-effect (THE) [2]. We reproduce the THE signatures and observe an accompanying large and current-linear imaginary impedance at low temperatures over broad current density and frequency ranges, signaling the EEMI from the low-energy dynamics of pinned interface skyrmions.

MA 29.2 Wed 15:15 H20

Surface acoustic wave based movement of skyrmions — •Philipp Schwenke, Ephraim Spindler, Vitaliy Vasyuchka, Philipp Pirro, Abbass Hamadeh, and Mathias Weiler — Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, 67663 Kaiserslautern, Germany

Magnetic skyrmions have significant potential for utilization in spintronic devices, primarily due to their stability and the ability to be manipulated by electric currents. However, when a current is applied, the skyrmions do not move in a direction parallel to the current flow due to the skyrmion Hall effect [1]. Consequently, the precise control of their movement is challenging. Recently, it has been demonstrated that a skyrmion can be moved using a surface acoustic wave (SAW) [2]. Here, we propose an alternative scheme for acoustic manipulation of magnetic skyrmions. Our approach is based on exploiting skyrmion pinning and non-sinusoidal SAWs. To demonstrate feasibility of our approach, we performed micromagnetic simulations using Mumax in a realistic pinning energy landscape.

Quantum skyrmions and antiskyrmions in monoaxial chiral magnets — •Štefan Liščák, Andreas Haller, Andreas Michels, Thomas L. Schmidt, and Vladyslav Kuchkin — Department of Physics and Materials Science, University of Luxembourg

Classical monoaxial chiral magnets represent a unique magnetic system that allows for the stabilization of both skyrmions and antiskyrmions of equal energy. Unlike a similar situation in frustrated magnets, the energy landscape here is much simpler, consisting of four states: the saturated ferromagnetic state, spin-spiral, skyrmion, and antiskyrmion. This simplicity makes such systems interesting for potential applications that rely on manipulating these states. We study the quantum analog of the already established classical theory by investigating the low-excitation spectra of a spin-1/2 quantum Heisenberg model with monoaxial Dzyaloshinskii-Moriya interaction. We establish that such a model supports the existence of skyrmion and antiskyrmion states of equal energy using the density matrix renormalization group method (DMRG). This degeneracy allows for the existence of a mesoscopic Schrödinger cat state exhibiting properties of both skyrmion and antiskyrmion. To characterize this superposition, we calculate two-point correlation functions, which can be measured in neutron scattering experiments. Finally, we introduce a perturbation in the form of a magnetic field gradient to induce a non-trivial time evolution of the superposition state. We study this time evolution both using a numerical variational approach and the collective coordinates method.

MA 29.4 Wed 15:45 H20

Magnetometry on the low-temperature skyrmion state in Cu_2OSeO_3 — Christian Oberleitner[1], •Lukas Heindl[1], Johannes Friedrich[1], Andreas Bauer[1,2], Denis Mettus[1,3], Helmut Berger[4], and Christian Pfleiderer[1,2,3] — [1]Physik-Dep., TU Munich, D-85748 Garching — [2]ZQE, TU Munich, D-85748 Garching — [3]MLZ, TU Munich, D-85747 Garching — [4]Inst. de Phys., EPFL, CH-1015 Lausanne

In cubic chiral magnets, skyrmion lattice states emerge near the magnetic ordering temperature, stabilized by thermal fluctuations [1]. Recently, a distinct low-temperature skyrmion state (LTS) was observed in Cu_2OSeO_3 for magnetic fields along the ⟨100⟩ axes, emphasizing the role of cubic anisotropies [2, 3]. Nucleation of this state at low temperatures requires an intermediate phase, the tilted conical phase, and has been studied mainly along major crystallographic axes [4].

Here, we examine the nucleation dynamics of the LTS under field rotation away from high-symmetry directions. Magnetization and ac susceptibility measurements on spherical and cuboid samples reveal key geometry effects. Spherical samples, with uniform internal field distributions, show significant spontaneous LTS nucleation. In contrast, cuboid samples, with inhomogeneous internal fields, need external field pumping to achieve substantial LTS populations[5].

MA 29.5 Wed 16:00 H20

Edge dislocations in helimagnets as mobile topological defects — •Maurice Colling[1], Manuel Zahn[1,2], Jan Masell[3], and Dennis Meier[1] — [1]NTNU Norwegian University of Science and Technology, Trondheim, Norway — [2]University of Augsburg (UniA), Augsburg, Germany — [3]Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany

Magnetic topological solitons, such as skyrmions and hopfions, represent fertile ground for emergent physical properties with potential applications in spintronics and unconventional computing. In my talk, I will present magnetic edge dislocations as intriguing nano-sized topological textures, which can serve as mobile information carriers. Edge dislocations naturally arise in the helimagnetic background of the B20-type material FeGe, which we study as a model system. Using micromagnetic simulations, we demonstrate how isolated dislocations can be initialized in a track-like geometry and how their movement can be controlled using spin-polarized currents and magnetic fields. Furthermore, we show how pinning sites can be introduced to achieve 'stop-and-go' motion, allowing to translate events (e.g. magnetic field or current pulses) into positional information. One key difference between dislocations and other topological solitons is their relaxation motion which is driven by the system's intrinsic tendency to revert toward the helimagnetic ground state. This feature makes them interesting candidates for sensing and computing applications and low-energy device technologies in general.

MA 29.6 Wed 16:15 H20

Cubic magnetic anisotropy in *B*20 magnets: Interplay of anisotropy and magnetic order in $Fe_{1-x}Co_xSi$ — •Gilles Gödecke, Julius Grefe, Stefan Süllow, and Dirk Menzel — Insitut für Physik der Kondensierten Materie, TU Braunschweig, D-38106 Braunschweig, Germany

The itinerant systems MnSi and $Fe_{1-x}Co_xSi$ are prominent members among the chiral *B*20 helimagnets. They are known to host chiral spin structures and magnetic skyrmions as a result from the competition of various magnetic interactions, one of which is magnetic anisotropy. Recently, a secondary skyrmion phase governed by cubic anisotropy was identified in the compound Cu_2OSeO_3 [1] raising the question wether such a phase also exists in MnSi and $Fe_{1-x}Co_xSi$. To aid the search for this phase, a better understanding of the cubic anisotropy in these systems would be beneficial.

Here, we report on the quantitative measurement of the cubic magnetocrystalline anisotropy constants in MnSi and $Fe_{1-x}Co_xSi$ ($0.08 \leq x \leq 0.70$) single crystals. Our work presents a systematic study regarding the cubic anisotropy at $T = 5\,K$ and $T = 10\,K$ by means of angle-resolved SQUID magnetization measurements. We observe that the cubic anisotropy is generally weaker than in familiar compounds and more pronounced in MnSi than in $Fe_{1-x}Co_xSi$. For $Fe_{1-x}Co_xSi$ the anisotropy gains at low Co-concentrations with increasing x, vanishes for $x = 0.50$, and is then finite for high x.

MA 29.7 Wed 16:30 H20

Imaging Topological Defect Dynamics Mediating 2D Skyrmion Lattice Melting — •Raphael Gruber[1], Jan Rothörl[1], Simon Fröhlich[1], Maarten Brems[1], Fabian Kammerbauer[1], Maria-Andromachi Syskaki[1], Elizabeth Martín Jefremovas[1], Sachin Krishnia[1], Asle Sudbø[2], Peter Virnau[1], and Msthias Kläui[1] — [1]Institute of Physics, JGU Mainz — [2]QuSpin, NTNU Trondheim

Two-dimensional (2D) phase transitions are mediated by topological defects, as predicted by KTHNY theory. Using real-time Kerr microscopy, we image the two-step melting of a 2D skyrmion lattice with high spatial and temporal resolution. Skyrmions in low-pinning thin-film systems offer tunability of their size and effective temperature [2,3], allowing us to controllably drive the phase transitions.

Our results reveal the emergence of an intermediate hexatic phase and identify topological defects as the key feature of the melting. We provide new insight into 2D melting dynamics and measure a dislocation diffusion coefficient orders of magnitude higher than skyrmion diffusion. This work highlights skyrmions as a versatile platform for studying phase behavior in 2D systems

Imaging Topological Defect Dynamics Mediating 2D Skyrmion Lattice Melting — Maarten A. Brems[1], Tobias Sparmann[1], •Simon M. Fröhlich[1], Leonie-C. Dany[1], Jan Rothörl[1], Fabian Kammerbauer[1], Elizabeth M. Jefremovas[1], Oded Farago[2], Mathias Kläui[1], and Peter Virnau[1] — [1]Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Ger many — [2]Biomedical Engineering Department, Ben Gurion University of the Negev, Be'er Sheva 84105, Israel

We demonstrate fully quantitative Thiele model simulations of magnetic skyrmion dynamics on previously unattainable experimentally relevant large length and time scales by ascertaining the key missing parameters needed to calibrate the experimental and simulation time scales and current-induced forces. Our work allows us to determine complete spatial pinning energy landscapes that enable quantification of experimental studies of diffusion in arbitrary potentials within the Lifson-Jackson framework. Our method enables us to ascertain the time scales, and by isolating the effect of ultra-low current density (order 10^6 A/m^2) generated torques we directly infer the total force acting on the skyrmion for a quantitative modelling. [2]

MA 29.9 Wed 17:15 H20

The dynamics of skyrmion shrinking — •Frederik Austrup[1], Wolfgang Häusler[2], Michael Lau[1], and Michael Thorwart[1] — [1]I. Institut für Theoretische Physik, Universität Hamburg — [2]Institut für Physik, Universität Augsburg

When magnetic skyrmions decay, their size in real space decreases in a finite time before they eventually collapse. We derive a continuum model to describe the shrinking behavior of skyrmions before they collapse. Using the Landau-Lifshitz-Gilbert equation and the time derivative of the vectorfield, we find a set of coupled nonlinear ordinary differential equation for the time dependent skyrmion radius and helicity. In particular, we use a triangular-shaped skyrmion profile of its polar angle. Contrary to the commonly expected simple exponential decrease in size, we reveal a more complicated time dependence, where the time-dependent radius crosses over from an exponential decay towards a square root decrease, $\sim (t - t_c)^{1/2}$, near a critical time t_c at which it collapses. This critical time is found to depend logarithmically on the lattice constant. Additionally, we present studies examining the interplay between the shrinking and a transformation through different skyrmion configurations, depending on the various system parameters. The findings are accompanied by numerical studies, supporting the predictions from the theoretical continuum model.

MA 29.10 Wed 17:30 H20

Effects of chiral polypeptides on skyrmion stability and skyrmion diffusion — Fabian Kammerbauer[1], Yael Kapon[2], •Theo Balland[1], Shira Yochelis[2], Sachin Krishnia[1], Yossi Paltiel[2], and Mathias Kläui[1] — [1]Institut für Physik, Johannes-Gutenberg-Universität Mainz, 55099 Mainz, Germany — [2]Institute of Applied Physics, Faculty of Sciences, The Hebrew University of Jerusalem, Jerusalem 9190401, Israel

CISS, chirality-induced spin selectivity is a phenomenon that has raised significant interest due to the large spin polarizations generated by organic molecules and other effects such as magnetic switching of ferromagnets induced by chiral molecules [1]. In hybrid systems, these chiral molecules have been observed to influence magnetic properties such as changes in the magnetization [2]. In this study, we investigate how chiral molecules of α-helix polyalanine interact with chiral spin structures, namely magnetic skyrmions, which are stabilized in ferromagnetic/heavy metal multilayers due to Dzyaloshinskii-Moriya interaction [3]. Using magneto-optic Kerr effect imaging, we show that chiral polypeptides can influence the stability of skyrmions by modifying the ranges of temperature and applied magnetic field in which they are stable. We also show that the chiral molecules affect the skyrmion dynamics, in particular the thermal diffusion of the skyrmions [4].

Interactions between Skyrmions with various topological charges — •László Udvardi and Mátyás Török — Department of Theoretical Physics, Budapest University of Technology and Economics, Budapest, Hungary

Magnetic Skyrmions exhibit intriguing and novel phenomena due to their topologically non-trivial spin textures. Their exceptional stability makes them possible candidates for information carriers for future spintronic devices.

We have determined the parameters appearing in a classical spin model from first principle for a FePd bilayer on Ir(111) and $Pt_{95}Ir_{05}$/Pd(111) overlayer. Optimizing the energy of the spin model several local minima have been identified as a Skyrmion with various topological charges. We demonstrate that the frustration of the isotropic exchange interactions is responsible for the creation of these various types of skyrmionic structures. We focused on objects with topological charge of Q=-1 (Skyrmion) and Q=1 (anti Skyrmion) and explored the interactions between them. We found that although the interaction between Skyrmions with Q=-1 is always repulsive it has attractive part between anti Skyrmions. The excitation of an isolated Skyrmion and a lattice has been also investigated.

MA 29.12 Wed 18:00 H20

RC circuit based on magnetic skyrmions — •Ismael Ribeiro de Assis, Ingrid Mertig, and Börge Göbel — Institut für Physik, Martin-Luther-Universität Halle-Wittenberg

Skyrmions are nano-sized magnetic whirls attractive for spintronic applications due to their innate stability. They can emulate the characteristic behavior of various spintronic and electronic devices such as spin-torque nano-oscillators, artificial neurons and synapses, logic devices, diodes, and ratchets. Here, we show that skyrmions can emulate the physics of an RC circuit*the fundamental electric circuit composed of a resistor and a capacitor*on the nanosecond time scale. The equation of motion of a current-driven skyrmion in a quadratic energy landscape is mathematically equivalent to the differential equation characterizing an RC circuit: the applied current resembles the applied input voltage, and the skyrmion position resembles the output voltage at the capacitor. These predictions are confirmed via micromagnetic simulations. We show that such a skyrmion system reproduces the characteristic exponential voltage decay upon charging and discharging the capacitor under constant input. Furthermore, it mimics the low-pass filter behavior of RC circuits by filtering high-frequencies in periodic input signals. Since RC circuits are mathematically equivalent to the Leaky-Integrate-Fire (LIF) model widely used to describe biological neurons, our device concept can also be regarded as a perfect artificial LIF neuron.

MA 29.13 Wed 18:15 H20

Intrinsic non-reciprocity in skyrmion dynamics in synthetic antiferromagnet — •Mona Bhukta[1], Takaaki Dohi[1], Fabian Kammerbauer[1], Maria-Andromachi Syskaki[1,2], Duc Minh Tran[1], Markus Weigand[3], Sebastian Wintz[3], Simone Finizio[4], Jörg Raabe[4], Robert Frömter[1], and Mathias Kläui[1] — [1]Institut für Physik, Johannes Gutenberg-Universität Mainz, Staudingerweg 7, 55128 Mainz, Germany — [2]Singulus Technologies AG, 63796 Kahl am Main, Germany. — [3]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, 14109 Berlin, Germany — [4]Paul Scherrer Institut, Swiss Light Source, Forschungsstrasse 111 5232 PSI Villigen, Switzerland.

In this work, we investigate the dynamics of isolated AFM skyrmion tubes in synthetic antiferromagnetic (SyAFM) multilayers composed of 30-50 ferromagnetic (FM) layers, antiferromagnetically coupled via the interlayer exchange interaction. Using element-specific time-resolved scanning transmission X-ray mi-

croscopy (STXM), we demonstrate the current-induced dynamics of the resulting AFM skyrmions. In uncompensated SyAFM, we observe a current-polarity-dependent, non-reciprocal skyrmion Hall effect of individual AFM skyrmions, arising from the unique intrinsic properties of the hybrid chiral skyrmion tubes in the flow regime. This nonreciprocity can be tuned by the degree of magnetic compensation and vanishes in highly compensated SyAFM [1]. References [1] T. Dohi, M. Bhukta, et al., Observation of a non-reciprocal skyrmion Hall effect of hybrid chiral skyrmion tubes in synthetic antiferromagnetic multilayers,arxiv (2024).

MA 29.14 Wed 18:30 H20

Hybrid magnonic crystal based on skyrmions — •Krzysztof Szulc[1,2], Mateusz Zelent[2], and Maciej Krawczyk[2] — [1]Institute of Molecular Physics, Polish Academy of Sciences, Poznań, Poland — [2]ISQI, Faculty of Physics and Astronomy, Adam Mickiewicz University, Poznań, Poland

We study a hybrid magnonic crystal consisting of a Py waveguide over which the periodic chain of Co/Pt dots is placed [K. Szulc et al. arXiv:2404.10493]. In the dots, the Dzyaloshinskii-Moriya interaction is present, thus it is possible to stabilize the single-domain state and the skyrmion state. We show that the dispersion relation changes with the change of the magnetization configuration of the dot. The sizes of bandgaps significantly differ in these systems. Due to different character of excitation of the both states, the system with skyrmions in dots can interact with the waveguide at lower frequencies or even be excited below the frequencies of the waveguide. Furthermore, I show that one part of the skyrmion modes hybridize with the waveguide modes, sometimes inducing additional band gaps in the spectrum, while the second part does not interact, forming bound states. Such a system of waveguide coupled to the chain of dots forms a reconfigurable spin-wave platform which can be used in spin-wave filtering and artificial neural networks.

MA 30: Bulk Materials: Soft and Hard Permanent Magnets

Time: Wednesday 16:00–18:00 Location: H18

Invited Talk MA 30.1 Wed 16:00 H18

Boosting Coercivity in Additively Manufactured Magnets Through Nano-Functionalization of NdFeB Powder — •Anna Ziefuss — Technical Chemistry I and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg Essen, 45141 Essen, Germany

Permanent magnets are indispensable in the 21st century, powering applications in energy generation, transportation, and telecommunications. However, the high cost of rare-earth magnets, their supply, and availability represent critical factors, and novel technologies that avoid or minimize the use of such rare elements in permanent magnets need to be developed immediately. Additive manufacturing (AM) offers a promising solution by enabling complex structures with minimal material waste, reducing rare-earth usage. Yet, the successful printing of magnetic powders remains challenging, as printed magnets often exhibit brittleness and low magnetic properties. This contribution highlights how nanotechnology-driven innovations address limitations in additive manufacturing, unlocking the potential of printed magnets for sustainable, high-performance applications. Nano-functionalization emerges as a crucial approach to enhancing coercivity in additively manufactured magnets, emphasizing the importance of understanding the entire process chain - from nanoparticle production and feedstock modification to evaluating printed magnet properties.

MA 30.2 Wed 16:30 H18

Strategies for Nd-Fe-B Magnet Recycling in a Circular Economy — •Aybike Paksoy[1], Amrita Khan[1], Abdullatif Durgun[1], Mario Schönfeldt[1,2], Mahmudul Hasan[2], Iliya Radulov[2], Jürgen Gassmann[2], Imants Dirba[1], and Oliver Gutfleisch[1] — [1]TU Darmstadt, Department of Materials and Geosciences, Functional Materials, Peter-Grünberg-Str. 16, 64287 Darmstadt, Germany — [2]Fraunhofer IWKS, Fraunhofer Research Institution for Materials Recycling and Resource Strategies, Aschaffenburger Str. 121, 63457 Hanau, Germany

Nd-Fe-B magnets have the highest energy product (BH)max at room temperature, making them the preferred material for various applications. However, their reliance on critical rare earth elements raises significant environmental, economic, and geopolitical challenges, particularly due to China's dominance as the primary global supplier. Both industry and academia are increasingly focusing on recycling end-of-life Nd-Fe-B permanent magnets.For an environmentally friendly product, it is necessary to reduce the criticality and increase the sustainability of rare earth permanent magnets [1]. We compare three advanced recycling routes to produce sustainable Nd-Fe-B magnets without sacrificing their performance. Scrap magnet material is processed via the hydrogen-assisted magnet-to-magnet route as well as the nanocrystalline hot pressing route and spark plasma sintering. The resultant magnetic properties and microstructure are systematically studied comparing the advantages and disadvantages of each process. [1] M. Schönfeldt et al., J. Alloys and Compounds (2023)

MA 30.3 Wed 16:45 H18

3D magnetic of interaction domains in nanostructured Nd-Fe-B using X-ray imaging techniques — •P. Klassen[1], D. Günzing[2], A. Aubert[3], T. Feggeler[4], B. Eggert[1], J. Neethirajan[5], L. Schäfer[3], F. Maccari[3], M. Guizar-Sicairos[6,7], V. Scagnoli[8,6], M. Holler[6], D. Shapiro[2], A. Ditter[2], E. Bruder[3], H. Wende[1], K. Skokov[3], O. Gutfleisch[3], C. Donnelly[5], and K. Ollefs[1] — [1]Fac. of Phys., UDE, Duisburg GER — [2]LBNL, ALS, CA US — [3]Mat. Sc., TU Darmstadt GER — [4]BNL, NSLS-II, NY US — [5]MPI CPfS, Dresden GER — [6]PSI, SLS, Villigen CH — [7]Inst. of Physics, EPFL, Lausanne CH — [8]Dep. of Mat., ETH Zürich CH

Nd-Fe-B magnets play a key role in sustainable energy conversion, for example in wind turbines or electric motors, due to their superior magnetic performance and high energy density. Here, we provide insights into the 3D magnetic domain structure of (therm.) demagnetized nanostructured Nd-Fe-B magnets obtained by X-ray ptychography and tomography at room temperature. We have imaged the magnetic interaction domains inside a hot-deformed, anisotropic, nanocrystalline Nd2Fe14B magnet to correlate the crystal and microstructure and the configuration of the magnetic moments. The combination of hard and soft X-rays enables the comparison of the domain structure between bulk and lamellae and provides detailed insights into the complex magnetic structure in deeper sections of the magnet and down to individual grains, which can be shown to partly exhibit a single-domain state. We gratefully acknowledge funding from the DFG via CRC/TRR 270.

MA 30.4 Wed 17:00 H18

Combined theoretical and experimental study of magnetic properties of Fe-Sn intermetallics — •Martin Friák[1], Petr Čípek[1,2], Pavla Roupcová[1], Oldřich Schneeweiss[1], Jana Pavlů[2], Dominika Fink[3], Šárka Msallamová[3], and Alena Michalcová[3] — [1]Inst. Phys. Mater., Czech Acad. Sci., Brno, Czech Rep. — [2]Dept. Chem., Masaryk Uni., Brno, Czech Rep. — [3]Dept. Metal Corr. Eng., Uni. Chem. Technol. Prague, Czech Rep.

There are conflicting literature reports related to Fe-Sn intermetallic phases, when, for example, the $FeSn_2$ phase is theoretically predicted to be dynamically unstable due to imaginary phonon modes (see, e.g, C.-J. Yu et al., New J. Chem. 44 (2020) 21218, DOI:10.1039/d0nj04537c). We have, therefore, performed a combined theoretical and experimental study of both $FeSn_2$ and FeSn intermetallics. The theoretical part consists of quantum-mechanical calculations of ground-state properties, including structural, vibrational and magnetic properties. Computing phonon modes allowed for testing the dynamic stability and the thermodynamic properties were subsequently assessed using quasi-harmonic approximation (QHA). The $FeSn_2$ phase is computed stable, i.e., free of imaginary phonon modes. We have also characterized Fe-Sn phases using Mössbauer measurements of magnetic properties, including a temperature-dependent Mössbauer factor, which we compared with theoretical results based on quantum-mechanical calculations of thermal vibrations.

MA 30.5 Wed 17:15 H18

Pr-Fe-B hot deformed magnets for low-temperature applications — •Priyatosh Sahoo[1], Alex Aubert[1], Fernando Maccari[1], Yuye Wu[2], Konstantin Skokov[1], and Oliver Gutfleisch[1] — [1]Technische Universität Darmstadt, Germany — [2]Beihang University, China

Nd-Fe-B based PMs are the most prevalent in various applications due to their high coercivity and remanence, which result in exceptional energy product values near room temperature. However, their performance significantly diminishes below 135 K due to Spin Reorientation Transition (SRT). In contrast, when Nd is substituted by Pr, these magnets do not exhibit such transitions at low temperatures, making them preferable for cryogenic applications such as space industry. In our study, we compared the low-temperature performance of Pr17Fe76.5Cu1.5B5 and Nd17Fe76.5Cu1.5B5 hot deformed (HD) magnet. The microstructure of HD magnets consists of grains in the range of the critical single domain particle size of these systems, i.e., 200-300 nm, which enhances coercivity without the necessity of adding heavy rare earth elements. We conducted a comprehensive analysis that examined intrinsic magnetic properties based on single crystal studies and the transition to extrinsic properties through microstructure engineering along the hot deformation process. Additionally,

we explored the effect of doping Pr-Fe-B with Cu in the hot deformation process and correlated its influence on the magnetic properties and microstructure. We acknowledge Deutsche Forschungsgemeinschaft's (DFG) funding within the CRC/TRR 270 (Project-ID 405553726).

MA 30.6 Wed 17:30 H18

Peculiar low-temperature properties in the ferromagnetic pyrochlore metal $LuInCo_4$ — •Taiki Shiotani[1], Hiroyuki Nakamura[1], and István Kézsmárki[2] — [1]Department of Materials Science and Engineering, Kyoto University, Kyoto 606-8501, Japan — [2]Experimental Physics V, Institute of Physics, University of Augsburg, D-86159, Augsburg, Germany

The pyrochlore lattice, a network of corner-sharing tetrahedra, is attracting attention due to geometrical frustration as well as nontrivial topology of the band structure. $LuInCo_4$ is C15b-type laves phase compound with a Co-based pyrochlore sublattice. We have successfully synthesized single crystals of $LuInCo_4$ and found strong ferromagnetism with the T_C = 306 K [1]. The ferromagnetic nature was reproduced by density functional theory calculations, suggesting that Co-3d flat bands near the fermi level induce the spin polarization. The magnetization has no detectable anisotropy down to ≈100 K, below which the anisotropy gradually becomes stronger with the cubic 100-type axes being the easy-axes. For fields applied along the cubic 111-type directions the material goes through a metamagnetic transition.

Here, we will focus on the low-temperature phase of $LuInCo_4$ to discuss the origin of the anomalous behavior of the magnetization.

MA 30.7 Wed 17:45 H18

Laser powder bed fusion of hard magnetic composites — •Kilian Schäfer — Functional Materials, Institute of Material Science, Technical University of Darmstadt

Hard magnetic materials are essential for advancing carbon-neutral technologies and medical devices. While traditional manufacturing methods suit large, simple magnets, there is increasing demand for resource-efficient processes to create intricate small magnetic components. Additive manufacturing offers a promising solution, enabling the production of complex, tailored magnetic components with improved efficiency. This study explores composites made via laser powder bed fusion, combining hard magnetic powders with polyamide and thermoplastic polyurethanes. It examines how the magnetic powder*s fraction, morphology, and particle size impact performance. Results show that anisotropic magnetic properties can be achieved with specific powder particle shapes. Additionally, localized mechanical properties were achieved by adjusting laser parameters, enabling the production of magnetically controllable actuators for applications like biomedical devices. These findings provide guidelines for optimizing hard magnetic composite performance using laser powder bed fusion.

MA 31: Poster II

Time: Wednesday 17:00–19:30 Location: P1

MA 31.1 Wed 17:00 P1

Near-Room-Temperature Compensation Temperature In Terbium Iron Garnet Thin Films — •Mehak Loyal, Akashdeep Akashdeep, Mathias Kläui, and Gerhard Jakob — Institute of Physics, Johannes Gutenberg University Mainz, Staudingerweg 7, 55128 Mainz, Germany

Rare-earth iron garnets (REIGs) with perpendicular magnetic anisotropy (PMA) have emerged as promising materials for spintronic applications. The compensation temperature (T_{comp}), where the net magnetization for the ferrimagnet becomes zero, plays a crucial role in determining potential application. While bulk REIGs have a T_{comp} well below room temperature, researchers have shown that it can be tuned in thin films. $Tb_3Fe_5O_{12}$ (TbIG) with bulk compensation temperature ~240 K, in particular has gained interest as recent report shows a near-room-temperature T_{comp} for TbIG thin films.

We investigate the factors that tune the compensation temperature (T_{comp}) of TbIG thin films to near-room-temperature. This would have significant implications for the development of spintronics applications, potentially enabling more efficient and stable operation at ambient conditions. PMA TbIG thin films are deposited on (111)-oriented $Gd_3Ga_5O_{12}$ (GGG) substrates using pulsed laser deposition (PLD). The magnetization reversal of TbIG thin films at different temperatures are probed using transverse magneto-resistance measurement. The study contributes to the broader understanding of REIGs and paves the way for integration into practical spintronic applications.

MA 31.2 Wed 17:00 P1

Polarized inelastic neutron scattering studies on magnetic excitations in the SDW ordered state of qasi 2D $Sr_{1.5}Ca_{0.5}RuO_4$ — •Felix Wirth[1], Yvan Sidis[2], Paul Steffens[3], and Markus Braden[1] — [1]II. Physic. Inst., Univ. Cologne, Germany — [2]LLB, CEA Saclay, France — [3]ILL, Grenoble, France

Superconductivity in the layered ruthenate Sr_2RuO_4 emerges near competing magnetic fluctuations. The different d orbitals of Ru^{4+} give rise to the multiband structure causing spin fluctuations with incommensurate (IC) propagation vector due to fermi-surface nesting. These antiferromagnetic fluctuations are anisotropic and condensate to static spin density wave (SDW) order with moments oriented along c when Sr is replaced by 25 % of isovalent Ca. Only a few realizations of SDW in metals have been studied concerning their magnetic excitations. Cr exhibits strong anisotropy as well as new excitations like the Fincher-Buke mode, while the spin-orbit coupling (SOC) is much smaller than in $Sr_{1.5}Ca_{0.5}RuO_4$. This renders it an ideal material for studying SDW state in the presence of SOC. Our contribution presents inelastic polarized neutron scattering measurements on the IC SDW signal. With scattering vector within the layer, we discriminated between transversal and longitudinal excitations. We see longitudinal or c-polarized spectral weight enhancement at low energy. At the same time, the transversal or in-plane response is suppressed over a broad temperature range and exhibits single-relaxor behavior like in the pure compound. SOC induces strong anisotropy in the magnetic fluctuations in $Sr_{1.5}Ca_{0.5}RuO_4$.

MA 31.3 Wed 17:00 P1

Structural and magnetic properties of Bi-bonded Mn-Al-C-Ti magnets — •Semih Ener, Fernando Maccari, Konstantin P. Skokov, and Oliver Gutfleisch — Functional Materials, Technical University of Darmstadt, Peter-Grünberg-Str. 16, D-64287, Darmstadt, Germany

In this study, the influence of Ti doping on the phase formation and magnetic properties of Mn-Al-C-Ti alloys is investigated. The alloys were synthesized by melt spinning followed by thermal treatment to obtain the ferromagnetic τ-phase, which was determined to be 20 min at 550 °C for all Ti compositions.

However, the Ti-doped samples exhibited β-phase formation due to partial phase decomposition, with TiC precipitates observed at higher Ti concentrations. Doping resulted in an increase in the Curie temperature from 557 K in the undoped sample to 600 K in the Ti-doped samples.

In order to increase the coercivity, a combination of ball milling and hot compaction was used along with the introduction of Bi as a metallic binder. This resulted in an increase in coercivity, from 0.18 T to 0.33 T, as the addition of Bi facilitated the formation of a grain boundary phase, which aided in densification. This work demonstrates how compositional and processing modifications can be used to improve the magnetic properties of Mn-Al based magnets.

MA 31.4 Wed 17:00 P1

Comparative study on magenetical and structural properties Mn_3XC (X=Sn,Ga,In,Zn) antiperovskites — •Lennart Endler, Benedikt Eggert, Katharina Oleffs, Mehmet Acet, and Heiko Wende — Faculty of Physics and CENIDE, University of Duisburg-Essen

The family of Mn_3XC antiperovskites shows a wide variety of properties ranging from large magnetocaloric effects, giant magnetoresistance to negative thermal expansion [1], which makes them an interesting material class for researchers and industry. Starting with ternary compounds, we also investigate the effect of multiple elements on the X-site, as done for perovskite oxides in the past, revealing a correlation between Neel temperature and Goldschmidt tolerance factor and therefore the chosen elements [2]. For the chemical, structural and magnetic characterisation, we have used EDX, X-ray diffraction, magnetometry and if possible ^{119}Sn Mössbauer spectroscopy. Based on the analysis of the ternary compounds prepared by solid state reaction, the foundation for a comparison to medium and high entropy Mn-antiperovskites is held to further explore and potentially control their properties.

We acknowledge the financial support through the Deutsche Forschungsgemeinschaft wihtin the framework of the CRC/TRR270 HoMMage (Project 405553726-TRR270).

MA 31.5 Wed 17:00 P1

Effect of Ni addition to Fe-B-Si-Nb alloy on magnetic and thermal properties — •Purbasha Sharangi[1], Uma Rajput[2], Amirhossein Ghavimi[2], Ralf Busch[2], Isabella Gallino[3], Gabriele Barrera[1], Enzo Ferrara[1], and Paola Tiberto[1] — [1]INRIM, Istituto Nazionale di Ricerca Metrologica, Strade delle Cacce, 5, 10135 Torino, Italy. — [2]Saarland University, Chair of Metallic Materials, Campus C6.3 66123, Saarbrücken, Germany — [3]Technical University of Berlin, Chair of Metallic Materials, Ernst-Reuter Platz 1, 10587 Berlin, Germany

The next generation of electrical equipment, such as motors and generators, and power electronics, depend heavily on soft magnetic materials. It has been reported that the addition of Ni to Fe-Si-B-Nb BMGs has shown significant improvements in both their soft magnetic properties and plasticity. Fe-based BMGs that incorporate Ni exhibit a good glass forming ability (GFA), reasonable soft magnetic properties and improved mechanical performance. In this work we have investigated the effect of Ni addition and annealing on the microstructural, thermal and magnetic properties of Fe-B-Si-Nb alloy. It has been observed that the GFA is improved from 800 μm to almost 1000 μm upon the addition of 2 to 5 at. % Ni. A slight increment in saturation magnetization and reduction in coercive field have been observed with increasing the Ni% for the as cast ribbons. Further, the soft magnetic properties improve significantly in the form of reduced coercivity and energy losses after annealing the ribbons at 320 $^{\circ}$C for 2 hours due to the relief of frozen-in stresses.

MA 31.6 Wed 17:00 P1

A materials library for cryogenic magnetocaloric cooling — •T. Gottschall, E. Bykov, M. Strassheim, T. Niehoff, C. Salazar-Mejía, and J. Wosnitza — Helmholtz-Zentrum Dresden-Rossendorf, Dresden High Magnetic Field Laboratory (HLD), Dresden, Germany

Magnetic cooling is a refrigeration technique that is based on the so-called magnetocaloric effect, the change of temperature caused by a magnetic field. It can be utilized to construct environmentally friendly cooling devices, air conditioners, and heat pumps. Originally, magnetic cooling was used to achieve ultra-low temperatures near absolute zero. Recently, low temperatures have once again become the focus of attention as an area of application for magnetocaloric cooling namely for efficient hydrogen liquefaction. In this contribution, we will present our materials library for cryogenic applications. The basis for this is our research infrastructure at the Dresden High Magnetic Field Laboratory, which includes both static and pulsed fields. Our aim is to gain a better understanding of the magnetocaloric materials required for the cooling process, to provide consistent data sets for simulations, and to drive magnetic hydrogen liquefaction forward making it an energy efficiency alternative to conventional technology.

MA 31.7 Wed 17:00 P1

Inverse magnetocaloric effect in Tb_3Ni: So hot right now — •T. Niehoff[1,2], B. Beckmann[3], K. Skokov[3], A. Herrero[4], A. Oleaga[5], M. Strassheim[1,2], T. Wosnitza[1,2], and T. Gottschall[1] — [1]Dresden High Magnetic Field Laboratory (HLD-EMFL), HZDR, Dresden, Germany — [2]Institut für Festkörper- und Materialphysik, TU Dresden, Dresden, Germany — [3]Institut für Materialwissenschaft, TU Darmstadt, Darmstadt, Germany — [4]Departamento de Física Aplicada, UPV/EHU, Vitoria-Gasteiz, Spain — [5]Departamento de Física Aplicada, UPV/EHU, Bilbao, Spain

The magnetocaloric effect (MCE) is a cornerstone of promising, environmentally friendly cooling technologies, particularly for cryogenic applications. In this presentation, we use Tb_3Ni as a case study, previously reported to exhibit a strong inverse MCE at very low temperatures based on magnetization measurements. By comparing these findings with other techniques, we show that neither Tb_3Ni nor similar materials with metamagnetic transitions from antiferromagnetic to ferromagnetic exhibit the predicted inverse effect. To support our claims and further investigate the MCE, we conducted specific-heat measurements and direct T_{ad} in pulsed-field experiments. These reveal no effects, while the pulsed-field data even show a significant positive effect, which we attribute to dissipative heating. Our findings highlight the importance of using complementary measurement techniques to accurately characterize the MCE and fully understand the behavior of these materials.

MA 31.8 Wed 17:00 P1

Design of $Cr_xFe_{1-x}MnCoNiGeSi$ high-entropy alloy with large barocaloric effect — •Yong Guo[1,2], Yuanyuan Gong[1], Tingting Zhang[1], Zhishuo Zhang[1], Bin Chen[1], Fenghua Chen[3,4], Zhengyi Jiang[4], Feng Xu[1], and Luana Caron[2,5] — [1]MIIT Key Laboratory of Advanced Metallic and Intermetallic Materials Technology, School of Materials Science and Engineering, Nanjing University of Science and Technology , Nanjing 210094, PR China — [2]Faculty of Physics, Bielefeld University, Bielefeld 33501, Germany — [3]School of Materials Science and Engineering, Taiyuan University of Science and Technology, Taiyuan 030024, PR China — [4]School of Mechanical, Materials, Mechatronic and Biomedical Engineering, University of Wollongong, Wollongong, NSW 2522, Australia — [5]Helmholtz-Zentrum Berlin für Materialien und Energie, 12489 Berlin, Germany

This paper presents a high-entropy system exhibiting a large barocaloric effect. Experimental results confirm that equiatomic FeMnCoNiGeSi and CrMnCoNiGeSi are high-entropy solid-solutions with hexagonal and orthorhombic structures at room temperature, respectively. Further tuning Fe/Cr ratio in $Cr_xFe_{1-x}MnCoNiGeSi$ establishes a thermal-induced hexagonal-orthorhombic structural transformation. For the alloy with $x = 0.44 - 0.50$, the structural transformation occurs at room temperature and can be induced by hydrostatic pressure. The barocaloric effect reaches -30.6 J/kgK for a pressure change from 5 to 0 kbar, and the entropy change per kbar is comparable to widely studied intermetallic compounds.

MA 31.9 Wed 17:00 P1

Collective out-of-plane stripe domain magnetization reversal via a single point of irreversibility — •Peter Heinig[1,2], Ruslan Salikhov[2], Fabian Samad[1,2], Lorenzo Fallarino[2,3], Attila Kákay[2], Nikolai S. Kiselev[4], and Olav Hellwig[1,2] — [1]Chemnitz University of Technology — [2]Helmholtz-Zentrum Dresden-Rossendorf — [3]CIC energiGUNE — [4]Forschungszentrum Jülich

Periodic stripe domain structures in thin films with perpendicular magnetic anisotropy are well-studied, however, the detailed field reversal of such systems in the transition regime between in-plane (IP) and out-of-plane (OOP) magnetization remains intriguing, with unexpected effects. In particular, the $[Co(3.0\ nm)/Pt(0.6\ nm)]_X$ multilayer system undergoes this transition[1]. We examine samples with $X = 10$ and $X = 11$ repetitions, which display a remanent state with both significant OOP as well as IP magnetization components, here referred to as the "tilted" stripe domain state[1,2]. Using vibrating sample magnetometry, magnetic force microscopy, and micromagnetic simulations, we analyze the unusual OOP field reversal behavior, which is characterized by a single point of irreversibility and parallel stripe domains at remanence. While these two characteristics seem at first sight mutually exclusive, we will reveal how they still can evolve simultaneously. In addition to the unusual OOP reversal, we also observe a significant IP angular dependence of the susceptibility around remanence induced by the parallel stripe domain alignment.

MA 31.10 Wed 17:00 P1

Epitaxy and Magnetic Properties of Fe films on GaAs(001) in Dependence of the Electrodeposition Procedure — •Danny P. Quint[1], Raphael Kohlstedt[2,3], Olav Hellwig[2,3], and Karin Leistner[1] — [1]Institute of Chemistry, TU Chemnitz — [2]Institute of Physics, TU Chemnitz — [3]Research Center MAIN, TU Chemnitz

Epitaxial Fe/GaAs heterostructures are of great interest for spintronic devices.[1] The quality of the epitaxial growth is crucial for the functionality. While MBE is traditionally used to fabricate Fe/GaAs structures, electrodeposition (ED) offers a cost-efficient alternative. [2,3] We systematically examined the impact of an initial voltage pulse during ED of Fe films (approx. 20 nm thick) on GaAs(001) on their epitaxy and magnetic behavior. We compare depositions without a pulse (A), with a pulse after immersion in the electrolyte (B), and with a pulse during immersion in the electrolyte (C). The angle-dependent ferromagnetic resonance field, remanence and coercivity of the deposited films were analyzed by in-plane FMR and MOKE, respectively. The results show an enhanced fourfold anisotropy for the films prepared with the pulsed routines, with method C approaching the expected behavior for dominating cubic magnetocrystalline anisotropy in epitaxial Fe(001) films. The quality of epitaxial growth is investigated by X-ray diffraction. This work highlights the importance of optimizing the ED procedure to achieve epitaxial Fe films on GaAs and opens pathways for the broader application of ED in spintronic materials research.

MA 31.11 Wed 17:00 P1

Pt-catalyzed hydrogen magneto-ionics in Co/Pd multilayers — •Felix Engelhardt[1,2], Rico Ehrler[1,2], Olav Hellwig[1,2], Karin Leistner[1,2], and Markus Gössler[1] — [1]Chemnitz University of Technology, D-09107 Chemnitz, Germany — [2]Research Center MAIN, D-09126 Chemnitz, Germany

Magneto-ionics, which is the electrochemical reconfiguration of magnetic materials at low gating voltages, offers a highly energy-efficient method to control magnetism. One major issue of this mechanism, however, is its response time, which is limited by the timescale of the electrochemical reactions. Here, we demonstrate that the hydrogen-based magneto-ionic effect in sputtered Co/Pd multilayers [1] can be accelerated catalytically via an additional Pt layer at the surface.

We investigate how the thickness of such a Pt overlayer affects the magneto-ionic effect strength and hydrogen insertion kinetics in the Co/Pd multilayer system. To analyze these effects, we use in-situ MOKE microscopy to monitor the magneto-ionic behavior, while flow-cell coulometry measurements are carried out to quantify the hydrogen concentration in the multilayers.

Our findings reveal that a Pt overlayer with a thickness of 0.5-2 nm significantly enhances the strength of the magneto-ionic effect by a factor of 2, while also reducing the time required for hydrogen insertion by a factor of 10. Our results highlight a route towards faster switching speeds in magneto-ionic devices, which is crucial for future magnetic memory applications.

MA 31.12 Wed 17:00 P1

Investigating Micromagnetic Structures in Dy-Fe Ferrimagnetic Thin Films — •Pranati Parui[1], Tamer Karaman[1], Felix Büttner[1,2], and Manfred Albrecht[1] — [1]University of Augsburg, Augsburg, Germany — [2]Helmholtz-Zentrum Berlin, Berlin, Germany

Ferrimagnetic thin films present a unique platform for studying emergent spin textures and magnetic phenomena due to the interplay between the transition-metal and rare-earth sublattices. Here, we investigate ferrimagnetic Dy-Fe alloy thin films, which exhibit a broad spectrum of magnetic properties that are highly sensitive to composition and temperature. Despite their potential, a systematic investigation of Dy-Fe thin films remains unexplored. This work focuses on the sputter deposition of thin films with varying compositions and employs comprehensive characterization techniques, including SQUID magnetometry, magneto-optical Kerr effect (MOKE) measurements, magnetic force microscopy (MFM), and Lorentz transmission electron microscopy (LTEM), to unravel their micromagnetic structures, domain patterns, and domain wall chirality.

MA 31.13 Wed 17:00 P1

Detecting correlation between surface and interface magnetism of Mn/Fe thin film heterostructures on the atomic scale — •Toshio Miyamachi[1,2], Shuhei Nakashima[1], Yasumasa Takagi[3], Toshiohiko Yokoyama[3], and Fumio Komori[1] — [1]ISSP, The University of Tokyo, Japan — [2]IMaSS, Nagoya University, Japan — [3]Institute for Molecular Science, Japan

The magnetic coupling between ferromagnetic (FM) and antiferromagnetic (AFM) layers has been the focus of interest for magnetic multilayer devices. The fundamental magnetic properties of FM/AFM magnetic multilayers, e.g., magnetic moment, magnetic anisotropy rely much on their interfacial structural and electronic properties. In this work, we investigated structural, electronic and magnetic properties of AFM/FM Mn/Fe thin film heterostructures grown on Cu(001) by spin-polarized scanning tunneling microscopy (Sp-STM) and x-ray absorption spectroscopy/x-ray magnetic circular dichroism (XAS/XMCD) [1]. With the help of surface sensitivity of SP-STM and element specificity of XAS/XMCD, electronic and magnetic properties of surface Mn and interface Fe layers were separately investigated. Sp-STM measurements revealed a new type of surface magnetic structures of Mn layers, which could be interpreted in term of the magnetic coupling with underlying Fe layers.

MA 31.14 Wed 17:00 P1

Integration of a dual broadband characterization setup for time-resolved magneto-optical spectroscopy — •Richard Leven, Sophie Bork, David Gutnikov, Umut Parlak, and Mirko Cinchetti — Department of Physics, TU Dortmund, 44227 Dortmund, Germany

We present a recently developed setup for broadband ultrafast magneto-optical pump-probe spectroscopy, optimized for operation at low temperatures and high magnetic fields. The setup utilizes a broadband supercontinuum (white light) probe beam, spanning wavelengths from the near UV to the near IR region. Two independent CMOS detector arrays enable simultaneous data acquisition across all available wavelengths, providing comprehensive insights into transient reflectivity ($\Delta R/R$) and polarization rotation ($\Delta\theta$) measurements in a single experiment. The system operates at variable repetition rates, ranging from <10 kHz to ~100 Hz, combining the precision of a femtosecond laser source with high sensitivity for low-light conditions. To validate the setup, we conduct experiments on the semiconducting antiferromagnet CrSBr, ensuring the spectrum encompasses the material's bandgap and exciton excitation energies. This poster will detail the technical specifications of the setup, its characterization results, and its performance benchmarks, highlighting its potential for studying ultrafast dynamics in a variety of magnetically ordered systems.

MA 31.15 Wed 17:00 P1

Element-resolved study of antiferromagnetic/ferromagnetic magnetization dynamics in epitaxial CoO/Fe bilayer — •Chowdhury Shadman Awsaf[1], Sangeeta Thakur[1], Markus Weissenhofer[2], Jendrik Gördes[1], Marcel Walter[1], Niko Pontius[3], Christian Schüssler-Langeheine[3], Peter Oppeneer[2], and Wolfgang Kuch[1] — [1]Institut für Experimentalphysik, Freie Universität Berlin — [2]Department of Physics and Astronomy, Uppsala University — [3]Helmholtz-Zentrum Berlin für Materialien und Energie

We examine the transient AFM spin structure in an epitaxial Fe/CoO bilayer on an Ag(001) single-crystal substrate after excitation by 60 fs laser pulses of 800 and 400 nm wavelength, below and above the CoO band gap, respectively, by evaluating the time-resolved x-ray magnetic linear dichroism in reflectivity at the Co L2 edge. The findings are compared to time-resolved x-ray magnetic circular dichroism measurements at the Fe L3 edge. Both layers exhibit a fast drop in magnetic order within 300 fs. Simulating an atomistic two-temperature model, coupled with the stochastic Landau Lifshitz-Gilbert equation for the spin degrees of freedom, indicates a direct energy transfer from hot Fe electrons to CoO spins in the case of 800 nm excitation. For demagnetization at 400 nm pump, above-band-gap excitation in CoO has to be assumed in the simulation to reproduce the experimental result [1]. [1] C. S. Awsaf et al., arXiv:2408.14360.

MA 31.16 Wed 17:00 P1

Laser-induced magnetostriction in Gd, Tb and Dy probed by UXRD — •Florian Baltrusch[1], Alexander von Reppert[1], Steffen P. Zeuschner[1], Maximilian Mattern[1], Matthias Rössle[2], Florin Boariu[2], Karine Dumesnil[3], and Matias Bargheer[1,2] — [1]Institut für Physik und Astronomie, Universität Potsdam, Potsdam, Germany — [2]Helmholtz-Zentrum Berlin, Berlin, Germany — [3]Institut Jean Lamour, Universite Lorraine, Nancy, France

In ultrafast X-ray experiments, we compare the laser-induced magnetostriction in Gd, Tb and Dy upon femtosecond laser excitation at temperatures above and below the magnetic ordering temperatures. These rare earths exhibit giant spontaneous magnetostriction and consequently negative thermal expansion (NTE). The coupling between magnetic order and the lattice below the Curie temperature leads to a competition between the expansive stresses from electrons and phonons and the contractive stress due to magnetic order. Thus, upon femtosecond laser excitation, the ultrafast dynamics show a variety of interesting results, such as transforming a typical bipolar strain wave into a unipolar pulse. By comparing equilibrium thermal expansion and heat capacities, we separate electronic, phononic, and magnetic stress contributions using an extended Grüneisen model based on energy densities in each of the three subsystems. This enables fitting ultrafast strain dynamics and identifying subsystem coupling constants.

MA 31.17 Wed 17:00 P1

Towards ultrafast time-resolved SHG imaging of ferroic materials — •Andrin Caviezel, Gerrit Horstmann, Thomas Lottermoser, and Manfred Fiebig — Department of Materials, ETH Zurich, Zurich, Switzerland

Ferroic materials enable the storage and manipulation of information within their domain structures, a fundamental property underpinning their technological potential. Second-harmonic generation (SHG) imaging is a well-established method for probing ferroic domain patterns at equilibrium, while optical excitation with femtosecond laser pulses holds promise for achieving ultrafast domain switching. However, studying the non-equilibrium dynamics of ferroic domains demands an imaging technique that offers both high temporal and spatial resolution. In this work, we present an ultrafast time-resolved SHG imaging setup designed specifically to investigate non-equilibrium dynamics in ferroic materials. By utilizing the high pulse energies of an amplified laser system, our setup enables direct wide-field imaging of ferroic structures. Additionally, the ability to tune the laser wavelength and employ sequences of pump pulses provides precise control over optical excitation conditions. This approach allows us to study ultrafast processes both in bulk ferroics with microscopic domain structures and micrometer-sized flakes of van der Waals ferroics under cryogenic conditions, advancing our understanding of their dynamic behavior.

MA 31.18 Wed 17:00 P1

Influence of defects on the ultrafast orbital Hall effect in metallic nanoribbons — •Theresa Albrecht, Franziska Ziolkowski, Oliver Busch, Börge Göbel, Ingrid Mertig, and Jürgen Henk — Institut für Physik, Martin-Luther-Universität, D-06099 Halle

The time-dependent orbital Hall effect, which is generated by a femtosecond laser pulse, called the ultrafast orbital Hall effect (UOHE) is investigated. We present the influence of different types of defects on the UOHE in a Cu nanoribbon. The laser-driven electron dynamics is numerically calculated by our theoretical framework Evolve based on a real-space tight-binding approach for finite systems and the solution of the von Neumann equation for the calculation of the occupation numbers [1]. As a result we discuss charge redistribution and charge currents as well as orbital angular momenta and their currents with atomic resolution in the time domain. The role of defects is analysed quantitatively which is particularly important to compare with experiments.

MA 31.19 Wed 17:00 P1

Ultrafast magneto-elastic phenomena in highly magnetostrictive materials with systematic variation of anisotropy — •Constantin Walz[1], Fried Weber[1], Karine Dumesnil[2], Alexander von Reppert[1], and Matias Bargheer[1,3] — [1]Institut für Physik und Astronomie, Universität Potsdam, Germany — [2]Institut Jean Lamour, Université Lorraine, Nancy, France — [3]Helmholtz-Zentrum Berlin, Germany

Highly magnetostrictive Rare Earth-Iron compounds ($REFe_2$ with RE = Tb, Dy, $Tb_{0.3}Dy_{0.7}$) are well known for their giant (inverse) magnetostriction, with more than 10^{-3} lattice constant change when applying a magnetic field. Because of that they are widely used as ultrasonic transducers in the MHz regime. Their

laser-induced magnetization dynamics are less explored, though they have potential as field-tunable magneto-acoustic transducers in the GHz regime or even for strain driven magnetization switching. Here we compare polar transient magneto-optical Kerr effect (trMOKE) data on three (110)-oriented $REFe_2$. The rare-earth ion influences the cubic magnetocrystalline anisotropy energy, leading to nontrivial demagnetization and precession responses with opposing signs for Dy and Tb. We discuss non-resonant strain-driven magnetization dynamics that follow the lattice deformation with a delay. Glass-capped $TbFe_2$ films help to disentangle signal contributions from unipolar strain pulses, quasi-static strain and spin disorder.

MA 31.20 Wed 17:00 P1

Controlling Spin periodicity in a Helical Heisenberg Antiferromagnet — •Hyein Jung[1,2], Abeer Arora[2], Deeksha Gupta[3], Franziska Walther[4], Kristin Kliemt[4], Victoria C. A. Taylor[2], Túlio de Castro[2], Hanqian Lu[1,2], Christian Schüssler-Langeheine[3], Niko Pontius[3], Urs Staub[5], Cornelius Krellner[4], Laurenz Rettig[2], Ralph Ernstorfer[1,2], and Yoav W. Windsor[1,2] — [1]Technische Universität Berlin, Berlin, Germany — [2]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany — [3]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany — [4]Goethe-Universität Frankfurt, Frankfurt, Germany — [5]Paul Scherrer Institut, Villigen, Switzerland

Manipulating antiferromagnetic spin structures is a promising route to new spintronics functionality. This is particularly desirable on ultrafast time scales due to the growing demands for device speeds. Here we investigate the chiral antiferromagnet EuCo2P2 using resonant X-ray diffraction and manipulate the periodicity of its spins under three distinct conditions: (a) femtosecond laser pulse excitation, (b) applied magnetic fields, and (c) heating. These represent fundamentally distinct microscopic routes for manipulation, and their combination can provide an essential basis for achieving precise control of antiferromagnetic spin structures.

MA 31.21 Wed 17:00 P1

Ultrafast demagnetization via 4f-multiplet excitations in Terbium investigated by tr-ARPES — •Timo Dully, Gaurav Kshetry, Xinwei Zheng, Christian Strüber, and Martin Weinelt — Freie Universität Berlin

The magnetic properties of rare earth metals are governed by the localized electrons in the partially filled 4f electron shell and the interaction with the itinerant 3d electrons. Spin polarization of the 4f electrons decreases much faster in Terbium than in Gadolinium [1]. This has been attributed to enhanced coupling to the lattice caused by the anisotropic shape of the electronic wavefunction in Terbium. However, recent XMCD and RIXS experiments demonstrate an additional excitation pathway that is involved in drastically increasing the response of the magnetic system to optical excitation [2]. Scattering of optically excited 5d electrons with the 4f-subsystem allows for an efficient excitation of the 4f-multiplet.

In our time- and angle-resolved photoemission spectroscopy (tr-ARPES) setup using a hemispherical energy analyzer we measure the demagnetization of Tb as a function of time and fluence. We observe transient changes to the 4f photoemssion signal indicating a substantial excitation of the 4f-multiplet by energy transfer from the 5d valence electrons.

MA 31.22 Wed 17:00 P1

Probing magnetic dimensional crossover in CrSiTe3 through picosecond strain pulses — •Anjan Kumar Naralapura Manohara[1,2], Soumya Mukherjee[2], Abhirup Mukherjee[2], Ajinkya Punjal[3], Shubham Purwar[4], Thirupathaiah Setti[4], Shriganesh Prabhu[3], Siddhartha Lal[2], and Natarajan Kamaraju[2] — [1]Institute of Solid State and Materials Physics, TUD Dresden University of Technology, Dresden, Germany, 01069 . — [2]Department of Physical Sciences, Indian Institute of Science Education and research, Kolkata, West Bengal, India, 741246. — [3]Department of Condensed Matter Physics and Materials Science, Tata Institute of Fundamental research, Mumbai, Maharashtra, India, 400005. — [4]Department of Condensed Matter and Materials Physics, S. N. Bose National Centre for Basic Sciences, Kolkata, West Bengal, India, 700 106.

Two-dimensional van der Waals materials provide a unique platform to investigate the evolution of magnetic order from short-range 2D intraplanar to long-range 3D interplanar configurations. Employing non-degenerate pump-probe spectroscopy, we have generated and detected picosecond acoustic strain pulses in CrSiTe3. By analysing the distinct signatures of these pulses, we have elucidated a multi-stage pathway for the magnetic dimensional crossover. Furthermore, our study reveals novel insights into the intricate interplay between spin dynamics and lattice vibrations, as manifested in both picosecond strain pulses and ultrafast carrier dynamics.

MA 31.23 Wed 17:00 P1

Low-temperature XPEEM to study functional properties of magnetic 2D materials — •Shubhada Patil[1], Alevtina Smekhova[2], and Florian Kronast[3] — [1]Helmholtz-Zentrum Berlin für Materialien und Energie, Albert-Einstein-Straße 15, 12489 Berlin, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Albert-Einstein-Straße 15, 12489 Berlin, Germany — [3]Helmholtz-Zentrum Berlin für Materialien und Energie, Albert-Einstein-Straße 15, 12489 Berlin, Germany

Two-dimensional (2D) magnetic van der Waals materials are particularly promising for electronic and spintronic devices. They exhibit novel electronic and magnetic properties that are ideally suited for investigation with surface-sensitive X-ray photoemission electron microscopy (XMCD-PEEM). In this poster, the experimental capabilities of the low-temperature PEEM facility at BESSY II are presented, including the possibility to study responses to optical excitations of a femtosecond laser system.

The results presented will focus on investigations of the magnetic properties of 2D heterostructures prepared by mechanical exfoliation of FexGeTe2 crystals (x=3, 4 or 5) with a thickness of up to a few monolayers on gold-coated Si/SiO2 substrates with h-BN capping layer in an inert atmosphere. Element-specific low-temperature imaging in XPEEM with a special sample environment is used to identify the magnetic domain configurations and their dynamic response to optical excitation with fs laser pulses.

MA 31.24 Wed 17:00 P1

Magnon-phonon scattering on ultrafast timescales — •Nabil Makadir, Kai Leckron, and Hans Christian Schneider — Physics Dept, University of Kaiserslautern-Landau (RPTU), Kaiserslautern, Germany

In the ultrafast demagnetization of ferromagnets, electron-magnon scattering likely plays an important role. Recently it has been shown in the framework of a two-band Stoner model (arXiv:2304.14978) that electron-magnon scattering processes lead to the creation of non-equilibrium magnons at large wave vectors on ultrafast time scales. In this contribution, we investigate how a large density of high-q magnons, as it is created during the demagnetization process, relaxes due to magnon-phonon and magnon-electron interactions. Treating phonons as bosons, we solve the dynamical equations for the magnon and phonon distributions including the relevant interactions at the level of Boltzmann scattering integrals. From the numerical results, we draw conclusions for the remagnetization process.

MA 31.25 Wed 17:00 P1

Ultrafast spin flop in Fe/Gd bilayers — Dominic Lawrenz[1], Tim Amrhein[1], Jonathan Weber[1], Wibke Bronsch[1], Niko Pontius[2], Christian Schüssler-Langeheine[2], Nele Thielemann-Kühn[1], and •Martin Weinelt[1] — [1]Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany — [2]Helmholtz-Zentrum Berlin, Albert-Einstein-Str. 15, 12489 Berlin, Germany

Using time-resolved X-ray magnetic circular dichroism in reflection (XMCD-R) at the femtoslicing facility of BESSY II (Helmholtz-Zentrum Berlin) we studied ultrafast magnetization dynamics in an Fe(5 nm)/Gd(11 nm) bilayer on W(110). Structural and magnetic depth profiles of the bilayer were characterized by static $\Theta/2\Theta$ XMCD-R scans. The magnetization $\vec{M}$ lies in-plane with antiparallel alignment of $\vec{M}_{Fe}$ and $\vec{M}_{Gd}$ at the Fe/Gd interface. At 300 K, Gd is magnetized only at the interface. Upon optical excitation Gd demagnetizes within 2 ps reaching a transient ferromagnetic state for $\sim$ 20 ps, comparable to simulations for Co/Gd in [1]. Close to the compensation temperature of 235 K, $\vec{M}_{Fe} = -\vec{M}_{Gd}$ are oriented nearly perpendicular to the external field and twisted into the field direction with increasing distance to the interface. Upon optical excitation we observe a transient spin flop by 6° of the Gd magnetization within 300 fs. This is attributed to spin-transfer torque caused by ultrafast spin currents [2] and may hint to spin vacuum switching [3].

MA 31.26 Wed 17:00 P1

Setting up current-induced spin-wave Doppler shift experiments — •Linda Nesterov, Julian Strassburger, Johannes Demir, Karsten Rott, and Timo Kuschel — Universität Bielefeld, Germany

The coupling of coherent spin waves with incoherent spin transport, such as spin-polarized electrons, results in the transfer of angular momentum via spin-transfer torque, enabling the so-called spin-wave Doppler shift [1]. Our research aims to deepen the understanding of this fundamental process, which plays a significant role in the development of next-generation memory devices and other spintronic applications. Propagating spin-wave spectroscopy is used to detect a possible Doppler shift in spin waves generated by charge currents in a 20 nm thick $Ni_{81}Fe_{19}$ strip. The experiments are conducted using a vector network analyzer with both in-plane and out-of-plane magnetic fields applied perpendicular to the direction of the propagating spin wave, which is excited with the use of a coplanar waveguide design. In contrast to published works [1,2], this study uses Ta_2O_5 as an insulating material, chosen for its high permittivity, leading to

a different impedance matching within the system.

MA 31.27 Wed 17:00 P1

Angle-dependent pumping of magnon Bose-Einstein condensates — •Franziska Kühn[1], Matthias R. Schweizer[1], Georg von Freymann[1,2], Alexander A. Serga[1], and Burkard Hillebrands[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Fraunhofer Institute for Industrial Mathematics ITWM, Fraunhofer Platz 1, 67663 Kaiserslautern, Germany

Our work focuses on the generation and behavior of magnon Bose-Einstein condensates (BEC) in yttrium-iron-garnet films. To create a magnon BEC, the magnon gas must be populated above the thermal level by external injection of magnons. Conventionally, this is done by parallel parametric pumping, where magnons are injected into spin-wave modes at half the pumping frequency. This work aims to optimize the pumping configuration by changing the direction of the microwave pumping field relative to the external magnetic field. This concept of oblique pumping promises higher efficiency and easier manipulation of the magnon BEC. The measurements are performed using a vector magnet for the rotation of the external magnetic field and Brillouin light scattering spectroscopy as an optical detection method for magnons. First results promise lower thresholds for the pumping power and thus easier excitation of magnons leading to a magnon BEC. This research was funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation)-TRR 173/3-268565370 Spin+X (Project B04)

MA 31.28 Wed 17:00 P1

Towards Aharonov–Casher effect based nonreciprocal electrical control of the magnon phase in a perpendicularly magnetised YIG film — •Gabriel Schwöbel[1], Alexander A. Serga[1], Vitaliy I. Vasyuchka[1], Rostyslav O. Serha[2], and Burkard Hillebrands[1] — [1]Fachbereich Physik and Landesforschungszen- trum OPTIMAS, RPTU, 67663 Kaiserslautern — [2]Faculty of Physics, University of Vienna, 1090 Vienna

Modulation of phase and amplitude of spin waves plays a crucial role in the realization of ultra-low power magnon-based computing. Therefore, we study the magnon phase change, induced by an applied electric field, in yttrium iron garnet (YIG), which has favourable magnetic properties such as a very low spin wave damping.

Recent studies [1] performed in in-plane magnetized single crystal YIG films have allowed us to evaluate different contributions to this phase change and to provide experimental evidence for the theoretically predicted magnonic Aharonov–Casher effect. This effect describes the accumulation of a geometric phase when a magnon passes through an electric field. In our new setup, which provides a more homogeneous and stable magnetic field, we investigate the nonreciprocal effects of magnon phase accumulation when a tangential electric field is applied to an out-of-plane magnetized YIG film.

[1] R.O. Serha et al., *Towards an experimental proof of the magnonic Aharonov–Casher effect*, Phys.Rev. B **108**, L220404 (2023)

MA 31.29 Wed 17:00 P1

Towards magnetically controlled phononic crystals — •Philipp Knaus, Maximilian Alexander Thiel, Kaya Gauch, and Mathias Weiler — Fachbereich Physik and Landesforschungszentrum Optimas, RPTU Kaiserslautern, Germany

Phononic crystals (PnCs) are materials with periodic modulations in their elastic properties that allow precise tuning of the phonon dispersion relation, enabling control of phonon propagation, including bandgaps, waveguiding and confinement. Recent advances have focused on 2D PnCs, which support innovative applications such as nanoscale information processing, optomechanical systems and thermal management [1]. This work represents a first step towards magnetically controlled PnCs based on surface acoustic waves, where the phononic properties of the material can be tuned. We study a magnetically controlled PnC based on Lithium Niobate $LiNbO_3$/CoFeB heterostructure. We characterize our prototype by electrical transmission measurements using a vector network analizer and optical measurements based on Brillouin Light Scattering and the time-resolved magneto-optic Kerr effect. Based on our results, we discuss potential applications and device optimization.

MA 31.30 Wed 17:00 P1

Spin Hall driven spin-wave emission in Ga:YIG/Pt heterostructures — •Moritz Bechberger[1], David Breitbach[1], Björn Heinz[1], Carsten Dubs[2], and Philipp Pirro[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]INNOVENT e.V. Technologieentwicklung, Jena, Germany

The development of a DC driven and scalable spin-wave source that exhibits a self-adaptive frequency is desirable. In particular, spin currents can be used for these spin-wave sources, but instead of radiating energy in the form of propagating spin waves, localized oscillations occur in most systems due to the underlying negative nonlinear frequency shift. Here, a heterostructure consisting of an yttrium iron garnet thin film substituted with gallium atoms (Ga:YIG), which exhibits a perpendicular magnetic anisotropy, and a thin layer of platinum is employed. The heterostructure allows studies in the positive nonlinear frequency shift regime for in-plane magnetization. A spin current is locally injected into the Ga:YIG film via the spin Hall effect by applying a direct current to the platinum pad. This allows for the study of the spin-wave emission into the adjacent Ga:YIG waveguide. The emission of spin waves was found to be partially decoupled from the auto-oscillation and is restricted to a narrow frequency and wave-vector range. This work provides a proof-of-concept and the fundamental basis for the development of spin-wave emitters utilizing this mechanism. This research is funded by the DFG - Project No. 271741898, TRR 173-268565370 (B01), and the ERC Grant No. 101042439 CoSpiN.

MA 31.31 Wed 17:00 P1

Controlling the Bi/Fe ratio in bismuth iron garnet thin films deposited by confocal magnetron sputtering for enhanced Faraday rotation — Gajendra L. Mulay[1,2], •Shraddha Choudhary[3], Bhagyashree A. Chalke[1], Rudheer D. Bapat[1], Jayesh B. Parmar[1], Manish B. Ghag[1], Vilas J. Mhatre[1], Shriganesh Prabhu[1], Ashwin A. Tulapurkar[2], and Venu Gopal Achanta[1,4] — [1]TIFR, Mumbai, 400005, India. — [2]IIT Bombay, Mumbai, 400076, India. — [3]Institute of Physics, University of Münster, Wilhelm-Klemm-Str. 10, Münster, 48149, Germany. — [4]On lien at CSIR-NPL, New Delhi, 110012, India.

Among all known garnet films bismuth-iron-garnet (BIG;$Bi_3Fe_5O_{12}$) films not only demonstrate the highest Faraday rotation in visible light but also exhibit minimal optical losses. We have successfully deposited high-quality BIG epitaxial thin films on single-crystal gadolinium-gallium-garnet (GGG; $Gd_3Ga_5O_{12}$) (111) substrates via Radio frequency confocal sputtering, utilizing separate bismuth and iron oxide sputtering targets and optimized thermal treatments. The Bi/Fe ratio in the deposited BIG thin films can be varied by controlling the sputter process parameters. These deposited thin films exhibit homogeneity and surface root mean square roughness of less than 2 nm. The epitaxial film quality is confirmed by X-ray diffraction and Transmission electron microscopy. Moreover, the films demonstrate low optical loss and a magneto-optical Faraday rotation as high as $-34^o \pm 1^o/\mu$m at a wavelength of 535 nm for a BIG thin film with a Bi/Fe ratio of 0.7 and an annealing temperature of 510^oC.

MA 31.32 Wed 17:00 P1

Ultrafast dynamics in photoexcited antiferromagnets — •Katja Sophia Moos[1], Yun Yen[2], Arnau C. Romaguera[3], Hiroki Ueda[3], and Michael Schüler[1,2] — [1]Department of Physics, University of Fribourg, 1700 Fribourg, Switzerland — [2]PSI Center for Scientific Computing, Theory and Data, 5232 Villigen PSI, Switzerland — [3]PSI Center for Photon Science, 5232 Villigen PSI, Switzerland

State-of-the-art time-resolved probes provide unprecedented access to the dynamics of interacting quasiparticles in solids on their natural time scales. Although a significant body of work exists on the dynamics of electrons and phonons, much less is known about the ultrafast response of magnetic moments. Here, we study pump-induced out-of-equilibrium magnetism in the Mott insulator CuO, combining measurements of resonant magnetic X-ray scattering with quantum-kinetic simulations. In particular, the diffuse scattering reveals time-dependent magnetic correlations, which we interpret in terms of interacting magnons. For quantitative insights, we solve the time-dependent quantum Boltzmann equation to study magnon-magnon scattering. The calculations are consistent with experimental observations and provide a detailed picture of magnetic dynamics in terms of non-thermal magnons and their subsequent thermalization.

MA 31.33 Wed 17:00 P1

Investigating Spin Cherenkov Radiation in Magnetic Materials Using MuMax3 Simulations — •Kawa Noman, Matthias Schweizer, Vitaliy Vasyuchka, and Mathias Weiler — Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany

Spin Cherenkov Radiation (SCE) is a groundbreaking mechanism that enables the emission of spin waves (magnons) in ferromagnetic materials when an external perturbation surpasses the minimum phase velocity of these spin waves. In this study, we employ MuMax3 micromagnetic simulations to investigate SCE induced by high-amplitude Surface Acoustic Waves (SAWs) in Yttrium Iron Garnet (YIG) thin films. Our simulations reveal that SAWs propagating at velocities exceeding the spin wave phase velocity efficiently excite coherent spin wave modes, exhibiting characteristic Cherenkov like conical wavefronts. Through comparative analysis with Cobalt Iron Boron (CoFeB), we affirm the universal nature of SCE across diverse ferromagnetic materials, thereby highlighting its significant potential for advanced applications in magnonic and spintronic devices. This study not only establishes spin Cherenkov Radiation as a fundamental physical phenomenon but also paves the way for innovative technologies that leverage controlled spin wave emission.

MA 31.34 Wed 17:00 P1

Excitation of spin waves via surface acoustic waves in complex magnetic domain structures — •Mohammad Javad Kamali Ashtiani[1], Alexandre Abbass Hamadeh[2], Ephraim Spindler[1], Mathias Weiler[1], and Philipp Pirro[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Center de Nanosciences et de Nanotechnologies, CNRS, Universite Paris-Saclay, 91120, Palaiseau, France

We investigated the interaction of surface acoustic waves (SAWs) with spin waves (SWs) in micrometer-sized cobalt-iron-boron (CoFeB) dots on a piezoelectric – ScAlN– substrate. These dots exhibit particular domain structures leading to complex magnon-phonon coupling. SAWs, generated using interdigital transducers across a broad GHz frequency range, were observed to excite SWs in the CoFeB structures. The dynamics were characterized using micro-focused Brillouin light scattering (*BLS) spectroscopy, allowing direct detection of SAW and SW excitations. Nitrogen-vacancy magnetometry provided high-resolution insights into the magnetic domain arrangement. Also, Mumax3 simulations confirmed the complex domain textures. The response of SWs at specific resonance magnetic fields was observed and shifted across different frequencies. Our findings highlight the potential of hybrid phonon-magnon systems for tunable magnonic devices, advancing wave-based information processing technologies.

This research was supported by DFG under TRR 173/3 - 268565370 Spin+X (Project B01).

MA 31.35 Wed 17:00 P1

All-Magnonic Frequency Multiplication in Ferromagnetic Microstructures — •Alexandra Schrader[1], Chris Körner[1], Rouven Dreyer[1], Niklas Liebing[2], and Georg Woltersdorf[1] — [1]Martin-Luther-Universität Halle-Wittenberg — [2]Fraunhofer Institute for Electronic Nano Systems ENAS, Chemnitz

We have observed all-magnetic frequency multiplication and a six-octave frequency comb in polycrystalline NiFe thin films [1]. At low bias fields, magnetic ripples cause local magnetization tilting, and MHz-range excitation induces rapid switching and high-harmonic spin wave emission. To enable practical applications, it is essential to miniaturize active components and optimize the frequency multiplication efficiency, aiming to generate GHz-range spin waves using MHz rf excitation in minimal-sized elements.

Recently, frequency multiplication has also been observed in extended CoFeB layers [2]. This motivates us to investigate the effect in both thin films as well as microstructures of CoFeB. Using micromagnetic simulations, we analyze how various parameters - such as saturation magnetization, anisotropy, static bias field and the shape, size and thickness of micrometer-sized CoFeB elements - influence generation efficiency. These numerical results are then compared to experimental measurements performed via NV magnetometry and SNS-MOKE techniques on actual samples.

Magnetoacoustic coupling in Yttrium Iron Garnet / Aluminium Scandium Nitride heterostructures — •Kevin Künstle[1], Kaya Gauch[1], Yannik Kunz[1], Agne Žukauskaite[2,3], Stephan Barth[2], and Mathias Weiler[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Fraunhofer Institute for Electron Beam and Plasma Technology FEP, 01277 Dresden, Germany — [3]Institute of Solid State Electronics, Technische Universität Dresden, 01062 Dresden, Germany

The magnetoelastic coupling between surface acoustic waves (SAWs) and spin waves (SWs) has garnered significant attention in recent years. Magnetoelastic excitation of SWs is particularly appealing in ferrimagnets with low magnetic damping, such as yttrium iron garnet (YIG). To enable the electrical excitation of SAWs, a piezoelectric layer is required. We have demonstrated that ZnO is a suitable choice [1]. In this study, a novel heterostructure comprising a YIG/GGG bilayer covered by a piezoelectric AlScN thin film is investigated to explore this coupling. The interaction of SAW and SW is characterized using micro-focused Brillouin light scattering (BLS) spectroscopy and vector network analyzer (VNA) measurements. Additionally, the observed magnetoelastic coupling is benchmarked against the coupling in the more established ZnO/YIG/GGG heterostructure.

MA 31.37 Wed 17:00 P1

Efficient all-magnonic frequency multiplication in nano-scale devices — •Chris Körner[1], Anna Kiefel[1], Rouven Dreyer[1], Alexandra Schrader[1], Niklas Liebing[2], and Georg Woltersdorf[1] — [1]Martin-Luther-Universität Halle-Wittenberg, Institut für Physik, Von Danckelmann Platz 3, 06120 Halle (Saale) — [2]Fraunhofer-Institut für Elektronische Nanosysteme ENAS, Technologie-Campus, 3 09126 Chemnitz

We recently have observed all-magnonic frequency multiplication and the generation of a 6-octave spanning frequency comb within an extended polycrystalline NiFe layer [1]. At low bias fields the magnetization locally tilts due to a magnetic ripple effect in the film. Driving the magnetization with frequencies far below ferromagnetic resonance, i.e. in the MHz range, causes rapid synchronous switching and leads to high harmonic spin wave emission. To make use of this effect in an actual device it is necessary to shrink the dimensions of the active components and to enhance the efficiency of the frequency multiplication process. The aim is to generate spin waves in the range of up to 10 GHz most efficiently in elements as small as possible, just from r.f. excitation with MHz frequencies. We employ micromagnetic simulations to investigate how the generation efficiency is influenced by external parameters, such as bias field and the shape, size, and thickness of micrometer sized NiFe elements. We find that the comb generation process can still be efficient even if we scale down the elements to just a few microns and compare these results to NV-center and SNS-MOKE measurements.

MA 31.38 Wed 17:00 P1

Realization of Inverse-Design Magnonic Logic Gates — •Fabian Majcen[1,2], Noura Zenbaa[1,2], Claas Abert[1,3], Florian Bruckner[1,3], Norbert Mauser[3,4], Thomas Schrefl[3,5], Qi Wang[6], Dieter Süss[1,3], and Andrii Chumak[1,3] — [1]University of Vienna, Faculty of Physics, Vienna 1090, Austria — [2]University of Vienna, Vienna Doctoral School in Physics, Vienna 1090, Austria — [3]Research Platform MMM "Mathematics-Magnetism-Materials", University of Vienna, Vienna 1090, Austria — [4]Faculty of Mathematics, University of Vienna, Vienna 1090, Austria — [5]Center for Modelling and Simulation, Donau-Universität Krems, Wiener Neustadt, 2700, Austria. — [6]School of Physics, Hubei Key Laboratory of Gravitation and Quantum Physics

The field of Magnonics, which utilizes magnons, the quanta of spin waves, for energy-efficient data processing, has made significant advancements through the application of inverse design. A universal magnonics processor has been developed, utilizing a 7x7 array of independent current loops to generate local inhomogeneous magnetic fields, thereby scattering spin waves in an Yttrium-Iron-Garnet film to achieve various functionalities. In this system, binary data ('0' and '1') is encoded in the spin-wave amplitude, and by making use of the nonlinearity of spin waves and applying the inverse-design process, logic gates including NOT, OR, NOR, AND, NAND, and a half-adder have been successfully created.

MA 31.39 Wed 17:00 P1

Yttrium iron garnet nanostructures for spin-wave computing — •Jannis Bensmann[1], Ahmad El Kadri[1], Dmitrii Raskhodchikov[1,2], Kirill O. Nikolaev[3], Robert Schmidt[1], Johannes Kern[1], Shraddha Choudhary[1], Vladislav E. Demidov[3], Steffen Michaelis de Vasconcellos[1], Wolfram H. P. Pernice[1,2,4], Sergej O. Demokritov[3], and Rudolf Bratschitsch[1] — [1]University of Münster, Institute of Physics and Center for Nanotechnology, 48149 Münster, Germany — [2]University of Münster, Center for Soft Nanoscience, 48149 Münster, Germany — [3]University of Münster, Institute of Applied Physics, 48149 Münster, Germany — [4]Heidelberg University, Kirchhoff-Institute for Physics, 69120 Heidelberg, Germany

The ever-increasing demand for computing power, particularly driven by the recent advances in the field of artificial intelligence, has triggered research into novel system architectures to improve the performance of current computing technology. Here, spintronics appears as a promising candidate, as spin waves are energy-efficient, broadband (up to THz), and can have wavelengths down to the nanometer scale. In order to realize hardware-based spin-wave computing, we employ nanofabrication techniques to create devices from 100-nm-thick films of yttrium iron garnet (YIG), a material well known for its exceptional low-damping. We evaluate the performance of individual building blocks using optical measurements such as Brillouin light scattering, which provides detailed insights into the spin-wave propagation.

MA 31.40 Wed 17:00 P1

Manipulation of spin waves in YIG/FM heterostructures — •Julien Schäfer, Akira Lentfert, Björn Heinz, and Philipp Pirro — Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany

The concept of using spin waves as data carriers is a promising alternative to existing communication standards with the potential for energy efficient data transfer. In magnonics, communication building blocks, such as time-delay lines for phase modulation, can be realized by exploiting the magnetic field-dependent spin-wave group velocities in e.g. yttrium-iron-garnet (YIG). In particular, the spin wave propagation in Damon-Eshbach geometry can be modified by the deposition of an additional ferromagnetic layer, leading to a strong frequency nonreciprocity induced by dipolar interaction. Here, we report an on-chip configurable magnonic frequency filter/phase shifter device consisting of a YIG transmission line with iron stripes deposited on top. These stripes act as Fabry-Pérot (FP) resonators due to the spin-wave reflections at the boundaries. Destructively interfering spin waves are filtered by such a resonator, while the transmitted spin

waves accumulate an additional phase due to the altered dispersion relation in the bilayer region. We present micromagnetic studies investigating the tunability of these FP resonators by means of external parameters such as local magnetic fields and the stripe magnetization configuration. This research is funded by the European Union within HORIZON-CL4-2021- DIGITAL-EMERGING-01 (No.101070536, MandMEMS).

MA 31.41 Wed 17:00 P1

Mapping of the Morin Transition in alpha-Fe2O3 using Surface Acoustic Waves — •Katharina Lasinger[1,2], Florian Kraft[1], Yannik Kunz[1], Kevin Künstle[1], Finlay Ryburn[2], John F. Gregg[2], and Mathias Weiler[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, Germany — [2]Clarendon Laboratory, Department of Physics, University of Oxford, United Kingdom

Antiferromagnets (AFMs) hold great potential for applications due to their insensitivity to external magnetic fields, the absence of associated stray fields and and their ability to host fast spin dynamical phenomena [1,2]. While AFMs interact only weakly with external magnetic fields, their magnetic order couples to elastic deformation. We investigate the manipulation of AFMs using magnetoelasticity and demonstrate both the possibility to probe changes in the static magnetization as well as map out the Morin transition of alpha-Fe2O3 through concurrent modification of its elastic properties. To achieve this, surface acoustic waves (SAWs) are launched in an alpha-Fe2O3 | ZnO heterostructure while magnetic field sweeps are performed. We observe significant changes in SAW group velocity and amplitude depending on the angle of the external magnetic field relative to the crystallographic c-axis and the SAW propagation direction. A temperature-dependent study around the Morin transition reveals the critical fields at each temperature required for the antiferromagnetic phase transition to occur.

MA 31.42 Wed 17:00 P1

Interlayer coupling in Co/Pd multilayers with perpendicular magnetic anisotropy — •Raphael Kohlstedt[1,2], Rico Ehler[1,2], Peter Heinig[1,2], and Olav Hellwig[1,2,3] — [1]Chemnitz University of Technology, D-09107 Chemnitz, Germany — [2]Research Center MAIN, D-09126 Chemnitz, Germany — [3]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, D-01328 Dresden, Germany

Antiferromagnetically (AF) coupled perpendicular magnetic anisotropy (PMA) multilayers (MLs) are widely utilized in magnetic devices. In Co/Pd MLs with PMA, the coupling is implemented via non-magnetic spacer layers like Ru or Ir. Using Pd itself as a spacer would be beneficial, since purely-Pd-based systems are promising candidates for applications in magneto-ionics, as demonstrated in recent reports [1-3]. In sputtered Co/Pd/Co trilayers, aging under ambient conditions induces a transient coupling effect, leading to a transition from ferromagnetic to antiferromagnetic coupling [4]. Building onto these experiments, we investigate the coupling behavior in Co/Pd/Co trilayers and Co/Pd MLs separated by a thicker Pd spacer. In our samples, we observe AF coupling as well as distinctly time-dependent effects, differing from those reported previously.

Magnetometry of Buried Co-based Nanolayers by Hard X-ray Photoelectron Spectroscopy — •Andrei Gloskovskii[1], Christoph Schlueter[1], and Gerhard Fecher[2] — [1]Photon Science / DESY, Hamburg — [2]Max Planck Institute for Chemical Physics of Solids, Dresden

Magnetic circular dichroism (MCD) effect has a cos (θ) dependence where θ is the angle between light polarization and sample magnetization. This yields direct information about the magnetization direction with respect to the polarization of the synchrotron X-ray beam for both ferromagnetic and antiferromagnetic materials. In the hard X-ray regime, the beam polarization can be conveniently modified utilizing the phase shift produced by a diamond phase plate in the vicinity of a Laue or Bragg reflection. Extracting quantitative information about absolute values of local magnetic moments is very challenging, because of the complicated structure of photoelectron spectra. For example, the 4eV Co satellite cannot be explained by the solid-state calculations. The satellite obviously exhibits strong dichroism.

The electronic and magnetic properties of CoFe, CoFeB and Co-based Heusler nanolayers were studied using MCD. Both the polarization-dependent spectra and the dichroism indicate that the lines of the multiplet extend over the entire spectral range. It is demonstrated that MCD in HAXPES is an effective and powerful technique to perform element- and depth-specific magnetometry of deeply buried ferromagnetic and antiferromagnetic magnetic materials.

MA 31.44 Wed 17:00 P1

Kerr Microscopy Studies of Magnetic Domains in proximity-coupled 3d FM-EuO Heterostructures — •Katharina Wehrstein, Seema Seema, Pia Maria Düring, and Martina Müller — FB Physik, Universität Konstanz

Europium monoxide (EuO) is a promising material for future spintronic applications as it is an insulator with a similar band gap to silicon, is ferromagnetic (FM) up to a Curie temperature (T_c) of 69 K and shows good spin-filter qualities. Since the low T_c is limiting for applications, methods to increase T_c are actively investigated. For this purpose, it is important to understand the magnetic behavior of EuO below, near and above T_c. One possible option to increase T_c is the proximity coupling of EuO with room temperature (RT) FM such as Fe or Co. Here, the temperature- and thickness-dependent magnetization of EuO thin films and 3d FM coupled EuO heterostructures synthesized by molecular beam epitaxy was investigated using magneto-optical Kerr microscopy. Systematic temperature- and thickness-dependent investigations on one hand revealed that the magnetic domain structure in Fe undergoes significant modifications in the presence of EuO, compared to Co. On the other hand, coercivity gets more affected due to the presence of Co than Fe. Such observations could lead to tuning thickness of EuO and overlayer choice in proximity-coupled heterostructures with T_c close to RT for applications.

MA 31.45 Wed 17:00 P1

Phase Modulation of Spin Waves via Surface Acoustic Waves — •Tim Vogel, Björn Heinz, and Philipp Pirro — Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau

The interaction of spin waves and surface acoustic waves (SAWs) offers promising opportunities for advanced spintronic and magnonic applications. This study investigates the feasibility of using low-frequency SAWs in the MHz range to modulate the phase of high-frequency spin waves in the GHz range. Using micromagnetic simulations with mumax3, we investigate the dynamic coupling mechanisms and conditions necessary for effective phase manipulation of propagating spin waves.

While the primary focus is theoretical, this work also provides a framework for potential experimental validation to elucidate key factors such as coupling efficiency, propagation dynamics and system geometry. These results will contribute to a deeper understanding of magnon-phonon interactions.

We acknowledge funding by the European Union via Horizon Europe project MandMEMS, Grant No. 101070536.

MA 31.46 Wed 17:00 P1

Antiferromagnetic coupling in Co/Au/Co tri-layers — Lokesh Rasabathina[1], Rico Ehrler[1], Markus Gössler[1], Karin Leistner[1], Georgeta Salvan[1,2], and •Olav Hellwig[1,2,3] — [1]Chemnitz University of Technology, Chemnitz, Germany — [2]Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Chemnitz University of Technology,Chemnitz, Germany — [3]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

Magnetic thin film systems are of great interest for many applications, such as magnetic memory, storage, sensor devices, etc. Specifically synthetic antiferromagnets (SAFs) with perpendicular magnetic anisotropy are of interest in the fabrication of nanomagnetic and spintronic devices[1]. In reference to earlier studies[2], we fabricate thin films consisting of $Au_{seed}/Co_{(1)}/Au_{interlayer}/Co_{(2)}/Au_{cap}$ layer stack using magnetron sputtering in ultra-high vacuum conditions. Varying the $Au_{interlayer}$ thickness the $Co_{(1)}$ and $Co_{(2)}$ layers either reverse separately at different switching fields or jointly at the same switching field. We investigate if the interaction between the two cobalt layers originates from RKKY coupling, orange-peel coupling or through growth induced asymmetry between the two cobalt layers[3]. The Au_{seed} layer thickness also seems to affect the observed reversal behaviour. For our sample characterization, we use different types of magnetometry and magnetic microscopy techniques.

MA 31.47 Wed 17:00 P1

Site-selective substitution effects on the magnetic phase diagram of multiferroic $Fe_2Mo_3O_8$ — Lilian Prodan[1], •Dorina Croitori[2], Irina G. Filippova[2], Sergiu Shova[3], Vladimir Tsurkan[1,2], and Istvan Kezsmarki[1] — [1]University of Augsburg — [2]Moldova State University — [3]Romanian Academy

Antiferromagnetic materials hold great promise for the design of ultra-fast and energy-efficient spintronic devices. Therefore, understanding the robustness of crystals, their magnetic structures, and their manipulation is of high importance. Here, we report the effect of site-selective substitution of Zn^{2+} for Fe^{2+} ions on the crystal structure, magnetic and thermodynamic properties of the multiferroic $Fe_2Mo_3O_8$. We found the strong preference of Zn to occupy the tetragonal positions for substitution concentrations $\mathbf{0} \geq \mathbf{x} \leq \mathbf{1.3}$. This contrasts the previously reported results for related system $Co_2Mo_3O_8$ [1]. Site-selective substitution affects the magnetic phase diagram of $Fe_2Mo_3O_8$ influencing both the intra and inter-layer exchange interactions. This leads to the stabilization of the FiM phase for $\mathbf{x} \geq \mathbf{0.2}$ and to the decrease of T_C with increasing the Zn content. [1]. L. Prodan, I. Filippova, et al. Phys Rev B 106 (2022) 174421.

MA 32: Spin Transport and Orbitronics, Spin-Hall Effects II (joint session MA/TT)

Time: Wednesday 17:30–19:00 Location: H19

MA 32.1 Wed 17:30 H19

Orbital torques and orbital pumping in two-dimensional rare-earth dichalcogenides — •Mahmoud Zeer[1,2,3], Dongwook Go[3], Mathias Kläui[3,4], Wulf Wulfhekel[5], Stefan Blügel[1], and Yuriy Yuriy Mokrousov[1,3] — [1]Peter Gr *unberg Institute, Forschungszentrum J *ulich, 52425 J *ulich, Germany — [2]Department of Physics, RWTH Aachen University, 52056 Aachen, German — [3]Institute of Physics, Johannes Gutenberg-University Mainz, 55099 Mainz, Germany — [4]Centre for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology, 7491 Trondheim, Norway — [5]5Physikalisches Institut, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany

The design of spin-orbit torque (SOT) properties in two-dimensional (2D) materials represents a key challenge in modern spintronics. We now explore ferromagnetic Janus H-phase monolayers of 4f-Eu rare-earth dichalcogenides EuSP, EuSSe, and EuSCl using first-principles calculations. Our findings reveal that these compounds exhibit substantial SOT, primarily driven by the colossal current-induced orbital response of Eu f-electrons. Additionally, the resulting orbital torques can generate strong in-plane currents of orbital angular momentum with non-trivial orbital polarization directions. These results establish f-based 2D materials as a highly promising platform for in-plane orbital pumping and SOT applications, positioning f-based 2D materials as a promising platform for next-generation orbitronic and spintronic technologies with 2D materials.

MA 32.2 Wed 17:45 H19

Orbital Topology of Chiral Crystals for Orbitronics — •Ying-Jiun Chen[1], Kenta Hagiwara[1,2], Dongwook Go[3], Xin Liang Tan[1,2], Sergii Grytsiuk[1], Kui-Hon Ou Yang[4], Guo-Jiun Shu[5], Jing Chien[4], Yi-Hsin Shen[4], Xiang-Lin Huang[5], Iulia Cojocariu[1], Vitaliy Feyer[1,2], Minn-Tsong Lin[4,6], Stefan Blügel[1], Claus Michael Schneider[1,2], Yuriy Mokrousov[1,3], and Christian Tusche[1,2] — [1]Forschungszentrum Jülich — [2]University of Duisburg-Essen — [3]Johannes Gutenberg University Mainz — [4]National Taiwan University, Taiwan — [5]National Taipei University of Technology, Taiwan — [6]Academia Sinica, Taiwan

Chirality is ubiquitous in nature and manifests in a wide range of phenomena including chemical reactions, biological processes, and quantum transport of electrons. In quantum materials, the chirality of fermions, given by the relative directions between the electron spin and momentum, is connected to the band topology of electronic states. Here, we show that in structurally chiral materials like CoSi, the orbital angular momentum (OAM) serves as the main driver of a nontrivial band topology in this new class of unconventional topological semimetals, even when spin-orbit coupling is negligible. A nontrivial orbital-momentum locking of multifold chiral fermions in the bulk leads to a pronounced OAM texture of the helicoid Fermi arcs at the surface. Our findings highlight the pivotal role of the orbital degree of freedom for the chirality and topology of electron states, in general, and pave the way towards the application of topological chiral semimetals in orbitronic devices.

MA 32.3 Wed 18:00 H19

Vectorial flow of the Berry curvature and its relation to the transport and band structure — •Jaroslav Hamrle[1,2], Ondřej Stejskal[1], Milan Vrána[2,1], and Martin Veis[2] — [1]Czech Technical University, Prague, Czechia — [2]Charles University, Prague, Czechia

Berry curvature expresses the curvature of the reciprocal space, in a similar manner as magnetic field express curvature of the real space, resulting in a curved transport of electrons in solids. Therefore, Berry curvature is a base of various lossless transport phenomena such as anomalous Hall effect, anomalous Nerst effect, orbital magnetization or electric polarization. Here, in model materials bcc Fe and Fe_3Ga, we demonstrate details of the vectorial flow of the Berry curvature (monopole source, 1-dimensional flow, 2-dimensional flow), and its relations to the band structure, orbital magnetization as well as anomalous Hall and Nerst effects.

[1] O. Stejskal, M. Veis, J. Hamrle, Sci Rep **12**, 97 (2022) [doi: 10.1038/s41598-021-04076-z]

MA 32.4 Wed 18:15 H19

Finite-temperature transport properties of magnetic/non-magnetic alloys: trends in the longitudinal and in the transverse charge and spin currents — •Alberto Marmodoro[1], Yang Wang[2], Yuqing Lin[3], and Ilja Turek[4] — [1]Institute of Physics (FZU), Czech Academy of Sciences, Prague, Czech Republic — [2]Pittsburgh Supercomputer Center (PSC), Carnegie Mellon University, Pittsburgh, USA — [3]Mellon College of Science, Carnegie Mellon University, Pittsburgh, USA — [4]Institute of Physics of Materials, Czech Academy of Sciences, Brno, Czech Republic

Alloys composed of magnetic and non-magnetic metals exhibit non-trivial transport trends as a function of composition and temperature. The stoichiometry controls not only the Curie point, but also the slope of resistivity vs. temperature. Beside affecting longitudinal currents, this has further implications also for transverse charge and spin currents, i.e. on anomalous Hall effects [1]. We report first-principles results based on density functional theory (DFT), relativistic linear response and Green function methods based on the multiple scattering Korringa-Kohn-Rostoker (KKR) or linear muffin tin orbitals (LMTO) frameworks.

MA 32.5 Wed 18:30 H19

Impact of the substrate on angular momentum transport between separated ferromagnets — •Fiona Sosa Barth[1,2], Matthias Grammer[1,2], Richard Schlitz[3], Tobias Wimmer[1,2], Janine Gückelhorn[1,2], Luis Flacke[1,2], Sebastian T.B. Goennenwein[3], Rudolf Gross[1,2,4], Hans Huebl[1,2,4], Akashdeep Kamra[5], and Matthias Althammer[1,2] — [1]Walther-Meißner-Institut, BAdW, Garching, Germany — [2]School of Natural Sciences, TUM, Garching, Germany — [3]Department of Physics, University of Konstanz, Konstanz, Germany — [4]Munich Center for Quantum Science and Technology, München, Germany — [5]RPTU Kaiserslautern-Landau, Kaiserslautern, Germany

Spintronics relies on the transfer of angular momentum between electrons and solid state excitations such as magnons and phonons. In our recent work, we demonstrate angular momentum transfer between two ferromagnetic strips on diamagnetic substrates [1] by converting a DC current at one of the electrodes to a non-equilibrium magnon accumulation. Due to dipolar and potentially phononic coupling, angular momentum is transferred to the magnonic system of the second FM electrode and measured by the inverse processes. In this work, we investigate the substrate influence on the angular momentum transport by comparing our results for SiOx and SiN layers on Si substrates. As a next step, we investigate substrate-supported strips versus freestanding strings to separate phononic contributions from dipolar coupling. [1] R. Schlitz et al., Phys. Rev. Lett. 132, 256701 (2024)

MA 32.6 Wed 18:45 H19

Orbital Edelstein contribution to the spin-charge conversion in Germanium Telluride — •Sergio Leiva-Montecinos[1], Libor Vojáek[2], Jing Li[2], Mairbeck Chshiev[2], Ingrid Mertig[1], and Annika Johansson[3] — [1]Martin Luther University Halle-Wittenberg, Halle (Saale), Germany — [2]Université. Grenoble Alpes, CEA, CNRS, SPINTEC, Grenoble, France — [3]Max Planck Institute of Microstructure Physics, Halle (Saale), Germany

The Edelstein effect (EE) is a promising mechanism for generating spin and orbital polarization from charge currents in systems without inversion symmetry. In ferroelectric materials, such as Germanium Telluride (GeTe), the combination of bulk Rashba splitting and voltage-controlled ferroelectric polarization provides a pathway for reversible spin-charge interconversion [1, 2].

In this work, we investigate current-induced spin and orbital magnetization in bulk GeTe using Wannier-based tight-binding models derived from DFT calculations and semiclassical Boltzmann theory. Employing the modern theory of orbital magnetization (MTOM), we demonstrate that the orbital Edelstein effect (OEE) entirely dominates its spin counterpart (SEE). This difference is visualized through the spin and orbital textures at the Fermi surfaces, where the orbital moment surpasses the spin moment by one order of magnitude. Moreover, the OEE remains largely unaffected when we suppress the spin-orbit coupling, highlighting its distinct physical origin compared to the SEE.

MA 33: Non-Skyrmonic Magnetic Textures I

Time: Thursday 9:30–13:00 Location: H16

MA 33.1 Thu 9:30 H16

Anomalous quasielastic scattering in centrosymmetric helimagnets — N. D. Andriushin[1], J. Grumbach[1], A. A. Kulbakov[1], Y. V. Tymoshenko[2,1], Y. A. Onykiienko[1], R. Firouzmandi[3], E. Cheng[3], S. Granovsky[1], Y. Skourski[4], J. Ollivier[5], H. C. Walker[6], V. Kocsis[3], B. Büchner[3], M. Doerr[7], •D. S. Inosov[1], and D. C. Peets[1] — [1]IFMP, TU Dresden, Germany — [2]JCNS, FZ Jülich, Germany — [3]IFW Dresden, Germany — [4]HZDR, Dresden, Germany — [5]ILL, Grenoble, France — [6]ISIS, RAL, Didcot, UK — [7]MPI-FKF, Stuttgart, Germany

Centrosymmetric helimagnets which host spin helices or skyrmion-like topological spin structures comprise a distinct subclass of materials in which helical order is stabilized by bond frustration in contrast to the more common path of antisymmetric exchange interactions. Here we will present the spin-dynamical properties of the $SrFeO_3$ [1] and $Sr_3Fe_2O_7$ [2] perovskites. Inelastic neutron scattering reveals that with increasing temperature, high-energy magnons increasingly lose coherence, and the spin fluctuations become dominated by a distinct quasielastic component at low energies, concentrated at the ordering wave vectors. This quasielastic component likely originates from helical domain walls. We anticipate that this could be generic to all symmetric helimagnets in which the chiral symmetry is spontaneously broken by the magnetic order.

MA 33.2 Thu 9:45 H16

Characterising 3D Topological Magnetic Textures using the Hopf index: Hopfions, Fractional Hopfions and Screw Dislocations — •Maria Azhar, Sandra Chulliparambil Shaju, Ross Knapman, Alessandro Pignedoli, and Karin Everschor-Sitte — Faculty of Physics and CENIDE, University of Duisburg-Essen.

In magnetic systems, twisted, knotted, linked, and braided vortex tubes manifest as Skyrmions, Hopfions, Fractional hopfions, or screw dislocations [1]. These complex textures are characterized by topologically non-trivial quantities, such as a Skyrmion number, a Hopf index H, a Burgers vector (quantified by an integer), and linking numbers.

We address the common challenges and pitfalls associated with numerically calculating H using the traditional Whitehead integral [2]. We present an alternative analytical method for determining H, introducing a new discrete geometric formulation [3]. This approach separates H into contributions from the self-linking and inter-linking of flux tubes of the emergent magnetic field.

Our analysis reveals the natural emergence of fractional Hopfions or textures with non-integer H, which we interpret as "mixed topology" states. These states can smoothly transform into one of several possible topological sectors with integer H. We establish a robust physical foundation for the Hopf index to assume integer, non-integer, or specific fractional values, depending on the system's underlying topology. [1] M. Strain-induced spin spiral in Dy-doped Ferrite films — •Holger Meyerheim[1], Anupam Singh[1], Verena Ney[2], Andreas Ney[2], Arthur Ernst[2], Malleshwararao Tangi[1], Ilya Kostanovski[1], Manuel Valvidares[3], Pierluigi Gargiani[3], Jean-Marc Tonnerre[4], Stuart S. P. Parkin[1], and Katayoon Mohseni[1] — [1]MPI f. Mikrostrukturphysik, D-06120 Halle — [2]Johannes Kepler University, A-4040 Linz (Austria) — [3]ALBA Synchrotron, E-08290 Cerdanyola del Valles (Spain) — [4]Institut Neel, CNRS & Univ. J. Fourier, F-38042 Grenoble (France)

Ferrites are known as textbook ferrimagnets. Recent interest in oxides as low-dissipation materials in spintronics has also focused interest on the modification of the spin texture of oxides in general [1]. Here we present a combined experimental and theoretical study which shows that in 5-40 nm thick Dy-doped Ni-ferrite films the local structural strain and the resulting concomitant symmetry reduction induced by the large Dy^{3+} ions incorporated in the percent concentration range into the octahedral sites of the spinel-type structure leads to the emergence of the chiral Dzyaloshinskii-Moriya interaction (DMI). The DMI is responsible for the onset of a non-collinar spin texture. Using soft x-ray resonant magnetic reflectivity and x-ray magnetic circular dichroism experiments in the vicinity of the Fe- and Ni-$L_{2,3}$- and the Dy-$M_{4,5}$ edges we develop a model in which the Fe and Ni magnetic moments are aligned in a spiral-like spin texture with a q-vector almost parallel to [001]. This work is supported by the DFG under grant MO 4198/2-1. [1] L. Caretta, et al., Nat. Comm. 11, 1090 (2020)

Quantum Bloch points in magnetic systems — •Vladyslav Kuchkin, Štefan Liščák, Andreas Haller, Andreas Michels, and Thomas Schmidt — University of Luxembourg

A Bloch point represents a three-dimensional hedgehog singularity of a magnetic vector field in which the magnetization vanishes at the center. Experimentally, the appearance of such points is well-established; at the same time, the standard micromagnetic theory is only suitable for fixed-length continuous magnetization vector fields and is thus not applicable to such singularities. To approach this problem, we study a Bloch point in a quantum Heisenberg model for the case of spin-1/2 particles. Such a state can be stabilized by adding a Zeeman term that imposes a boundary condition. We obtain the ground state and the corresponding magnetization profile by performing an exact diagonalization and using density matrix renormalization group techniques. Our findings show a smooth change of the spin length in the quantum model, leading to zero magnetization at the Bloch point. This behavior is generic for different system sizes. Our results indicate the necessity of generalizing the classical micromagnetic model, relying on a magnetization vector field of constant length, by adding a third degree of freedom of the spin: the ability to change its length. We achieve this by introducing a regularized $\mathbb{S}^3$ model that describes a four-dimensional order parameter of unit length. In contrast to earlier attempts to describe magnetization profiles of varying lengths, our approach satisfies the quantum mechanical constraints on spin operators.

MA 33.5 Thu 10:30 H16

Magnetic solitons in hierarchical 3D magnetic nanoarchitectures of nanoflower shape — •Olha Bezsmertna[1], Rui Xu[1], Oleksandr Pylypovskyi[1], David Raftrey[2,3], Andrea Sorrentino[4], Jose A. Fernandez-Roldan[1], Ivan Soldatov[5], Daniel Wolf[5], Axel Lubk[5], Rudolf Schäfer[5], Peter Fischer[2,3], and Denys Makarov[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf e.V., Dresden, Germany — [2]University of California Santa Cruz, Santa Cruz CA, USA — [3]Lawrence Berkeley National Laboratory, Berkeley CA, USA — [4]Alba Light Source, Cerdanyola del Vallès 08290, Spain — [5]Leibniz Institute for Solid State and Materials Research, Dresden, Germany

Curvilinear magnetism is an emerging field that explores how magnetic properties and responses are modified in geometrically curved objects [1]. Here, we synthesize large-scale, highly-periodic 3D nanomembranes [2] of 50-nm-thick permalloy of a nanoflower shape interconnected by close-to-hemispherical indentations. Nanoflowers with a size of about 200 nm exhibit a variety of magnetic states, e.g. domain walls, flower, vortex and a state with two Bloch lines. The ground magnetic state is a vortex, which is shifted away from the geometric center of the nanoflower. Micromagnetic simulations show nonlocal symmetry breaking, which is specific to 3D curved geometries enabling interactions between surface and volume magnetostatic charges, responsible for the shift of the vortex [3]. MA 33.6 Thu 10:45 H16

Emergence of topological superconductivity in the presence of chiral magnetism in 2D $CrInTe_3$ — •Arnob Mukherjee[1], Fengyi Zhou[2], Soheil Ershadrad[1], Tanay Nag[3], Duo Wang[2], and Biplab Sanyal[1] — [1]Department of Physics and Astronomy, Uppsala University, Box-516, 75120 Uppsala, Sweden — [2]Faculty of Applied Sciences, Macao Polytechnic University, Macao SAR, 999078, China — [3]Department of Physics, BITS Pilani-Hyderabad Campus, Telangana 500078, India

We propose a framework for designing two-dimensional (2D) topological superconductors (TSCs) using a bilayer hybrid system of monolayer $CrInTe_3$ with noncoplanar magnetic textures coupled to a 2D s-wave superconductor. This hybrid system induces a topological superconducting phase, serving as a platform for realizing the 2D Kitaev model and supporting Majorana zero-energy modes via emergent p-wave pairing. Using Density functional theory calculations, we calculate the essential magnetic parameters, such as Heisenberg exchange and Dzyaloshinskii-Moriya interactions (DMI) using the LKAG approach. Large-scale Monte Carlo simulations reveal that the substantial DMI stabilizes a noncoplanar spiral magnetic state without external fields. In this phase, we observe a transition from dipolar to edge modes in the zero-energy local density of states as the chemical potential varies. Under finite magnetic fields, the system exhibits a mixed magnetic state with isolated skyrmions and spiral domain walls, leading to unique low-energy electronic states and insulating behavior.

MA 33.7 Thu 11:00 H16

Topological textures in antiferromagnetic thin-films stabilized by interfacial magnetostrictive destressing — •Lukas D Cavar[1], Julian Skolaut[2], Olena Gomonay[1], Simon J Sochiera[1], David Anthofer[1], Miela Gross[3], Evangelos Golias[4], Dirk Backes[5], Caroline A Ross[3], and Angela Wittmann[1] — [1]JGU, Mainz, DE — [2]IEAP, CAU, Kiel, DE — [3]MIT, Cambridge, USA — [4]MAX IV, Lund, SE — [5]DLS, Didcot, UK

Weakly-compensated antiferro- and ferrimagnets present us with ultrafast dynamics, along with a weak magnetization vector that is legible, accessible, and robust to external perturbations. This makes them ideal candidates for the next generation of computing materials, where information may be encoded in the form of topological magnetic textures. Conventional long-range interaction– namely, the stray field– is not sufficient to stabilize such textures on its own. Here we discuss the magnet-substrate interface, where a magnetostriction-dependent interfacial incompatibility gives rise to long-range destressing fields capable of stabilizing topological textures in easy-plane magnetic thin-films with nearly-compensating staggered spin ordering. We investigate two such materials– α-Fe_2O_3 (hematite) and dysprosium iron garnet (DyIG) near its compensation temperature– by x-ray magnetic linear dichroism microscopy and indeed observe a rich landscape of topological textures. Thereby we tread towards a rigorous understanding of the interfacial destressing field and begin to uncover a promising new source of topological mesostructure.

Towards stabilizing 360° domain walls in dysprosium iron garnet through magnetoelastic interactions — •Julian Skolaut[1,2], Lukas Cavar[1], Olena Gomonay[1], Miela Gross[3], Simon Sochiera[1], David Anthofer[1], Evangelos Golias[4], Dirk Backes[5], Caroline A. Ross[3], and Angela Wittmann[1] — [1]JGU, Mainz, DE — [2]present address: IEAP, CAU, Kiel, DE — [3]MIT, Cambridge, US — [4]MAX IV, Lund, SE — [5]DLS, Didcot, UK

Topologically protected magnetic textures, including 360° domain walls (DWs), are of considerable interest for next-generation data storage and computing technologies. Realizing such textures in ferri- and antiferromagnetic systems allows us to capitalize on these materials' intrinsic robustness to external perturbations and faster dynamics. However, well-established mechanisms, such as stray fields, cannot stabilize 360° DWs at zero magnetic field. Hence, we must turn to more exotic stabilization mechanisms. One promising candidate is magnetoelastic destressing mediated by the substrate/magnetic film interface. Here, we report the observation of 360° DWs in ferrimagnetic dysprosium iron garnet thin films. These topological DWs are present in applied magnetic fields from zero to above coercivity, suggesting topological protection, and can be manipulated using magnetic fields. Upon return to zero magnetic field, the initial state is not reproduced, indicating hysteresis. This hints toward stabilization via magnetoelastic interactions. Corroborating these results with insights from other materials and theory will further the understanding of exotic mechanisms, such as destressing fields, as a source of topological magnetic textures.

MA 33.9 Thu 11:45 H16

Computational studies of novel Dzyaloshinsky-Moriya interactions — •Samuel Holt[1,2], Martin Lang[1,2], Swapneel Pathak[1,2], and Hans Fangohr[1,2,3] — [1]Max Planck Institute for the Structure and Dynamics of Matter, Luruper Chaussee 149, 22761 Hamburg, Germany — [2]Center for Free-Electron Laser Science, Luruper Chaussee 149, 22761 Hamburg, Germany — [3]Faculty of Engineering and Physical Sciences, University of Southampton, Southampton SO17 1BJ, United Kingdom

The exploration of magnetic phases in chiral magnets has gathered significant interest due to the unique physics and potential applications of these materials. A key factor in these systems is the Dzyaloshinsky-Moriya interaction (DMI), which arises from the asymmetric environment of interacting magnetic spins and is linked to non-centrosymmetric crystallographic point groups. While a few point groups have had their DMI extensively studied, many remain unexplored.

In this talk, we systematically explore the multidimensional parameter space of these new DMI terms using micromagnetic simulations to identify and classify magnetic phases. Machine learning algorithms, such as clustering and autoencoders, are employed to automate this process, enabling the rapid identification and grouping of similar magnetic phases across extensive parameter spaces. Funded by EU Horizon 2020, grants 101152613 and 101135546.

Interplay between magnetic and charge order in an ultra-clean van der Waals material — •Priya Baral[1], Sun Okumura[1], Moritz Hirschmann[2], Sebastian Esser[1], Rinsuke Yamada[1], Shun Akatsuka[1], Jonathan White[4], Samuel M. Moody[4], Stanislav Niktin[4], Nina-juliane Steinke[5], Shang Gao[6], Yoshichika Onuki[2], Taka-hisa Arima[2,7], Taro Nakajima[3], and Max Hirschberger[1,2] — [1]Department of Applied Physics, The University of Tokyo, Tokyo, JP — [2]RIKEN Center for Emergent Matter Science (CEMS), Saitama, JP — [3]Institute for Solid State Physics, University of Tokyo, Chiba, JP — [4]PSI Center for Neutron and Muon Sciences, Villigen PSI, CH — [5]Institut Laue-Langevin, 71 avenue des Martyrs, Grenoble, FR — [6]Department of Physics, University of Science and Technology of China, CHN — [7]Department of Advanced Materials Science, The University of Tokyo, JP

The interplay between charge-density wave order and magnetism has been a prominent area of research for decades, encompassing unconventional superconductors to more recent Kagome metals. The cooperative or competitive nature of these two phenomena has been a fundamental aspect of many-body physics. Recently, it has been demonstrated that RTe3 (R = rare earth) van der Waals materials exhibit helimagnetic textures coupled to an unconventional charge-density wave order. Here, we review recent developments in one of the ultra-clean members of the series, DyTe3. We reveal further evidence for the unconventional spin-charge coupling in this material by combining magnetic, transport and neutron scattering measurements.

MA 33.11 Thu 12:15 H16

Magnetic Ordering Temperature for Spin Spiral materials — •Varun Rajeev Pavizhakumari and Thomas Olsen — CAMD, Department of Physics, Technical University of Denmark, 2800 Kgs. Lyngby Denmark

Spin Spirals are the materials that show a helical arrangement of magnetic moments in the ground state. Thermal fluctuations from this state form collective excitations known as spin waves/magnons. As the thermal stability of a spin spiral is a decisive factor for its technological applications, there is considerable interest in the theoretical prediction of its critical temperature. This could be accomplished using two approaches - Holstein-Primakoff(HP) bosonization and the Green's function-Random Phase Approximation(RPA) where we can calculate the thermally renormalized magnon energies at each temperature. But these methods only exist for ferromagnetic and a few specific antiferromagnetic materials. In this work, we propose a single-Q spiral generalization of the HP bosonization and the Green's function-RPA to calculate the critical temperature. We benchmark these methods along with the classical Monte Carlo simulations and the Mean field theory, using their experimental exchange parameters for a diverse range of materials ; MnO and NiO(single site Neel state),MnF_2(altermagnetic),Cr_2O_3 and Fe_2O_3(two site Neel state) and $Ba_3NbFe_3Si_2O_{14}$(incommensurate). In all cases, we observe that the Green's function-RPA shows excellent agreement to the experiments and hence is as an ideal candidate to predict the critical temperature for any single-Q spirals.

MA 33.12 Thu 12:30 H16

Three-dimensional topological spin textures in curved chiral magnets — •Luke Turnbull[1,2], Max Birch[3], Marisel Di Pietro Martínez[1,2], Rikako Yamamoto[1,2], Jeffrey Neethirajan[1], Marina Raboni Ferreira[1,4], Rachid Belkhou[5], Simone Finizio[6], Dieter Suess[7], Geetha Balakrishnan[8], Claas Abert[7], Sebastian Wintz[9], and Claire Donnelly[3] — [1]MPI CPfS, Dresden, Germany — [2]WPI-SKCM2, Hiroshima, Japan — [3]RIKEN CEMS, Saitama, Japan — [4]Brazilian Synchrotron Light Laboratory, Sao Paulo, Brazil — [5]Synchrotron SOLEIL, Saint Aubin, France — [6]SLS, PSI, Villigen, Switzerland — [7]University of Vienna, Vienna, Austria — [8]Univeristy of Warwick, Coventry, UK — [9]HZB, Berlin, Germany

Nanoscale topologically non-trivial magnetization configurations generate significant interest due to both their fundamental properties, and their potential applications in ultra-efficient computing devices. While such textures have been widely studied in two dimensions, three dimensional (3D) ordering can yield more complex configurations, resulting in richer topologies and dynamic behaviours. However, reliably nucleating such 3D textures has proven challenging. Here, we achieve the controlled formation of a double helix ordering through the 3D nanopatterning of chiral single crystal helimagnets into nano-tori. We demonstrate that the interplay of intrinsic exchange interactions of the single crystal, with the extrinsic emergent effects of the patterned geometry, leads to the stabilisation of surface-localized topologically non-trivial double helices. Our approach has the potential to be applied to a wide range of quantum material systems.

MA 33.13 Thu 12:45 H16

Lifetime of toroidal Hopfions in bulk magnets with competing exchange interactions — •Moritz Sallermann[1,3], Hannes Jonsson[3], and Stefan Blügel[1,2] — [1]RWTH Aachen University, Germany — [2]PGI-1, Forschungszentrum Jülich, Germany — [3]University of Iceland, Iceland

Hopfions are three-dimensional topological solitons characterized by the Hopf invariant, which quantifies the pairwise linking number of constant magnetization pre-images. In simple models of bulk magnets with competing exchange interactions, Hopfions emerge as local energy minima in numerical simulations. However, to fully understand their stability against decay due to thermal fluctuations, merely identifying these local minima is insufficient. A more comprehensive understanding requires determining their expected average lifetimes. We employ the harmonic transition state theory framework, a computationally efficient yet approximate method, to estimate these lifetimes. This approach yields an Arrhenius-type expression comprising two key ingredients: the energy bar-

rier and an entropic prefactor. The energy barrier represents the minimal energy needed to initiate decay, while the entropic prefactor measures the relative entropy of the energy bottleneck, compared to the configuration space volume of the local minimum. We present our findings on the lifetimes of Hopfions in these systems and discuss technical challenges encountered, such as the treatment of Goldstone modes and the computation of sparse positive-definite determinants.

We acknowledge funding from the ERC grant "3D MAGIC".

Handling higher order ligand field parameters of single molecule magnets using deep learning — •Zayan Ahsan Ali, Julius Mutschler, Preeti Tewatia, and Oliver Waldmann — Physikalisches Institut, Universität Freiburg, D-79104 Freiburg, Germany

In recent decades, Single Molecule Magnets (SMMs) have sparked an interest not only due to their applications in quantum computing and spintronics, but also as an ideal platform for exploring fundamental principles of quantum magnetism. While substantial progress has been made towards the characterization of magnetic properties of 3d SMMs, the study of 4f SMMs remains challenging. This difficulty arises from the involvement of up to 27 ligand field parameters and the typically featureless nature of experimental magnetic data, leading to severe overparameterization. Moreover, the physically relevant regions in this parameter space are mostly unknown a priori. Although deep learning based inverse models, such as Conditional Variational Autoencoders and Invertible Neural Networks, have shown promise in addressing overparameterization, their performance degrades significantly when trained on uninformative parameter spaces, which dominate especially in high dimensional settings. This work investigates the use of Monte Carlo based parameter sampling for the higher order ligand field parameter space as a crucial precursor towards improving the deep learning inverse models. The resulting dataset represents a more informative prior, enabling insights into the effects of higher order ligand field parameters and the correlations between them.

MA 34.2 Thu 9:45 H18

Polarization of Electron Spin and Orbitals in Chiral Molecular Junctions on Semiconductors — •Peng Xiong[1], Yuwaraj Adhikari[1], Tianhan Liu[1,3], Hailong Wang[2], Zhenqi Hua[1], Haoyang Liu[1], Paul Weiss[3], Binghai Yan[4], and Jianhua Zhao[2] — [1]Florida State University, USA — [2]Institute of Semiconductors, Chinese Academy of Sciences, China — [3]University of California, Los Angeles, USA — [4]Weizmann Institute of Science, Israel

Electrical generation and transduction of polarized electron spins in semiconductors via nonmagnetic means are of broad interest in spintronics and quantum information science. One such pathway is chirality-induced spin selectivity (CISS), where real-space structural chirality induces spin polarization of electrons from a nonmagnetic electrode. We have studied the CISS effect through measurement of spin-selective transport in chiral molecular junctions comprising a nonmagnetic normal metal electrode and a self-assembled monolayer of chiral molecules on magnetic (GaMnAs) or nonmagnetic (n-GaAs) semiconductors, where the spin polarization is detected via the spin-valve conductance and Hanle effect, respectively. The results reveal several important characteristics of the CISS effect [1-3]: i) nontrivial linear-response magnetoconductance in two-terminal CISS spin valves, in apparent violation of the Onsager reciprocal relation; ii) crucial role of the spin-orbit coupling in the normal metal electrode, suggesting the importance of orbital polarization in the chiral molecules; iii) spin generation by CISS in semiconductors. 1. ACS Nano 14, 15983 (2020); 2. Nat. Commun. 14:5163 (2023) ; 3. Ad. Mater. 36, 2406347 (2024).

MA 34.3 Thu 10:00 H18

Effects of Boundary Condition on Quantization in the Spin-1/2 Heisenberg Chain — •Saketh Ravuri[1], Chenxiao Zhao[1], Pascal Ruffieux[1], and Roman Fasel[1,2] — [1]Empa, Dübendorf, Switzerland — [2]University of Bern, Bern, Switzerland

The spin-1/2 antiferromagnetic Heisenberg chain resides in a gapless spin liquid phase in the thermodynamic limit. In finite-length systems, however, quantization introduces a length-dependent excitation gap, which is further influenced by the boundary conditions. In this work, we investigate how open and periodic boundary conditions affect the quantization and gap behavior in spin-1/2 antiferromagnetic Heisenberg chains constructed by covalently linking magnetic nanographene units. For chains of fixed length, we demonstrate that open boundary conditions result in a smaller gap compared to periodic boundary conditions, as clearly evidenced by the inelastic electron tunneling spectra. This impact of boundary conditions diminishes with increasing chain length and vanishes in the thermodynamic limit. Moreover, in periodic rings with odd-numbered units, we investigated the scattering of a single spinon caused by J-fluctuations. These findings illuminate the role of boundary effects in finite-size quantum spin systems and contribute to the fundamental understanding of quantum magnetism and excitations in spin chains.

MA 34.4 Thu 10:15 H18

Approximate finite-temperature Lanczos modelling of dysprosium containing magnetic molecules — •Jürgen Schnack and Dennis Westerbeck — Bielefeld University, Faculty of Physics, 33615 Bielefeld

Dysprosium containing magnetic molecules are considered promissing building blocks of future quantum technology such as storage, quantum computing, quantum sensing, or magnetocalorics. The initial physical characterization includes measurements of magnetization or heat capacity as function of temperature and applied magnetic field.

A theoretical modelling of an approximate quantum spin model by means of exact diagonalization of multicenter systems is virtually impossible due to the large magnetic moment of dysprosium. We resort to the finite temperature Lanczos method which however converges rather slowly [1]. We explain the reasons, our solutions and results for recent Dy containing molecules [2].

MA 34.5 Thu 10:30 H18

Annealing Induced Ordered Structures of H2Pc Monolayer on γ'-Fe4N Thin Film — •Hiroki Ono[1], Yoshitaka Umeda[1], Kaito Yoshida[1], Kenzaburo Tsutsui[1], Kohei Yamamoto[2], Osamu Ishiyama[2], Toshihiko Yokoyama[2], Masaki Mizuguchi[1], and Toshio Miyamachi[1] — [1]Nagoya University, Nagoya, Japan — [2]Institute for Molecular Science, Okazaki, Japan

Organic-inorganic hybrid interface has been studied because its interfacial spin state can be controlled through proximity effect. Spin state depends on local interface structures as well as electronic interaction between organic molecules and magnetic substrates. Therefore, controlling the interface structure is essential but remains challenging because of strong interaction between organic and inorganic materials.

In this work, we fabricate organic-inorganic hybrid thin films using iron nitride as a ferromagnetic substrate and phthalocyanine(H2Pc) as an organic molecule. Iron nitride atomic layers with γ'-Fe4N stoichiometry uniformly grow and show weaker interaction than typical ferromagnetic substrate. Therefore, γ'-Fe4N is a candidate to create structurally controlled interface. We investigate interface structure by using scanning tunneling microscopy(STM) and low energy electron diffraction(LEED), and electronic/magnetic properties by using x-ray absorption spectroscopy/magnetic circular dichroism(XAS/XMCD). We confirm the magnetic coupling occurs at H2Pc/γ'-Fe4N bilayer interface from XAS/XMCD results. H2Pc monolayer on γ'-Fe4N bilayer do not have any long-range lattice manner. But, we find annealing induces well-ordered structure while preserving interface magnetic coupling.

MA 34.6 Thu 10:45 H18

CuCu4 metallacrowns on the Au(111) surface: A density functional study — •Ariyan Tavakoli[1], Stefan Lach[1], Benjamin Stadtmüller[2], Christiane Ziegler[1], Peter Puschnig[3], and Hans Christian Schneider[1] — [1]Department of Physics and Research Center OPTIMAS, University of Kaiserslautern-Landau, Kaiserslautern, Germany — [2]Experimentalphysik II, Institute of Physics, Augsburg University, Augsburg, Germany — [3]Department of Physics, University of Graz, Graz, Austria

Metallacrowns [1] combine chemical and structural features that make them a promising material system for single-molecule magnets. Here, we present a first-principles study of the electronic and magnetic properties of the metallacrown (HNEt3)2CuII [12-MCYN(Shi)-4] (Y=CuII), in short CuCu4, in the gas phase and on the Au(111) surface. First, we study the magnetic properties of CuCu4 metallacrown in the gas phase by applying the broken symmetry approach [2], where we benchmark the performance of various (range-separated) hybrid functionals compared to the computationally cheaper GGA+U approach. In the second step, we explore the magnetic configurations of CuCu4 metallacrown adsorbed on an Au(111) surface using density functional theory (DFT) with GGA+U framework. The analysis highlights the changes of the ligand structure and the density of state (DOS) around the metal centers by a comparison between the isolated molecule and the adsorbed one on the surface.

MA 34.7 Thu 11:15 H18

Cooperative and Selective Redox Doping Switches Single-Molecule Magnetism — Fabian Paschke[1], Matteo Briganti[2], Vivien Enenkel[1], Tobias Birk[1], Jan Dreiser[3], Peter Schmitt[4], Rainer F. Winter[4], Federico Totti[2], and •Mikhail Fonin[1] — [1]Fachbereich Physik, Universität Konstanz, 78457 Konstanz, Germany — [2]Department of Chemistry 'Ugo Schiff' and INSTM Research Unit, University of Florence, 50019 Sesto Fiorentino, Italy — [3]Swiss Light Source, Paul Scherrer Institute, 5232 Villigen PSI, Switzerland — [4]Fachbereich Chemie, Universität Konstanz, 78457 Konstanz, Germany

The controlled manipulation of electronic and magnetic states in single-molecule magnets (SMMs) is crucial for their implementation in molecular spintronics. In typical SMMs, key properties like magnetic anisotropy and slow magnetic relaxation are imposed by complex ligand shells, whose bulky and three-dimensional structures hamper efficient manipulation of the molecular magnetism by chemical methods. Here, we demonstrate highly selective chemical doping of an Fe_4 nanomagnet on a Pb(111) surface using lithium atoms. Scanning tunneling microscopy, X-ray absorption spectroscopy, and ab initio calculations reveal the cooperative incorporation of three Li atoms per Fe_4 molecule, resulting in a selective, threefold reduction of its iron-based magnetic core. The doping modifies the intramolecular exchange interaction, turning from antiferromagnetic to ferromagnetic coupling, and changes the molecular magnetic anisotropy from easy-axis to easy-plane.

MA 34.8 Thu 11:30 H18

Tuning spin-injection into metallacrown/thin-metal film systems — •David Anthofer[1], Ashish Moharana[1], Dominik Laible[2], Fabian Kammerbauer[1], Alexander Hagenow[2], Eva Rentschler[2], and Angela Wittmann[1] — [1]Institut für Physik, Johannes-Gutenberg Universität Mainz, Deutschland — [2]Department Chemie, Johannes-Gutenberg Universität Mainz, Deutschland

Single-molecular magnets (SMMs) have recently gained significant interest due to their ability to retain magnetic information at the molecular level, offering potential applications in high-density data storage devices. A crucial challenge hindering their application in technology is the integration with thin-film devices. To tackle this challenge, we explore the spin-injection efficiency in hybrid molecule/non-magnetic metal thin film heterostructures to understand the impact of hybridization. For this, we utilize molecules based on the metallacrown system, chosen for their unique combination of synthetic versatility and structural stability. We inject a pure spin current at ferromagnetic resonance into the hybrid interface, allowing us to measure the magnetic damping of the system. We observe a notable increase in damping after adsorption of Dysprosium-based metallacrown SMMs. In contrast, no change in damping was observed after deposition of Copper-based metallacrowns indicating the significance of molecular composition on the spin-injection efficiency at the hybrid interface. Further optimization of the ferro- and nonmagnetic metal layer thicknesses proves to affect the observed change in damping, paving the path toward a sensitive framework to study hybridization at the molecule/metal interface.

MA 34.9 Thu 11:45 H18

Probing magnetic exchange interactions in cobalt-based molecular magnets using magneto-Raman spectroscopy — •Komalavalli Thirunavukkuarasu[1], David Hunger[2], Julia Netz[3], Duncan Moseley[4], Ziling Xue[4], Dmitry Smirnov[5], Andreas Koehn[3], and Joris van Slagaren[2] — [1]Department of Physics, Florida A & M University, Tallahassee, FL, USA — [2]Institute of Physical Chemistry, University of Stuttgart, Stuttgart, Germany — [3]Institute of Theoretical Chemistry, University of Stuttgart, Stuttgart, Germany — [4]Department of Chemistry, University of Tennessee, Knoxville, USA — [5]National High Magnetic Field Laboratory, Tallahassee, USA

Combining spectroscopy with one or more external parameters such as low temperature, high pressure, and high magnetic fields, allows us to probe interplay between spin, charge, orbital, and lattice degrees of freedom. Spin exchange interactions play an important role in single-molecule magnets and molecular qubits that feature magnetic bistability. However, there have been few detailed studies to experimentally find the energy scale of these interactions such as spin-phonon coupling. Recently, we employed magneto-Raman spectroscopy together with theoretical work on single molecular magnets to reveal the signatures of spin-phonon interactions in these materials. In this talk, the magneto-Raman experimental results from mononuclear cobalt(II) and radical-bridged dinuclear cobalt(II) complexes and the outcome will be discussed.

MA 34.10 Thu 12:00 H18

The Role of Quantum Vibronic Effects in the Spin Polarization of Charge Transport through Chiral Molecular Junctions — •Samuel Rudge[1], Christoph Kaspar[1], Riley Preston[1], Joseph Subotnik[2], and Michael Thoss[1] — [1]Institute of Physics, University of Freiburg — [2]Department of Chemistry, Princeton University

The chirality-induced spin selectivity (CISS) refers to the experimentally observed phenomenon that the transport of spin-polarized electrons through chiral mediums can be highly asymmetric between the two spin orientations and enantiomers [1]. Although the exact mechanism underpinning the CISS effect is still unknown, one of the leading ideas is that it is connected to the coupling of transport electrons to molecular vibrations. In this contribution, we follow this theme by investigating CISS in the context of charge transport through a chiral molecular nanojunction via the numerically exact, fully quantum hierarchical equations of motion (HEOM) approach [2]. Specifically, we calculate charge currents through a two-site, two-mode model [3], focusing on the highly nonadiabatic regime of low-voltage charge transport, in which we find significant spin polarization.

MA 34.11 Thu 12:15 H18

Chiral-induced unidirectional spin-to-charge conversion — •Ashish Moharana[1], Yael Kapon[2,3], Fabian Kammerbauer[1], David Anthofer[1], Shira Yochelis[2,3], Mathias Klaüi[1], Yossi Paltiel[2,3], and Angela Wittmann[1] — [1]Institute of Physics, Johannes Gutenberg University Mainz, Mainz 55128, Germany — [2]Institute of Applied Physics, The Hebrew University of Jerusalem, Jerusalem 9190401, Israel — [3]Center for Nanoscience and Nanotechnology, The Hebrew University of Jerusalem, Jerusalem 9190401, Israel

The chiral-induced spin selectivity (CISS) effect has recently gained significant attention in the field of spintronics. The remarkably high efficiency of the spin polarizing effect has recently gained substantial interest due to the high potential for future sustainable hybrid chiral molecule magnetic applications. While so far research has predominantly focused on transport properties, in our work, we explore spintronic phenomena at hybrid chiral molecule magnetic interfaces to elucidate the underlying mechanisms of the chiral-induced spin selectivity effect. For this, we investigate the interfacial spin-orbit coupling in chiral molecule/metal thin film heterostructures by probing the chirality and spin-dependent spin-to-charge conversion. Our findings validate the central role of spin angular momentum for the CISS effect, paving the path toward the functionalization of hybrid molecule-metal interfaces via chirality.

MA 34.12 Thu 12:30 H18

Interplay between spin induced polarization and quantum entanglement in triangular magnetic molecules — •Zhirayr Adamyan[1,2], Vadim Ohanyan[1,2], and Ani Chobanyan[1] — [1]Laboratory of Theoretical Physics, Yerevan State University, 1 Alex Manoogian, 0025 Yerevan, Armenia — [2]CANDLE, Synchrotron Research Institute, 31 Acharyan Str., 0040 Yerevan, Armenia

The quantum entanglement of spin states in molecular magnets has important applications in quantum information technologies and quantum computing. Currently, qubit models based on magnetic molecules are being used to develop quantum computation and communication technologies. We consider two models of three-spin molecular magnets with additional features that allow one to manipulate and enhance their entanglement. The first model is a mixed-spin (1/2, 1, 1/2) triangle with two g-factors. The second model is a spin-1/2 triangle with the Katsura-Nagaosa-Balatsky (KNB) mechanism, providing the coupling between spin degrees of freedom and the external electric field. It is shown that non-conserving magnetization originated from the non-uniformity of g-factors leads to an essential increase of the entanglement of certain spin states along with the rich structure of zero-temperature phase diagrams. Whereas, the model with magnetoelectric coupling due to the KNB mechanism offers a wide possibility of manipulation of quantum entanglement by the electric field, both using its magnitude and direction.

MA 35: PhD Focus Session: Using Artificial Intelligence Tools in Magnetism

Over the last decade, the field of artificial intelligence (AI) has experienced significant growth and progressively offers applications across a wide range of topics, becoming an integral part of our daily lives. Its importance was also underscored by the 2024 Nobel Prize in Physics awarded to John J. Hopfield and Geoffrey E. Hinton 'for foundational discoveries and inventions that enable machine learning with artificial neural networks'. The application of AI methods is also becoming increasingly relevant in research for prediction and data analysis to enhance research, making it faster and more efficient. Typically, these AI tools come from the domain of machine learning, centered on deep learning architectures such as neural networks, convolutional neural networks, and transformer networks. To ensure young researchers, especially in the field of magnetism, can benefit from this progress, we organize the PhD Focus session 'Using Artificial Intelligence Tools in Magnetism'. In this session, experts will demonstrate in highly pedagogical presentations how AI tools can be applied in material science and magnetism. Additionally, there will be a direct, practical introduction to this area of AI tools in magnetism with a hands-on part, where each participant can engage and explore the fascinating world of AI tools for magnetism firsthand using a prepared repository. You can find the repository at https://github.com/kfjml/AI-Magnetism-Session-Regensburg-2025 , please follow the instructions in the Readme, ideally before the session. Alternatively, you can download the repository as a ZIP file, including the instructions in the Readme, from https://download.klaeui-lab.de/AI-Magnetism-Session-Regensburg-2025.

Introduction

Invited Talk MA 35.1 Thu 9:35 H20

Artificial Intelligence for Materials Science: Critical Importance of Rare Events, Active Learning, and Uncertainties — •Matthias Scheffler — The NOMAD Laboratory at the Fritz Haber Institute of the Max Planck Society, 14195 Berlin, DE

Materials properties are often governed by an intricate interplay of many processes. As a consequence, the description in terms of meaningful analytical equations is typically inappropriate, and we are promoting the concept of 'materials genes'. These are elemental materials features that 'correlate' with the materials property of interest. Thus, they address the full intricacy and describe (in a statistical sense) the material's property and function.[1]

AI and machine learning (ML) exhibit diminished reliability when entering uncharted data regions. When the training data are representative of the full population (or iid), extrapolation may work. However, for materials this requirement is hardly fulfilled. Still, materials scientists are searching for 'statistically exceptional' situations, and properties are often triggered by 'rare events' that are not or not well covered by the available data, or smoothed out by the ML regularization. This all implies caution when applying ML. In my talk I will explain these issues and routes toward solutions. Key issues are the 'range of applicability' of ML models, the awful overconfidence of prediction uncertainties, and the needs for active learning.

(**) In collab. with Lucas Foppa, Kisung Kang, and Akhil S. Nair.

Invited Talk MA 35.2 Thu 10:05 H20

Physics meets data: decoding magnetic inhomogeneities through latent analysis — •Karin Everschor-Sitte — Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen

Physicists are trained to simplify complex problems into their fundamental components, often using effective minimal models to describe experimentally observed phenomena. This approach's standard challenges include the difficulty of directly measuring model parameters and the frequent oversimplification or neglect of sample inhomogeneities. As a result, models often fail to make accurate predictions when critical effects are overlooked or inadequately represented. In contrast, data-driven approaches focus on learning directly from the data, ideally without making restrictive assumptions about the data. This talk addresses the problem of hidden features in data and presents computationally efficient, physics-inspired data analysis tools - latent entropy and latent dimension [1,2] - that, for example, allow uncovering magnetic inhomogeneities from video data.

Invited Talk MA 35.3 Thu 10:35 H20

AI used for micromagnetic simulations — •Thomas Schrefl[1], Felix Lasthofer[1], Qais Ali[1], Heisam Moustafa[2], Harald Oezelt[2], Alexander Kovacs[2], Masao Yano[3], Noritsugu Sakuma[3], Akihito Kinoshita[3], Tetsuya Shoji[3], and Akira Kato[3] — [1]Christian Doppler Laboratory for magnet design through physics informed machine learning, Wiener Neustadt, Austria — [2]University for Continuing Education Krems, Wiener Neustadt, Austria — [3]Advanced Materials Engineering Division, Toyota Motor Corporation, Susono, Japan

Micromagnetic simulations are an excellent means for prediction of magnetic properties. However, the required computational resources limit the use of micromagnetics for materials design. Machine learning models can serve as surrogate for evaluating target properties during optimization. Artificial intelligence can sort pictures based on content or create new images given keywords. Treating the magnetization distribution as an image, methodologies from image processing can be applied in magnetism. We used this approach to predict the magnetization dynamics of thin film elements. The magnetic states are encoded by a convolutional neural network. For bulk magnets a different approach is required. Their three-dimensional grain structure can be represented by a graph. The regular pixels are replaced by the nodes and edges of a graph. We applied graph neural networks to predict hysteresis properties of permanent magnets. Trained machine learning models can be used for inverse design. Given certain targets, optimized magnets are suggested.

Invited Talk MA 35.4 Thu 11:15 H20

Future method for estimating parameters in magnetic films using machine learning — •Kenji Tanabe — Toyota Technological Institute, Nagoya, Japan

Estimating material parameters in fabricated materials is a crucial experiment in the field of materials science. Some parameters are difficult or time-consuming to measure. In spintronics, parameters such as the Dzyaloshinskii-Moriya exchange constant are good examples of this. If these parameters could be easily and quickly estimated, our research field would grow rapidly. Here, we present a new method for estimating parameters in magnetic films from a magnetic domain image using machine learning. A magnetic structure is well-known to be deeply related to magnetic parameters. Although a complicated magnetic structure, which often appears in an as-grown magnetic film, is considered random by human eyes, it is influenced by several magnetic energies. Thus, the characteristics of such parameters are probably hidden in the random magnetic structure. Such a relationship suggests that parameters can be estimated from a magnetic domain image by using pattern recognition. We collected a huge number of datasets of magnetic parameters and magnetic domain images made by micromagnetic simulation and/or taken by magnetic microscopes. The datasets were used as training and test data for the convolution neural network, which is a famous technique in machine learning for pattern recognition. We succeeded in the estimation of the parameters from the magnetic image using machine learning. This result may relieve future researchers from the difficulty of measuring parameters.

MA 35.5 Thu 11:45 H20

Hands-on workshop for using AI in magnetism research — •Kilian Leutner[1], Thomas B. Winkler[2], Jan Maskill[3], Kübra Kalkan[4], and Robin Msiska[4] — [1]Institute of Physics, Johannes Gutenberg-University Mainz — [2]Institute for Molecules and Materials, Radboud University — [3]Department of

Physics, University of Kaiserslautern-Landau — [4]Faculty of Physics, University of Duisburg-Essen

In this workshop, participants will receive a practical introduction to applying artificial intelligence (AI) in magnetism research. As a hands-on session, everyone can actively engage. We will demonstrate how to automatically analyze magneto-optical Kerr microscopy images of magnetic skyrmions using AI. The critical and significant step in the analysis involves segmenting the Kerr images using the Skyrmion U-Net, a convolutional neural network [1]. The participants will use their own devices to explore a repository, learning and executing the steps necessary to train and apply a skyrmion U-Net model. The required experimental Kerr data, pre-trained Skyrmion U-Net models, and code are available in a repository at https://github.com/kfjml/AI-Magnetism-Session-Regensburg-2025 or can be downloaded as a ZIP file from: https://download.klaeui-lab.de/AI-Magnetism-Session-Regensburg-2025. Please follow the instructions in the Readme file prior to the session, to make most use of it. This presented approach, is adaptable to other magnetic textures or imaging methods and can also be applied beyond magnetism.

MA 36: Focus Session: Ising Superconductivity in Monolayer Transition Metal Dichalcogenides (joint session TT/HL/MA)

Superconducting monolayer transition metal dichalcogenides (TMDs) like $NbSe_2$, TaS_2, and gated WSe_2 or MoS_2, have attracted lot of interest in recent years. On the one hand Ising spin-orbit coupling pins the electron's spin out of plane, and hence is responsible for critical in-plane magnetic fields by far exceeding the Pauli limit. On the other hand, while the underlying pairing mechanism is still under debate, recent experiments provide strong evidence for its unconventional, multiband, nature. The Focus Session will feature experimental and theoretical advances on the superconductivity in monolayer TMDs, with focus on universal features, a possible Luttinger-Kohn mechanism, a nodal or even chiral nature of the gap functions, and their phase diagram.

Organizers: Milena Grifoni (Universität Regensburg), Julian Siegl (Universität Regensburg)

Time: Thursday 9:30–12:45 Location: H36

See TT 44 for details of this session.

MA 37: Magnetic Imaging Techniques

Time: Thursday 15:00–17:45 Location: H16

MA 37.1 Thu 15:00 H16

Magnetic particle spectroscopy of ferrite nanoparticles: Controlling the Néel to Brownian relaxations — •Ondřej Kaman[1], Tereza Voltrová[1,2], Lenka Kubíčková[1,2], Ali Hassan[1], Pavel Veverka[1], Kyo-Hoon Ahn[1], Karel Knížek[1], Denisa Kubániová[2], and Jaroslav Kohout[2] — [1]FZU - Institute of Physics, CAS, Praha, Czech Republic — [2]Faculty of Mathematics and Physics, Charles University, Praha, Czech Republic

The Fourier transform of the magnetization response of a suspension of magnetic particles to a sinusoidal AC magnetic field provides so-called magnetic particle spectrum, i.e., a series of higher harmonics that originate in the non-linear $M(H)$ dependence. This characteristic is crucial for magnetic particle imaging (MPI), which is an emerging technique employing magnetic particles, typically in the superparamagnetic state, as exogeneous tracers for medical imaging. The magnetization dynamics of such tracers is governed by two distinct mechanisms, the Néel relaxation of magnetic moments and the Brownian rotation of whole particles. The present study is based on a series of hydrothermally prepared and thoroughly characterized (XRD, XRF, TEM, SQUID magnetometry) samples of $Co_{1-x}Ni_xFe_2O_4$ particles with x=0–0.5 and the mean crystallite size of 8–9 nm. Their silica-coated clusters, forming colloidally stable aqueous suspensions, were prepared, and MPI study was performed by means of an in-house built system (interchangeable coils impedance-matched to ~10, 15, 25, 35, and 50 kHz; magnetic field up to 20 mT).

MA 37.2 Thu 15:15 H16

Nanoscale magnetic imaging with color centers in fiber-coupled diamond nanobeams — •Gesa Welker[1], Yufan Li[1], Richard Norte[2], and Toeno van der Sar[1] — [1]Delft University of Technology, Faculty of Applied Sciences, Lorentzweg 1, 2628 CJ Delft, the Netherlands — [2]Delft University of Technology, Faculty of Mechanical Engineering, Mekelweg 2, 2628 CD Delft, the Netherlands

Nitrogen vacancy centers (NV-centers) in diamond are powerful magnetic field sensors that are excited and read out optically. They are an established tool for imaging weak magnetic signatures of condensed matter samples such as skyrmions, spin waves or 2D magnetism [1]. We present a unique fiber-coupled approach to scanning probe magnetometry, where a diamond nanobeam with NV-centers at its apex is attached to a tapered optical fiber and scanned across a sample [2]. Fiber-coupling could enable a higher excitation and collection efficiency compared to traditional setups. It also simplifies measurements at low temperatures, because it eliminates the need for re-alignment of free-space optics. We demonstrate diamond nanobeam fabrication via quasi-isotropic etching and a robust nanobeam-fiber assembly using optical glue. With this setup, we performed a 2D scan of the magnetic stray field of a current-carrying wire with sub-micrometer resolution [3]. Our method is also promising for magnetic sensing with recently emerged color centers such as tin vacancy centers (SnV-centers) [4].

MA 37.3 Thu 15:30 H16

Planar scanning probe microscopy enables nanoscale vector magnetic field imaging with nitrogen-vacancy centers — •Paul Weinbrenner[1,2], Patricia Klar[3], Christian Giese[3], Luis Flacke[4,5], Manuel Müller[4,5], Matthias Althammer[4,5], Stephan Geprägs[4], Rudolf Gross[4,5,6], and Friedemann Reinhard[1,2,6] — [1]Institute for Physics, University of Rostock, Rostock, Germany — [2]Department of Life, Light and Matter, University of Rostock, Rostock, Germany — [3]Fraunhofer Institute for Applied Solid State Physics, Freiburg, Germany — [4]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [5]Physics Department, Technical University of Munich, Garching, Germany — [6]Munich Center for Quantum Science and Technology, Munich, Germany

We present imaging of vector magnetic fields on the nanoscale using planar scanning probe microscopy with nitrogen-vacancy (NV) centers in diamond as magnetic field sensors. Instead of traditional tip-based scanning probes, we employ an extended bulk diamond doped with NV centers. Despite the probe's large lateral size, it can still be scanned in nanoscale proximity to a planar sample.

We perform repeated measurements with NV centers with different orientations to obtain a direct image of the three-dimensional vector magnetic field of magnetic vortices in a thin-film magnetic heterostructure. Our result opens the possibility of quantum sensing using multiple qubits within the same scanning probe, which can be used for entanglement-enhanced and massively parallel sensing schemes.

MA 37.4 Thu 15:45 H16

Nanostructure and Coercivity Mechanism of Single-Phase $Ce(Co_{0.8}Cu_{0.2})_{5.4}$ — •Tatiana Smoliarova[1], András Kovács[2], Nikita Polin[3], Esmaeil Adabifiroozjaei[4], Shangbin Shen[4], Xinren Chen[3], Leopoldo Molina-Luna[4], Oliver Gutfleisch[4], Konstantin Skokov[4], Michael Farle[1], Baptiste Gault[3], and Rafal E. Dunin-Borkowski[2] — [1]Faculty of Physics and Center for Nanointegration, Universität Duisburg-Essen, Duisburg, Germany — [2]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons, Forschungszentrum Jülich, Germany — [3]Max-Planck-Institut für Nachhaltige Materialien GmbH, Düsseldorf 40237, Germany — [4]Institute of Materials Science, Technische Universität Darmstadt, 64287 Darmstadt, Germany

$CeCo_5$ rare-earth RCo_5 permanent magnets achieve high coercivity (H_C = 1 T) upon the addition of Cu up to 20%, making Ce-based magnets an abundant R-alternative to Sm-based magnets. Here, we report a study that employs TEM

in conjunction with APT to investigate the $Ce(Co_{0.8}Cu_{0.2})_{5.4}$ magnet, prepared by induction melting followed by controlled heat treatment and water quenching. The process results in the formation of a cellular structure characterized by elongated along the *c*-axis, Cu-rich precipitates with a diameter of ~ 5 nm and a length of ~ 20 nm, surrounded by a Cu-poor matrix with a thickness of ~ 10 nm. The alignment of the Cu-rich precipitates creates a preferential direction for zigzag-shaped domain walls, yielding effective pinning and $H_C = 1 \pm 0.05$ T. Financial support by DFG, CRC/TRR 270 (project ID 405553726) is acknowledged.

MA 37.5 Thu 16:00 H16

Transport of Intensity Phase Retrieval in the Presence of Intensity Variations and Unknown Boundary Conditions — •Oleksandr Zaiets[1,2], Axel Lubk[1,2], Radmilla Kyrychenko[1], Daniel Wolf[1], Maximilian Wegner[1], Max Herzog[1], Moritz Winter[1,3,4], Praveen Vir[3], Johannes Schultz[1], Claudia Felser[3], and Bernd Büchner[1,2] — [1]Leibniz Institute for Solid State and Materials Research Dresden, Dresden, Germany — [2]Institute of Solid State and Materials Physics, TU Dresden, Dresden, Germany — [3]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [4]Dresden Center for Nanoanalysis, cfaed, Technical University Dresden, Dresden, Germany

Transport of Intensity Equation (TIE) phase retrieval technique is widely applied in light, X-ray and electron optics to reconstruct, e.g., refractive indices, electric and magnetic fields in solids. The TIE method reconstructs the phase from two or three mutually slightly defocused microscopy images by solving an elliptic partial differential equation - the TIE. Here, we present a largely improved TIE reconstruction algorithm, which properly considers intensity variations as well as unknown boundary conditions in a finite difference implementation of the TIE. That largely removes reconstruction artifacts encountered in state-of-the-art Poisson solvers of the TIE, and hence significantly increases the applicability of the technique. We demonstrate the improved performance of the TIE reconstruction algorithm at a set of simulated and experimental image intensities arising from magnetic structures investigated in TEM.

MA 37.6 Thu 16:15 H16

Fast spectroscopic imaging using extreme ultraviolet interferometry — •Hannah C. Strauch[1], Fengling Zhang[2], Stefan Mathias[1], Thorsten Hohage[3], Stefan Witte[2,4], and G. S. Matthijs Jansen[1] — [1]University of Göttingen, 1st Institute of Physics, Göttingen, Germany — [2]Advanced Research Center for Nanolithography, Amsterdam, The Netherlands — [3]University of Göttingen, Institute of Numerical and Applied Mathematics, Göttingen, Germany — [4]Imaging Physics department, TU Delft, The Netherlands

Extreme ultraviolet (EUV) pulses generated by high harmonic generation (HHG) offer element-specificity in spectroscopic applications [1], and an excellent platform for nanoscale coherent diffractive imaging. Thus, the combination of time-resolved spectroscopy and microscopy using HHG light is highly promising, but it is only hardly explored due to the challenge of extracting full spectroscopic and microscopic information from measurements of reasonable duration.

We will present FTSH, an interferometric solution that combines Fourier-transform spectroscopy (FTS) and holography [2], employing a pair of phase-locked EUV pulses. This combination explicitly encodes the EUV spectral information in the diffraction pattern. Compared to traditional FTS, FTSH dramatically reduces the interferometric sampling requirements. This enables full spectroscopic images in less than two minutes and makes our approach particularly promising for femtosecond time-resolved spectroscopic imaging.

MA 37.7 Thu 16:30 H16

Magnetic vector field imaging with single domain magnetooptical indicator films — •Michael Path and Jeffrey McCord — Institute for Materials Science, Kiel University, Germany

Robust and fast magnetic vector field imaging is essential for the characterization of, e.g., electronic systems. We present a magnetooptical method for quantitative and spatially resolved magnetic vector field imaging based on the use of magnetooptical indicator films. Simultaneous magnetooptical temperature extraction ensures temperature independent quantification of the magnetic field amplitude and angle. Yttrium-iron-garnet indicator films with in-plane and out-of-plane magnetic anisotropy can be used for this method. In both cases, a magnetic bias field is applied to bring the indicator film into a single-domain state along four different directions. By measuring the out-of-plane tilt of the magnetization with four images using magnetooptical microscopy, the local magnetic vector field distribution and the local temperature are obtained. As an example, the magnetic vector field distribution generated by the current of an integrated circuit is observed and compared with the calculations. The accuracy of this method is verified by means of relative and statistical error analysis.

15 min. break

MA 37.8 Thu 17:00 H16

Characterization of the periodic stray field along ferromagnetic domain textures in synthetic antiferromagnets — •R. J. Peña Román[1], S. Maity[1], F. Samad[2,3], A. Kákay[2], O. Hellwig[2,3], K. Kern[1,4], and A. Singha[5,1] — [1]Max Planck Institute for Solid State Research — [2]Institute of Ion Beam Physics and Material Research, Helmholtz-Zentrum Dresden-Rossendorf — [3]Insititute of Physics, Chemnitz University of Technology — [4]Institute de Physique, École Polytechnique Fédérale de Lausanne — [5]Institute of Solid State and Materials Physics, Dresden University of Technology,

Magnetic imaging of domains and domain walls (DWs) composing the texture of any magnetic material is a crucial step toward understanding their properties and finding solutions to tailor the material properties to achieve new technology-driven functionalities. Synthetic Antiferromagnets (SAFs) are particularly interesting due to their highly tunable properties since their magnetic texture can be controlled by adjusting the design parameters during fabrication. Here, we use diamond Nitrogen-Vacancy Scanning Probe Microscopy (NV-SPM) to investigate and characterize ferromagnetic domains with periodic stray fields in SAFs. The magnetic field in the sample is sensed by measuring the Zeeman splitting that it produces on the NV electron spin states, while the magnetic noise is detected due to its impact on the NV spin relaxation time. NV-SPM allows us to explore the sample properties quantitatively with high magnetic sensitivity and non-invasively at the nanoscale. It is essential to identify the nature of the DWs and engineer them for potential applications in magnonics or spintronics.

MA 37.9 Thu 17:15 H16

Investigation of charge-state stability in shallow NV centers with surface treatments — •Atharva Paranjape[1], Olga Shevtsova[1], Lisa Ebo[1], Toni Hache[1,2], Rainer Stöhr[2], Jörg Wrachtrup[2], and Aparajita Singha[1,3] — [1]Max Planck Institute for Solid State Research, Stuttgart — [2]3rd Institute of Physics and Research Center SCoPE, University of Stuttgart — [3]IFMP, Technical University of Dresden

Nitrogen-vacancy (NV) centers in diamond are optically active defects which can be used for precise measurement of magnetic fields. While near-surface NV centers can provide high spatial resolution in magnetic imaging, they also face charge-state instability, which is aggravated in in ultra-high-vacuum (UHV). Here we aim to develop surface-treatment methods to reduce charge-state instability of shallow (< 10 nm from surface) NV centers in UHV conditions. We show that a TiO_2 coating using Atomic Layer Deposition (ALD) on nanostructured diamond stabilizes the charge state by modifying the local environment. These experiments are crucial for the development of a scanning NV magnetometer in UHV with a high spatial resolution.

MA 37.10 Thu 17:30 H16

Magnetic Force Microscopy: High Quality-Factor Two-Pass Mode — •Christopher Habenschaden[1], Sibylle Sievers[1], Alexander Klasen[2], Andrea Cerreta[2], and Hans Werner Schumacher[1] — [1]Physikalisch-Technische Bundesanstalt, 38116 Braunschweig — [2]Park Systems Europe GmbH, 68199 Mannheim

Magnetic Force Microscopy (MFM) is an effective technique for characterizing magnetic micro- and nanostructures, typically detecting interactions between a magnetically coated tip on an oscillating cantilever and the sample. MFM sensitivity is enhanced under vacuum conditions due to the higher cantilever quality factor (Q-factor), which significantly improves force sensitivity. However, the commonly used two-pass mode in MFM faces challenges under vacuum, as the high Q-factor can lead to tip crashing when surface forces overpower the restoring force during topography imaging.

Here, we present a novel approach for high-sensitivity vacuum MFM measurements while maintaining stable topography detection. Implemented on a Park Systems NX-Hivac AFM, this method modifies the two-pass mode to create a high Q-factor two-pass mode [1]. In the first pass, the cantilever's Q-factor is artificially lowered to ensure stable non-contact topography imaging. In the second pass, a phase-locked loop (PLL) measures the frequency shift, maintaining the maximum Q-factor for optimal sensitivity in magnetic field measurements. This approach prevents tip crashes during the first pass and eliminates non-linear phase response in the second pass, ensuring robust and precise measurements.

[1] Rev. Sci. Instrum. 95, 113704 (2024).

MA 38: Magnetic Particles / Clusters & Biomagnetism

Time: Thursday 15:00–18:00 Location: H18

Invited Talk MA 38.1 Thu 15:00 H18

Liquid-mediated surface-surface interactions investigated by close-to-surface magnetic particle transport — •Rico Huhnstock, Yahya Shubbak, and Arno Ehresmann — Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Heinrich-Plett-Str. 40, D-34132 Kassel

Studying phenomena at the liquid-solid interface has tremendous significance for the physical, chemical, biological, and nanostructure sciences [1]. Experimental access to the underlying interactions is a non-trivial task, demonstrated for instance by the difficulties connected with performing atomic force microscopy measurements in liquids. In this talk, we propose a novel technique to inspect liquid-mediated surface-surface interactions based on guiding magnetic microparticles (MPs), surrounded by a quiescent fluid, along defined trajectories in the vicinity of a solid interface. The MP motion is induced by harnessing engineered magnetic stray field landscapes (MFLs) emerging from customized magnetic domain patterns imprinted into a topographically flat substrate. We will give an overview of the MFL fabrication process and discuss the influence of MP [2], liquid, and MFL [3] properties on the MP motion. Finally, we highlight, that the MP motion dynamics can be studied to identify changes in liquid-mediated DLVO interactions between surfaces of the MP and the underlying substrate.

MA 38.2 Thu 15:30 H18

Exploring iron nitrides: Insights from Mössbauer spectroscopy — •Lenka Kubíčková[1,2], Jaroslav Kohout[1], Tomáš Kmječ[1], Karel Knížek[2], Štefan Hricov[2,3], Ondřej Kaman[2], Yevhen Ablets[4], Robin Kidangan Paul[4], Stanislav Mráz[5], Jochen Schneider[5], Oliver Gutfleisch[4], and Imants Dirba[4] — [1]Faculty of Mathematics and Physics, Charles University, 180 00 Praha 8, Czechia — [2]FZU - Institute of Physics of the CAS, 162 00 Praha 6, Czechia — [3]Faculty of Science, Charles University, 128 00 Praha 2, Czechia — [4]Functional Materials, Institute of Materials Science, TU Darmstadt, 64287 Darmstadt, Germany — [5]Materials Chemistry, RWTH Aachen University, 52074 Aachen, Germany

Mössbauer spectroscopy, a powerful tool for probing the local electronic and magnetic properties of materials containing Mössbauer isotopes, will be employed to investigate selected examples of iron nitrides. First, we will show spectra of air-sensitive Fe_3N nanoparticles, which exhibit a high degree of structural disorder. Moreover, we will discuss formation of an oxide layer by their passivation, whose nature and extent is difficult to assess from other methods but is crucial for medical applications. Second, conversion-electron Mössbauer spectroscopy (CEMS) of $Fe_{4-x}Ge_xN$ (x = 0, 0.5 and 1) crystalline thin films allows us to determine not only the direction of magnetization in the film of the undoped phase, but also, together with the DFT calculations, position of the Ge atoms in the Fe_4N structure. Such local insights are valuable for designing and optimizing iron-based films, e.g., for their magnetic or thermoelectric applications.

MA 38.3 Thu 15:45 H18

Tunable magnetic behavior in $[CoFe_2O_4]_n$@Pt hybrid nanoparticles — •Joachim Landers[1], Moritz Raphael[2], Soma Salamon[1], Heiko Wende[1], and Annette Schmidt[2] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen — [2]Department of Chemistry, Institute of Physical Chemistry, University of Cologne

$[CoFe_2O_4]_n$@Pt hybrid nanoparticles were prepared by growing monodisperse $CoFe_2O_4$ (CFO) nanocubes epitaxially on the corners of 6 nm cubic Fe/Co-doped Pt seeds. The hybrid particles display a defined configurational order, in which the CFO cubes cover the corner positions, allowing the formation with a variable number n of CFO cubes in reproducible geometries. Thereby, the hybrid particles represent a system of tunable intraparticular magnetic dipolar interaction, acting in superposition to the high cubic magnetocrystalline anisotropy of the CFO nanocubes. This competition creates a complex temperature-dependence of the shape of the magnetic hysteresis curves, dependent on the size and number of attached CFO nanocubes. In the future, this could facilitate the production of high-anisotropy and -magnetization hybrid particles of widely controllable magnetic behavior. To analyze the acting mechanisms and resulting magnetic properties, in-field Mössbauer spectroscopy and different magnetometry protocols were employed. The experimental observations are compared to micromagnetic simulations utilizing MuMax3. Funding by the DFG projects SCHM1747/16-1 and LA5175/1-1 is gratefully acknowledged.

MA 38.4 Thu 16:00 H18

Inductive Heating of ZnFe Nanoparticles — •Esra Uz[1], Yohei Fujita[2], Marina Spasova[1], Tatiana Smaliarova[1], Ivan Tarasov[1], Michael Farle[1], Yuko Ichiyanagi[2], and Ulf Wiedwald[1] — [1]Universität Duisburg Essen — [2]Yokohama National University

Hyperthermia is a novel medical treatment that uses magnetic fields in combination with specially designed magnetic nanoparticles for the non-invasive elimination of pathological cells. The ZnFe nanoparticles (6-19 nm) have been chemically synthesized and analyzed with a focus on applications in magnetic hyperthermia. The structure and morphology of the nanoparticles have been investigated using X-ray diffraction (XRD) and transmission electron microscopy (TEM). The results confirm the cubic spinel structure of the nanoparticles. Vibrating sample magnetometry (VSM) revealed a ferromagnetic character of the 19 nm particles with a saturation magnetization of 79.8 Am*m/kg. The smaller particles, however, have shown superparamagnetic behavior. For two distinct particle sizes, 11 nm and 19 nm, agarose gel electrophoresis was applied to experimentally measure the heating power in an alternating magnetic field (100-250 kHz, 0-50 mT). For the specific loss power (SLP), determined by calorimetry, our experiments show a maximum value of 71 W/g at a frequency of 247 kHz and B = 40 mT. These findings demonstrate that ZnFe nanoparticles are a promising candidate for applications in the context of magnetic hyperthermia.

MA 38.5 Thu 16:15 H18

Simulation of Dynamics and Self-assembly of Magnetically Decorated Particles — •Maximilian Neumann, Sibylle Gemming, Oliver G. Schmidt, Daniil Karnaushenko, and Aaron Steinhäusser — TU Chemnitz, Chemnitz, Germany

Self-assembly allows for the aggregation of highly complex structures from simple components. Coupled with the highly tunable properties and susceptibility to external fields of magnetic particles this results in the potential to fashion systems with a plethora of applications. By decorating tubular particles with permanent magnets in specific patterns of up/down configuration we create different species of particles, whose behaviour is governed by a mix of attractive and repulsive interactions between individual magnets. This results in selective assembly between specific species, position and orientation. We show simulations of the interaction and dynamics of these particles with and without the influence of external fields and the surrounding medium.

MA 38.6 Thu 16:30 H18

Arranging dipoles on a ring to create homogenous fields — •Ingo Rehberg[1] and Peter Blümler[2] — [1]Experimental Physics, University of Bayreuth, D-95440 Bayreuth, Germany — [2]Institute of Physics, University of Mainz, 55128 Mainz, Germany

Homogeneous magnetic fields can be generated using appropriately arranged permanent magnets. Halbach rings serve as a prominent example of this approach [1], particularly effective when employing very long magnetic rods, often modelled as line dipoles. However, for shorter magnets, the optimal configuration of magnetic moments diverges from the traditional Halbach geometry [2]. In this talk, we present an experimental setup utilizing magnetic cubes and visualize the anticipated fields through an open-source animation of point dipole clusters [3].

Quantum Mechanical Analysis of Complex Ferrimagnetic States in Iron Oxide Nanoparticles — •Valentína Berecová[1,2], Martin Friák[1], Naděžda Pizúrová[1], and Jana Pavlů[2] — [1]Inst. Phys. Mater., Czech Acad. Sci., Brno, Czech Republic — [2]Dept. Chem., Masaryk Uni., Brno, Czech Republic

Maghemite (γ-Fe_2O_3) is a biocompatible ferrimagnetic iron oxide that crystallizes in an inverse spinel lattice and can be viewed as magnetite (Fe_3O_4) with iron vacancies. Iron oxide nanoparticles related to maghemite have numerous applications in the biomedical field thanks to the combination of their magnetic properties, biocompatibility, low cytotoxicity and small size. Density functional theory calculations were employed to examine the local magnetic moments of individual atoms in two maghemite-related nanoparticles. Our calculations for the nanoparticles were inspired by bulk maghemite γ-Fe_2O_3, where tetrahedrally

and octahedrally coordinated Fe sublattices have opposing orientations of local magnetic moments. Importantly, our results show that the nanoparticle surfaces create far more complex magnetic states compared to the magnetic ordering found in bulk. These complex magnetic states were described as "nested" ferrimagnetism, which is characterized by local magnetic moments of Fe atoms with mutually opposite orientations appearing even within each of the two (tetrahedral or octahedral) sublattices. Financial support from the Czech Academy of Sciences (*Praemium Academiae* of M.F.) is gratefully acknowledged. Computational resources were provided by the e-INFRA CZ project and IT4Innovations National Supercomputing Center.

MA 38.8 Thu 17:15 H18

Iron Nitride Magnetic Nanoparticles for Biomedical Applications — •Sayar Das[1], Yevhen Ablets[1], Lenka Kubíčková[2], Imants Dirba[1], and Oliver Gutfleisch[1] — [1]TU Darmstadt, Germany — [2]FZU, Praha, Czech Republic

With the urgent need for advanced materials in healthcare, magnetic nanoparticles (MNPs) have emerged to be helpful in versatile biomedical applications such as Hyperthermia for cancer treatment, contrast agents for Magnetic resonance Imaging, drug delivery, and others. For such applications, MNPs must be small in size and have high saturation magnetization (M_s) for better performance. Typically, iron oxide nanoparticles are used as they are inexpensive, chemically stable, and show low toxicity. Owing to the superior properties of iron nitride phases, it is considered a promising candidate over traditionally used iron oxides. This study systematically investigates the synthesis and characterization of iron nitride nanoparticles for intended biomedical applications. MNPs are synthesized via the thermal decomposition method using $Fe(CO)_5$ as a precursor, where nitriding is realized with ammonia as a carrier gas. Key findings demonstrate that surfactant-free synthesis yields ε-Fe_3N nanoparticles with M_s up to 122 Am^2/kg and a mean particle size of 14 nm. Synthesis with surfactants results in nanoparticles with higher yields and enhanced M_s. Moreover, using pure hydrogen as a reducing agent during synthesis significantly improves magnetic properties, with room temperature M_s reaching 162 Am^2/kg at a particle size of 15 nm, which is the highest M_s in iron nitride nanoparticles prepared by wet chemical routes up to date.

MA 38.9 Thu 17:30 H18

Magnetophoretic distinction of differently surface-functionalized magnetic microparticles by transport in a quiescent liquid — •Yahya Shubbak, Katharina Eichhorn, Nikolai Weidt, Arne Vereijken, Rico Huhnstock, and Arno Ehresmann — Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Heinrich-Plett-Strasse 40, 34132 Kassel, Germany

Magnetic particles (MPs) transported in a quiescent liquid close to the surface of a substrate with a periodic magnetic domain pattern is a promising Lab-on-a-chip technology for the detection of MP-bound analytes, even when their size is negligible compared to the MP size. As a proof of principle, we show an all-optical method to distinguish single MPs of the same nominal size that are surface-functionalized with two different chemical groups. More specifically, MPs measuring 2 micrometer in diameter with a polymer coating with only carboxyl end groups (COOH) or a mixture of carboxyl and amino (NH2) groups, respectively, have been studied. Harnessing a variation of liquid-mediated surface interaction forces in our close-to-substrate MP transport scheme, the different MP surface potentials lead to different magnetophoretic mobilities. Accordingly, transport of these MPs in double-distilled water showed a remarkable difference in the average velocity where the COOH MPs were almost twice as fast as the NH2 counterparts. A thorough investigation using external magnetic field pulses of varying durations revealed a significant distinction between both MP species using only moderate flux densities of a few mT.

MA 38.10 Thu 17:45 H18

Structural, magnetic properties and induction heating behavior studies of Mn doped cupper ferrite nanopowders synthesized using co-precipitation method — •Mahmoud Ismail[1] and Diaa EL-Rahman Rayan[2,3] — [1]Biophysics Branch and Physics Department, Faculty of Science, Al-Azhar University, Nasr City, Cairo, Egypt — [2]Central Metallurgical Research and Development Institute (CMRDI), P.O. Box: 87 Helwan, 11421, Egypt — [3]Department of Physics, Deraya University, New Minia, Minya, Egypt

In this research synthesizes nanocrystalline CuFe2O4 spinel structure using co-precipitation method. The pure copper ferrite is substituted by manganese MnxCu(1*x)Fe2O4 nanopowders (x from 0.0 to 1.0). XRD, HR-TEM, UV-visible-Spectrophotometer and vibrating sample magnetometer (VSM) are utilized in order to study the effect of variation of Mn2+ ions substitution and its impact on crystalline size, lattice parameters, microstructure and optical and magnetic properties of the formed nanopowders. Indeed, heating properties of the MnxCu(1-x)Fe2O4 nanoparticles in an alternating magnetic field at 160 kHz were estimated. The results reveal that the sonochemical method for polyethylene glycol (PEGylated) MnxCu(1-x)Fe2O4 nanoparticles with size 5 nm leads to pseudo-single domain with smallest loop area. Of note, it is clear that the specific heat rate SAR values were in the range from 104.5 to 302.0 W/g at different synthesis conditions. Finally, large SAR values are obtained within 10*15 min using low magnetic field, making Cu-Mn ferrite appropriate for hyperthermia treatment of cancer.

MA 39: Magnetic Thin Films

Voltage control of magnetism using hydrogen — •Markus Gössler — Chemnitz University of Technology, Chemnitz, Germany

Voltage-controlled magnetic properties have entered the research spotlight as they hold great potential for future spintronic and magnetic memory devices. The use of electrochemistry in voltage-controlled magnetism, dubbed magneto-ionics,[1] promises a superior energy efficiency compared to many conventional mechanisms. Here, we present a versatile magneto-ionic concept based on the hydrogen-loading into [Co/Pd]-based bilayers and multilayer structures with perpendicular anisotropy. We show that the magnetic properties of [Co/Pd] multilayers sensitively depend on the absolute hydrogen concentration in the material and that this concentration can be set electrochemically via the applied voltage.[2] Reversibility and switching speed, as the two main limitations towards practical magneto-ionic devices, can be improved by a targeted multilayer engineering, exploiting synergies with hydrogen electrocatalysis. Funding from DFG-499361641 and ERC-101125178 is acknowledged. [1] Nichterwitz et al. APL Mater. (2021) 030903; [2] Bischoff et al., Adv. Funct. Mater. (2024) 2405323

MA 39.2 Thu 15:30 H19

Magneto-ionic control of coercivity in electrodeposited Ni_xFe_{1-x} films — •Anna Ullrich[1], Florin L. Hambeck[1], Francesca Sgarbi Stabbellini[1,2], and Karin Leistner[1,2] — [1]Institute of Chemistry, TU Chemnitz — [2]Leibniz IFW Dresden

Magneto-ionic effects provide a promising route for low-voltage, non-volatile control of magnetic materials, essential for next-generation, energy-efficient devices. Prior research has mainly focused on iron- or cobalt-based thin films and nanostructures.[1] So far only few works mention magneto-ionic effects for Ni-based alloys,[2,3] which are promising due to their unique magnetic properties. This study systematically investigates the magneto-ionic behavior of electrodeposited Ni_xFe_{1-x} films with thicknesses of (160 ± 30) nm as a material platform to enhance magneto-ionic functionality. Coercivities range from (0.4 ± 0.3) mT in $Ni_{80}Fe_{20}$ (permalloy) to (44.6 ± 0.6) mT in pure Fe, as measured by magneto-optical Kerr effect magnetometry. Magneto-ionic control upon electrolytic gating in 1 M KOH reveals a reduction of coercivity of up to 50 % (e.g., in $Ni_{70}Fe_{30}$) at −1.18 V versus Ag/AgCl. We discuss this modification in the context of a surface oxide reduction reaction, which can modify the domain wall pinning.[4] The observed effects highlight the potential of magneto-ionic Ni-Fe alloys, especially in thicker films, for sensing and actuation applications. Zehner et al., Adv. Electron. Mater. 2020, 6, 2000406.

MA 39.3 Thu 15:45 H19

Structural, magnetic and electrical properties of oxygen-deficient $La_{0.6}Sr_{0.4}CoO_{3-\delta}$ thin films — Suqin He[1,2,3], •Oleg Petracic[1], Valeria Lauter[4], Lei Cao[1,5], Yunxia Zhou[5], Moritz Weber[2,3], Jürgen Schubert[6], Omar Concepción[6], Regina Dittmann[2,3], Rainer Waser[2,3], Thomas Brückel[1,3], and Felix Gunkel[2,3] — [1]JCNS-2, Forschungszentrum Juelich GmbH, 52425 Juelich, Germany — [2]PGI-7, Forschungszentrum Juelich GmbH, 52425 Juelich, Germany — [3]JARA-FIT, RWTH Aachen University, 52056 Aachen, Germany — [4]Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA — [5]Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany — [6]PGI-9, Forschungszentrum Juelich GmbH, 52425 Juelich, Germany

In $La_{0.6}Sr_{0.4}CoO_{3-\delta}$ (LSCO) the gradual oxygen release triggers a phase transition from the initial ferromagnetic perovskite to an oxygen vacancy layered antiferromagnetic brownmillerite structure. We have studied LSCO thin films fabricated by pulsed laser deposition. In situ x-ray diffraction and polarized neutron diffraction reveals the topotactic phase transition of the LSCO thin films, which can be attributed to the release of oxygen and ultimately the transition

to a coherently ordered BM phase. By comparing the magnetic and electronic properties of the sample at different oxygen deficient states, we demonstrate that the magnetic and electronic transitions are apart from the structural phase transition. S. He, O. Petracic, V. Lauter, L. Cao, Y. Zhou, M. L. Weber, J. Schubert, O. Concepción, R. Dittmann, R. Waser, T. Brückel, F. Gunkel, Adv. Funct. Mater. 2024, 34, 2313208.

MA 39.4 Thu 16:00 H19

Double Exchange Bias (EB) Effects in IrMn/CoFe/IrMn Systems — •Arne Vereijken, Varun Vanakalapu, Rico Huhnstock, and Arno Ehresmann — Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Kassel, Germany

The EB effect, characterized as an unidirectional anisotropy in a ferromagnet (FM) coupled to an antiferromagnet (AFM) through a shared interface[1], is utilized in Lab-on-Chip (LOC) systems[2], among other technologies. In LOC systems, it is combined with ion bombardment induced magnetic patterning (IBMP) to engineer magnetic stray field landscapes (MFLs)[2]. This work demonstrates that adding a second EB interface to the same FM adds a degree of freedom for tailoring MFLs, achieving stronger and steeper stray field gradients beneficial for LOC applications. Whether the two EBs are independent of each other, particularly when aligned parallel or at an angle, poses an intriguing question. Investigations using vibrating sample magnetometry and magneto-optical Kerr effect measurements and comparisons with advanced EB models tailored for polycrystalline systems and the specific measurement conditions[3], reveal that the EB strength in the employed Ir17Mn83/Co70Fe30/Ir17Mn83 systems slightly exceeds twice that of single EB systems. This is attributed to additive, mostly independent EBs, making the second EB a great candidate for refining MFL engineering. [1] Meiklejohn, W. H. et al. (1956). Phys. Rev. 102, 1413 [2] Holzinger, D. et al. (2015). ACS Nano 9 (7), 7323-7331 [3] Merkel, M. et al. (2022). Phys. Rev. B 106, 014403

MA 39.5 Thu 16:15 H19

Layer-resolved Vector Magnetometry using Generalized Magneto-optical Ellipsometry — •Carmen Martín Valderrama, Irene Prieto, Mikel Quintana, and Andreas Berger — CIC nanoGUNE BRTA, E-20018 Donostia-San Sebastián, Spain

For a detailed and quantitatively precise understanding of magnetic multilayers it is crucially important to determine their spatial magnetization configurations, particularly along the depth of their structures. Here, we demonstrate that it is possible to achieve layer-resolved vector magnetometry in nanoscale magnetic multilayer films by means of a single magneto-optical reflection experiment. We designed, fabricated, and measured a set of epitaxial ferromagnetic/non-magnetic/ferromagnetic multilayer samples that exhibit in-plane uniaxial anisotropy and a tunable ferromagnetic interlayer coupling strength through the non-magnetic interlayer. By means of Generalized Magneto-optical Ellipsometry measurements, we obtain the entire optical reflection matrix R of a given sample for each applied field value, which allows us to monitor the field evolution of the magnetization vector for the two ferromagnetic layers independently. Hereby, we observe that the magnetization switching of one layer can trigger a discontinuous change of the magnetization in the second layer even for weak ferromagnetic interlayer coupling. Moreover, we reproduce the obtained behavior using a model of two coupled macrospins, which corroborates even the unexpected aspects of our experimental results and thus reinforces the sensitivity and reliability of our experimental layer-resolved vector magnetometry.

MA 39.6 Thu 16:30 H19

Ferrimagnetic moment arrangement in the Ti-doped Barium hexaferrite revealed by EMCD — •Hitoshi Makino[1], Devendra Singh Negi[2], Ján Rusz[3], Bernd Rellinghaus[1], and Darius Pohl[1] — [1]DCN, TUD Dresden University of Technology — [2]Indian Institute of Technology Jodhpur — [3]Uppsala University

Barium hexaferrite is a well-known ferrimagnetic complex oxide with good durability at high temperatures and in erosive environments. Previous research has indicated that Titanium substitutions can enhance the coercivity at elevated temperatures. Our efforts aim at elucidating the underlying mechanism through measurements of electron energy loss magnetic chiral dichroism (EMCD) in the transmission electron microscope (TEM). We conducted EMCD experiments on three samples with different Titanium concentration ($BaFe_{12-x}Ti_xO_{19}$, x=0, 0.6, 1.0). We have deconvoluted the Fe L-edges as obtained from classical EMCD measurements into different oxidation states of iron ($Fe^{3+} \rightarrow Fe^{2+}$ generated by Titanium-substitution) to observe the changing of magnetic moment arrangement. High resolution EELS mapping revealed, that Ti^{4+} ion substitute mainly for the $4f_2$ site, an atomic site with parallel magnetic Fe moment. The EMCD signal of the Ti-rich sample ($BaFe_{12-x}Ti_xO_{19}$, x=1.0) indicate an antiparallel Fe^{2+} magnetic moment arrangement. This discrepancy will be discussed by using inelastic scattering simulations as well as DFT calculations. A detailed analysis of the underlying measurement errors and the involved limitations of the method will be presented.

MA 39.7 Thu 16:45 H19

Imaging Local Magnetic Moments with Atomic-Scale Electron Vortex Beams via EMCD in $BaFe_{11}TiO_{19}$ — •Darius Pohl[1], Hitoshi Makino[1], Bernd Rellinghaus[1], Rolf Erni[3], Devendra Singh Negi[5], Arthur Ernst[4], and Ján Rusz[2] — [1]DCN, TUD Dresden University of Technology, Dresden, Germany — [2]Uppsala University, Uppsala, Sweden — [3]Empa, Dübendorf, Switzerland — [4]JKU, Lenz, Austria — [5]Indian Institute of Technology Jodhpur

Electron magnetic circular dichroism (EMCD), the electron wave counterpart of X-ray magnetic circular dichroism (XMCD), enables element-specific measurement of spin and orbital magnetic moments with nanometer-scale resolution in transmission electron microscopy. Electron vortex beams (EVBs), recently discovered to carry quantized orbital angular momentum (OAM), are emerging as a promising tool for EMCD measurements, facilitating the analysis of magnetic properties in materials. Since EVBs can be tightly focused to sub-nanometer scales, this approach offers unprecedented potential for quantifying spin and orbital magnetic moments with exceptional spatial resolution. We employ specially designed condenser apertures to produce isolated, atomic-scale EVBs with user-defined OAM. As a proof-of-concept, we demonstrate vortex EMCD measurements on ferrimagnetic barium hexaferrite samples. For the first time, EVB-EMCD achieves the resolution necessary to resolve local ferrimagnetic order. The experimental findings are further corroborated by inelastic scattering simulations and density functional theory (DFT) calculations.

MA 40: Frustrated Magnets II

Time: Thursday 15:00–17:45 Location: H20

MA 40.1 Thu 15:00 H20

Magnetism of rare-earth A2Ir2O7 pyrochlore single crystals — •Filip Hájek[1], Daniel Staško[1], Kristina Vlášková[1], Jiří Kaštil[2], and Milan Klicpera[1] — [1]Charles University, Faculty of Mathematics and Physics, Department of Condensed Matter Physics,Ke Karlovu 5, 121 16 Prague 2, Czech Republic — [2]Institute of Physics of the Czech Academy of Sciences, Na Slovance 2, 182 21 Prague 8, Czech Republic

The rare-earth A2Ir2O7 pyrochlore iridates form a heavily studied series of materials revealing a plethora of complex properties. Geometrically frustrated lattice, strong spin-orbit coupling comparable to the strength of electron correlations, or f-d exchange between rare-earth and iridium sites lead to, e.g., spin ice state [1], spin liquid [2], topological Mott insulator [3], axion insulator [4] or Weyl semimetal [4,5].

Among the A2Ir2O7 series, we focus on the previously less studied heavy rare-earth members, namely Ho2Ir2O7, Er2Ir2O7, and Lu2Ir2O7 single crystals. In these materials, the Ir sublattice magnetically orders above 100 K, inducing a transition from a (semi-)metal to an insulating state just below the ordering temperature. Our present work is aimed at the magnetism of newly synthesised A2Ir2O7 single crystals, which is discussed in the framework of antiferromagnetic domains and ferromagnetic domain interfaces.

MA 40.2 Thu 15:15 H20

Crystal growth and anisotropic magnetic properties of quasi-one-dimensional zigzag chain antiferromagnet: CaCoP2O7 — •Koushik Chakraborty[1], Aditi Agrawal[1], Isha Isha[1], M. Isobe[2], and Arvind Kumar Yogi[1] — [1]UGC-DAE Consortium for Scientific Research, University Campus, Khandwa Road, Indore-452001, India — [2]Max-Planck-Institut f\"{u}r Festk\"{o}rperforschung, Heisenbergstr. 1, D-70569 Stuttgart, Germany

We report crucible free optical floating zone crystal growth and anisotropic magnetic properties of quasi-one-dimensional zigzag chain antiferromagnetic compound CaCoP2O7. In this quasi one-dimensional zigzag chain compound, magnetic lattice is formed by the Co2+ ions. We have characterized the single-crystals and analyzed them by using x-ray and Laue diffraction which reveals single-phase nature and the as grown single-crystals were found of ultra high quality. Magnetic susceptibility and magnetization measurements reveal antiferromagnetic ordering, evidenced by a pronounced downturn in susceptibility below the Neel temperature (TN =6.6 K) and negative Curie-Weiss temperatures (Theta-CW = -39.4 K). Further, we found clear signature of field-induced phase

transition where on application of field AFM order is going to quantum paramagnetic state or maybe liquid phase (which needs further study to confirm).

MA 40.3 Thu 15:30 H20

Ultrasound Investigation of the Magnetic Phase Diagram of Rouaite $Cu_2(OH)_3NO_3$ — •Nikolai Pavlovskii[1], Anton Kulbakov[1], Aswathi M. Chakkingal[1], Justus Grumbach[1], Kaushick K. Parui[1], Ulrike Stockert[1], Maxim Avdeev[2,3], Ramender Kumar[4], Issei Niwata[4], Ellen Häussler[1], Roman Gumeniuk[5], Ross J. Stewart[6], Vladimir Pomjakushin[7], Sergey Granovsky[1], Mathias Doerr[1], Elena Hassinger[1], Sergei Zherlitsyn[8], Andreas Hauspurg[8], Yoshihiko Ihara[4], Darren C. Peets[1], and Dmytro Inosov[1] — [1]TU Dresden, Germany — [2]ANSTO, Sydney, Australia — [3]University of Sydney, Australia — [4]Hokkaido University, Japan — [5]TU Bergakademie Freiberg, Germany — [6]ISIS, United Kingdom — [7]PSI, Villigen, Switzerland — [8]HZDR, Dresden, Germany

Rouaite, $Cu_2(OH)_3NO_3$, is a low-dimensional quantum magnet with alternating ferromagnetic and antiferromagnetic spin chains. Its magnetic phase diagram has been studied using techniques such as magnetization and specific heat, revealing field-induced transitions. This work focuses on ultrasonic investigations, which uncover the coupling between magnetic and elastic properties. New results under hydrostatic pressure further demonstrate the tunability of the magnetic phases, highlighting the material's sensitivity to lattice modifications.

MA 40.4 Thu 15:45 H20

Emergent degeneracies in weakly coupled sawtooth chains: the case of bobkingite — •P. Peter Stavropoulos[1], Aleksandar Razpopov[1], Harrison LaBollita[2], Antia S. Botana[3], Michael R. Norman[4], and Roser Valentí[1] — [1]Goethe University, Frankfurt, Germany — [2]Flatiron Institute, New York, USA — [3]Arizona State University, Tempe, USA — [4]Argonne National Laboratory, Lemont, USA

The sawtooth chain, otherwise known as the Δ chain, has a long history as a minimal model of frustrated magnetism, serving as a realization of Shastry-Sutherland type solitons. While many material candidates, like delafossite, euchroit, atacamite, as well as fluorides, have been investigated, they leave much to be desired in the way of the ideal sawtooth chain. Here we present a proposal for revisiting a copper hydrate, bobkingite. Using ab initio methods we estimate the magnetic exchanges between copper sites, and find a spin model consisting of nearly ideal sawtooth chains, weakly coupled to its neighbors. We analyze the classical model of the coupled sawtooth chains, revealing emergent system size scaling degeneracies.

MA 40.5 Thu 16:00 H20

Trigonal distortion in the Kitaev candidate honeycomb magnet BaCo2(AsO4)2 — •M.M. Ferreira Carvalho[1,2], S. Roessler[1], Z. Hu[1], C.F. Chang[1], S. M. Valvidares[3], P. Gargiani[3], M. W. Haverkort[4], P. K. Mukharjee[5], P. Gegenwart[5], A. A. Tsirlin[6], and L.H. Tjeng[1] — [1]Max Planck Institute for Chemical Physics of Solids,Dresden — [2]Institute of Physics II, University of Cologne — [3]ALBA Synchrotron Light Source, Barcelona, Spain — [4]Institute for theoretical physics, Heidelberg University — [5]Lehrstuhl für Experimentalphysik VI, Universität Augsburg — [6]Felix Bloch Institute for Solid-State Physics, University of Leipzig

We conducted X-ray linear dichroism (XLD) and magnetic circular dichroism (XMCD) measurements on single crystals of the Kitaev candidate honeycomb lattice compound BaCo2(AsO4)2. The measurements employed the bulk sensitive inverse partial fluorescence yield technique, which is ideal for acquiring reliable X-ray absorption spectra from highly insulating samples , enabling precise quantitative analysis. Our experimental results revealed a significant LD signal, indicating strong trigonal distortion in the CoO6 octahedra in BaCo2(AsO4)2. We performed a detailed analysis of the experimental XAS and XMCD spectra using a full-multiplet cluster model within the configuration interaction approach. This analysis indicated that the hole density is predominantly localized in the a1g orbital. Through XMCD sum rules and theoretical calculations, we quantified both the spin and orbital magnetic moments.

MA 40.6 Thu 16:15 H20

Single crystal growth and anisotropic magnetic properties of honeycomb quantum antiferromagnets: Ba2A(PO4)2 (A = Ni, Co, Mn) — •Aditi Agrawal[1], Koushik Chakraborty[1], Isha Isha[1], M. Isobe[2], and Arvind Kumar Yogi[1] — [1]UGC-DAE Consortium for Scientific Research, University Campus, Khandwa Road, Indore-452001, India — [2]Max-Planck-Institut f\"{u}r Festk\"{o}rperforschung, Heisenbergstr. 1, D-70569 Stuttgart, Germany

The magnetic framework (monoclinic-lattice) of the title compounds are composed of the honeycomb-lattice. We present a study of high-quality Ba2A(PO4)2 (A = Ni, Co, Mn) optically floating zone grown single crystals. Sharp anomalies were found in the thermodynamic measurements. The anomalies corresponding to the long-range-ordering (LRO) for all three single-crystals of honeycomb family were evident just below 5 K, reveals a long-range antiferromagnetic order in these single-crystalline samples. The dc-susceptibilities for in-plane and out-of-plane magnetic fields are strongly anisotropic. Our Curie-Weiss analysis for Ni, Co, and Mn suggest strong orbital magnetism but it was found significant for Co2+ case, as it is known due to its Kramers' degeneracy nature. Further, on application of external magnetic field, all compound shows spin-flop transition at moderate field. However, Ba2Co(PO4)2 is interestingly driven to another ordered phase due to the field-induced transition via a field tuned quantum critical point which is expected close to the critical field of Bc ~ 6.5 T, as evident from our phase boundaries analysis on in B-T plane.

Modelling thermal transport in spiral magnets — •Margherita Parodi[1,2] and Sergey Artyukhin[1] — [1]Italian Institute of Technology, Genova — [2]University of Genova, Italy

Magnetic memory and logic devices, including prospective ones based on skyrmions, inevitably produce heat. Thus, controlling heat flow is essential for their performance. Here we study magnon contribution to thermal conductivity in the most basic non-collinear magnet with a spin spiral ground state. Non-collinearity leads to anharmonic terms, resulting in magnon fusion and decay processes. These processes determine the magnon lifetime which can be used to estimate thermal conductivity in single mode approximation. However, by solving the full Boltzmann equation numerically, we find much higher thermal conductivity. This signifies that heat is carried not by individual magnons but by their linear combinations, called relaxons [1]. The thermal conductivity is found to be increasing with the diminishing twist angle, consistent with recent experiments [2]. The results pave the path to understanding magnetic thermal transport in other non-collinear magnets.

MA 40.8 Thu 17:00 H20

Pressure-tuning $Na_3Co_2SbO_6$ in the Kitaev Quantum Spin Liquid state — •Steven Gebel[1], Swarnamayee Mishra[1], Martin Sundermann[2], Marein Rahn[3], and Jochen Geck[1] — [1]Institute of Solid State and Materials Physics, Technische Universität Dresden, Haeckelstr. 3, 01069 Dresden, Germany — [2]PETRA III, Deutsches Elektronen-Synchrotron DESY, Notkestraße 85, 22607 Hamburg, Germany — [3]Center for Electronic Correlations and Magnetism, University of Augsburg, Universitätsstraße 1, 86159 Augsburg, Germany

Honeycomb cobaltates with Co^{2+} ($3d^7$) ions have been proposed as materials that can host Kitaev's quantum spin liquid state (QSL). Specifically, $Na_3Co_2SbO_6$ has been predicted to exhibit a Kitaev QSL upon reduction of the trigonal ligand and crystal field splitting, which in turn might be possible via the elastic tuning of the lattice structure. This compound hosts edge-sharing CoO_6 octahedra and exhibits antiferromagnetic (AFM) zig-zag ordering below 7 K, reminiscent of other well-known QSL-candidate, α-$RuCl_3$. In this study, a combination of x-ray diffraction (XRD) and spectroscopy (NIXS) in diamond anvil cells (DACs) is used to establish the pressure dependence of the lattice structure and its effect on the electronic 3d-shell. The pressure dependent Co L-edge spectra are compared to multiplet calculations based on the structural data obtained from refinements of the XRD data. Combining elastic tuning of the lattice structure with XRD, Co L-edge spectra and core-level-spectroscopy simulations, is a very promising approach to confirm whether honeycomb cobaltates can be driven into the Kitaev QSL state.

MA 40.9 Thu 17:15 H20

Easy-axis Heisenberg model on the triangular lattice: from supersolid to gapped solid — •Martin Ulaga[1], Jure Kokalj[2,3], Takami Tohyama[4], and Peter Prelovšek[3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Faculty of Civil and Geodetic Engineering, University of Ljubljana, Ljubljana, Slovenia — [3]Department of Applied Physics, Tokyo University of Science, Tokyo, Japan — [4]Jožef Stefan Institute, Ljubljana, Slovenia

We investigate the easy-axis Heisenberg model on the triangular lattice by numerically studying excitations and the dynamical spin structure factor $S^{\mu\mu}(\mathbf{q},\omega)$. Results are analyzed within the supersolid scenario, characterized by the translation-symmetry-breaking parameter m_z and the supersolid off-diagonal order parameter $m_\perp$. We find very robust $m_z > 0$ in the whole easy-axis anisotropy regime $\alpha = J_\perp/J_z > 0$, even enhanced by the magnetic field $h > 0$. Results also support $m_\perp > 0$ for intermediate $\alpha < 1$ and $h > 0$. Still, at small $\alpha \lesssim 0.2$, relevant for recent experiments on the magnetic material $K_2Co(SeO_3)_2$, we find at $h = 0$ rather vanishing $m_\perp \sim 0$, consistent with numerical evidence of a finite magnon excitation gap

MA 40.10 Thu 17:30 H20

Localized Magnons in the Generalized Model of the Sawtooth Chain with Dzyaloshinskii-Moriya Interactions — •Vadim Ohanyan[1,2], Johannes Richter[3,4], Michael Sekania[5,6], Marcus Kollar[7], and Lucas Giambattista[7] — [1]Laboratory of Theoretical Physics, Yerevan State University, 1 Alex Manoogian, 0025 Yerevan, Armenia — [2]CANDLE, Synchrotron Re-

search Institute, 31 Acharyan Str., 0040 Yerevan, Armenia — [3]Institut für Physik, Universität Magdeburg, P.O. Box 4120, D-39016 Magdeburg, Germany — [4]Max-Planck-Institut für Physik Komplexer Systeme, Nöthnitzer Straße 38, D-01187 Dresden, Germany — [5]Reichenzentrum, University of Augsburg, 86135 Augsburg, Germany — [6]Center for Condensed Matter Theory and Quantum Computations, Ilia State University, 0162, Tbilisi, Georgia — [7]Theoretical Physics III, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, 86135 Augsburg, Germany

We consider a generalized model of a spin-S sawtooth chain with three distinct exchange couplings and Dzyaloshinskii-Moriya (DM) interactions. The primary focus of our research is on various scenarios for magnonic flat-band formation and the corresponding properties of localized magnons. A general flat-band constraint is derived, which, due to the large number of parameters in the model, allows for a broad diversity of flat-band scenarios. We provide a detailed analysis of different solutions to the flat-band constraint, construct the associated localized magnon states, and study the properties of the one-magnon spectrum.

MA 41.1 Thu 15:00 P3

Electrical coupling of superparamagnetic tunnel junctions mediated by spin-transfer-torques — •Sinan Shu[1], Leo Schnitzspan[1,2], Mathias Kläui[1,2], and Gerhard Jakob[1,2] — [1]Institute of Physics, Johannes Gutenberg-University Mainz, 55122 Mainz, Germany — [2]Max Planck Graduate Center Mainz, 55122 Mainz, Germany

Superparamagnetic tunnel junctions (SMTJs) have garnered significant interest as potential building blocks for neuromorphic computing due to their unique stochastic switching behavior, driven by thermal excitations. This work investigates the impact of electrical coupling on the stochastic dynamics of two in-plane magnetized SMTJs, combining experimental measurements with simulation studies. The coupling mechanism, enabled by spin-transfer torque, modulates the state probability of each SMTJ and influences their cross-correlation. By analyzing time-lagged cross-correlation, we determine the strength and direction of the coupling, revealing that high positive voltages induce the strongest coupling effect. Furthermore, we demonstrate voltage-tunable state probabilities and coupling control. Our findings highlight the emergence of similarity and dissimilarity effects in the state probability transfer curves of coupled SMTJs [1]. These results not only provide new insights into the interplay between spin-transfer torque and stochastic behavior but also underline the potential of SMTJs for applications in energy-efficient neuromorphic computing.

MA 41.2 Thu 15:00 P3

Self-ordered colloid of surfactant-free hard ferromagnetic hexaferrite nanoplatelets: SAXS study — •Andrei Chumakov[1], Matthias Schwartzkopf[1], and Dirk Menzel[2] — [1]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [2]Technische Universität Braunschweig, Braunschweig

A novel type of stable magnetic colloids based on hard magnetic SrFe12O19 particles stabilized by electrical charge and dispersed in water was studied as an object of investigation. The colloidal single crystalline nanoparticles possess a plate-like shape with a mean lateral size of about 50 nm and thickness of 5 nm. Each particle carries a large permanent magnetic moment M and exhibits the highest intrinsic coercivity field HC values of about 0.4 T. The magnetic properties of a ferromagnetic colloid exhibit a minimal magnitude of the coercive force of the order of several Oe., which allows the change of particle's orientation easily under the action of an external magnetic field. Depending on the concentration, the nanoparticle can exist in the water media in the free 'gas', concentrated liquid crystal, and super concentrated 'solid' phases. Structural ordering in the concentrated magnetic colloids of nanoparticles was investigated by SAXS, SEM, and SQUID techniques. It was revealed that the self and externally-induced liquid crystal phase consists of stacks of magnetic nanoplatelets, which can be ordered to nematic or similar phases by the external magnetic field. Various methods for creating a concentrated liquid crystalline phase are considered. The features of interaction within alternating and constant magnetic fields were studied.

MA 41.3 Thu 15:00 P3

Current Induced Markov State Modeling with Skyrmions in Geometrical Confinements — Thomas Brian Winkler[1], Grischa Beneke[2], •Yuean Zhou[2], Johan Mentink[1], and Mathias Kläui[2] — [1]Radboud University, Institute for Molecules and Materials, Netherlands — [2]Institut für Physik, Johannes Gutenberg-Universität Mainz, Germany

Magnetic skyrmion in geometrical confinements have recently gained attention as a platform for neuromorphic computing for instance for Brownian Reservoir Computing [1, 2]. Despite significant progress with coarse-grained particle-based modeling of the stochastic dynamics of skyrmion [3], the interplay between stochasticity and device defects remains underexplored. Here, we extract the stochastic transitions of skyrmion between pinning sites using a simple Markov state framework. The resulting Markov state model enables system behavior prediction based on the effective energy landscape of the device. The time step for Markov state evolution is significantly faster than traditional simulations, which makes the system well-suited for leveraging the digital twin for predicting experimental outcomes and evaluating reservoir metrics. We also aim to implement energy-efficient Markov chain Monte Carlo algorithms in-materio.

MA 41.4 Thu 15:00 P3

Statistical Tests for True-Random-Number Generation with Superparamagnetic Tunnel Junctions — •Robin Tietgen[1], Leo Schnitzspan[1], Mathias Kläui[1,2], and Gerhard Jakob[1] — [1]Institute of Physics, Johannes Gutenberg University, Staudingerweg 7, 55128 Mainz, Germany — [2]Max Planck Graduate Center Mainz, Mainz 55122, Germany

Superparamagnetic tunnel junctions (SMTJs) change their magnetoresistance due to switching of the ferromagnetic free layer by thermal excitations. This property of the SMTJ can be utilized to design a random number generator (RNG). Evaluating RNG output signals with statistical tests such as the NIST Statistical Test Suite (NIST STS) [1] provides a measure for the randomness quality and therefore the quality of the RNG itself. This quality assessment is crucial when deciding whether a (pseudo) RNG is suitable for a specific application.

We show nanosecond timescale random telegraph noise (RTN) generated by SMTJs with encryption-quality randomness [2].

Fast and high quality RNGs facilitate upcoming unconventional computing techniques such as probabilistic computing and machine learning with noise-based learning algorithms. For these applications SMTJs are promising true RNGs, offering very fast RTN, ultra-low power consumption and excellent scalability.

MA 41.5 Thu 15:00 P3

Local spin textures stabilised by geometrically-induced strain in 2D magnet Fe3GeTe2 — •Yuhan Sun[1], Max Birch[2], Simone Finizio[3,5], Lukas Powalla[1], Sayooj Satheesh[1], Eberhard Goering[1], Bettina Lotsch[1], Klaus Kern[1], Alexander Holleitner[4], Markus Weigand[5], Sebastian Wintz[5], and Marko Burghard[1] — [1]Max Planck Institute for Solid State Research, Heisenbergstrasse 1, 70569 Stuttgart, Germany — [2]RIKEN Center for Emergent Matter Science, Wako 351-0198, Japan — [3]Swiss Light Source, Paul Scherrer Institut, 5232 Villigen PSI, Switzerland — [4]Walter Schottky Institute and Physics Department, Technical University of Munich, 85748 Garching, Germany — [5]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Institut Nanospektroskopie, 12489 Berlin, Germany

Two-dimensional (2D) van der Waals ferromagnets have emerged as promising platforms for next-generation electronic and spintronic devices. However, achieving precise local control over magnetic domains and spin textures in these materials remains a significant challenge. Here, we demonstrate nanoscale manipulation of magnetism in the 2D ferromagnet Fe3GeTe2 (FGT) using geometrically-induced strain fields. Employing high-resolution scanning transmission X-ray microscopy, we directly visualize the impact of spatially varying uniaxial and shear strain profiles on the magnetic order of FGT sheets stamped onto nanopillar arrays. We observe that a strain of less than 0.5% locally elevates the Curie temperature of FGT by 10 K and stabilizes magnetic textures near the pillar corners.

MA 41.6 Thu 15:00 P3

Harnessing Van der Waals $CrPS_4$ and Surface Oxides for Nonmonotonic Exchange Bias in Fe_3GeTe_2 heterostructures — Aravind Puthirath Balan[1], Aditya Kumar[1], •Sadeed Hameed[1], and Mathias Kläui[1,2] — [1]Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Germany — [2]Centre for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology, 7491 Trondheim, Norway

Due to their atomically flat interfaces, two-dimensional van der Waals (vdW) heterostructures serve as the ideal platform to study interfacial effects like exchange bias. In this study, exchange bias in a vdW heterostructure composed of the antiferromagnetic material $CrPS_4$ and the ferromagnetic material Fe_3GeTe_2 (FGT) with a naturally oxidized surface layer (O-FGT) is investigated by per-

forming Anomalous Hall measurements. The observed exchange bias in this heterostructure exhibits a distinct and non-monotonic trend as a function of temperature below 140 K, which is attributed to the presence of ferrimagnetic Fe_3O_4 in the surface oxide layer whose induced exchange bias is modulated by the presence of the antiferromagnetic $CrPS_4$ layer. These findings highlight the multifaceted nature of exchange bias in van der Waals heterostructures and their potential for tailored manipulation and control of material properties.

MA 41.7 Thu 15:00 P3

Exploring spin-lattice coupling in the Van-der-Waals Antiferromagnet FePS3 — •David Gutnikov, Fabian Mertens, David Mönkebüscher, Richard Leven, Sophie Bork, Umut Parlak, and Mirko Cinchetti — Department of Physics, TU Dortmund University, Otto-Hahn-Straße 4, 44227 Dortmund, Germany

Femtosecond laser pulses drive coherent ultrafast lattice dynamics and hybridized phonon-magnon interactions in the antiferromagnetic van der Waals semiconductor $FePS_3$. This study investigates the coupling between lattice vibrations and the magnetic system by examining the effects of excitation photon energy, sample temperature, and applied magnetic field on their dynamic interplay. Building on our previous findings [1], we conducted additional femtosecond white-light transient absorption measurements. In addition to the previously reported 3.2 THz coherent phonon mode — whose amplitude diminishes near the Néel temperature and vanishes in the paramagnetic phase — we confirmed its strong hybridization with a magnon under an external magnetic field, resulting in a coupled phonon-magnon mode that underscores the rich magneto-elastic interactions in this material. Beyond this, we identified a previously hidden phonon mode at 7.5 THz and shear oscillations around 20 GHz. These findings provide deeper insights into the spin-lattice coupling in $FePS_3$ and open new avenues for controlling THz magnonic dynamics in van der Waals antiferromagnets, with significant implications for advancing two-dimensional spintronic technologies.

MA 41.8 Thu 15:00 P3

Pauli-Equation on Riemannian Manifolds — •Johann Posanski, Benjamin Schwager, and Jamal Berakdar — Marthin-Luther-Universität Halle-Wittenberg Institut für Physik

Describing the behavior of quantum systems under geometric constraints is of relevance both for research in the foundations of physics and in applied fields, such as the development of designer materials. Implementing the restriction of a quantum particle to a Riemannian manifold with an explicit confining potential provides an effective description of the reduced quantum dynamics and implies a potential-like term dependent on the geometric invariants of the space. Expanding this formalism to spin-1/2 particles, such as electrons, is an active area of research. In this work, the dynamics of non-relativistic spin-1/2 particles on a two-dimensional Riemannian manifold embedded in three-dimensional Euclidean space are derived. We find that the spin degree of freedom is unaffected by real-space constraints and the tangent Pauli equation fully describes the spinor dynamics when the whole structure is exposed to an electromagnetic field. The Zeeman energy is found to be unaffected by the confinement and remains gauge-invariant.

MA 41.9 Thu 15:00 P3

Interplay of valley and spin at the interface of $MnPS_3|WS_2$ heterostructure — •Purba Dutta and Nirmal Ganguli — Indian Institute of Science Education and Research Bhopal, MP, India

This work is focused on the proximity-induced effects of the $MnPS_3|WS_2$ heterostructure, particularly on the change of valley and spin splitting in some high symmetry points under the effect of SOC, exhibits a unique interplay of electronic, spintronic, and valleytronic properties due to its type-II band alignment and strong spin-orbit coupling. This heterostructure facilitates efficient charge separation, driven by the staggered band alignment, making it ideal for optoelectronic applications such as spin-polarized photodetectors. The magnetic proximity effect from MnPS* induces a tunable U-dependent Rashba spin-splitting at the interface, where the magnitude of the Rashba effect can be controlled by the on-site Coulomb interaction parameter (U). This coupling enables robust control over spin texture and spin-dependent transport. Moreover, circularly polarized light selectively excites carriers in the distinct valleys of WS_2, leading to enhanced valley polarization, further modulated by the magnetic exchange interaction from $MnPS_3$. This synergy between Rashba like effect-induced spin textures and valley polarization creates a platform for multifunctional optospintronic devices, offering avenues for tunable spin and valley-selective photodetection, spin filters. The Interplay of valley and spin at the interface of $MnPS_3|WS_2$ heterostructure heterostructure thus provides a versatile framework for advancing spintronic and valleytronic technologies.

MA 41.10 Thu 15:00 P3

Manipulating the sign of the interlayer exchange coupling — Nathan Walker[1] and •George Browne[2] — [1]The Open University, Milton Keynes, UK — [2]The Open University, Milton Keynes, UK

We demonstrate, using computer simulations and a non-equilibrium Greens function approach, that the sign of the out-of-equilibrium interlayer exchange coupling (ooeIEC) changes in the presence of an external bias. The system consists of a double barrier connected to an exchange coupled ferromagnetic trilayer. We find a strongly non-linear dependence of the spin current on voltage which results in the exchange coupled tri-layer switching between parallel and antiparallel configurations. Our results are in excellent agreement with earlier theoretical calculations, which predict an approximately 2π topological phase change of the (equilibrium) IEC. We believe that this could act as an energy efficient mechanism for magnetic switching which does not rely on spin-transfer torque (STT). There are potential applications to magnetoresistive random-access memory (MRAM), one of the principal contenders for a universal memory.

MA 41.11 Thu 15:00 P3

Enhancing the ultrafast THz emission in spintronic emitters via interface engineering — •Krishna Rani Sahoo[1], David Stein[2], Jannis Bensmann[1], Alexander Heise[2], Robert Schmidt[1], Steffen Michaelis de Vasconcellos[1], Manfred Albrecht[2], and Rudolf Bratschitsch[1] — [1]Institute of Physics, University of Münster, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany — [2]Institute of Physics, University of Augsburg, Universitätsstr. 1 Nord, 86159 Augsburg, Germany

Ultrafast THz spintronic emitters are based on the generation of THz radiation due to spin-to-charge conversion in magnetic (M) and nonmagnetic (NM) bilayer stacks. The development of THz spintronic emitters focuses on enhancing their intensity, manipulating the THz signal, and exploring potential applications. To improve the performance of THz spintronic emitters, it is important to choose suitable material combinations (M/NM) and tailor the interface between the M and NM layers. In this study, we focus on engineering the interface of archetypical Fe/Pt THz spintronic emitters via irradiation with foreign atoms. Indeed, we find that the THz emission can be substantially increased by the implantation of ions at the Fe/Pt interface. Our result paves the way for efficient low-cost ultrafast THz spintronic emitters based on thin metal films.

MA 41.12 Thu 15:00 P3

Exploring the Coupling of Broadband Terahertz Dipoles to Metasurfaces — •Daniel Geyer[1], Rieke von Seggern[1], and Sascha Schäfer[1,2] — [1]Department of Physics, University of Regensburg, Regensburg, Germany — [2]Regensburg Center for Ultrafast Nanoscopy (RUN), Regensburg, Germany

Terahertz (THz) spectroscopy has emerged as a powerful tool for accessing low-energy excitations in matter, offering direct insights into fundamental material properties that govern electronic, thermal, and magnetic behaviors. In addition to large-area THz emission spectroscopy, a strongly confined THz source can be employed to locally map a material's response.

In this work, we explore the implementations of ultrathin THz sources coupled to plasmonic structures. Firstly, we demonstrate the microscale mapping of the coupling strength between resonator structures and localized terahertz dipoles on a patterned spintronic emitter [1]. In addition, we investigate the THz response of near-field-coupled topological metasurfaces based on the Su-Schrieffer-Heeger (SSH) model [2]. Lastly, we discuss the application of novel THz sources based on two-dimensional van-der-Waals materials.

MA 41.13 Thu 15:00 P3

Enhancement of spintronic terahertz frequency conversion efficiency via grating structures — •Hatice Nur Koyun[1], Ruslan Salikhov[1], Ciaran Fowley[1], Jürgen Lindner[1], Stephan Winnerl[1], Artur Erbe[1,2], Manfred Helm[1,2], Jürgen Fassbender[1,2], and Sergey Kovalev[1,3] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstraße 400, 01328 Dresden, Germany — [2]Technische Universität Dresden, 01062, Dresden, Germany — [3]Technische Universität Dortmund, 44227, Dortmund, Germany

Spintronic terahertz (THz) frequency conversion in ferromagnet/heavy-metal heterostructures has the potential to develop spintronic THz emitters for the high-speed communication and data processing units. Applying the ultrafast demagnetization gives rise to spintronic THz frequency conversion with the appearance of THz second harmonic generation (TSHG). In the case of optimizing the potential for the spintronic THz frequency conversion, the limitations of low power efficiency can be overcome by using subwavelength structures such as an arrays of slits. In this study, we explore a pathway for efficiency enhancement by utilizing periodic gold arrays with a grating period smaller than the THz wavelength, which results in increased local THz fields. By varying the gap and width of the gold arrays, we find that the TSHG power efficiency increases with decreasing gap size of the grating. Furthermore, we demonstrate the potential for cavity enhancement, which can improve and control THz emission from spin-

tronic THz emitters by placing a gold periodic array on the backside of a quartz glass substrate.

MA 41.14 Thu 15:00 P3

Terahertz field induced spin wave excitation in thin ferromagnetic metals — •Sergei Ovcharenko, Hoppe Wolfgang, Alexey Melnikov, and Georg Woltersdorf — Institute of Physics, Martin Luther University Halle-Wittenberg, Von-Danckelmann-Platz 3, Halle 06120, Germany

In the novel concepts of charge-less data processing technologies spin waves are proposed as a carriers of data. One of the ways to excite and study the properties of spin waves on the picosecond time scale is to use the laser pulsed excitation and magneto optical probe. Optical excitation of spin waves in ferromagnetic metals has now been demonstrated using a short pulse of spin current leading to spin torque localized at the interfaces of a ferromagnetic and nonmagnetic metal, both with optical [1] and Terahertz (THz) excitation [2]. The use of short optical pulses in the THz spectral range to induce spin currents and generate spin-orbit torque (SOT) offers undeniable advantages: the SOT is linearly proportional to the THz field amplitude, the excitation and spin-wave frequencies can be well-matched, and minimal heating occurs due to the low excitation energy.

In our work, we demonstrate the optical excitation of spin waves in thin layers of ferromagnetic metals using the THz pump-optical probe technique, with a spintronic emitter as the source of THz radiation. We investigate the dependence of the excited modes on the thickness of the ferromagnetic metal. [1] Brandt Liane et al. Physical Review B 104.9 (2021): 094415. [2] Salikhov Ruslan et al. Nature Physics 19.4 (2023): 529-535.

MA 41.15 Thu 15:00 P3

Wide-field magnetic microscopy of two-dimensional magnetic materials with chiral overlayers — •Buddhika Hondamuni[1], Nir Bar-Gill[3], Angela Wittmann[2], and Dmitry Budker[1] — [1]Helmholtz Institute Mainz, Staudingerweg 18, 55128 Mainz, Germany — [2]Johannes Gutenberg-Universität Mainz, 55128 Mainz, Germany — [3]Hebrew University, Jerusellem, Israel

The objective is to investigate the interplay between magnetic domain structures (or skyrmions) in samples with Perpendicular Magnetic Anisotropy (PMA) and chiral polypeptides. Using Nitrogen Vacancy (NV) center-based continuous wave Optically Detected Magnetic Resonance (cw-ODMR) for stray magnetic field imaging in wide-field with a spatial resolution of $\sim$ 0.8 μm and magnetometric sensitivity up to sub-μT/$\sqrt{\text{Hz}}$ range within a field of view (FOV) of approximately 60×60 μm^2, we study how chiral molecules influence magnetic textures including magnetic domain pinning and coercive force changes. The Chirality Induced Spin Selectivity (CISS) effect provides a unique mechanism for manipulating spin orientations through molecular symmetry, offering the potential to control and enhance magnetic domain behavior. This NV-based imaging technique paves the way for advanced magnetic materials and spintronic devices by enabling precise nanoscale analysis of magnetic textures. This work is supported by the Carl Zeiss Stiftung and conducted in collaboration with the Hebrew University of Jerusalem, Israel.

MA 41.16 Thu 15:00 P3

Investigating Magnetic Material Parameters Using Latent Measures — •Kübra Kalkan, Omer Fetai, Ross Knapman, Janine Graser, Atreya Majumdar, and Karin Everschor-Sitte — Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, 47057 Duisburg, Germany

Magnetic materials are vital in shaping modern technology [1]. Inhomogeneities, however, influence material properties and potentially degrade their performance.

In this study, we focus on quantifying how the local and global dynamic behaviour of the magnetic material is influenced by local material parameters. We apply latent inference methods [2,3] on simulated micromagnetic data to unveil the memory and stochastic properties of the magnetic material. A deep understanding of inhomogeneities is key to enhancing the properties of magnetic materials.

Modeling the magneto-optical Kerr effect in three-dimensional magnetic microstructures — •Florian Ott, Christian Janzen, Bhavadip Rakholiya, Rico Huhnstock, and Arno Ehresmann — Institute of Physics, University of Kassel, Germany

Topographically-elevated magnetic microstructures with complex three-dimensional geometries are promising for the discovery and study of novel magnetic effects [1]. These microstructures can in principle be magnetically characterized using MOKE-based measurement devices intended for conventional planar material systems, like for instance a Kerr microscope [2]. However, the interpretation of data is not trivial, because the MOKE depends on the local reflection geometry [3]. Theortical calculations have been performed to characterize MOKE in magnetic multilayer systems with arbitrary surface normals. Further, simulations of simple optical setups have been performed to investigate the effects of the associated surface tilt on the optical path of light in the system. It has been found that additional contributions to the change in polarization of light are obtained by considering the image forming optics of the measurement device.

Estimation of the exchange stiffness constant via domain wall widths using magnetic bilayers — •Florian Gossing, Michael Vogel, Dennis Seidler, and Jeffrey McCord — Nanoscale Magnetic Materials, Department of Materials Science, Kiel University, Kaiserstraße 2, 24143 Kiel, Germany

The exchange stiffness constant is a key parameter influencing the energy of (micro)magnetic systems. Magnetooptical measurements on compensating Néel walls of a FeCoSiB double layer structure are performed to determine the exchange stiffness constant. Parasitic magnetooptical effects such as the unavoidable magnetooptical gradient effect are removed by evaluating neighboring domain wall pairs of equal chirality. Corresponding modeled domain wall widths are compared with the experimentally determined widths, taking into account also the thickness dependent magnetooptical sensitivity function. Thus, the integral domain wall widths allow for an estimation of the exchange stiffness constant. The methodology is readily applicable to various thin film magnetic materials. The estimated exchange stiffness constants are compared with those obtained from ferromagnetic resonance measurements.

MA 41.19 Thu 15:00 P3

Observing static and dynamic magnetic textures with nanoscale resolution using NV magnetometry — •Ephraim Spindler[1], Philipp Schwenke[1], Duc Tran[2], Vitaliy Vasyuchka[1], Mathias Kläui[2], and Mathias Weiler[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Institut für Physik, Johannes Gutenberg-Universität Mainz, Mainz, Germany

Magnetization and stray field imaging is an essential tool for the characterisation of various magnetic materials and phenomena. Techniques such as Kerr microscopy, magnetic force microscopy or Lorentz transmission electron microscopy are well established and ideal for certain applications. However, their sensitivity, spatial resolution or invasiveness make them unsuitable for other applications. Scanning nitrogen vacancy (NV) magnetometry offers a solution with an excellent combination of high sensitivity and spatial resolution, without distorting the magnetic system of interest. The quantitative nature of the measurement principle allows the determination of the magnetic stray field at the sample surface, allowing the visualisation of magnetic textures even in materials with a very low saturation magnetization, such as canted antiferromagnets like hematite at room temperature. We employ NV magnetometry to study static magnetic textures in bulk hematite samples, and metallic multilayer stacks with perpendicular magnetic anisotropy. An outlook on NV center based spin wave spectroscopy is given.

MA 41.20 Thu 15:00 P3

Magneto-Optical Kerr microscopy of 3D non-planar non-curved magnetic thin films: simulation and experiment — •Christian Janzen, Florian Ott, Bhavadip Bharatbhai Rakholiya, and Arno Ehresmann — Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology,, University of Kassel, Germany

Extending magnetic thin film systems to the third dimension by deposition of magnetic materials onto defined templating structures results in a further degree of freedom to tailor magnetic properties by shape, topology, and chirality [1]. In this work, we present advances in characterizing such 3D systems utilizing conventional magneto-optical Kerr microscopy [2]. By investigating non-planar and non-curved 3D geometries experimentally as well as theoretically, geometric parameters can be manipulated in a systematic way. With this, the magnetic and non-magnetic contributions to the MOKE can be deconvolved. By studying the influence of geometrical parameters that effectively change the initial polarization of the incident light as well as the angle of incidence, we deepen the understanding of Kerr-microscopic signals measured on 3D curved nanomagnetic systems.

Exact exchange kernel for spin waves in the spin-polarized homogeneous electron gas — •Michael Neugum, Alexandre Borrameo Alcaïde, and Arno Schindlmayr — Universität Paderborn, Department Physik, 33095 Paderborn, Germany

Spin waves represent an important class of elementary excitations in magnetically ordered materials. *Ab initio* spin-wave calculations for real materials are often based on time-dependent density-functional theory. The crucial ingredient is the so-called exchange-correlation kernel, which incorporates the effects of the Coulomb interaction between the electrons. In general, the kernel is wavevector and frequency dependent, although its exact mathematical form is unknown. Practical implementations typically employ the adiabatic local-density approximation (ALDA), where the kernel is replaced by a simple constant. The results are generally in good qualitative agreement with experimental measurements but sometimes exhibit significant quantitative deviations. In this work, we implement the exact exchange kernel, which is based on a diagrammatic expansion to first order in the Coulomb interaction. We show results for the fully spin-polarized homogeneous electron gas in two and three dimensions. Overall, we observe a substantial discrepancy from the ALDA. In particular, the parabolic component of the dispersion, the spin-wave stiffness, is systematically lower for the exact exchange kernel. While the exact exchange kernel depends both on wavevector and frequency, the most significant effects are due to the wavevector dependence, whereas the frequency dependence may be neglected for practical purposes.

MA 41.22 Thu 15:00 P3

3D Trajectory Tracking of Remote-Controlled Superparamagnetic Particles in Liquid — •Nikolai Weidt, Rico Huhnstock, Yahya Shubbak, and Arno Ehresmann — Department of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Heinrich-Plett-Str. 40, D-34132 Kassel

To develop Lab-on-a-chip systems, superparamagnetic particles (SPPs) can be surface-functionalized to specifically bind targeted analytes. A promising strategy for achieving analyte binding and transfer involves the directed transport of SPPs over magnetically stripe-patterned exchange bias layer systems. By precisely analyzing the three-dimensional trajectories of SPPs in this setup, we can detect events of analyte binding. To capture movement in the third dimension, we measure the defocusing of particles that exit the microscope's focal plane during transport steps. In this study, we quantify defocusing by calculating the Tenenbaum gradient (TG) for individual particles. This makes it possible to use a conventional light microscope combined with a piezo-controlled sample holder for 3D Trajectory tracking. Through a calibration process, we derive the z-coordinate of SPPs from the measured TG. The resulting 3D trajectories are validated through numerical simulations of SPP motion.

MA 41.23 Thu 15:00 P3

Experimental system of clinostat and Helmholtz cage for microgravity experiments in zero-value Earth magnetic field — Maciej Malczyk[1], Tomasz Blachowicz[1], and •Andrea Ehrmann[2] — [1]Institute of Physics - Center for Science and Education, Silesian University of Technology, 44-100 Gliwice, Poland — [2]Institute for Technical Energy Systems (ITES), Faculty of Engineering and Mathematics, Bielefeld University of Applied Sciences and Arts, 33619 Bielefeld, Germany

Plant cultivation under special conditions, in particular under different magnetic and gravitational conditions, is a relatively new research trend in connection with the development of space technologies. In addition to experiments in space, many studies are carried out under simulated microgravity with the help of a clinostat. Here, a self-designed and built system of coupled devices, a two-axis clinostat and a Helmholtz cage, is presented. The clinostat can, on average, cancel the effective gravitational field, while the correctly mounted Helmholtz cage can cancel the Earth's natural magnetic field [1]. Biological samples, such as plants or microalgae, can be placed in the central part of the system, in the special cultivation sphere. The system makes it possible to control the basic physical parameters and directly observe the growth process visually. The first experimental results of growth tests will be presented.

MA 41.24 Thu 15:00 P3

Finite-temperature DMRG calculations for big spin systems using matrix product states — •Lukas Horstmann and Jürgen Schnack — University of Bielefeld, Bielefeld, Germany

Doing finite-temperature calculations on bigger spin systems is often limited by the size of the Hilbert spaces being too large for algorithms such as exact diagonalisation or finite-temperature Lanczos. In order to work around this problem White proposed a method based on the Density Matrix Renormalization Group (DMRG) in the late 90th which allows the calculation of bigger systems by applying multiple local optimisation steps while truncating the size of the Hilbert space by a large amount without loosing too much information about the system. This method works, but it is slow. Therefore, the whole method was translated into a tensor representation using matrix product states where the full system and its operators are described by a tensor network which allows faster linear algebra calculations [1]. In this contribution we will expand this method to finite-temperature calculations using imaginity-time evolution with TenPy [2] to calculate thermodynamic properties for larger spin systems.

Probing the magnetic anisotropy in mononuclear $4f$- and $5f$-complexes by high-field/high-frequency EPR — •J. Arneth, B. Beier, and R. Klingeler — Kirchhoff Institute for Physics, Heidelberg University, Germany

The quantitative experimental investigation of magnetic anisotropy in $4f$- and $5f$-compounds remains a challenging task as strong spin-orbit coupling and ligand field effects lead to complex electronic structures while magnetisation measurements often provide only scarce information. Here, we report high-frequency/high-field electron paramagnetic resonance spectroscopy (HF-EPR) studies on mononuclear Er(III) [1,2], U(IV) and U(V) [3] molecular complexes, the former in various ligand coordinations. Our experimental data allow for the direct determination of zero field splittings (ZFS) and effective g-factors of the magnetic ground state and the low-energy excited states. The effect of the ligand fields as well as its relevance for the static and dynamic magnetic properties are discussed.

Tunable π-magnetism in carbon-based materials — •Nan Cao[1] and Adam Foster[1,2] — [1]Department of Applied Physics, Aalto University, Helsinki, Finland — [2]WPI Nano Life Science Institute, Kanazawa University, Kanazawa, Japan

Carbon-based π-magnetic structures have gained increasing interest for their promising role in spintronics, quantum computing, and advanced magnetic materials. Tailored functionalities in these structures are desired for their diverse applications. This study presents a systematic investigation of the tunability of these structures by incorporating different chemical linkages and doping with diverse heteroatoms. Using density functional theory (DFT) calculations, we explore how different linkage types - such as single, double bonds and aromatic, antiaromatic rings - and the introduction of dopants like nitrogen, boron, and sulfur affect the magnetic properties and electronic configurations of the π-conjugated carbon frameworks. Our results show that specific linkages can enhance magnetic coupling and stability, while heteroatom doping allows for precise control over magnetic moments and bandgap modulation. Furthermore, we identify optimal combinations of linkages and dopants that maximize tunability, offering pathways for designing customized π-magnetic materials with desired properties. These analyses deepen our understanding of structure-property relationships in carbon-based π-magnetic systems and provide a practical strategy for engineering next-generation magnetic materials with customized properties.

MA 41.27 Thu 15:00 P3

Exploring Data Representation Techniques in Deep Learning Models for Determining Ligand Field Parameters of Single-Molecule Magnets — •Preeti Tewatia, Zayan Ahsan Ali, Julius Mutschler, and Oliver Waldmann — Physikalisches Institut, Universitat Freiburg, D-79104 Freiburg, Germany

Single-Molecule Magnets (SMMs) present an exciting frontier in molecular electronics and quantum computing. According to ligand field theory, the single-ion magnetic anisotropies have in general to be characterized by 27 ligand field parameters. However, typical experimental data such as magnetic susceptibility as function of temperature measured on powder samples is pretty featureless, leading to an inverse problem where multiple parameter sets can equally describe the data. To address this challenge, a deep learning approach based on a Variational Autoencoder and an Invertible Neural Network hybrid architecture was employed. The model has been demonstrated before to be capable of handling the above inverse problem. This work focuses on improving the results of the model using data representation and augmentation techniques. For instance, augmenting the input data with simulated susceptibility curves which include experimental errors were found to enhance the robustness of the model with respect to these errors. This approach leads to better performance than conventional fitting techniques.

MA 41.28 Thu 15:00 P3

Inelastic Neutron Scattering on a Family of 3*d*-4*f* Mn_2Ln_2 Single Molecule Magnets — •Vishali Vishali[1], Julius Mutschler[1], Amal Bouraoui[1], Christopher E. Anson[2], Oliver Waldmann[1], and Annie K. Powell[2] — [1]Physikalisches Institut, Universitat Freiburg, D-79104 Freiburg, Germany — [2]Institut of Inorganic Chemistry, Karlsruhe Institute of Technology (KIT), D-76131 Karlsruhe, Germany

Recent studies in the Single Molecule Magnet (SMM) research area have increasingly focused on 4*f* ions, which offer enhanced magnetic anisotropy and angular momentum, offering new avenues for SMM research. However, the analysis of experimental data remains a challenge for 4*f* based SMMs due to overparametrization, and in the case of Inelastic Neutron Scattering (INS) due to low scattering intensities in pure 4*f* SMMs. A promising approach to overcome these challenges involves expanding the study to heterometallic SMMs incorporating both 3*d* and 4*f* ions. The inclusion of 3*d* ions can enhance INS intensities and improve the quality of INS data. This increases the amount of information on the 4*f* ion properties which can be drawn from the experiment. In this work, high quality INS data of Mn_2Ln_2-square complexes with Ln = Y, Tb, Ho, and Dy are presented. A comprehensive analysis and interpretation of the INS data as well as magnetic data is presented, providing deeper insights into the magnetic behavior of these systems.

MA 41.29 Thu 15:00 P3

Magnetic behavior of cuprate 1/2 spin quantum molecular magnet — •Jakub Šebesta and Dominik Legut — IT4Innovations, VŠB-TU Ostrava, 17.listopadu 2172/15, 708 00 Ostrava-Poruba, Czech Republic

Magnetic materials have long been the subject of scientific inquiry. Nevertheless, the research started to expand its focus beyond aiming at low-dimensional systems. Exploring beyond the traditional bulk magnets could bring innovations thanks to different confinements and the resulting unique physical properties. Apart from layer materials, molecular magnets are significant representatives. In this work, we are discussing an organometallic cuprate 1/2 spin quantum magnet bearing a 2D layered magnetic structure. Combining DFt calculation, an evaluation of magnetic exchange interactions with experimental results, we discuss the complex magnetic structures and the interplay of particular constituent elements in relation to the experimental observation.

Spin Seebeck effect in post-annealed $NiFe_2O_4$ thin films with varying lattice constants — •Fabian Meier, Julian Strassburger, Jan Biedinger, Tapas Samanta, Luana Caron, and Timo Kuschel — Bielefeld University, Germany

The longitudinal spin Seebeck effect (LSSE) in nickel ferrite (NFO) is a widely studied subject in the field of spin caloritronics [1]. Here, the dependence of the LSSE on the lattice constant is investigated in the ferrimagnetic insulator NFO. Two sample series have been fabricated by reactive DC magnetron sputter deposition [2], consisting of 45 nm thick NFO layers grown on $MgAl_2O_4$ substrates and post-annealed in an oxygen atmosphere at different temperatures ranging from 400 °C to 800 °C. Subsequently, the samples are capped by 3 nm of Pt for the spin current detection via the inverse spin Hall effect. The varying lattice constants of NFO, induced by the post-annealing, are analyzed with x-ray diffraction. The LSSE saturation voltage is determined by comparing the LSSE curves with magnetization measurements. Therewith, a linear contribution due to the ordinary Nernst effect in Pt is removed by adjusting the slope of the LSSE curve to match the magnetization curve in the saturation region. Afterwards, the averaged saturation values are determined as a function of the heat flux flowing through the sample. The spin Seebeck coefficient is calculated for each sample and the dependence on the post-annealing temperature, the lattice constants and the unit cell volume is examined.

Sliding Through Topology: Unlocking the Tunable Hopf Index — Maria Azhar, •Sandra Chulliparambil Shaju, Ross Knapman, Alessandro Pignedoli, and Karin Everschor-Sitte — Faculty of Physics and CENIDE, University of Duisburg-Essen, 47057 Duisburg, Germany

Recently, there has been growing interest in three-dimensional magnetic structures [1-3], especially regarding their intriguing topological properties and the calculation of their topological index [4]. In this study, we introduce a new approach to determine the Hopf index of magnetic textures, focusing on contributions from both the self-linking and cross-linking of flux tubes [5]. This alternative perspective provides deeper insight into the topological nature of magnetic textures, particularly those exhibiting non-integer topological indices, which we interpret as states of "mixed topology". We emphasize the critical role of the background magnetization in these three-dimensional textures, which influences whether the Hopf index is an integer or not. To illustrate these concepts, we present examples of three-dimensional magnetic textures within various backgrounds, including ferromagnetic, helical, and screw-dislocation configurations.

Effective Geometric Model for a Magnetic Skyrmionium — •Finn Feldkamp, Alessandro Pignedoli, and Karin Everschor-Sitte — Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, 47057 Duisburg, Germany

A Skyrmionium consists of a Skyrmion nested within another Skyrmion of opposite topological charge, rendering it a non-topological magnetic soliton. We use an effective geometric model to describe a Skyrmionium as a closed-loop domain wall in a thin magnetic film, extending approaches previously used for Skyrmions [1]. Our model not only provides insights into the stability of a Skyrmionium but also facilitates the analytical investigation of its excitation modes.

MA 41.33 Thu 15:00 P3

Inelastic neutron scattering in multi-Q structures in centrosymmetric systems — •Artem Nosenko and Dmitri Efremov — Leibniz Institute for Solid State and Materials Research, Dresden, Germany

In the current study we investigate centrosymmetric spin systems on a square lattice with spin frustration. We show that spin frustration leads to several single-Q helical structures and a double-Q structure.

We study the magnon spectra and calculate the dynamical structure factor for these magnetic structures. The results obtained show that inelastic neutron scattering can be a perfect tool for the identification of double-Q structures.

MA 41.34 Thu 15:00 P3

Gesture recognition with Brownian reservoir computing using geometrically confined skyrmion dynamics — •Grischa Beneke[1], Thomas Brian Winkler[1], Klaus Raab[1], Maarten A. Brems[1], Fabian Kammerbauer[1], Pascal Gerhards[2], Klaus Knobloch[2], Sachin Krishnia[1], Johan Mentink[3], and Mathias Kläui[1,4] — [1]Institut für Physik, Johannes Gutenberg-Universität Mainz, Germany — [2]Infineon Technologies Dresden, Germany — [3]Radboud University, Institute for Molecules and Materials, the Netherlands — [4]Center for Quantum Spintronics, Norwegian University of Science and Technology, Norway

Physical reservoir computing utilizes complex physical systems' dynamics for efficient information processing, minimizing training and energy requirements. Magnetic skyrmions, topologically stabilized spin textures, offer promising reservoir computing capabilities through their stability, strong non-linear behaviour, and energy-efficient manipulation. We demonstrate a time-multiplexed skyrmion reservoir computing approach to overcome traditional limitations in temporal pattern recognition [1]. By aligning the reservoir's timescales with real-world data, our approach processes hand gestures captured by Range-Doppler radar. This method scales to the nanometer regime and demonstrates competitive or superior performance compared to energy-intensive software-based neural networks. Our hardware approach's key advantage is its ability to integrate sensor data in real-time without temporal rescaling, enabling numerous applications. [1] G. Beneke et al., Nat. Commun. 15, 8103 (2024).

MA 41.35 Thu 15:00 P3

Direct Manipulation of Topological Spin Textures with Magnetic Force Microscopy — •Minh Duc Tran[1], Elizabeth Martin Jefremovas[1], Mona Bhukta[1], Thomas Brian Winkler[1], Robert Frömter[1], Dennis Meier[2], and Mathias Kläui[1,3] — [1]Institute of Physics, Johannes Gutenberg University Mainz, 55128 Mainz, Germany — [2]Department of Materials Science and Engineering, Norwegian University of Science and Technology (NTNU), 7034 Trondheim, Norway — [3]Center for Quantum Spintronics, Norwegian University of Science and Technology, 7491 Trondheim, Norway

We present a method to manipulate skyrmions in CoFeB-based multilayer stacks using magnetic force microscopy (MFM). By employing single-pass MFM scans, we eliminate disturbances from the initial topography mapping, allowing for direct control over the interaction with the complex spin textures [1]. Through precise tuning of the scan parameters such as lift height and write speed, we achieve localized transformations of the metastable skyrmion state into the energetically favored stripe domains [2]. Our findings offer a potential approach for generating more exotic spin textures by selectively creating/annihilating magnetic domains in a confined region [3].

MA 41.36 Thu 15:00 P3

Minimizing pinning of magnetic skyrmions in multilayer thin films — •Alen John[1,2], Maria Andromachi Syskaki[1,2], Jürgen Langer[2], Gerhard Jakob[1], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg University Mainz, Germany — [2]Singulus Technologies AG, Kahl am Main, Germany

Topological solitons, such as skyrmions, have attracted widespread attention due to their potential applications in unconventional computing and sensing. In this work, we present an optimization process for creating and stabilizing magnetic skyrmions with low pinning in multilayer thin films, using magnetron sputtering. We investigate Ta/CoFeB/MgO stacks with perpendicular magnetic anisotropy, systematically varying deposition parameters like sputter power and pressure to optimize skyrmion formation. Additionally, we introduce a Ta dusting layer between the ferromagnetic and MgO layers to fine-tune the magnetic anisotropy. This approach enables the fabrication of ultra-low pinning skyrmion samples that host room-temperature, thermally diffusing skyrmions[1], which are particularly promising for a range of emerging unconventional computing applications, including reservoir computing [2].

Exploring Topological Magnetism in Magnet-Superconductor Hybrid Systems — •Sayan Banik[1] and Ashis Nandy[2] — [1]National Institute of Science Education and Research, Jatni 752050, India — [2]National Institute of Science Education and Research, Jatni 752050, India

In this study, we engineer magnet-superconductor hybrids (MSHs) by placing 3d transition metals (TM) on the surface of the s-wave superconductor (SC), Nb. By employing a systematic search approach, we select a few members within this MSH family that exhibit magnetism according to Hund's first rule, depending on two different superconducting surfaces. Interestingly, the weak spin-orbit coupling at these interfaces causes the magnetic behavior to differ from what Hund's rule predicts.

By employing detailed ab initio electronic structure calculations followed by spin-lattice simulations, we further explored these materials, discovering many complex and unusual spin textures. For example, Cr/Nb(110) and Mn/Nb(110) are found to exhibit antiferromagnetic spin spiral (AFM-SS) ground states. In contrast, Fe/Nb(001) exhibits antiferromagnetic (AFM) order, while Cr/Nb(001) displays a magnetic state with an AFM chain along the x-direction and a spin spiral modulation along the y-direction. The strain affects these magnetic ground states, finding that the AFM-SS of Mn/Nb(110) changes to AFM order when in-plane strain is applied.

We find a hexagonal skyrmion lattice by covering the top surface of the TM-SC with two layers of heavy metal.

MA 41.38 Thu 15:00 P3

Resonant X-ray Elastic Scattering of Chiral Magnets — Sina Mehboodi[1,3], •Mathew James[4], Victor Ukleev[2], Chen Luo[2], Florin Radu[2], Christian H Back[1,3], and Aisha Aqeel[1,3,4] — [1]Physik-Department, Technische Universität München, D-85748 Garching, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), München, Germany — [4]University of Augsburg, Augsburg, Germany

Resonant Elastic X-ray Scattering (REXS) is an element specific synchrotron X-ray technique that combines diffraction and spectroscopy. It can be used to study complex magnetic materials and provides a sensitive probe for the spatial modulation of spin configuration. This technique has been used to explore a chiral magnet Cu_2OSeO_3. Cu_2OSeO_3 is a unique magnetic insulator that exhibits a complex spin configuration, including helices, conical spirals, and skyrmions. We studied the skyrmion phase and the tilted cone phase of the high-quality single crystal Cu_2OSeO_3 at low temperature [1] using the REXS technique, which occurs when the energy of the incident X-ray photon is matched near the absorption edge of a magnetic element, in this case Cu. We carried out all the experiments by tuning the photon energy to the L_3 edge of Cu. We can directly observe the magnetic diffraction pattern caused by the magnetic arrangement of Cu^{2+} ions in different phases of Cu_2OSeO_3.

Topological Phase Transition and Topological Protection in Van Der Waals Ferromagnet Fe3GeTe2 Thin Flake — •Sourav Chowdhury[1], Michael Schneider[2], Soumyaranjan Dash[3], Christopher Klose[2], Chithra Sharma[4,5], Lisa-Marie Kern[2], Tim Butcher[2], Josefin Fuchs[2], Santanu Pakhira[6], Amir-Abbas Haghighirad[6], Sujit Das[7], Sanjeev Kumar[3], Bastian Pfau[2], and Moritz Hoesch[1] — [1]Deutsches Elektronen-Synchrotron, Hamburg, Germany — [2]Max-Born-Institut, Berlin, Germany — [3]Indian Institute of Science Education and Research, Mohali, India — [4]University of Hamburg, Hamburg, Germany — [5]Christian-Albrechts-University Kiel, Kiel, Germany — [6]Karlsruhe Institute of Technology, Karlsruhe, Germany — [7]Indian Institute of Science, Bengaluru, India

Topological spin textures in 2D van der Waals (vdW) magnets are increasingly sought for high-performance spintronic devices, presenting transformative potential for ultra-dense data storage, energy-efficient operation, and advanced data processing capabilities [1]. We image various topological spin textures within a vdW ferromagnet Fe3GeTe2 thin flake. We observed topological protection versus non-protection behavior at close-to versus well-below the ferromagnetic transition temperature. Monte-Carlo calculation suggests that the switching among distinct topological spin textures can be achieved with the interplay between the Rashba spin-orbit coupling and the uniaxial-magnetic-anisotropy.

Thiele model computer simulations of magnetic skyrmions — •Anna Endres, Simon M. Fröhlich, Jan Rothörl, Maarten A. Brems, Raphael Gruber, Leonie-C. Dany, Tobias Sparmann, Mathias Kläui, and Peter Virnau — Institute of Physics, Johannes Gutenberg University Mainz, Germany

Magnetic skyrmions can be approximated as rigid particles in 2D in the framework of the Thiele model [1]. This coarse-grained approach in principle enables simulations of hundreds or even thousands of skyrmions on experimentally relevant time and length scales [2]. Skyrmion interactions and pinning landscapes can be inferred directly from corresponding experiments [3][4]. Recently, we have also developed methods to match time and force scales of simulations with experiments, enabling quantitative and predictive simulations. In this poster we summarize our results and provide details on our modelling approach [5].

MA 41.41 Thu 15:00 P3

Effective field theory of the Quantum Skyrmion Hall Effect — •Vinay Patil[1,2], Rafael Flores-Calderòn[1,2], and Ashley M. Cook[1,2] — [1]Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Strasse 38, 01187, Dresden, Germany — [2]Max Planck Institute for Chemical Physics of Solids, Nöthnitzer Strasse 38, 01187, Dresden, Germany

Motivated by phenomenology of myriad recently-identified topologically non-trivial phases of matter, we introduce effective field theories (EFTs) for the quantum skyrmion Hall effect (QSkHE). We employ a single, unifying generalisation for this purpose: in essence, a lowest Landau level projection defining a non-commutative, fuzzy sphere with position coordinates proportional to SU(2) generators of matrix representation size N, may host an intrinsically 2+1 dimensional, topologically non-trivial many-body state for small N as well as large N . That is, isospin degrees of freedom associated with a matrix Lie algebra with N * N generators potentially encode some finite number of spatial dimensions for N > 1, where isospin has previously been treated as a label. This statement extends to more general p-branes subjected to severe fuzzification as well as membranes. As a consequence of this generalisation, systems with d cartesian spatial coordinates and isospin degrees of freedom encoding an additional δ fuzzy coset space coordinates can realise topologically non-trivial states of intrinsic dimensionality up to d+δ+1. We furthermore generalise these EFTs to space manifolds with local product structure exploiting the dimensional hierarchy of (fuzzy) spheres.

MA 41.42 Thu 15:00 P3

A C*-algebraic approach to orbital magnetization in skyrmion crystals and finite magnetic fields — •Pascal Prass[1], Duco van Straten[2], and Yuriy Mokrousov[1,3] — [1]Institute of Physics, Johannes Gutenberg University Mainz, Germany — [2]Institute of Mathematics, Johannes Gutenberg University Mainz, Germany — [3]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, Germany

Skyrmion crystals can induce orbital magnetization even in the absence of spin-orbit coupling [1]. This depends on the skyrmion density determining the strength of the emergent magnetic field. As the length scale of a skyrmion crystal approaches the lattice constant of its host material, topological gaps may open in the associated electronic system similar to the formation of Landau levels. However, the smooth texture approximation for the emergent magnetic field is no longer satisfied [2]. Therefore, we utilize a fully algebraic framework to describe a tight-binding system coupled to a skyrmion crystal, that allows us to numerically evaluate topological gap invariants [3] and orbital magnetization even in the presence of finite magnetic flux. This way, we can describe the dependence of the orbital magnetization on the magnetic field for different skyrmion densities. In the appropriate limit, this approach coincides with the expression from the modern theory of orbital magnetization [4]. [1] Göbel et al. Phys. Rev. B **99**, 060406(R) (2019). [2] Lux et al. Phys. MA 41.43 Thu 15:00 P3

Stoichiometry-control of topological ground states in the Kondo lattice CeAlGe — •Soohyeon Shin[1,2], Igor Plokhikh[2], Jonathan White[2], Vladimir Pomjakushin[2], Pascal Puphal[3], and Ekaterina Pomjakushina[2] — [1]Jülich Centre for Neutron Science (JCNS) at Heinz Maier-Leibnitz Zentrum (MLZ), Forschungszentrum Jülich, Lichtenbergstrasse 1, D-85747 Garching, Germany — [2]PSI Center for Neutron and Muon Sciences, Paul Scherrer Institut, CH-5232 Villigen PSI, Switzerland — [3]Max-Planck-Institute for Solid State Research, Heisenbergstraße 1, 70569 Stuttgart, Germany

CeAlGe crystalises in tetragonal structure I41md, where the spatial-inversion symmetry is broken, and is expected to exhibit Weyl fermions near a Fermi surface that becomes more stable by broken time-reversal symmetry. CeAlGe grown by the flux method, off-stoichiometric case, exhibits a commensurate antiferromagnetic order below T = 5.1 K, whereas the crystal grown by floating-zone methods with 30 bar of Ar gas (p=30 bar), stoichiometric case, exhibits an incommensurate order below T = 4.4 K in which topological Hall effects are induced by external magnetic fields applied in the c-axis. In this presentation, we show the newly synthesised CeAlGe using the same floating-zone method but with lower Ar pressure of p=5 bar. Our neutron diffraction and electrical Hall transport experiments revealed that the topological magnetism remains with shorter periodicity. Given all experimental results of flux-grown and two floating-zone-grown CeAlGe, we will discuss the mechanism of topological magnetism with respect to the Kondo coupling strength.

MA 41.44 Thu 15:00 P3

Quasiparticle interference in an altermagnetic tight-binding model — •Eric Petermann, Kristian Maeland, and Björn Trauzettel — Institute for Theoretical Physics and Astrophysics, University of Würzburg, 97074 Würzburg, Germany

Altermagnets constitute novel magnetic systems characterized by compensated magnetic ordering and momentum-dependent spin splitting without net magnetization. We employ tight-binding models to analyze quasiparticle interference (QPI) patterns in altermagnetic lattices. In the presence of impurities, scattering processes give rise to spatial modulations of charge and spin densities emerging from the interference of quasiparticles. This interference results in QPI patterns near those impurities. We relate the QPI patterns with the type of altermagnetic order.

MA 41.45 Thu 15:00 P3

Spin-Orbit Torque in RuO_2|Py multilayer systems — •Niklas Schmolka, Maik Gaerner, Jan Schmalhorst, and Günter Reiss — Bielefeld University, Germany

Spin torques like the Spin-Orbit torque (SOT) offer fast and energy efficient data writing techniques in magnetic memory devices (MRAM). As a new class of materials, Altermagnets, like RuO_2, are able to generate a current induced SOT while possessing zero net magnetization. As such, Altermagnets offer multiple advantages compared to existing MRAM devices based on Ferromagnets like higher stability against external magnetic fields and THz Switching [1][2].
Here, we use the harmonic Hall measurement technique to determine the Spin Hall Angle (SHA) in RuO_2|Py multilayer system via the Harmonic Response Modell [3]. To accurately determine the SHA we first characterize our samples using X-ray diffraction, X-ray reflection, Alternating Gradient Magnetometry and measure the magnetization and the Anomalous Hall Effect. We compare our experimental results to the existing literature and reflect on the influence of the crystal structure on the generated spin current [4].

Growth of altermagnetic MnTe thin films — •Lena Hirnet, Marco Dittmar, Hannes Haberkamm, Maximilian Ünzelmann, and Friedrich Reinert — Exp. Physik VII and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, Germany

Recently, altermagnets have attracted great attention combining antiferromagnetic spin alignment in real space with a momentum-dependent spin polarization of the electronic states in the band structure. One of the proposed altermagnet work horse materials is MnTe [1,2]. Here, we investigate the epitaxial growth of MnTe on different substrates ranging from trivial band insulators to topological van der Waals metals with spin-momentum-locked surface states. The atomic and electronic structure of these films is studied employing low-energy electron- and x-ray diffraction as well as soft x-ray angle-resolved photoemission spectroscopy, respectively.

MA 41.47 Thu 15:00 P3

Interplay and Robustness of Dual-sublattice Altermagnetic Ordering in $Er_2Ru_2O_7$ — •Michele Reticcioli[1], Paolo Radaelli[2], and Alessandro Stroppa[1] — [1]CNR-SPIN L'Aquila, Italy — [2]University of Oxford, United Kingdom

Altermagnets, a novel class of magnetic materials, bridge the gap between conventional antiferromagnets and ferromagnets by hosting spin-split electronic structures without net magnetization. These materials hold promise for spintronic applications due to their unique symmetry-driven properties. In this work, we explore altermagnetism in the oxide semiconductor $Er_2Ru_2O_7$, which exhibits a rare double altermagnetic ordering arising from the Er and Ru magnetic sublattices. Using density functional theory, we investigate the interplay between the two sublattices, giving rise to two Neel vector order parameters, revealing a complex interplay that shapes the material's magnetic behavior. Furthermore, we analyze the impact of doping on the magnetic properties. Our findings show that while the Er sublattice demonstrates remarkable robustness against p-doping, the Ru sublattice undergoes significant changes. Notably, local substitution of oxygen atoms with nitrogen dopants leads to a drastic alteration in the Ru-sublattice magnetic ordering. These results shed light on altermagnetism in oxides, particularly on the interplay between sublattices and the sensitivity to doping, opening new avenues for tailoring magnetic properties in altermagnets for technological applications.

MA 42: Members' Assembly

Time: Thursday 18:00–19:00 Location: H20

All members of the Magnetism Division are invited to participate.

MA 43: Skyrmions III / Non-Skyrmionic Magnetic Textures II

Time: Friday 9:30–13:15 Location: H16

All-Optical Control of Bubble and Skyrmion Breathing — •Tim Titze[1], Sabri Koraltan[2], Timo Schmidt[3], Dieter Suess[2], Manfred Albrecht[3], Stefan Mathias[1], and Daniel Steil[1] — [1]I. Physikalisches Insitut, University of Göttingen — [2]Physics of Functional Materials, Faculty of Physics, University of Vienna — [3]Institute of Physics, University of Augsburg

Topologically protected magnetic skyrmions promise tremendous potential for innovative applications, such as unconventional computing schemes. Deterministic control of the dynamics of such spin objects is one key ingredient for future data processing devices. Using ultrafast Kerr spectroscopy, we investigate the spin dynamics of ferrimagnetic $[Fe(0.35\,nm)/Gd(0.40\,nm)]_{160}$ multilayers hosting a dense bubble/skyrmion (BSK) lattice at ambient temperature [1, 2]. Ultrafast laser excitation of the BSK lattice leads to coherent spin dynamics in the form of BSK breathing [3]. By tuning the time delay between excitations in a dual pulse excitation scheme we demonstrate optical control of the breathing dynamics of the BSK lattice in amplitude and phase [4]. This fast and reversible technique presents a promising pathway towards future BSK-based spintronic and magnonic devices.

MA 43.2 Fri 9:45 H16

Spiral multiferroics as a natural skyrmion racetrack — •Luca Maranzana[1,2], Maxim Mostovoy[3], Naoto Nagaosa[4], and Sergey Artyukhin[1] — [1]Quantum Materials Theory, Italian Institute of Technology, Via Morego 30, Genoa, Italy — [2]Department of Physics, University of Genoa, Via Dodecaneso 33, Genoa, Italy — [3]Zernike Institute for Advanced Materials, University of Groningen, Nijenborgh 3, 9747 AG Groningen, Netherlands — [4]RIKEN Center for Emergent Matter Science (CEMS), Wako, Saitama 351-0198, Japan

Magnetic skyrmions are localized spin textures with a nontrivial topology. This property ensures excellent stability even at nanometer length scales, establishing skyrmions as promising information carriers in magnetic storage and processing devices. Still, their fate in a wide variety of magnetic backgrounds is poorly understood. Here, we show that spiral multiferroics, some of the most basic noncollinear magnets, host bimerons, a particular type of skyrmion. Multiferroic properties of a spin spiral endow the bimeron with magnetic and ferroelectric dipole moments that, surprisingly, depend on its position relative to the spiral. This enables precise positioning of the bimeron by a rotating magnetic field (e.g. of a circularly polarized electromagnetic wave). At low frequencies, the bimeron magnetic moment rotates in sync with the field, and this topological spin texture is pumped in the Archimedean screw fashion. The results establish spiral multiferroics as a natural racetrack, where one full rotation of the field moves the bimeron by one spiral period.

MA 43.3 Fri 10:00 H16

Pathways to Bubble and Skyrmion Lattice Formation in Fe/Gd Multilayers — Tim Titze[1], Sabri Koraltan[2], Timo Schmidt[3], Dieter Suess[2], Manfred Albrecht[3], Stefan Mathias[1], and •Daniel Steil[1] — [1]University of Goettingen — [2]University of Vienna — [3]University of Augsburg

Fe/Gd multilayers host a rich variety of magnetic textures, including topologically trivial bubbles and topologically protected skyrmions [1-4]. Using time-resolved Kerr spectroscopy, we highlight how different control strategies including temperature T, out-of-plane magnetic fields H and femtosecond light excitation can be used to create such textures via different pathways. We find that varying the magnetic field at constant temperature leads to a different (H,T) phase diagram of magnetic textures than moving along a temperature trajectory at constant magnetic field, which is corroborated by micromagnetic simulations. We furthermore show that bubble and skyrmion (BSK) creation by impulsive light excitation is at least partially a non-adiabatic process, as the creation occurs in parts of the (H,T) phase diagram, where neither the constant T nor the constant H trajectory predict their existence. We discuss a possible scenario for the creation of BSKs in this material system involving the inhomogeneity of the excitation process.

MA 43.4 Fri 10:15 H16

Nitrogen-vacancy scanning imaging of a room-temperature skyrmion lattice in a van der Waals ferromagnet Fe3-xGaTe2 — •Young-Gwan Choi[1], Hayden Binger[1], Luke Turnbull[1], Yejin Lee[1], Lotte Boer[1], Chenhui Zhang[2], Haneul Kim[3], Claire Donnelly[1], Hyunsoo Yang[2], and Uri Vool[1] — [1]Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany — [2]Department of Electrical and Computer Engineering, National University of Singapore, 117583 Singapore, Singapore — [3]Department of Physics, University of Ulsan, 44610 Ulsan, Korea

We report the visualization of the magnetic stray field from a room-temperature skyrmion lattice in the van der Waals ferromagnet Fe3-xGaTe2(FGaT) by nitrogen-vacancy (NV) scanning. By employing a field-cooled process, we observed the transition from labyrinth domain structures to a stable skyrmion lattice state, demonstrating the formation of a stable skyrmion lattice phase. The experiments were conducted on FGaT flakes with an approximate thickness of 100 nm, revealing detailed insights into the stable formation of the skyrmion phase even at room temperature. These results highlight the capability of NV scanning for direct and quantitative imaging of room-temperature skyrmions, offering valuable insights into their properties and advancing the understanding of skyrmion lattices. This study provides a basis for further exploration of skyrmion-based spintronic applications.

MA 43.5 Fri 10:30 H16

Controlling topolopogical spin textures in Heusler magnetic nanowires — •Rikako Yamamoto[1,2], Luke Turnbull[1,2], Marisel Di Petro Martinez[1,2], Jeffrey Neethirajan[1], José Claudio Corsaletti Filho[1], Simone Finizio[3], Tim Butcher[3,4], Igor Beinik[5], Claas Abert[6], Dieter Suess[6], Praveen Vir[1], Chandra Shekar[1], Claudia Felser[1], and Claire Donnelly[1,2] — [1]MPI-CPfS, Dresden, Germany — [2]WPI-SKCM2, Higashi-Hiroshima, Japan — [3]PSI, Villigen, Switzerland — [4]MBI, Berlin, Germany — [5]MAX-IV, Lund, Sweden — [6]University of Vienna, Vienna, Austria

Nontrivial topological spin textures, such as magnetic skyrmions and antiskyrmions, have been attracting considerable interest due to their fundamental properties and potential applications. Antiskyrmions, commonly found in materials with anisotropic Dzyaloshinskii-Moriya interactions, are of particular interest due to their complex winding, and prospect for unidirectional motion. However, such textures are energetically degenerate, and their formation remains open to exploration. Here we gain control over the formation and stability of antiskyrmions by nanopatterning anti-skyrmion-hosting Heusler magnets. By patterning nanowires oriented at different angles to the crystallographic unit cell, we combine intrinsic and geometrical anisotropies. Using x-ray dichroic ptychography to image the magnetic configuration of these nanowires, we observe that the competition between geometrical and intrinsic anisotropy can lead to preferential formation of topological objects in the nanostructure. This approach provides new opportunities for enhanced control of topological spin textures.

MA 43.6 Fri 10:45 H16

Confinement-Induced Magnetoresistances in Skyrmion-based Magnetic Tunnel Junctions — •Moritz Winterott[1,2] and Samir Lounis[1,2] — [1]Peter Grünberg Institut, Forschungszentrum Jülich & JARA, D-52425 Jülich, Germany — [2]Faculty of Physics, University of Duisburg-Essen and CENIDE, 47053 Duisburg, Germany

Innovations are essential to address the rapidly growing demand for data. One of the most promising solution are magnetic tunnel junctions [1] (MTJs) which utilize spin-dependent tunnelling between two ferromagnetic layers separated by an insulating barrier and present a high-speed, non-volatile, and energy-efficient memory solution. Combining MTJs with skyrmions offers great potential [2] due to the nanoscale size and topological protection of the later ones. However creation and efficient electrical detection of skyrmions in MTJs remains challenging. We demonstrate that a strong splitting of spin-channels leads to confined states inside the skyrmion, complementary to Friedel oscillations reaching far outside the skyrmion. These non-trivial signatures in the electronic structure induce new magnetoresistances augmenting the efficiency of those enabled by spin-orbit coupling and magnetic non-collinearity [3], which could facilitate electrical detection of skyrmions in MTJs. We employ a tight-binding scheme to explore the impact of the skyrmion size, Fermi energy and splitting of the spin-channels.

MA 43.7 Fri 11:00 H16

Field-induced Reversal of Magnetic Anisotropy in Skyrmion Hosts — •Hans-Albrecht Krug von Nidda, Bertalan Szigeti, Mamoun Hemmida, Dieter Ehlers, and István Kézsmárki — Experimental Physics V, Center for Electronic Correlations and Magnetism, University of Augsburg, D-86135 Augsburg, Germany

Skyrmions show up in non-centrosymmetric magnets due to the complex interplay of anisotropic Dzyaloshinskii-Moriya interaction, uniaxial magnetic anisotropy, and magnetic dipolar interactions. A magnet is commonly classified as either easy-axis or easy-plane, when the magnetic anisotropy forces the magnetization to align parallel or perpendicular to the high-symmetry axis, respectively. We show that this simple classification fails for systems with competing anisotropy terms. Our multi-frequency electron spin resonance spectroscopy study on the skyrmion hosts GaMo4S8 and GaV4Se8 reveals counteracting exchange and g-factor anisotropies. Consequently, the total aniotropy changes sign in moderate magnetic fields: GaMo4S8 turns from an easy- to a hard-axis magnet, while GaV4Se8 does the opposite. These findings underscore the significance of precisely quantifying all anisotropy components, because a single effective value, when encompassing conflicting terms, proves to be insufficient for an accurate description of magnetic states.

MA 43.8 Fri 11:15 H16

Short-pitch skyrmions in layered rare-earth frustrated magnets — •Vladislav Borisov[1], Rohit Pathak[1], Sagar Sarkar[1], Anna Delin[2,3,4], and Olle Eriksson[1,3] — [1]Uppsala University, Sweden — [2]KTH Royal Institute of Technology, Stockholm, Sweden — [3]Wallenberg Initiative Materials Science for Sustainability (WISE) — [4]SeRC (Swedish e-Science Research Center), KTH Stockholm, Sweden

While most skyrmionic systems rely on the presence of Dzyaloshinskii-Moriya interaction (DMI), there are a few known compounds, such as $GdRu_2Si_2$ with 122-type structure, where extremely compact skyrmions around 2 nm are stabilized without DMI, as discovered in recent experiments [1]. Several theory studies, including our recent work [2], suggest the importance of magnetic frustration and local anisotropy for the skyrmion stability. The present work explores further the variety of magnetic phases in other compounds with the 122-type crystal structure using density functional theory and atomistic spin dynamics at finite temperature and applied magnetic field. Various chemical compositions, included those from [3], are considered here and interesting trends for RKKY-like Heisenberg interactions between the rare-earth moments, calculated using magnetic force theorem, and real-space textures are analyzed.

MA 43.9 Fri 11:45 H16

Tunable magnetic skyrmion bubbles in centrosymmetric magnets — Dola Chakrabartty[1], István Kézsmárki[1], and •Ajaya Kumar Nayak[2] — [1]Experimentalphysik V, Center for Electronic Correlations and Magnetism, Institute for Physics, Augsburg University, D-86135 Augsburg, Germany — [2]School of Physical Sciences, National Institute of Science Education and Research, HBNI, Jatni, 752050, Bhubaneswar, India

Magnetic skyrmions are topologically protected spin textures that can avoid defects and be mobilized by low current densities, making them potential candidates for high-density and low-power consuming logic and memory devices. Skyrmion-like spin textures with different helicities and vorticities have recently been found also in centrosymmetric magnets, stabilized by competing dipolar interaction and out-of-plane magnetic anisotropy. The primary motivation of this study is to explore the extensive tunability of magnetic skyrmion bubbles in centrosymmetric magnets with internal and external parameters. We have demonstrated that in the centrosymmetric system by applying external magnetic field and tuning magnetic anisotropy one can transform skyrmions (topological number -1) to type-II bubble (topological number 0) through Bloch line formation. We found that the skyrmions are stable when there is only out-of-plane uniaxial anisotropy, whereas the introduction of small in-plane anisotropy turns them to type-II bubbles. Presently, we are in the process of exploring the tunability of skyrmions in such systems with other external stimuli, such as uniaxial strain and laser irradiation.

MA 43.10 Fri 12:00 H16

Gate-Voltage-Induced Changes of the Magnetic Properties of Skyrmion-Hosting Gd/Fe Multilayers — •Sebastian Hofmann[1], Steffen Wittrock[2], Tamer Karaman[1], Sascha Petz[2], Daniel Metternich[2], Krishnanjana Puzhekadavil Joy[2], Kai Litzius[1], and Felix Büttner[1,2] — [1]Universität Augsburg Institut für Physik, Universitätsstraße 1, 86159 Augsburg — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Hahn-Meitner-Platz 1, 14109 Berlin

Ionic gating has recently emerged as a versatile method to induce large and controllable changes of the local magnetic properties of thin films. This allows, for example, to manipulate the existence [1] and chirality [2] of magnetic skyrmions. However, existing gating experiments have focused on ultrathin films, where skyrmions are usually micron sized. Here, we show that ionic gating with oxygen and hydrogen can be used to control ferrimagnetic Gd/Fe multilayer materials with thicknesses of more than 40 nm, in which sub-100 nm skyrmion can be observed. We find that ionic gating can shift the compensation temperature by more than 100 K, i.e., by a similar magnitude as in sub-10 nm thick films [3]. However, unlike ultrathin films, our thicker materials exhibit vertical variation of magnetic properties, suggesting a pathway toward gate-control of spin textures in 3D. [1] Yang, S. et al. Adv. Mat. 2208881 (2022). [2] Fillion, C.-E. et al. Nat. Comm. 13, 5257 (2022). [3] Huang, M. et al. Nat. Nanotechnol. 16, 981 (2021).

MA 43.11 Fri 12:15 H16

Shape anisotropy in helimagnets — •Jan Masell[1], Maurice Colling[2], Mariia Stepanova[2], Mario Hentschel[3], and Dennis Meier[2] — [1]Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]NTNU Norwegian University of Science and Technology, Trondheim, Norway — [3]University of Stuttgart, Stuttgart, Germany

In chiral magnets, the competition between ferromagnetic exchange and Dzyaloshinskii-Moriya interaction (DMI) stabilizes a long-ranged helical state as the ground state. The orientation and pitch of the helix is described by the q-vector. For isotropic model systems, the q-vector can point in any direction while in real materials its orientation is pinned by anisotropies, such as exchange or single ion anisotropy.

In this talk, I will discuss the impact of the shape of the magnet on the orientation of the helical phase. While shape anisotropy is a well-established phenomenon in ferromagnets, its role in chiral magnets remains less explored. I will present our theoretical results for a new type of DMI-shape-anisotropy for non-trivial magnetic textures, caused by the competition between standard shape anisotropy and the chiral surface twist inherent to systems with DMI. Our experimental data on FeGe confirm the existence of such non-trivial anisotropy, challenging present models for magnetic textures in nanostructures with DMI.

MA 43.12 Fri 12:30 H16

Extraordinary return point memory of Pt/Co/Dy ferrimagnetic multilayers — •Tamer Karaman[1], Kai Litzius[1], Sebastain Wintz[2], Aladin Ullrich[1], Daniel Metternich[1,2], Steffen Wittrock[2], Krishnanjana Joy[1,2], Sebastian Hoffman[1], Timo Schmidt[1], Manfred Albrecht[1], and Felix Büttner[1,2] — [1]Institute of Physics, University of Augsburg, 86159 Augsburg, Germany — [2]Helmholtz-Zentrum Berlin, 14109 Berlin, Germany

Chiral magnetic spin textures are promising candidates for various spintronics applications [1]. These applications rely fundamentally on the controlled motion of spin textures under external stimuli. In this study, we report on the contrary and unique behaviour of Pt/Co/Dy rare-earth transition metal (RE-TM) ferrimagnetic multilayers, particularly their demonstration of full return-point memory. By studying the domain and domain wall response with field cycling using real-space imaging techniques, we observe deterministic behaviour where domains completely return to their original positions, even after exposure to high applied fields. Such observation is rarely documented in the literature and invites a variety of interpretations [2, 3]. This study emphasizes the significance of unexplored aspects of RE-TM ferrimagnets, advancing deeper exploration and broader utilization of these materials.

MA 43.13 Fri 12:45 H16

Fascinating mesoscale magnetic textures in the topological Kagome system $TbMn_6Sn_6$ — •Ralph Rajamathi[1], Manuel Zahn[1,2], Kai Litzius[1], István Kézsmárki[1], and Sándor Bordács[3] — [1]Center for Electronic Correlations and Magnetism, University of Augsburg — [2]Department of Materials Science and Engineering, Norwegian University of Science and Technology — [3]Department of Physics, Budapest University of Technology and Economics

In recent years, the Kagome ferrimagnet $TbMn_6Sn_6$ has garnered significant interest due to its unconventional band topology, which realizes exotic quantum states like a Chern insulating phase. It exhibits a spin-reorientation transition (SRT) from easy-axis to easy-plane at 310 K, where skyrmion bubbles have been observed in lamellae. However, magnetic textures in bulk crystals have been unexplored so far. Here, we used magnetic force microscopy (MFM) to image the magnetic pattern on the surface of bulk crystals, and magnetometry to study the role of second order magnetic anisotropy. Two types of textures were observed, namely long-ranged stripes that invert contrast on reversing the tip's magnetization, decorated by star-shaped structures whose contrast is independent from the the tip's magnetization. Reorientation of the stripes and creation/elimination of the "stars" in an external magnetic field indicate low magnetic pinning. Analyzing the in-plane magnetometry data, a metastable magnetization state was observed below the SRT temperature, indicating the possibility of an intermediate in-plane state, which was observed by MFM in the vicinity of SRT.

MA 43.14 Fri 13:00 H16

Domain walls with 90° magnetization rotation in the topological kagome magnet $TbMn_6Sn_6$ — •Manuel Zahn[1,2], Ralph Rajamathi[1], Kai Litzius[1], Dennis Meier[2], Sándor Bordács[3], and István Kézsmárki[1] — [1]Center for Electronic Correlations and Magnetism, University of Augsburg — [2]Department of Materials Science and Engineering, Norwegian University of Science and Technology (NTNU) — [3]Department of Physics, Budapest University of Technology and Economics

The layered Kagome ferrimagnet, $TbMn_6Sn_6$, attracts much attention due to its topologically non-trivial features. The bulk electronic band structure realizes a Chern insulating state and in the real space, skyrmion bubbles have been observed in thin lamellae of this compound. $TbMn_6Sn_6$ exhibits a zero-field first-order spin reorientation transition at T_{SR} = 315 K, below/above which the magnetic moment points perpendicular/parallel to the Kagome plane. Here, using magnetic force microscopy, we reveal peculiar domain textures in the vicinity of T_{SR} on the surface of bulk $TbMn_6Sn_6$ crystals. Upon approaching T_{SR} from lower temperatures, we observed a broadening of the domain walls separating regions oppositely magnetized perpendicular to the Kagome plane, and the emergence of a strictly in-plane magnetized region at the center of the walls. We compared these results with analytical calculations based on a continuum magnetic model and found that the $\pi/2$ stepwise rotation of the magnetization is a universal effect at the spin reorientation transition.

MA 44: Focus Session: Physics of the van der Waals Magnetic Semiconductor CrSBr II (joint session HL/MA)

The joint focus session of the divisions HL and MA presents the latest developments of the rapidly growing community working with the van der Waals magnetic semiconductor CrSBr with distinct excitonic and magnetic properties, and it is organized by Shengqiang Zhou (HZ Dresden-Rossendorf), Farsane Tabata-Vakili (TU Braunschweig), and Florian Dirnberger (TU Munich).

Time: Friday 9:30–13:00 Location: H17

See HL 60 for details of this session.

MA 45: Computational Magnetism

MA 45.1 Fri 9:30 H18

Magnetic Interactions and Spin Coupling in Endohedral Fullerene Nanostructures — •Arkamita Bandyopadhyay and Jamal Berakdar — Martin-Luther-Universität Halle-Wittenberg, Karl-Freiherr-von-Fritsch-Str. 3 06120 Halle/Saale

Our work investigates the spin-spin interactions in endohedral fullerene clusters, with a particular focus on the effects of different cluster geometries (linear, triangular, and more complex arrangements). By examining various configurations, we aim to provide a deeper understanding of how the interactions between spins in these clusters are governed by both the unique structural features of the fullerene molecules and their molecular levels. Our compuational study explores the role of spin exchange interactions, the potential for spin frustration, and how these phenomena can be manipulated to achieve desired magnetic behaviors, thus it can guide the design of new materials for spintronic devices, quantum information processing, and other applications where precise control over spin-spin interactions is key.

MA 45.2 Fri 9:45 H18

Intrinsic Spin Nernst Effect and Chiral Edge Modes in vdW Ferromagnetic Insulators: Dzyaloshinskii-Moriya vs. Kitaev Interactions — •Verena Brehm and Alireza Qaiumzadeh — NTNU Trondheim, Norway

The thermomagnetic Nernst effect and chiral edge states are key signatures of nontrivial topology and emerging Berry curvature in magnonic systems. Implementing atomistic spin simulations, we theoretically demonstrate the emergence of chiral magnon edge states at the boundaries of a ferromagnetic hexagonal lattice in the presence of Dzyaloshinskii-Moriya and Kitaev interactions, which are robust against nonlinear magnon interactions. In our simulations, we consider the spin parameters of CrI3 as a prototype of van der Waals magnetic layers. We show that the spin accumulation is reduced in the presence of Kitaev spin interactions compared to systems governed by Dzyaloshinskii-Moriya interactions. This reduction stems from the breaking of the U(1) symmetry, which leads to a shorter spin coherence length imposed by the Kitaev interaction. We propose that measuring the angular dependence of the Nernst signal in a magnetic field provides an effective indirect method for identifying the microscopic origin of topological magnons. Our findings hold promising potential for advancing next-generation energy-harvesting Nernst materials and facilitating the integration of topological magnetic materials with spintronic-based quantum technologies.

Origin of MAE and second order MAE due to the magnetostriction in tetragonal systems - FePt study — •Dominik Legut[1] and Pablo Nieves[2] — [1]IT4Innovations, VSB-TU Ostrava, Ostrava, Czechia — [2]University of Oviedo, Oviedo, Spain

The origin of magnetocrystalline anisotropic energy (MAE) guided by spin-orbit coupling in the $L1_0$-FePt alloy was analyzed and the correlations among MAE and magnetoelastic (magnetostriction) constants $b's(\lambda's)$ by means of the electronic structure eigenvalues (orbital energies) and eigenfunctions (orbital occupancies) were established[1]. Our numerical analysis includes the convolution of the projected wave-function (density of states) of each orbital of the Fe and Pt sub-lattices into their orbital energies and its contribution to the MAE,$b's$, and $\lambda's$. However, this corresponds to the zero strain situation. For a zero stress (realistic conditions used in experiments) situtation a very small correction is found for the first anisotropy constant $\Delta K_1/K_1 = 0.07\%$, while a much more significant contribution is obtained for the second one $\Delta K_2/K_2 = 21.86\%$. General analysis of this effect for tetragonal crystals is provided, finding that ΔK_1 will be always positive for any stable phase with this symmetry[2].

High-throughput workflow for predicting magnetic ground states — •Hao Wang and Hongbin Zhang — Technical University of Darmstadt, 64287 Darmstadt, Germany

Obtaining the correct magnetic ground state is crucial for understanding the nature of magnetism and serves as a foundation for engineering functional magnetic materials for interesting applications. In this work, we present a high-throughput computational workflow designed to accurately determine the exchange interaction J_{ij} matrices and other relevant parameters for a wide range of magnetic systems. Combining the four-state energy mapping method with the Green's function approach, we construct symmetrized Heisenberg Hamiltonians to model magnetic interactions. Furthermore, by integrating atomistic spin dynamics Vampire package, our framework enables the efficient prediction of magnetic ground states. This scalable workflow not only improves computational efficiency for complex magnetic materials but also provides a robust platform for exploring the fundamental properties of magnetic systems.

MA 45.5 Fri 10:30 H18

Semiclassical approach to the exchange interactions and spin waves in double-layered antiferromagnets — Seo-Jin Kim[1], Zdeněk Jirák[2], Jiří Hejtmánek[2], Karel Knížek[2], Helge Rosner[1], and •Kyo-Hoon Ahn[2] — [1]Max Planck Institute for Chemical Physics of Solids, D-01187 Dresden, Germany — [2]Institute of Physics, Czech Academy of Sciences, Cukrovarnická 10, 162 00 Praha 6, Czechia

We investigate the stability and magnonic properties of double-layered antiferromagnets using two model systems—the linear chain (LC) and a more complex railroad trestle (RT) geometry—as well as the real solid antiferromagnetic (AFM) CrN in its rock-salt structure. In the LC model, the spin-paired order $(\cdots{+}{+}{-}{-}\cdots)$ requires alternating ferromagnetic (FM) and AFM interactions. In contrast, the RT geometry allows some frustration, and the spin-paired order can be stable even for all magnetic exchange interactions being AFM. In the hypothetical cubic phase of CrN, magnetic Cr ions form a face-centered cubic lattice with equivalent AFM links to twelve nearest neighbors. However, the magnetostructural transition to an orthorhombically distorted phase below the Néel temperature (T_N = 287 K) diversifies the Cr-Cr nearest-neighbor distances, suppressing frustration. Using *ab initio* exchange parameters, we calculate the magnon dispersion relation and the temperature-dependent evolution of ordered magnetic moments. Our findings demonstrate that the stability of the double-layered AFM structure in CrN is attained, even when intra-sublattice interactions remain all AFM, consistent with the RT model.

Tuning Magnetic Anisotropy in Fe3Y Through Transition Metal Doping: An Ab-Initio High-Throughput Study — •Md Nur Hasan and Heike Herper — Department of Physics and Astronomy, Uppsala University, Box 516, SE-75120, Uppsala, Sweden

The advancement of permanent magnet systems is essential for various applications, including energy generation and information technology. This research focuses on developing and optimizing new permanent magnetic materials using an ab initio based first-principles approach. The Fe3Y system was initially selected for its in-plane magnetic anisotropy with a Curie temperature of 550 K, which, although advantageous, constrains its use in scenarios that require uniaxial (out-of-plane) anisotropy. The main goal of this study is to transition the magnetic anisotropy from the in-plane to a uniaxial configuration. Various transition metals were systematically introduced into both the Y and Fe sites of the Fe3Y structure to facilitate this shift. This doping approach enabled the tuning of the magnetic properties and provided insight into the mechanisms governing magnetic anisotropy. As a result, we identified several promising compositions with significant alterations in magnetic behavior, including systems that exhibit uniaxial anisotropy with Curie temperatures of ~ 550K, making them

suitable for high-performance magnetic applications. Initial findings suggest that certain transition metal dopants can significantly modify spin-orbit coupling and crystal field effects, achieving the desired anisotropy realignment with the potential to discover a new category of high-performance permanent magnets.

Programmable Magnetophononics: Selective Damping of Surface Acoustic Waves — •Michael Karl Steinbauer[1], Peter Flauger[1], Bernhard Emhofer[1], Matthias Küss[2], Stephan Glamsch[2], Manfred Albrecht[2], and Claas Abert[1] — [1]University of Vienna — [2]University of Augsburg

Surface acoustic wave (SAW) bandpass filters are an indispensable part of modern telecommunications infrastructure [1]. Spin waves (SWs) can be excited by SAWs in radio-frequency bands, making their coupling a topic of current scientific interest [2].

In this work, we utilize this magnon-phonon interaction to demonstrate the theoretical viability of a novel device composed of exchange-decoupled magnetic islets on a piezoelectric substrate. Depending on the magnetic orientation of neighboring islets, a shift in the dispersion relation of the SW is predicted to occur due to their stray field interaction. This shift increases or decreases the efficiency with which the SAW can excite the SWs, leading to a difference in the amount of energy the magnetic system absorbs. For certain geometries, a gap in the SAW power after traversing the device of 10 dB/mm or more is predicted to occur.

For this study, a new algorithm for efficiently calculating SAW attenuation under the assumption of a continuous signal was developed for the micromagnetic simulation library magnum.np [3].

MA 45.8 Fri 11:30 H18

Mean-Field Approximation and ab-initio calculations in Tetragonal Mn_2-based Heusler compounds. — •Jorge Cardenas-Gamboa[1,5], Arthur Ernst[2], Maia G Vergniory[3,4], Edouard Lesne[1], Claudia Felser[1], and Paul McClarty[6] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]Johannes Kepler University of Linz, Linz, Austria. — [3]Donostia International Physics Center, Donostia-San Sebastian,Spain — [4]Université de Sherbrooke, Sherbrooke J1K 2R1 QC, Canada. — [5]Leibniz Institute for Solid State and Materials Research, Dresden, Germany — [6]Universite Paris-Saclay, Gif-sur-Yvette, France.

Achieving flexible control over magnetic properties is possible in multicomponent systems consisting of several magnetic sublattices with competing interactions.In 2014, Meshcheriakova et al. demonstrated that the Heusler compound Mn_2RhSn exhibits substantial strong noncollinearity and its magnetic structure undergoes a spin-reorientation transition, driven by the competition between its magnetic sublattices. In this work, we use a mean-field approximation to analyze the exchange interactions between the sublattices and investigate how different magnetic regimes develop as a function of temperature. Additionally, we perform first-principles calculations to derive the exchange interactions and assess their influence on the magnetic properties, extending our analysis to other tetragonal Heusler magnets. We then explore the topological properties that arise from the magnetism, focusing on the Weyl nodes and surface states.

MA 45.9 Fri 11:45 H18

First-Principles Study of Non-Collinear Magnets: Spin Models and Cluster Multipole Theory — •Juba Bouaziz[1,2], Takuya Nomoto[3], and Ryotaro Arita[1,2,4] — [1]RCAST, University of Tokyo, Japan — [2]CEMS, RIKEN (Wako), Japan — [3]Tokyo Metropolitan University, Japan — [4]Department of Physics, University of Tokyo, Japan

We present a computational approach for modeling complex non-collinear magnets using the cluster multipole (CMP) method [1] to determine symmetry-allowed magnetic configurations. The magnetic ground state is obtained by comparing the energies of candidate CMP solutions within a spin model Hamiltonian that includes isotropic exchange interactions, relativistic anisotropic terms, and higher-order biquadratic interactions. The parameters of the spin model are systematically calculated using the magnetic force theorem from the paramagnetic reference state [2]. This method is successfully applied to the TM3X Kagome magnet family (TM = Mn, Fe; X = Ga, Ge, Sn), demonstrating its computational efficiency and potential for high-throughput studies of unconventional non-collinear magnetic systems.

MA 45.10 Fri 12:00 H18

Memory-Efficient Inverse Design for Advanced Magnonic Devices Using Level-Set Optimization — •Andrey Voronov[1,2], Marcos Cuervo Santos[2,3], Florian Bruckner[1,4], Dieter Suess[1,4], Andrii Chumak[1], and Claas Abert[1,4] — [1]Faculty of Physics, University of Vienna, Vienna, Austria — [2]Vienna Doctoral School in Physics, University of Vienna, Vienna, Austria — [3]Faculty of Sciences, University of Oviedo, Oviedo, Spain — [4]Research Platform MMM Mathematics - Magnetism - Materials, University of Vienna, Vienna, Austria

Inverse design in magnonics utilizes the wave nature of magnons and machine learning to develop logic devices with unique functionalities. However, existing methods face memory constraints, limiting the exploration of complex systems.

To address this, we integrate a level-set parameterization approach with an adjoint state method for memory-efficient simulations of magnetization dynamics. Implemented in neuralmag, a GPU-accelerated micromagnetic software, this framework enables efficient optimization of device topologies.

We validate the approach through two tasks: optimizing the shape of a magnetic nanoparticle to control hysteresis behavior and designing a 300-nm-wide yttrium iron garnet demultiplexer for frequency-selective spin-wave separation. These results showcase the algorithm's robustness and versatility in enabling the design of advanced magnonic devices for computational logic technologies.

MA 45.11 Fri 12:15 H18

Magnetoelectric coupling in type-I multiferroics via domain walls — •Aditya Putatunda and Sergey Artyukhin — Istituto Italiano di Tecnologia, Genova, Italy 16123

Type-I multiferroics, where ferroelectricity (FE) and magnetism arise independently with a large FE polarization but often tend to have a much weaker coupling to spins, e.g.: prototypical BiFeO3. Electric polarization, arising from inversion breaking, causes structural modifications across polarization domains in such materials. Here we demonstrate an effective coupling mechanism caused due to such structural modifications which in turn modifies the magnetic exchanges between the ions using first-principles density functional calculations. Magnetic domain walls, generally more mobile than polarization walls, depending on the nature of the materials, experience an effectively attractive or repulsive potential due to these modified exchanges. Such a potential can be taken advantage of in driving magnetic domain walls by sweeping polarization domains using electric field, thus giving rise to a cross-coupling mechanism, a highly sought phenomenon for novel low-power device applications.

MA 46: Surface Magnetism

MA 46.1 Fri 9:30 H19

Investigation of the magnetic structure of Eu on W(110) — •Patrick Härtl[1], Vijayalaxmi Sankeshwar[1,2], Markus Leisegang[1], and Matthias Bode[1] — [1]Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany — [2]Indian Institute of Science Education and Research(IISER), Pune, Maharashtra 411008, India

Rare earth metal (REM) films are renowned for their complex magnetic properties, primarily governed by the element-specific sign and wavelength of the RKKY interaction. Due to the complexity of their cleaning procedures, the magnetic domain structure of REM surfaces has remained largely unknown until today and is an ongoing topic of debate. In this study, we investigate the structural, electronic, as well as the complex magnetic structure of Europium (Eu) films on W(110) using spin-polarized scanning tunneling microscopy (SP-STM).

In the bulk, Eu has a half-filled $4f$- and an empty $5d$-shell and adopts a body-centered crystal structure. In thin epitaxial films, however, a metastable hexagonal close-packed structure is expected, accompanied by helical spin ordering below $T_{\text{Néel}} = 91$ K. With optimal preparation conditions, we successfully grew clean, smooth films. In the tunneling spectra of these Eu films we observed two intense peaks at positive bias voltages which we interpret as the unoccupied and exchange-split $5d_{z^2}$-like surface state. Beyond a critical film thickness, striped regions with a periodicity of $\approx$ 3 nm were identified. Experiments with differently magnetized STM tips and the application of an external magnetic field up to ± 2.5 T revealed the magnetic nature of the stripes.

MA 46.2 Fri 9:45 H19

The magnetic domain structure of Ho(0001)/W(110) — •Vijayalaxmi Sankeshwar[1,2], Patrick Haertl[2], and Matthias Bode[2] — [1]Indian Institute of Science Education and Research (IISER), Pune, Maharashtra 411008, India — [2]Experimentelle Physik II, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany

Rare-earth metal (REM) films exhibit diverse magnetic phenomena driven by the indirect RKKY coupling of localized $4f$ orbital moments, which promotes the formation of helical spin structures. Holmium (Ho), notable for its exceptionally high magnetic moment ($\approx 10\,\mu_B$), develops stable helical configurations across a wide temperature range [1]. In its bulk form, Ho crystallizes in a hexagonal close-packed structure, transitioning from a helical spin spiral state below $T_N = 131$ K to a conical magnetic state below $T_C = 20$ K. At reduced thicknesses, theoretical studies predict the emergence of intricate magnetic textures, including block spin structures [2].

We present an investigation of epitaxial Ho films grown on W(110) using spin-polarized scanning tunneling microscopy (SP-STM). Through a detailed, thickness-dependent analysis of the structural, electronic, and magnetic properties, we observed large in-plane magnetic domains spanning several hundred nanometers, interspersed with worm-like striped patterns exhibiting periodicities of $\approx$ 20 nm in the magnetic signal. Our findings provide valuable insights into the relationship between dimensionality and magnetic order in REM films.

MA 46.3 Fri 10:00 H19

Influence of higher order interactions on the thermal behaviour of magnetic order in Mn/Re(0001) — •Leo Kollwitz[1], Moritz Alexander Goerzen[2,1], Hendrik Schrautzer[3,1], and Stefan Heinze[1] — [1]Institute of Theoretical Physics and Astrophysics, Kiel University, 24098 Kiel, Germany — [2]CEMES, Université de Toulouse, CNRS, France — [3]Science Institute and Faculty of Physical Sciences, University of Iceland, 107 Reykjavík, Iceland

Non-trivial multi-Q states, which consist of the superposition of periodically modulated spin textures, are known to arise in Mn monolayers on the Re(0001) substrate due to higher-order exchange interactions (HOI) [1]. However, to date little is known about the thermodynamic properties of these highly ordered phases. Here, we perform Monte Carlo simulations based on an atomistic spin model parametrized by density functional theory, in order to investigate thermal phase transitions in this material. It is found that the explicit consideration of HOI in the simulations leads to a significant decrease of the Néel temperature and to an introduction of a new transition between single-Q and multi-Q states at low temperatures. Recent experiments show that a similar transition occurs in $Co_{1/3}TaS_2$ [2]. By modelling the free energy landscape of the system in terms of thermal excitations, which are expressed in the eigenbasis of the Hamiltonian, we further identify the important degrees of freedom responsible for this additional entropy mediated transition.

MA 46.4 Fri 10:15 H19

Anisotropic magnetic exchange in a metal-organic interface with $4f$ electrons: the case of Cu Phthalocyanine on $HoAu_2$ and $GdAu_2$ — •María Blanco-Rey[1,2,3], Rodrigo Castrillo[3], Frederik M. Schiller[3,2], and Laura Fernández[3] — [1]Universidad del País Vasco UPV/EHU, Spain — [2]Donostia International Physics Center DIPC, Spain — [3]Centro de Física de Materiales MPC-CSIC-UPV/EHU, Spain

Heterostructures formed by organic molecules on ferromagnetic substrates merge optoelectronic and spintronic functionalities. We have studied CuPc molecules deposited on monolayer-thick $REAu_2$ (RE=Ho, Gd) alloys, which exhibit long-range commensurability and vacuum level pinning of the LUMO. Many-body electron interactions renormalize the molecular levels. Here trivalent Ho and Gd species favour a downward shift of the HOMO, approaching ambipolarity [1]. The Curie temperatures are reduced from $\sim$ 20 K to $\sim$ 15 K due to CuPc, as the hybrid interfacial electronic structure affects the RKKY-mediated RE-RE exchange. The spin-orbit coupling of the RE leads to a dependence of the CuPc-RE antiferromagnetic exchange coupling constant $\mathscr{J}_{ex}$ on the field orientation, following the orbitally-dependent exchange (ODE) mechanism. ODE is enhanced by the large $L = 6$ value of trivalent Ho, yielding a ratio $\mathscr{J}_{ex}^{\parallel}/\mathscr{J}_{ex}^{\perp} = 4.2$, while the anisotropy is weak in the presence of Gd, with a half-field $4f$ shell [2].

MA 46.5 Fri 10:30 H19

Excitons design via topological spin-textures — •Karim Rezouali[1,2] and Samir Lounis[2,1] — [1]Faculty of Physics, University of Duisburg-Essen and CENIDE, 47053 Duisburg, Germany — [2]Peter Grünberg Institut, Forschungszentrum Jülich & JARA, D-52425 Jülich, Germany

Excitons are at the heart of many photonic and optoelectronic phenomena, including luminescence, lasing, and the operation of solar cells. Their study is essential for developing next-generation technologies, such as light-harvesting systems and quantum information devices. Here, we explore the impact of topological magnetism [1] on excitons by unveiling signatures of topology on the magnetic properties of excitons, their stability and manipulation. We address in particular skyrmions emerging in Pd/Fe/Ir(111) [2] surface, which affect the singlet and triplet exciton states hosted by a monolayer MoS_2 [3]. Our work promotes the use of skyrmions for the control and manipulation of excitons, which provides unprecedented opportunities for exciton-based devices.

MA 46.6 Fri 10:45 H19

Observation of the sliding phason mode of the incommensurate magnetic texture in Fe/Ir(111) — •Wulf Wulfhekel[1], Hung-Hsiang Yang[1], Louise Desplat[2], Volodymyr Kravchuk[1], Marie Hervé[1], Timofey Balashov[1], Simon Gerber[1], Markus Garst[1], and Bertrand Dupé[2] — [1]Karlsruhe Institute of Technology — [2]Université de Liège

The nanoscopic magnetic texture forming in a monolayer Fe/Ir(111) is uniaxially incommensurate with respect to the Ir(111) substrate. As a consequence, a low-energy magnetic excitation is expected that corresponds to the sliding of the texture along the incommensurate direction, i.e., a phason mode, that we confirm with atomistic spin simulations. Using Sp-STM, we observed this phason mode experimentally. It can be excited by the STM tip leading to a random telegraph noise in the tunneling current that we attribute to the presence of two minima in the phason potential due to the presence of disorder in the sample. This provides the prospect of a floating phase in cleaner samples and, potentially, a commensurate-incommensurate transition as a function of external control parameters.

Quantifying the interplay between local order and dynamics in a self-induced spin glass — •Lorena Niggli[1], Julian H. Strik[1], Anders Bergman[2], Mikhail I. Katsnelson[1], Daniel Wegner[1], and Alexander A. Khajetoorians[1] — [1]Institute for Molecules and Materials, Radboud University, Nijmegen, The Nether- lands — [2]Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden

Spin glasses are a puzzling form of magnetic matter characterized by an amorphous spin texture in space. They exhibit ongoing magneti- zation dynamics that are often referred to as aging. However, direct experimental access to the spatially dependent magnetization and its link to aging, has been limited. Here, we study the spatiotemporal dy- namics of the self-induced spin glass state of Nd(0001) [1, 2]. To this end, we induce magnetization dynamics through magnetic field cycles and resolve the local order using spin-polarized scanning tunneling microscopy. We develop a new method to access the spatiotemporal dynamics based on a wavelet transformation. Using this, we quantify the Q-dependent local order in space and follow its evolution over time. Together this provides insight into the complex energy landscape of a (self-induced) spin glass. [1] Kamber et al., Science 368 (2020). [2] Verlhac et al., Nature Physics 18 (2022).

MA 46.8 Fri 11:30 H19

Bilayer triple-Q state driven by interlayer higher-order exchange interactions — •Bjarne Beyer, Mara Gutzeit, Tim Drevelow, Isabel Schwermer, Soumyajyoti Haldar, and Stefan Heinze — Institute of Theoretical Physics and Astrophysics, University of Kiel, Germany

Superpositions of spin spirals – so-called multi-Q states – are complex spin structures which are of fundamental interest and promising for future spintronic applications. A prominent example is the triple-Q state predicted more than 20 years ago [1] and only recently observed in Mn monolayers on the Re(0001) surface [2,3]. Here, we predict a triple-Q state as the magnetic ground state of a Mn bilayer on the Ir(111) surface using first-principles calculations based on density functional theory (DFT). In a bilayer two types of the triple-Q state can occur which differ by the spin alignment between the layers. Based on an atomistic spin model, we demonstrate that the triple-Q state favored by DFT is stabilized by the interplay of antiferromagnetic interlayer exchange and interlayer higher-order exchange interactions. In this bilayer triple-Q state nearest-neighbor spins within a layer and between layers exhibit tetrahedron angles and the topological orbital moments of the two Mn layers are aligned in parallel [4].

Antiferromagnetic merons in a Mn monolayer on Ta(110) — •Tim Drevelow[1], Felix Zahner[2], André Kubetzka[2], Roland Wiesendanger[2], Stefan Heinze[1], and Kirsten von Bergmann[2] — [1]Institute of Theoretical Physics and Astrophysics, University of Kiel, Leibnizstraße 15, 24098 Kiel, Germany — [2]Department of Physics, University of Hamburg, Jungiusstraße 11, 20355 Hamburg, Germany

Non-collinear topological spin structures in ultrathin transition-metal films are interesting for spintronic applications. When hosted in antiferromagnets, they are robust to external perturbations, possess vanishing demagnetization fields, and the Skyrmion-Hall effect does not occur. Ultrathin Mn-layers are intrinsically antiferromagnetic and exhibit non-collinear spin structures, such as the conical spin structure in Mn on W(110) [1]. Here, using spin-polarized scanning tunneling microscopy and density functional theory, we discover a cycloidal spin spiral and a c(2 × 2) antiferromagnet in Mn mono- and double-layers on the Ta(110) surface, respectively. Micromagnetic simulations on the sublattice reveal a transition of spin spirals into antiferromagnetic, meronic spin structures of non-trivial topology near the interface to the collinear antiferromagnet of the film due to competing anisotropies of the Mn mono- and double-layer.

MA 46.10 Fri 12:00 H19

Magnetic bi-stability of columnar Transition-metal-oxide molecules on MgO films — •SUFYAN SHEHADA[1,2], Manuel dos Santos Dias[3], Muayad Abusaa[2], and Samir Lounis[1,4] — [1]Peter Grünberg Institut, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — [2]Department of Physics, Arab American University, Jenin, Palestine — [3]Scientific Computing Department, STFC Daresbury Laboratory, Warrington WA4 4AD, United Kingdom — [4]Faculty of Physics, University of Duisburg-Essen and CENIDE, 47053 Duisburg, Germany

At the heart of quantum information technology is the realization of stable atomic magnetic bits, which partly hinges on large out-of-plane magnetic anisotropy energy (MAE). Although the seminal work of Rau et al.[1] reported the maximum MAE for a 3d element by positioning a Co atom on MgO(100) [1], the system did not exhibit magnetic bi-stability. Motivated by that work, we explore via density functional theory (DFT) simulations columnar oxide molecules made of transition metals (TM-O), which might show large MAE while reducing the hybridization of the adatoms' electronic states with those of the substrate, increasing the chances of magnetic bi-stability. Following our initial investigations based on 3d elements [2], we address here the case of 4d atoms and focus on the scenario where the TM atoms are decoupled from the surface via an Oxygen atom.

–Work funded by (BMBF–01DH16027).

Tailoring magnetism in a 2D Van der Waals material with a chemical approach for magnonic applications — •Sourav Dey, Gonzalo Rivero, and José Baldoví — ICMol, University of Valencia, Valencia, Spain

The discovery of two-dimensional (2D) magnets offers an ideal platform for magnonics and spintronics at the limit of miniaturization given their high flexibility and tunability.The magnetic properties of this family of materials have been tuned by several approaches such as strain engineering, atomic layer substitution, or molecular deposition, among others. In the latter case, the effect of organometallic/inorganic complexes on the magnetic properties of 2D magnetic materials is still unexplored. To investigate this, we have selected two molecular qubits (quantum bits) with long coherence time such as CpTiCOT (Cp = η5-cyclopentadienyl, COT = η8-cyclooctatetraene) and VOPc (Pc = phthalocyanine) which are proved to be stable after the deposition on metallic substrate. Here, we analyze and interpret the magnetic properties of single-layer CrSBr after deposition of CpTiCOT and VOPc, via first-principles calculations. Our results predict a significant modulation of magnetic exchange in CrSBr after deposition due to the significant charge transfer from the molecules to 2D material, allowing us to corroborate both properties. Furthermore, a significant change in the magnon frequencies and group velocities was observed, which opened new avenues in designing smart molecular/2D materials where magnons can be fine-tuned by a chemical approach.

Growth and spectroscopy of altermagnetic MnTe — •Marco Dittmar, Lena Hirnet, Hannes Haberkamm, Maximilian Ünzelmann, and Friedrich Reinert — Exp. Physik VII and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, Germany

As a new type of fundamental magnetic order next to ferro- and antiferromagnetism, altermagnetism has recently attracted great attention [1]. It is characterized by antiferromagnetic spin alignment combined with rotational lattice symmetry, which results in a momentum-dependent spin-split band structure with spin polarized electronic states. One of the "workhorse" materials potentially exhibiting this type of magnetic order is MnTe in its hexagonal NiAs-type crystal structure [1,2]. Here, we investigate MnTe thin films grown by molecular beam epitaxy. The high film quality is confirmed by structural characterization methods, while we assess the three-dimensional bulk band structure using soft X-ray angle-resolved photoemission spectroscopy. The experimentally observed spectral features agree well with band structure calculations and — based on that — the possible occurance of the characteristic momentum-dependent spin splitting will be discussed.

Phonon-mediated unconventional superconductivity in altermagnets: A solid-state analog of the A_1 phase of superfluid Helium 3 — •Kristoffer Leraand[1], Kristian Maeland[2], and Asle Sudbø[1] — [1]Center for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology, NO-7491 Trondheim, Norway — [2]Institute for Theoretical Physics and Astrophysics, University of Würzburg, D-97074 Würzburg, Germany

We have considered the possibility of phonon-mediated unconventional superconductivity in a recently discovered new class of antiferromagnets, dubbed altermagnets. Within a weak-coupling approach, and using a minimal band model for altermagnets [1], we have found a dominant superconducting instability odd in momentum and even in spin with fully spin-polarized Cooper pairs, a 2D solid-state analog of the A_1-phase of superfluid Helium 3 [2]. We discuss the origin of this unusual result in terms of phonon-modes and electron form factors. [1] B. Brekke, A. Brataas, and A. Sudbø, PRB 108, 224421 (2023). [2] G. Volovik, The Universe in a Helium Droplet, Oxford Science Publications (2003).

MA 47.3 Fri 10:00 H20

Non-linear anomalous Edelstein response at altermagnetic interfaces — •Mattia Trama[1,2], Irene Gaiardoni[3], Claudio Guarcello[3,4], Jorge I. Facio[5], Alfonso Maiellaro[3,6], Francesco Romeo[3,4], Roberta Citro[3,4,6], and Jeroen van den Brink[1,2] — [1]IFW Dresden — [2]Würzburg-Dresden Cluster of Excellence ct.qmat — [3]Università degli studi di Salerno — [4]INFN - Sezione collegata di Salerno — [5]Centro Atomico Bariloche, Instituto de Nanociencia y Nanotecnologia (CNEA-CONICET) and Instituto Balseiro — [6]CNR-SPIN

In altermagnets, time-reversal symmetry breaking spin-polarizes electronic states, while total magnetization remains zero. In addition, at altermagnetic surfaces Rashba-spin orbit coupling is activated due to broken inversion symmetry, introducing a competing spin-momentum locking interaction. Here we show that their interplay leads to the formation of complex, chiral spin textures that offer novel, non-linear spin-to-charge conversion properties. Whereas altermagnetic order suppresses the canonical linear in-plane Rashba-Edelstein response, we establish the presence of an anomalous transversal Edelstein effect for planar applied electric and magnetic field, or alternatively, an in-plane magnetization. Moreover the non-linear Edelstein response resulting purely from electric fields also triggers the anomalous out-of-plane magnetization. We determine the anomalous response with a model based on the ab-initio electronic structure of RuO2 bilayers, ultimately opening experimental avenues to explore spin-charge conversion phenomena at altermagnetic interfaces.

MA 47.4 Fri 10:15 H20

A Heisenberg model for g-wave altermagnets: the comparative analysis of CrSb and MnTe — •Volodymyr Kravchuk[1,2], Kostiantyn Yershov[1,2], Oleg Janson[1], and Jeroen van den Brink[1] — [1]Leibniz Institute for Solid State and Materials Research, 01069 Dresden, Germany — [2]Bogolyubov Institute for Theoretical Physics of the National Academy of Sciences of Ukraine, 03143 Kyiv, Ukraine

Here we construct a discrete Hamiltonian of the magnetic subsystem of altermagnets belonging to the crystallographic group 6/*mmm*. The altermagnetic properties are captured through the additional Heisenberg exchange interactions whose symmetry respects the positions of the nonmagnetic atoms. We derive the dispersion relation for magnons for two opposite cases of magnetocrystalline

anisotropy: easy-axis (as for CrSb) and easy-plane (as for MnTe). Due to the different magnetic ground states of CrSb and MnTe, their magnon spectra are drastically different. While the splitting of the magnon bands of CrSb possesses the g-wave symmetry, the splitting of the magnon bands of MnTe does not alternate sign within the Brillouin zone and does not possess g-wave symmetry. We formulate the continuous approximation of the model and derive the expression for magnetization of the noncollinear magnetization structures. We find that the amplitude of the magnetization of a domain wall in CrSb depends on the domain wall orientation relative to crystallographic axes, and determine twelve orientations that correspond to the maximal magnetization.

MA 47.5 Fri 10:30 H20

P-wave magnetism and spin symmetries — •Anna Birk Hellenes[1], Tomáš Jungwirth[2,3], Rodrigo Jaeschke-Ubiergo[1], Atasi Chakraborty[1], Jairo Sinova[1,4], and Libor Smejkal[1,2,5,6] — [1]JGU Mainz — [2]Czech Academy of Sciences — [3]University of Nottingham — [4]Texas A&M University — [5]MPI-PKS — [6]MPI-CPfS

The recent discovery of altermagnets was enabled by an unorthodox symmetry toolbox, crystallographic spin groups, allowing for the rigorous delineation of all collinear spontaneous exchange symmetry breakings. This raises a question: are further magnets with hitherto unknown symmetries and electronic structures hiding in plain sight? Our contribution will start with a brief history of a century-long debate on whether p-wave magnetic orders can exist. We will resolve this debate by demonstrating p-wave magnetism using the spin group formalism. We show that a collinear p-wave order arises in coplanar magnets for a subclass of noncentrosymmetric, noncollinear magnets with a combined translation and time-reversal symmetry. Contrary to common assumptions, we establish that such magnets can display non-relativistic spin-split electronic band structures. We demonstrate that these splittings preserve time-reversal symmetry, starkly contrasting splittings in ferromagnets and altermagnets, which break it. With first-principles calculations and symmetry analysis, we predict large, non-relativistic spin-splittings of several hundred meV and identify more than 40 realistic material candidates. Our work opens a wide range of possibilities for studying p-wave magnetism and using it for spintronics and topological physics. arXiv:2309.01607v3

MA 47.6 Fri 10:45 H20

Spin polarons in Altermagnets — •Maria Daghofer[1], Krzysztof Wohlfeld[2], and Jeroen van den Brink[3] — [1]FMQ, Universität Stuttgart, Stuttgart, Germany — [2]University of Warsaw, Warsaw, Poland — [3]IFW Dresden, Dresden, Germany

We numerically investigate hole motion in altermagnetic Mott insulators, beyond the weakly interacting case, where a mean-field description is applicable. In this strongly correlated regime, hole motion is strongly affected by coupling to quantum fluctuations of the magnetic background. We find that the underlying altermagnetic symmetries manifest themselves in spin-momentum locking of the coherent quasi-particle: At certain momenta, it has a spin-polarized character, while states corresponding to the opposite spin are considerably more incoherent. We also address the impact of quantum fluctuations.

MA 48.1 Fri 11:15 H20

Measurement of time resolved magneto-optic Kerr effect on ruthenium dioxide — •Holger Grisk[1], Maik Gaerner[2], Jakob Walowski[1], Timo Kuschel[2], and Markus Münzenberg[1] — [1]Institute of Physics, Greifswald University, Germany — [2]Faculty of Physics, Bielefeld University, Germany

Altermagnetism is a novel fundamental phase of magnetism with exciting properties such as spin split bands.Ruthenium dioxide is one of the mostly investigated altermagnetic candidates. The antiparallel alignment of the Ru spins along with the anisotropic distribution of oxygen atoms leads to time reversal symmetry breaking and non-relativistic, anisotropic spin-splitting in the band structure. We used the time-resolved magneto-optic Kerr effect to measure the transient Kerr angle and reflectivity change after excitation with a femtosecond laser pulse to access the potential magnetic properties of ruthenium dioxide. The setup for the measurement exploits the pump-probe technique. A femtosecond laser pulse is split into a powerful pump and a low-power probe beam. The pump beam is used to photoexcite the electrons in the ruthenium dioxide. The probe beam is used to measure the shift in the Kerr rotation. Delaying the pump temporally and probing the evolution of the Kerr signal we can measure the ultrafast spin dynamics of ruthenium dioxide. The measurement shows Terahertz dynamics in the Kerr signal that is an order of magnitude faster than conventional ferromagnets. The studies were performed at room temperature and with small in plane magnetic field.

MA 48.2 Fri 11:30 H20

Dynamical renormalization of the magnetic excitation spectrum via high-momentum nonlinear magnonics — •Julian Bär[1], Lennart Feuerer[1], Alfred Leitenstorfer[1], Dominik Juraschek[2], and Davide Bossini[1] — [1]Department of Physics and Center for Applied Photonics, University of Konstanz, D-78464 Konstanz, Germany — [2]Department of Applied Physics and Science Education, Eindhoven University of Technology, Eindhoven, Netherlands

Manipulating the macroscopic properties of solids with light is a key challenge in condensed matter physics. While resonantly driving low-momentum collective excitations has led to nonlinear lattice and spin dynamics [1,2], controlling magnon spectra in terms of amplitude and frequency remains unexplored. In my talk I will discuss the resonant excitation of pairs of high-momentum magnons in Hematite (α-Fe2O3). By exciting hematite in its weak-ferromagnetic phase, our approach results in a direct coupling between high- and low-momentum magnons. In particular, the spectrum of the latter is modified. This astonishing effect is explained with a resonant light-scattering mechanism that couples high- and low-momentum eigenmodes across momentum space [3]. As hematite undergoes a phase transition at 260 K to a collinear antiferromagnetic state, we have developed a cryogenic pump-probe setup. Preliminary results reveal behaviour distinct from that observed in the weak ferromagnetic phase. [1] A. S. Disa et al., Nat Phys 17, 1087-1092 (2021). [2] Z. Zhang et al., Nat Phys., 1-6 (2024). MA 48.3 Fri 11:45 H20

Bias field studies of all-optical helicity-dependent switching. — •Kevin Jäckel[1], Marcel Kohlmann[1], Jakob Walowski[1], Markus Münzenberg[1], Yuta Sasaki[2], and Karel Carva[3] — [1]University of Greifswald, Germany — [2]Research Center for Magnetic and Spintronic Materials, Japan — [3]Charles University, Czech Republic

The mechanisms underlying all-optical helicity-dependent switching AOHDS need a better understanding to improve the process towards single pulse switching. We apply external magnetic fields (anti-) parallel of up to $H_{\mathrm{ext}} = 72\,\mathrm{mT}$, (opposing) supporting the desired magnetization direction in FePt granular media to disentangle the contribution of the inverse Faraday effect IFE within the switching process. Those measurements, performed on samples with varying average grain size diameters of $d = 10\,\mathrm{nm}$, $d = 6\,\mathrm{nm}$ nm, and $d = 4\,\mathrm{nm}$, reveal a grain size dependent impact of the applied field strength. Using the helicity-dependent refractive index calculated from density functional theory (DFT) calculations, we calculate the absorbed laser fluence for each grain size using the transfer matrix method. The absorption data, combined with the inverse Faraday constant, allows us to quantify the optically induced magnetization ΔM by the IFE. From this data, we can estimate the contribution of the IFE to the switching process. The research is funded by DFG, Fundamental aspects of all-optical pulse switching in nanometer-sized magnetic storage media Project number: 439225584.

MA 48.4 Fri 12:00 H20

Terahertz study of antiferromagnetic resonance in α MnTe — •Michal Šindler[1], Roman Tesař[1], Karel Výborný[1], Stáňa Tazlerů[1], Christelle Kadlec[1], Peter Kubaščík[2], Lukáš Nádvorník[2], Marcin Bialek[3], Jan Dzian[2,4], and Milan Orlita[4] — [1]Institute of Physics of the Czech Academy of Sciences, Prague, Czech Republic — [2]Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic — [3]Institute of High Pressure Physics Polish Academy of Sciences, Warszawa, Poland — [4]Laboratoire National des Champs Magnétiques Intenses, Université Grenoble Alpes, CNRS-UPS-INSA-EMFL, Grenoble, France

Antiferromagnetic resonance in bulk α-MnTe crystal was studied in the terahertz (THz) range. First, we will describe the three experimental methods used: (i) infrared Fourier transform spectroscopy,(ii) time-domain THz spectroscopy, and (iii) frequency-domain terahertz spectroscopy with linearly and circularly polarized THz beams. Second, we will present experimental results featuring a magnon mode ($k = 0$) with the low-temperature energy of 3.5 meV and its temperature and magnetic field evolution. Finally, we will show how to extract the out-of-plane component of the single-ion magnetic anisotropy $D \approx 40\,\mu$eV using a simple spin model of antiferromagnetic resonance in an easy-plane antiferromagnet.

MA 48.5 Fri 12:15 H20

Indications of terahertz spin transport in the altermagnet candidate RuO2 — •Oliver Gueckstock[1], Clara Simons[1], Maik Gaerner[2], Zdenek Kaspar[3], Jiri Jechumtal[3], Tom S. Seifert[1], Lukas Nadvornik[3], Günter Reiss[2], and Tobias Kampfrath[1] — [1]FU Berlin — [2]U Bielefeld — [3]Charles University Prague

The recently emerging material class of altermagnets has large potential to offer properties like strong spin splitting, which are so far rather typical for classical ferromagnets [1]. RuO2 appears to be a promising metallic altermagnet candidate with huge spin splitting in the electronic band structure and for photoinduced spin and orbital transport with a Néel temperature above room temperature [1,2]. Here, we apply femtosecond laser pulses to RuO2(110)|HM stacks consisting of a twinned RuO2 layer and a heavy-metal layer HM of Pt or W. We observe THz emission signals with distinct pump-polarization dependence. The signals change sign when HM=Pt is replaced by W and exhibit a marked temperature dependence, thereby suggesting a magnetism-related signal origin. We discuss possible mechanisms of THz-signal generation, including an ultrafast photoinduced spin current from RuO2 to HM and its conversion into in-plane charge in HM, which gives rise to the emission of a THz electromagnetic pulse.

MA 48.6 Fri 12:30 H20

THz emission control in exchange-coupled spintronic emitters. — •Roman Adam[1], Derang Cao[1,2], Daniel Bürgler[1], Sarah Heidtfeld[1], Christian Greb[1], Fangzhou Wang[1], Debamitra Chakraborty[3], Jing Cheng[3], Ivan Komissarov[3], Markus Büscher[1], Martin Mikulics[4], Hilde Hardtdegen[4], Roman Sobolewski[3], and Claus Schneider[1] — [1]Research Centre Jülich, Peter Grünberg Institute (PGI-6), 52425 Jülich, Germany — [2]College of Physics, Qingdao University, 266071 Qingdao, China — [3]University of Rochester, Rochester, New York 14627-0231, USA — [4]Research Centre Jülich, Ernst Ruska Centre (ERC-2), 52425 Jülich, Germany

Optical laser pulses impinging at the ferromagnet/metal thin film stacks can generate a pico-second electro-magnetic transients with frequency content extending into THz frequency range. We fabricated Si/SiO2//Ta/Fe/Ru/Ni/Al2O3 and Si/SiO2//Pt/Fe/Cr/Fe/Pt spintronic THz emitters in which we varied interlayer exchange coupling between the ferromagnetic thin films by varying the thicknesses of either the Ru or Cr spacer layer. As a result, THz emission shows a dramatic variation of amplitude in weak external magnetic fields due to an interference of THz transiens generated at the individual Fe/Ru, Ru/Ni or Fe/Pt emitters. We explore the effect of the ambient temperature and the spacer layer thickness variations on the THz amplitude.

MA 48.7 Fri 12:45 H20

On-Chip Multilayer Spintronic THz Emitters — •Wolfgang Hoppe[1], Amine Wahada[2], Stuart Parkin[3], and Georg Woltersdorf[1] — [1]Institute of Physics, Martin-Luther-Universität Halle-Wittenberg, Von-Danckelmann-Platz 3, 06120 Halle, Germany — [2]Department of Physical Chemistry, Fritz Haber Institute, Faradayweg 4-6, 14195 Berlin, Germany — [3]Max Planck Institute for Microstructured Physics, Weinberg 2, 06120 Halle, Germany

Nanometer thin ferromagnet/heavy metal bilayers illuminated by intense short laser pulses have proven to be a realiable source for THz emission [1]. When integrated into a gold waveguide structure, the bilayer can be used as an on-chip source for ultrafast current pulses from the GHz to the THz regime [2]. Stacking severeral bilayers, each separated by a thin MgO interlayer enhances the charge current amplitude, as the MgO suppresses spin-currents in between the individual bilayers [3]. In this way we construct multilayers where all charge currents add up constructively, enhancing the signal up to a factor of three. As one possible application these ultrafast currents could be used to switch the magnetization of an adjacent ferromagnet, similar to previous experiments [4]. Electro-optic sampling is employed to characterize the charge current with sub-ps time resolution.

Sessions

– Invited Talks, Topical Talks, Tutorials, Contributed Talks, and Posters –

MM 1: Tutorial: Automated Worksflows (joint session MM/TUT)

Participants in the tutorial will be able to run all the examples shown in the presentation interactively on their own laptops. There is no need to install any code, just a standard web browser to explore the applications interactively.

Time: Sunday 16:00–18:15 Location: H15

Tutorial MM 1.1 Sun 16:00 H15

Hands-on Tutorial: Automated Workflows and Machine Learning for Materials Science Simulations — •Jörg Neugebauer[1], Tilmann Hickel[2], and Ralf Drautz[3] — [1]MPI für Nachhaltige Materialien, Düsseldorf, Germany — [2]BAM, Berlin, Germany — [3]ICAMS, Ruhr-Universität Bochum, Germany

Machine learning techniques in physics and materials science have revolutionized simulations and experimental analysis. Using these techniques to accurately predict, for example, material properties requires the manipulation and use of vast amounts of data. Manual processing and analysis quickly become impractical and error-prone, so the availability of automated workflows is critical to their efficient, reliable, and consistent application.

In this hands-on tutorial, we provide an interactive, practical introduction to workflow management using Pyiron (www.pyiron.org). Pyiron is an integrated materials science development environment based on Python and Jupyter notebooks that can be used for a wide range of simulation tasks, including rapid prototyping, coupling with experiments, and high-performance computing. The tutorial gives a general introduction to the use of Pyiron with a focus on atomistic simulation tasks. As a practical example, all steps of the workflow for the construction of ab initio phase diagrams will be performed interactively by all participants, e.g. the generation of DFT datasets, the training and validation of machine learning potentials as well as the construction of the phase diagram.

MM 2: Invited Talk: R. de Souza

Time: Monday 9:30–10:00 Location: H10

Invited Talk MM 2.1 Mon 9:30 H10

Probing Ion Migration in ABX_3 Perovskite Compounds: Five Fallacies of Simulations — •Roger De Souza — Institute of Physical Chemistry, RWTH Aachen University, Aachen, Germany

Simulation studies play a central role, in interpreting and explaining experimental data on ion transport, in providing insights at the atomic scale, and in predicting data for new systems. Ion migration in ABX_3 perovskites has been examined with both molecular-static and molecular-dynamic calculations, employing classical pair potentials, reactive force-fields or quantum-mechanical calculations.

In this contribution, taking ion migration in $BaTiO_3$, $CaTiO_3$, and $MAPbI_3$ as examples, I draw attention to problems that may arise when using molecular-static calculations to obtain activation barriers for higher symmetry perovskite phases. In general, a far more critical consideration of simulation results in the literature is required.

MM 3: Data-driven Materials Science: Big Data and Worksflows

Machine Learning, Potential Development

Time: Monday 10:15–13:00 Location: H10

MM 3.1 Mon 10:15 H10

Benchmarking DFT Functionals at Finite Temperature with ASSYST and MLIPs — •Marvin Poul and Jörg Neugebauer — Max-Planck-Institut für Nachhaltige Materialien

A key ingredient to the accuracy of Density Functional Theory (DFT) calculations is the chosen approximation to the exchange-correlation functional. Local Density Approximation (LDA) and Generalized Gradient Approximation (GGA) calculations often bracket experimental observations, but systematic exploration of the behavior of different density functionals is hindered by the high computational cost of DFT in realistic applications, especially concerning finite temperature properties. Using the ASSYST[1] method, we automatically generate unary, general purpose Atomic Cluster Expansion (ACE) Machine Learning Interatomic Potentials (MLIPs) for a range of metals using LDA, PBE and r2SCAN functionals. The key advantage of ASSYST lies in the small cells ($\leq$ 10 atoms per cell) that it generates as training data. This allows us to relabel the data using different functionals very efficiently. We then use these potentials to calculate melting curves, thermal expansion, and formation energies of various defects (grain boundaries, surfaces, point defects) to systematically assess strengths and weaknesses of the DFT functionals. In general, we find good agreement with corresponding DFT results, showing that ASSYST can reliably create transferable potentials for metals at DFT accuracy.

MM 3.2 Mon 10:30 H10

Assessing the role of physical constraints in machine learning potentials — •Marcel F. Langer, Sergey N. Pozdnyakov, Filippo Bigi, and Michele Ceriotti — Laboratory of Computational Science and Modeling (COSMO) and National Centre for Computational Design and Discovery of Novel Materials (MARVEL), Institute of Materials, École Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland

Machine learning potentials, which approximate the potential energy surface of atomistic systems to enable larger and longer simulations than first-principles methods, have advanced rapidly in recent decades. Much of this development has been driven by the increasingly sophisticated treatment of physical symmetries, in particular invariances, in the underlying machine learning models. However, the rise of so-called unconstrained models, which replace exact invariance with learned approximations, has sparked debate over this approach. Some models even choose to directly predict forces, rendering the resulting force fields non-conservative. We investigate the effectiveness of such models and evaluate the impact of disregarding physical constraints for practical simulations. In particular, we study the effects of breaking rotational symmetry in a machine-learning potential for water [1] and discuss the potential consequences of direct force predictions.

MM 3.3 Mon 10:45 H10

Fast and flexible range-separated models for atomistic machine learning — •Philip Loche, Marcel F. Langer, and Michele Ceriotti — Laboratory of Computational Science and Modeling (COSMO), Institute of Materials, École Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland

Most machine learning (ML) interatomic potentials rely on a locality ansatz, decomposing energy into short-ranged, atom-centered contributions. This limits their ability to describe problems dominated by long-range physical effects, such as electrostatics. We present a framework integrating established algorithms for non-bonded interactions – including Ewald summation, PME, and P3M – into atomistic ML. Reference implementations are provided in PyTorch and JAX. Beyond Coulomb potentials, we introduce Exterior Potential Features for general long-range ML applications. Our modular libraries enable accurate physical force evaluations, seamless integration with local ML schemes via automatic

differentiation, and flexible architectures for advanced models. We benchmark these tools for molecular dynamics, range-separated ML potentials, and long-range atomic descriptors.

MM 3.4 Mon 11:00 H10

Beyond Numerical Hessians: Applications for Higher Order Derivatives in Machine Learning Interatomic Potentials — •Nils Gönnheimer[1,2], Karsten Reuter[1], and Johannes T. Margraf[2] — [1]University of Bayreuth — [2]Fritz-Haber-Institut der MPG, Berlin

The development of machine learning interatomic potentials (MLIPs) has revolutionized computational chemistry by enhancing the accuracy of empirical force fields while retaining a large computational speed-up compared to first-principles calculations. Despite these advancements, calculating Hessian matrices remains challenging due to the lack of analytical second-order derivatives, necessitating the use of computationally expensive finite difference methods (which can lead to numerical instabilities because of rounding errors). Automatic differentiation (AD) offers a promising approach to reducing this computational effort and making the calculation of Hessian matrices more efficient and accurate. In this contribution, we discuss the implementation of AD Hessians in the equivariant MACE framework. This new methodology finds applications in screening the heat capacities of metal-organic frameworks (MOFs) and in the calculation of infrared (IR) spectra, which are an ubiquitous tool for molecular characterization.

MM 3.5 Mon 11:15 H10

Diversity-Driven Active Learning of Interatomic Potentials for Reaction Network Exploration — •Francesco Cannizzaro, King Chun Lai, Patricia Poths, Sebastian Matera, Vanessa J. Bukas, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin

We present an automatic workflow for the simultaneous active learning of Machine-Learning Interatomic Potentials (MLIPs) and exploration of complex networks of activated events. This workflow consists of alternating periods of training and the generation of candidate structures for the enrichment of the training set using the recently developed Automatic Process Explorer (APE) [1]. This allows us to determine elementary processes and corresponding barriers without the need of human supervision. From the output of the APE explorations, we identify maximally diverse atomic structures utilizing the DECAF fuzzy classification algorithm [2] and add only these to the training set. We exemplify this strategy on carbon intercalation in Pd, using GAP and MACE as MLIP frameworks. We find that this diversity driven approach outperforms state-of-the-art training set designs based on molecular dynamics for finding activated events and corresponding barriers. Particularly, our workflow performs very well in reducing outliers, which is of utmost importance for activated event dynamics since this is often controlled by only a few barriers.

MM 3.6 Mon 11:45 H10

Accelerating Materials Exploration with Active Machine Learning: Integrating SISSO with FHI-aims — Yi Yao[1,2], Lucas Foppa[1], Akhil Sugathan Nair[1], Andrei Sobolev[1,2], •Konstantin Lion[1,2], Sebastian Kokott[1,2], and Matthias Scheffler[1] — [1]NOMAD Laboratory at the Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [2]Molecular Simulations from First Principles e.V., Berlin, Germany

We present a user-friendly web application for active learning-based materials exploration with the goal of broadening the usability of AI tools. The platform integrates the SISSO (Sure Independence Screening and Sparsifying Operator) method [J. Chem. Phys. 159, 114110 (2023)] with FHI-aims software [Comp. Phys. Commun. 180, 2105 (2009)] to provide interpretable modeling and reliable property predictions. SISSO dynamically updates models during the exploration process, while FHI-aims ensures accurate all-electron density functional theory (DFT)-based calculations. The property prediction workflow is managed using the atomate2 library, providing many "standard" DFT workflows and efficient utilization of compute resources ranging from local machines to cloud infrastructures. By leveraging SISSO-based uncertainty prediction, the application implements active learning to efficiently identify materials with desirable target properties. Two case studies, the exploration of the bulk modulus in perovskites and the prediction of stable oxides under harsh conditions, demonstrate the platform's ability to accelerate materials discovery.

MM 3.7 Mon 12:00 H10

Data-driven design of mechanically hard soft magnetic high-entropy alloys — •Mian Dai[1], Yixuan Zhang[1], Xiaoqing Li[2], Stephan Schönecker[2], Liuliu Han[3], Ruiwen Xie[1], Chen Shen[1], and Hongbin Zhang[1] — [1]Institute of Materials Science, Technical University of Darmstadt, Darmstadt, Germnay — [2]Department of Materials Science and Engineering, KTH - Royal Institute of Technology, Stockholm, Sweden — [3]Max Planck Institute for Sustainable Materials, Düsseldorf, Germany

The rational design of mechanically hard soft magnets, combining high hardness with magnetically soft properties, represents a critical frontier in materials science. Here, we introduce a comprehensive data-driven framework to navigate the vast compositional space of high-entropy alloys (HEAs) and identify candidates optimized for these dual functionalities. Utilizing a curated dataset of 1,842,628 density functional theory calculations, encompassing 45,886 quaternary and 414,771 quinary equimolar HEAs derived from 42 elements, we employ ensemble learning to synergistically integrate multiple predictive models. This methodology captures the relationships between composition, crystal structure, mechanical performance, and magnetic behavior, enabling the identification of alloys with a unique combination of high hardness and magnetic softness. Our framework establishes a robust pathway for the accelerated discovery of next-generation hard-soft magnetic materials, underscoring the transformative potential of data-driven strategies in materials design.

MM 3.8 Mon 12:15 H10

Autonomous optimization of coin-cell batteries and thin-film growth — •Edan Bainglass[1,6], Peter Kraus[2,5], Francisco Ramirez[3,6], Enea Svaluto-Ferro[2], Loris Ercole[3,6], Benjamin Kunz[2], Sebastiaan Huber[3,6], Nukorn Plainpan[2], Nikita Shepelin[1], Nicola Marzari[1,3,6], Corsin Battaglia[2,3,4], and Giovanni Pizzi[1,3,6] — [1]PSI, Villigen, Switzerland — [2]Empa, Dübendorf, Switzerland — [3]EPFL, Lausanne, Switzerland — [4]ETH Zurich, Zurich, Switzerland — [5]TUB, Berlin, Germany — [6]MARVEL, Switzerland

Advancements in materials science are increasingly driven by the integration of automation of both experiments and simulations, machine learning, and robust data management frameworks. In this talk, we discuss the integration of experimental systems with the AiiDA [1] workflow management system, both battery coin cell assembly and cycling [2], and for thin film growth by pulsed laser deposition (PLD). We discuss the ongoing integration of these platforms with the FINALES [3] fast intention-agnostic learning server towards fully autonomous optimization of battery end-of-life (EOL) performance. We also discuss preliminary results demonstrating the feasibility of autonomously optimizing the layer-by-layer thin-film growth with PLD. These case studies demonstrate the potential of automated workflows to accelerate the discovery and optimization of functional materials.

MM 3.9 Mon 12:30 H10

Learning Disorder in Generative Materials Discovery - Bridging Prediction and Experiment — •Konstantin Jakob[1], Aron Walsh[2], Karsten Reuter[1], and Johannes T. Margraf[1,3] — [1]Fritz-Haber-Institut der MPG, Berlin, Germany — [2]Imperial College London, London, UK — [3]University of Bayreuth, Bayreuth, Germany

In recent years, generative machine learning (ML) models have demonstrated tremendous potential for the design and discovery of new materials. This has led to extensive predictions of previously unknown, potentially stable inorganic materials. However, current models suffer from the fact that the underlying training data is purely based on density functional-calculations for small, ideal crystals. As a consequence, many of the supposedly new materials are in fact experimentally known as disordered crystals. In this work, we address this issue by performing a thorough analysis of crystal disorder in the experimental structures of the Inorganic Crystal Structure Database (ICSD). Based on this, we develop disorder classification models and representations that can predict the likelihood of disorder across chemical space. Eventually, these concepts will allow us to extend current generative models to realistic crystal systems and bridge the gap between prediction and experiment.

MM 3.10 Mon 12:45 H10

Materials-Discovery Workflows Guided by Symbolic Regression: Identifying Stable Oxides for Catalytic Applications — •Akhil S. Nair, Lucas Foppa, and Matthias Scheffler — The NOMAD Laboratory at the FHI of the Max Planck Society, Berlin, Germany

AI-driven workflows will accelerate materials discovery by efficiently guiding experiments or simulations towards materials with desired properties. However, probabilistic AI approaches commonly used in these workflows are limited by the relatively small size of high-quality datasets and they rely on typically unknown, low-dimensional representations. Herein, we discuss the recent advancements in applying symbolic regression based on the sure-independence screening and sparsifying operator (SISSO) approach within iterative frameworks for materials discovery. This involves an ensemble approach for the uncertainty quantification of SISSO models as well as the development of optimization strategies to efficiently explore promising regions of the materials space. These developments present an opportunity to integrate SISSO into sequential-learning workflows for materials discovery. Importantly, SISSO provides materials-property maps covering the entire materials space, further reducing the risk that the workflow misses promising materials that were overlooked in the initial dataset. We demonstrate the effectiveness of the SISSO-guided workflows by identifying stable oxides for catalytic applications.

MM 4: Materials for the Storage and Conversion of Energy

Metal Hydrides, Hydrogen Embrittlement

Time: Monday 10:15–13:00 Location: H22

MM 4.1 Mon 10:15 H22

Atomic cluster expansion potential for the palladium hydride system — •Minaam Qamar[1], Apinya Ngoipala[2], Matous Mrovec[1], and Matthias Vandichel[2] — [1]ICAMS, Ruhr-University Bochum, Germany — [2]Department of Chemical Sciences and Bernal Institute, University of Limerick, Ireland

Palladium (Pd) is extensively studied for metal-hydrogen interactions due to its remarkable ability to absorb large amounts of hydrogen under standard temperature and pressure conditions, forming stable palladium hydride structures. This property makes Pd a critical material for various hydrogen-related applications, including hydrogen storage and as a catalyst for hydrogen evolution reactions. We developed a highly accurate and computationally efficient Atomic Cluster Expansion (ACE) potential to unravel atomistic insights into the Pd-H interaction. This potential was utilized to perform molecular dynamics and Monte Carlo simulations, providing a detailed understanding of the formation mechanisms of palladium hydride nanoclusters and bulk structures.

MM 4.2 Mon 10:30 H22

Hydrogen kinetics in HPT-deformed bulk Mg and Mg-based alloys — •Giorgia Guardi[1], Sabine Schlabach[1,2,3], Julia Ivanisenko[2], Stefan Wagner[1], and Astrid Pundt[1] — [1]Karlsruhe Institute of Technology (KIT), Institute for Applied Materials (IAM-WK), Karlsruhe, Germany — [2]Karlsruhe Institute of Technology (KIT), Institute of Nanotechnology (INT), Karlsruhe, Germany — [3]Karlsruhe Institute of Technology (KIT), Karlsruhe Nano Micro Facility (KNMFi), Karlsruhe, Germany

Magnesium (Mg) is a light and abundant element that can store hydrogen with a gravimetric density of 7.6 wt. % and a volumetric density of 110 kgH/m^3. Therefore, it is a highly promising hydrogen storage material for a sustainable energy economy. However, its technical use is hindered by an inherent kinetic blockade in magnesium hydride. A high content of grain boundaries is expected to improve hydrogen kinetics in Magnesium samples, particularly in the magnesium hydride phase. This can be achieved in bulk samples through the use of severe plastic deformation techniques, such as High-Pressure Torsion (HPT).

High-pressure torsion is not fully effective in reducing the grain size in pure bulk magnesium due to dynamic recrystallization. To overcome this lower limit to bulk magnesium grain size, Mg- 2.3 at.% Zn- 0.17 at. % Zr alloys are used, reaching a final grain size of approximately 100 nm after HPT. This study examines the impact of the sample's microstructure on hydrogen kinetics. Hydrogen absorption is studied at room temperature by gas-phase and electrochemical hydrogen loading.

MM 4.3 Mon 10:45 H22

A first principles study on the free energy landscape of chemisorbed hydrogen atoms on a Pt (111) surface modified by transition metals — •Bingxin Li, Sudarsan Surendralal, Mira Todorova, and Jörg Neugebauer — Max-Planck-Institut für Nachhaltige Materialien GmbH, Max-Planck-Straße 1, 40237 Düsseldorf

Platinum (Pt) is considered an excellent catalyst for the hydrogen evolution reaction (HER) due to its optimal hydrogen binding strength, as suggested by the Sabatier principle and the volcano plot of the HER. In surface-catalysed electrochemical reactions, the incorporation of adsorbates or dopants into a host surface can significantly enhance the catalytic selectivity, activity, and stability compared to the pristine surface while also introducing some novel properties not observed on the parent surfaces. Transition metals (TMs), such as Cu, Ag, Au, Pd, Ru, Rh, and Ir, form metal-hydrogen bonds with unique characteristics, resulting in varied H adsorption patterns and distinct hydrogen evolution behaviours. Consequently, doping these transition metals into a Pt (111) surface can significantly alter its catalytic properties for the HER, either by modifying H adsorption configurations or by impacting the reaction barrier of the fundamental steps for the hydrogen evolution, though the underlying mechanisms remain unclear. To this end, we employ ab initio molecular dynamics (AIMD) simulations to investigate H adsorption on TM-doped Pt (111) surfaces in the presence/absence of explicit water by constructing laterally resolved free energy maps of chemisorbed H atoms.

MM 4.4 Mon 11:00 H22

Local hydrogen concentration and distribution in Pd nanoparticles: An in-situ STEM-EELS approach — •Svetlana Korneychuk[1,2], Stefan Wagner[1], Darius Rohleder[3], Philipp Vana[3,4], and Astrid Pundt[1] — [1]IAM-WK, Karlsruhe Institute of Technology — [2]Karlsruhe Nano Micro Facility (KNMFi), Karlsruhe Institute of Technology — [3]Institute of Physical Chemistry, Georg-August-University Göttingen — [4]Wöhler Research Institute for Sustainable Chemistry (WISCh), Georg-August-University Göttingen

Local detection of hydrogen concentration in metals is of central importance for many areas of hydrogen technology, such as hydrogen storage, detection, catalysis, and hydrogen embrittlement. We demonstrate a novel approach to measure the hydrogen concentration in a model system consisting of cubic palladium nanoparticles, with a lateral resolution down to 4 nm. By measuring the shift of the Pd bulk plasmon peak with scanning transmission electron microscopy combined with energy electron loss spectroscopy during in-situ hydrogen gas loading and unloading, local detection of the hydrogen concentration is achieved in TEM [1]. With this method, concentration changes inside the NPs at various stages of hydrogenation/dehydrogenation are observed with nanometer resolution. The versatility of in-situ TEM allows to link together microstructure, hydrogen concentration and local strain, opening up a new chapter in hydrogen research. [1] S. Korneychuk, et al., 'Local hydrogen concentration and distribution in Pd nanoparticles: An in-situ STEM-EELS approach', Small, accepted

MM 4.5 Mon 11:15 H22

Hydride formation in open thin film metal hydrogen systems: Cahn-Hilliard-type phase-field simulations coupled to elasto-plastic deformations — •Stefan Wagner[1], Alexander Dyck[2], Johannes Gisy[2], Frederik Hille[2], Astrid Pundt[1], and Thomas Böhlke[2] — [1]Institute for Applied Materials (IAM-WK), Karlsruhe Institute of Technology (KIT), Germany — [2]Institute of Engineering Mechanics (ITM), Karlsruhe Institute of Technology, Germany

Metal-hydrogen systems are versatile model systems to study alloy thermodynamics and structural phase transitions. Hydrogen absorption and hydride formation in metals induce a volume expansion of the metal, leading to incompatibility stresses at internal and external interfaces. Resulting changes of the thermodynamic stability of phases in response to the mechanical constraint conditions can be understood by investigating the chemo-mechanical coupling [1,2]. Utilizing niobium-hydrogen thin films, combining a Cahn-Hilliard type phase-field theory and Finite-Element-Modeling (FEM) we study the feedback-loop of the local stress state, elasto-plastic deformations and hydrogen diffusion, determining the driving force of precipitation and growth of the hydride phase under open-system conditions. The simulation results are informed by and compared to measurements of the concentration-dependent stress state, chemical potential and phase separation in epitaxial niobium-hydrogen thin films adhered to sapphire substrates [3]. [1] A. Dyck, T. Böhlke, A. Pundt, S. Wagner, Scr. Mat. 247 (2024) 116117. [2] A. Dyck et al., Scr. Mat. 251 (2024) 116209. [3] A. Dyck et al., accepted to Mech. of Mat.

MM 4.6 Mon 11:30 H22

Hydrogen: a catalyst for abnormal grain growth in inert-gas condensed nanocrystalline Pd-Au? — •Fabian Andorfer[1], Jules M. Dake[1], Markus Ziehmer[1], Johannes Wild[2], Torben Boll[2], Dorothée Vinga Szabó[2], Stefan Wagner[2], Astrid Pundt[2], and Carl E. Krill III[1] — [1]Institute of Functional Nanosystems, Ulm University — [2]Institute of Applied Materials - Materials Science and Engineering (IAM-WK), Karlsruhe Institute of Technology

Heat treatment causes some polycrystalline materials to manifest abnormal grain growth (AGG), during which a few grains acquire a significant growth advantage compared to the remaining matrix grains, resulting in a bimodal distribution of grain sizes. Inert-gas condensed nanocrystalline Pd-Au alloys undergo an extreme form of AGG. This system is known to absorb hydrogen. When Pd-Au alloys are exposed to hydrogen below a certain gas pressure, hydrogen atoms primarily occupy grain boundaries and interstitial sites. This segregation is expected to lower the excess energy of the grain boundaries, which should have a noticeable effect on subsequent grain growth. To test this, Pd-Au samples were heat treated in argon and hydrogen atmospheres, respectively. The average size of the abnormally grown grains was determined, and the grain shape was characterized by calculating the circularity. Hydrogen appeared to increase the rate of abnormal grain "nucleation" without affecting the resulting grain shape.

MM 4.7 Mon 11:45 H22

The liquid intermediate phase for a hydrogen storage material — •Anastasiia Thase[1], Oliver Alderman[2], Chiara Milanese[3,4], Alessandro Girella[4], Claudio Pistidda[5], Martin Müller[5,6], and Sebastian Busch[1] — [1]GEMS MLZ, Helmholtz-Zentrum Hereon WPN — [2]ISIS Neutron and Muon Source — [3]C.S.G.I. Department of Chemistry, Physical Chemistry Division, University of Pavia — [4]Pavia Hydrogen Lab — [5]Helmholtz-Zentrum Hereon WTN — [6]CAU zu Kiel, Leibnitzstr. 19, 24098 Kiel, Germany

Hydrogen storage in light hydrides for mobile applications is a widely discussed but a highly controversial topic because of its ability to form explosive mixtures with oxygen. However, this danger is eliminated, if hydrogen is stored in complex hydrides, which provide hydrogen only under significant heat impact.

The main issue for complex hydride mixtures is the kinetics of the reversible reaction with hydrogen. One of prospective candidates is $6Mg(NH_2)_2$:9LiH, which promptly interacts with hydrogen when doped with $LiBH_4$. Its catalytic impact is explained by the formation of low-melting intermediate phases with high Li-ion conductivity: a metastable $Li_2BH_4NH_2$ and a peritectically melting $Li_4BH_4(NH_2)_3$.

In the $LiNH_2 - LiBH_4$ phase diagram, the eutectic point is located at the 1:2 ratio and 90°C. This eutectic mixture was characterized by various techniques, including neutron total scattering, and its intrinsic structure under the reaction conditions was elucidated by EPSR, which gave a hint about its role as a liquid-phase catalyst in the corresponding hydrogen storage composition ($6Mg(NH_2)_2$:9LiH:6$LiBH_4$).

MM 4.8 Mon 12:00 H22

Machine Learning Interatomic Potentials for Studying Hydrogen Storage in TiCr2 Laves Phase Alloys — •Pranav Kumar, Blazej Grabowski, and Yuji Ikeda — Institut für Materialwissenschaft, Universität Stuttgart, Pfaffenwaldring 55, 70569 Stuttgart, Germany

Efficient hydrogen storage is a crucial challenge for the widespread absorption of hydrogen as a clean energy carrier. TiCr2 Laves phase alloys, with their exceptional hydrogen absorption and diffusion properties, represent a promising class of materials for this purpose. This study employs a multiscale computational strategy, integrating density functional theory (DFT) and machine learning interatomic potentials (MLIPs), to investigate hydrogen behavior in TiCr2 Laves phases. Key areas of focus include hydrogen binding energies, diffusion pathways, and the complex effects of hydrogen clustering, which influence storage capacity and transport. Notably, our findings reveal possible equilibrium hydride structures consistent with experimental observations, offering valuable validation of the computational models. By leveraging large-scale DFT simulations within an active learning framework, we develop accurate MLIPs that enable efficient exploration of the phase space across diverse hydrogen concentrations. These MLIPs bridge atomic-scale simulations, facilitating precise calculations of hydrogen diffusion coefficients and shedding light on the mechanisms of hydrogen mobility. The insights derived from this work enhance our understanding of hydrogen-metal interactions and provide critical information for optimizing hydrogen storage materials.

MM 4.9 Mon 12:15 H22

The impact of Mn and Al on the trapping and diffusion of hydrogen in γ-Fe: An atomistic insight — •Bikram Kumar Das[1], Poulami Chakraborty[1], Mauricio Rincón Bonilla[1], and Elena Akhmatskaya[1,2] — [1]Basque Center for Applied Mathematics, Bilbao, Spain — [2]Ikerbasque - Basque Foundation for Science, Spain

We propose a first principles-based framework to systematically unlock the physical underpinnings of local distribution of the solute atoms on hydrogen trapping and diffusion in Mn/Al-alloyed γ-Fe. In our scheme, all thermodynamically stable substitutional solute sites were identified (<= 5.4 wt% Mn; <= 4 wt% Al) up to the third nearest neighbour (NN) shell of a single H atom. The impact of Mn/Al on H-binding was quantitatively evaluated, indicating a surprisingly strong correlation with the local Al distribution regardless Mn content, and indirect stabilization by Al when present in the 2nd NN shell. Nonetheless, Al strongly repels H bonding. The contradictory role of Al was explained in terms of bonding/antibonding orbitals occupancy in H-M interactions (M = Al, Mn, Fe). The barriers to H hopping between adjacent local environments and the corresponding jump frequencies were subsequently calculated, providing insights into the limits imposed by the presence of Al and Mn on H mobility in Mn/Al-alloyed γ-Fe. Most notably, presence of Al in the 2nd NN shell of H severely reduces the H jump frequency, leading to irreversible trapping at high Al contents. Such behaviour may critically contribute to mitigate H-induced delayed fracture in Al-rich austenite steel.

MM 4.10 Mon 12:30 H22

Hydrogen - Microstructure Interaction in Ferritic Steels: From Ab-initio Simulations to Experiments — •Onur Can Şen[1,2,3], Santiago Benito[2], Sebastian Weber[2], and Rebecca Janisch[3] — [1]IMPRS SusMet, Max Planck Institute for Sustainable Materials, Germany — [2]Institute for Materials, Chair of Materials Technology, Ruhr-University Bochum, Germany — [3]ICAMS, Ruhr-University Bochum, Germany

Hydrogen embrittlement (HE) is a phenomenon where hydrogen negatively impacts the mechanical properties of metallic materials. Mitigating HE requires minimizing hydrogen diffusion in microstructures and understanding how local heterogeneities influence this process across different length scales. While advanced experimental and computational methods exist, their application to varying systems complicates model validation. To address this, simplified ferritic Fe-based alloys were produced, and subjected to thermomechanical treatments, and their microstructures were characterized using EBSD. This approach aims to assess the hydrogen storage capacities of microstructural heterogeneities and their influence on the effective diffusion coefficient. Complementary ab initio density functional theory calculations were performed to evaluate hydrogen trapping energies and diffusion barriers under different chemical environments and CSL boundaries. These calculations inform predictions of hydrogen solubility and distribution within the experimental microstructures, to be validated experimentally. This work shows the importance of combining simulations and experiments to understand microstructural heterogeneities' role in HE.

MM 4.11 Mon 12:45 H22

Hydrogen Embrittlement in fatigue damage of ferritic steel: Theoretical investigation of failure mechanisms in varying hydrogen environments — •Alexandra Stark[1,2], Petra Sonnweber-Ribic[1], and Christian Elsässer[2] — [1]Robert Bosch GmbH, CR, 71272 Renningen — [2]Fraunhofer IWM, 79108 Freiburg

In this theoretical study, the influence of hydrogen on the fatigue behavior of a ferritic steel is examined by using a coupled hydrogen-diffusion and crystal-plasticity finite-element (CPFE) model. The damaging effect of hydrogen on structural materials, particularly ferritic and martensitic steels, poses a significant challenge for a wide range of technical applications. Despite being known for about 150 years, the underlying mechanisms of hydrogen embrittlement remain the subject of scientific debates. CPFE models are suitable for ensuring a microstructure-sensitive modelling and enabling the description of local plastic deformation, both essential factors in the complex process of metal fatigue. The presented study investigates the individual and combined effects of different damage models based on proposed hydrogen embrittlement failure mechanisms [1]. Furthermore, the work explores the impact of diverse environmental conditions on the cyclic material damage. The effects of varying local hydrogen concentration and distribution on the fatigue damage, as implemented in the CPFE model, are examined and discussed. [1] A. Stark, P. Sonnweber-Ribic, and C. Elsässer, Theoretical study of individual and combined effects of HELP- and HEDE-based damage models on the fatigue behavior of ferritic steel by hydrogen, submitted (2024).

MM 5: Invited Talk: X. Fang (joint session MM/KFM)

Time: Monday 15:00–15:30 Location: H10

Invited Talk MM 5.1 Mon 15:00 H10

Room-temperature dislocations in oxide ceramics: from understanding to active engineering — •Xufei Fang — Institute for Applied Materials, Karlsruhe Institute of Technology, Karlsruhe, Germany

In the conventional picture, dislocations are most relevant for metals while ceramics are considered brittle and exhibit little or no plasticity at room temperature. However, recent years' research on dislocations in ceramics suggests that dislocations may have been much under-appreciated in ceramics. Proofs-of-concept for dislocation-tuned functional properties suggest that dislocations may hold great technological potential in advanced ceramics. As the prerequisite to harvest dislocation-tuned properties, engineering dislocations into ceramics without brittle fracture has thus become a pressing bottleneck. To tackle this challenge, we have separately examined the dislocation behavior including dislocation nucleation, multiplication and motion, enabling us to tune dislocations into ceramic oxides at room temperature. We can now achieve a dislocation density up to ~10^15/m^2 with a plastic zone size of up to milli-/centimetres using a mechanical deformation toolbox. We further extend the material toolbox by discovering and reporting more oxide perovskites that can be plastically deformed at room temperature across the length scale. The combined deformation and material toolboxes offer a new platform for studying the dislocation-tuned functional properties (e.g., electrical and thermal conductivity) and the mechanical properties (such as plasticity, toughness, and damage tolerance) over a wide range of length scales.

MM 6: Phase Transformations

Time: Monday 15:45–18:30 Location: H10

MM 6.1 Mon 15:45 H10

Phase transitions in 2D halide perovskites using machine learned potentials — •Erik Fransson, Julia Wiktor, and Paul Erhart — Chalmers University of Technology, Gothenburg, Sweden

Hybrid halide perovskites are a promising class of materials for various applications, including high-efficiency solar cells, lasers, and light-emitting diodes. So-called two-dimensional (2D) halide perovskites, composed of a small number of perovskite layers stacked on top of each other and separated by organic cations that act as spacers, have much improved stability compared to their 3D counterparts. Here, we focus on the prototypical perovskite methylammonium lead halide (MAPI), and demonstrate that the dimensionality of these 2D materials and the choice of organic linker molecules can have a strong impact on phase transitions in these systems. This is investigated through large-scale molecular dynamics simulations using machine-learned potentials. We analyze the phase transition temperatures and characteristics with varying numbers of perovskite layers to understand how the transition properties change as a function of the system's dimensionality. For a larger number of perovskite layers, the 3D bulk phase transition temperature is recovered, whereas, for only a few perovskite layers, the phase transition temperature shifts up by about 100 K. Additionally, we observe surface effects, such as the surface layers (closest to the organic linker) exhibiting stronger octahedral tilting and undergoing phase transitions at higher temperatures (about 100 K) compared to the interior bulk layers.

MM 6.2 Mon 16:00 H10

Quantum phase diagram of sulfure hydride — •Marco Cherubini and Michele Casula — IMPMC, CNRS, Paris, France

In the recent rush towards room temperature superconductivity, hydrogen-based materials are the most prosiming candidates. Sulfulr hydride exhibits a maximum superconductive critical temperature of about 200K at 150 GPa. To our knowledge, a comprehensive theoretical characterization of the phase diagram of sulfur hydride in a wide temperature range is still missing in literature. To address this, we performed path integral molecular dynamics simulations (PIMD). The description of the low temperature regime has been made feasible by the use a machine learning potential trained on ab-initio data. We found three different regimes. At high pressure, the phase diagram is dominated by a paraelectric phase, with symmetric hydrogen bonds. Reducing the pressure, we observed first a regime characterized by finite local dipole moments and finally, at even lower pressures, the ferroelectric regime. Quantum simulations show that the formation of finite local moments is temperature-independent, unlike the transition to the ferroelectric regime. Classical simulations, by contrast, showed stronger temperature dependence for both the transitions and significantly higher critical pressures, highlighting the impact of quantum nuclear fluctuations.

MM 6.3 Mon 16:15 H10

Magnetic-field induced phase transition crossover in the triangular-lattice antiferromagnet: Ba_3CoSbO_9 — •Sanjay Kumar[1], Koushik Chakraborty[2], Aditi Agrawal[2], Shalini Mishra[3], M. P. Saravanan[2], Arvind Kumar Yogi[2], Satyapal S. Rathore[4], and Rashi Nathawat[1] — [1]Functional Ceramics and Smart Materials Lab, Department of Physics, Manipal University Jaipur, Jaipur - 303007, India — [2]UGC-DAE Consortium for Scientific Research, University Campus, Khandwa Road, Indore-452001, India — [3]Department of Physics, Govt. Holkar Science College, Indore (M.P.) 452001, India — [4]Department of Physics, Cluster University of Jammu, Jammu * 180001, India

We report magnetic and structural properties of triangular-lattice antiferromagnet Ba_3CoSbO_9 by means of x-ray diffraction (XRD), magnetic susceptibility, specific heat, x-ray photoelectron spectroscopy (XPS), and dielectric measurements. Thermodynamic measurements show a long-range ordered (LRO) state at Néel temperature T_N = 3 K which was found to be shift at higher temperatures at about T_N = 4.1 K under the higher magnetic fields. Moreover, we have found higher Curie-Weiss temperature θ_{CW} ~-133.2 K from the inverse susceptibility fit which reveals frustration parameter about 44, suggesting magnetic lattice is highly frustrated. Further, a spin-glass state signature was evident at around 6.5 K, which was found to be fully suppressed at a higher magnetic field (H ~16 T). Interestingly, Ba_3CoSbO_9 exhibits a broad maximum at around T_{max} ~5 K which becomes pronounced as the magnetic field is increased.

MM 6.4 Mon 16:30 H10

Anomalous spin-lattice coupling in the quasi-one-dimensional spin-1 corrugated skew-chain antiferromagnet: $Ni_2V_2O_7$ — •Arvind Kumar Yogi[1], Hemant Singh Kunwar[1], Koushik Chakraborty[1], Aditi Agrawal[1], Binoy Krishna De[1], Pragati Sharma[1], Shalini Mishra[2], D. T. Adroja[3], Mayanak Kumar Gupta[4], R. Mittal[4], R. Venkatesh[1], and V. G. Sathe[1] — [1]UGC-DAE Consortium for Scientific Research, University Campus, Khandwa Road, Indore-452001, India — [2]Department of Physics, Govt. Holkar Science College, Indore (M.P.) 452001, India — [3]ISIS Neutron and Muon Facility, STFC, Rutherford Appleton Laboratory, Chilton, Oxfordshire OX11 0QX, United Kingdom — [4]Solid State Physics Division, Bhabha Atomic Research Centre, Trombey, Mumbai-400005, India

We report spin-lattice coupling through detailed structural, magnetic, and lattice-dynamics studies of the S = 1 quasi-one-dimension lattice $Ni_2V_2O_7$ compound. Our susceptibility χ (T) and heat capacity measurements (C_P/T) measurement conclusively show that the antiferromagnetic transition occurs at T_{N1} = ~6.7 K and T_{N2} = ~5.8 K. From detailed lattice dynamics, two Raman mode showed anomalous lattice softening below ~100 K due to Ni dimerization as supported by ordering of the J_1 exchange interaction. Importantly, the spin-lattice coupling has been established below ~100 K and the spin-lattice coupling constant (λ_{sp}) for various Raman modes has been deduced which shows multiferroic behaviour below T_{N1}. In addition, the detailed study of lattice dynamics by first principle calculation is presented.

MM 6.5 Mon 16:45 H10

Chirality in the Kagome Metal CsV_3Sb_5 — H.J. Elmers[1], O. Tkach[1], Y. Lytvynenko[1], P. Yogi[1], M. Schmitt[2,3], D. Biswas[2], J. Liu[2], S.V. Chernov[4], Q. Nguyen[5], M. Hoesch[4], D. Kutnyakhov[4], N. Wind[4,6], L. Wenthaus[4], M. Scholz[4], K. Rossnagel[4,6], A. Gloskovskii[4], C. Schlueter[4], A. Winkelmann[7], A.-A. Haghighirad[8], T.-L. Lee[2], M. Sing[3], R. Claessen[3], M. Le Tacon[8], J. Demsar[1], G. Schönhense[1], and •O. Fedchenko[1] — [1]JGU Mainz, Germany — [2]DIAMOND, Didcot, United Kingdom — [3]Physikalisches Institut Würzburg, Germany — [4]DESY, Germany — [5]SLAC, Menlo Park, USA — [6]CAU Kiel, Germany — [7]University of Krakow, Poland — [8]KIT, Karlsruhe, Germany

Using x-ray photoelectron diffraction (XPD) and angle-resolved photoemission spectroscopy, we study photoemission intensity associated with the changes in the geometric and electronic structure of the kagome metal CsV_3Sb_5 upon transition to an unconventional charge density wave (CDW) state. The XPD patterns reveal the presence of a chiral atomic structure in the CDW phase. Using circularly polarized x-rays, we have found a pronounced non-trivial circular dichroism in the angular distribution of the valence band photoemission in the CDW phase, indicating a chirality of the electronic structure. This observation is consistent with the proposed orbital loop current order. The results suggest an antiferromagnetic coupling of the orbital magnetic moments along the c-axis.

MM 6.6 Mon 17:15 H10

Pressure-temperature phase diagram of calcium using quantum-accurate finite-temperature free energies — •Raynol Dsouza[1], Marvin Poul[1], Liam Huber[2], and Jörg Neugebauer[1] — [1]Max Planck Institute for Sustainable Materials, Düsseldorf, Germany — [2]Grey Haven Solutions, Vancouver, Canada

Pure calcium has been experimentally shown to exhibit several stable phases across a range of high pressures. While many of these phases have been theoretically predicted using T=0 K ab inito calculations [1], the relative stability of the distorted simple cubic phases above 30 GPa at finite temperatures remains unclear. To address this ambiguity, we developed an Atomic Cluster Expansion (ACE) potential [2] for calcium, fitting it to a structural dataset generated using the ASSYST methodology outlined in [3]. Quantum-accurate finite-temperature free energies were determined using the Temperature Remapping Approximation (TRA) [4]. The resulting pressure-temperature phase diagram offers new insights into the phase stability of calcium at elevated pressures and temperatures.

MM 6.7 Mon 17:30 H10

Phase-stability Study of the Marcasite-Structure Solid Solutions (Fe, TM)Sb_2 (TM = Cr, Ni) Synthesized via Combinatorial Co-Deposition and Antimonization — •Martin Kostka[1], Luqman Mustafa[1], Maik Golombiewski[1], Jill Fortmann[2], Aurelija Mockute[2], Alan Savan[2], Alfred Ludwig[2], Adreas Kreyssig[1], and Anna Böhmer[1] — [1]Experimental physics IV, Ruhr University Bochum, 44801 Bochum — [2]Materials Discovery and Interfaces, Institute for Materials, Ruhr University Bochum, 44801 Bochum

Transition-metal di-pnictides of the pyrite-marcasite family are model systems for crystal chemistry. We investigate phase formation and stability of transition-metal di-antimonides in the orthorhombic marcasite structure. We employ a two-step synthesis of granular films, using combinatorial co-deposition of the

transition metals and subsequent antimonization at different temperatures. This technique allows efficient exploration of substitution ranges and lattice parameter evolution within the marcasite structure. We investigate the formation and crystal structures of the (Fe,Ni)Sb_2 and (Fe,Cr)Sb_2 substitution series. We evidence the continuous substitution of $FeSb_2$ (class A marcasite) with Ni up to $Fe_{0.5}Ni_{0.5}Sb_2$, and a clear phase separation between $Fe_{0.5}Ni_{0.5}Sb_2$ and a Ni-rich $Ni_{1-z}Fe_zSb_2$ phase (class B marcasite). Cr-substituted $FeSb_2$ shows a subtle phase separation into an Fe-rich $Fe_{1-y}Cr_ySb_2$ and a Cr-rich $Cr_{1-z}Fe_zSb_2$-phase (both class A marcasite) when synthesized at 500°C, but not at higher Temperatures. We acknowledge support from DFG (TRR288,A02).

MM 6.8 Mon 17:45 H10

Investigation of glass formation in Pd40Ni40P20 metallic glass via fast scanning calorimetry — •Hongshuai Li, Sher Bahadur Raut, and Gerhard Wilde — Institute of Materials Physics, University of Münster, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany

Pd-Ni-P metallic glasses (MGs) exhibit exceptional glass-forming ability; in fact, Pd40Ni40P20 was the first bulk metallic glass-forming alloy discovered. Understanding glass formation in these materials requires exploring factors that impede correlated atomic motions in glass-forming liquids. This study investigates the atomic relaxation and thermal history of Pd40Ni40P20 MG, utilizing data from multiple cycles of heating around the glass transition temperature, activation energy determined by flash differential scanning calorimetry (DSC), and critical cooling rates. Additionally, we examine the effects of annealing time on the DSC signals at high heating rates of up to 1000 K/s. Our results demonstrate that adjustments in cooling rates and annealing duration significantly influence glass transition behavior and thermal stability. These findings enhance our understanding of the mechanisms underlying glass formation in Pd-Ni-P MGs and their potential applications in advanced materials.

MM 6.9 Mon 18:00 H10

Tuning excitonic transition by Cr doping and associated lattice softening in the vdW chalcogenide: Ta2NiSe5 — •Isha Isha[1], Koushik Chakraborty[1], Aditi Agrawal[1], M. Isobe[2], and Arvind Kumar Yogi[1] — [1]UGC-DAE Consortium for Scientific Research, University Campus, Khandwa Road, Indore-452001, India — [2]Max-Planck-Institut für Festkörperforschung, Heisenbergstr. 1, D-70569 Stuttgart, Germany

We have successfully grown defect free ultra-high quality single crystals of Cr doped Ta2NiSe5, maximum of 10% at Ni site in the lattice. Our preliminary STM results unambiguous provide clear signature of CDW phase, vdW layers and the vdW gap for Ta2NiSe5 which was found to be ~3.5 Å. We found a clear anomaly at the critical temperature Tc = 326 K in our transport measurement over rod shaped crystals - a transition into an excitonic insulator ground state as reported for parent Ta2NiSe5 compound. It is noteworthy to highlight our finding that Cr doping significantly suppresses the insulating ground state and the 10% doping reduces the resistivity of three orders. In addition, our detailed high-temperature Raman scattering for parent as well as Cr doping reveals sharp Raman modes and significant shift and suppression for 230 cm-1 phonon mode which might be associated with electron-phonon coupling, which may helps in resistivity drop as evident in our transport data. In addition, our detailed Raman scattering study suggests the persistence of lattice softening which may be due to strong electron-lattice coupling, and the origin is presumably due to strong excitonic fluctuations.

MM 6.10 Mon 18:15 H10

Magnetic Imaging of the Local Insulator to Metal Transition in CaRuO by NV Magnetometry — •Hayden Binger[1], Cissy Suen[2], Elina Zhakina[1], Luke Turnbull[1], Yejin Lee[1], Young-Gwan Choi[1], Max Krautloher[2], Bernard Keimer[2], Claire Donnelly[1], and Uri Vool[1] — [1]Max Planck Institute for the Chemical Physics of Solids,Dresden, Germany — [2]Max Planck Institute for Solid State Research, Stuttgart, Germany

The current-driven insulator to metal transition in $Ca_2Ru_2O_4$ is a fascinating phenomenon where increasing current driven across a sample causes a smaller voltage difference to develop. While this transition has been well studied in bulk $Ca_2Ru_2O_4$ through transport, and recently investigated by ARPES, little is known about the local character of the transition - especially in nanoscale devices. In this work we utilize scanning NV magnetometry to measure the local magnetic field induced by the local current in 100 nm thick lamellas of $Ca_2Ru_2O_4$. We observe a nonuniform field distribution that reveals the local current channels, allowing us to image the local character of the insulator to metal transition in $Ca_2Ru_2O_4$.

MM 7: Materials for the Storage and Conversion of Energy

Hydrogen related Surface Effects

Time: Monday 15:45–17:00 Location: H22

MM 7.1 Mon 15:45 H22

Effect of stress induced nanohydride formation on dislocation nucleation and pinning in FeCr alloys — •Ali Tehranchi[1], Jing Rao[2], Lekshmi Sreekala[2], Jazmin Duarte[2], Gerhard Dehm[2], Jörg Neugebauer[2], and Tilmann Hickel[1] — [1]BAM Federal Institute for Materials Research and Testing, ali.tehranchi@bam.de, Germany — [2]Max Planck Institute for Sustainable Materials

The detrimental effects of hydrogen (H) on the mechanical properties of metals are universally acknowledged. However, the mechanisms behind these effects remain unclear. In situ nano-indentation experiments are powerful tools for probing the effect of H on the hardness and plasticity of metals. In this work, ab initio calculations and stress dependent phase diagrams in chemical potential space are used to clarify the effect of nanohydrides on the pop-in load of in situ nanoindentation of FeCr alloys. It is shown that the anisotropic stress field of the indenter with a radius of 170 nm facilitates the formation of nanohydrides with significantly lower elastic constants and containing high eigen shear strain. The shear stress associated with these inhomogeneous inclusions is responsible for the experimentally observed reduction in critical shear for dislocation nucleation and the pop-in loads in these indentation experiments. On the other hand, for indenters with a larger radius, the pop-in load is increased due to the pinning of the pre-existing dislocations by the same nanohydrides which are not capable to form underneath the indenter because of the lower magnitude of its induced stress field. The formation of nanohydrides under loading has significant implications for H-embrittlement and H-storage.

MM 7.2 Mon 16:00 H22

Spherical nanoindentation during electro chemical nanoindentation — •Verena Maier-Kiener, Stefan Zeiler, and Anna Jelinek — Montanuniversität Leoben, Leoben, Österreich

Nanoindentation enables efficient characterization of material flow behavior, offering reliable results with minimal effort. While established for hardness and Young*s modulus, its potential for deriving localized flow curves remains underexplored due to challenges in correlating spherical indentation and uniaxial data. A calibration procedure addressing tip imperfections allows strain-rate-controlled experiments and accurate constraint factor evaluation. Using an innovative in-situ electrochemical charging method, side-charging cell, it is shown that electrochemical charging increases hardness and flow stress while reducing the constraint factor, providing valuable insights into deformation behavior.

MM 7.3 Mon 16:15 H22

Hydrogen-based reduction of iron oxide surfaces studied by ab-initio calculations — •Ahmed Abdelkawy, Mira Todorova, and Jörg Neugebauer — Max Planck Institute for Sustainable Materials, Max-Planck-Str.1, 40470 Düsseldorf

The production of pure iron from the iron oxide ores is a very energy-intensive process. Additionally, the dependency on carbon and carbon monoxide as reducing agents results in CO2 as an intrinsic byproduct of the reaction. Consequently, the steel industry is responsible for more than 6% of the global CO2 emissions. Using Hydrogen (H) as a reducing agent would result in water being released instead. Two important aspects in this context are (i) the relative thermodynamics stability of iron oxide facets under different conditions, as this will determine their abundance and (ii) the interaction of H with the oxide surfaces, as these will catalyse the reaction. This work, which is an initial step toward understanding the complex process of the H-based reduction of iron oxides, focuses on Hematite (Fe2O3). Using density functional theory (DFT) calculations we explore the surface stability of different facets under relevant thermodynamic conditions. Additionally, we use transition state theory to describe different H reaction paths and their activation barriers. Keeping in mind the impact the description of the electronic structure may have on the considered quantities, the calculations were performed using both GGA-PBE and GGA-PBE+U. While our results indicate that both methods result in the same preferential reaction path, the electron localization from the (+U) term results in a significant reduction in the activation barrier.

MM 7.4 Mon 16:30 H22

Atomic Cluster Expansion potential for hydrogen-based direct reduction of iron oxides — •Baptiste Bienvenu[1], Mira Todorova[1], Jörg Neugebauer[1], Matous Mrovec[2], Yury Lysogorskiy[2], Ralf Drautz[2], and Dierk Raabe[1] — [1]Max Planck Insitute for Sustainable Materials, Max-Planck-Straße 1, 40237 Düsseldorf, Germany — [2]Interdisciplinary Centre for Advanced Materials Simulation, Ruhr Universität Bochum, 44780 Bochum, Germany

Modeling atomistic mechanisms underlying hydrogen-based direct reduction of iron oxides poses many great challenges, due to the combined structural and electronic complexities of the bulk materials, but also due to the involved chemical reactions. To allow for atomic scale modeling of such processes over the relevant length and time scales, an accurate yet affordable interatomic potential is needed.

Following our previous work, which focused on the development of an Atomic Cluster Expansion (ACE) potential for iron and its oxides, we present in this work the extension of the model to include hydrogen. Based on an extensive DFT-computed database encompassing both iron and its oxides in a wide range of atomic environments involving hydrogen, we fit the extended ACE potential, also including magnetic degrees of freedom. To demonstrate the capabilities of the ACE potential, we focus on its ability to capture some basic mechanisms involved in the hydrogen-based reduction of iron oxides in various environments, including iron oxides-hydrogen (reactions at surfaces, bulk defects), iron oxides-water (surface oxidation), iron-water (surface reactions) and iron-hydrogen (trapping, interactions with defects).

MM 7.5 Mon 16:45 H22

Investigating phase diagram and phonons in superconducting Lanthanum Hydride through an accurate treatment of anharmonicity and nuclear quantum effects — •Abhishek Raghav[1], Kousuke Nakano[2], and Michele Casula[1] — [1]Institut de Minéralogie, de Physique des Matériaux et de Cosmochimie (IMPMC), Sorbonne Université, Paris, France — [2]Center for Basic Research on Materials, National Institute for Materials Science (NIMS), Tsukuba, Japan

Hydrogen rich materials with clathrate structures are an important class of superconducting materials. Lanthanum hydride (LaH_{10}) is one such material, demonstrated to show superconductivity at 250 K and 170 GPa. Phase diagram, phonon spectrum and electron-phonon coupling are important ingredients used to predict superconductivity, being of BCS type. However, computing these accurately for hydrogen clathrate materials requires including anharmonicity due to nuclear quantum effects (NQE). In this work, we use the path integral molecular dynamics (PIMD) and the stochastic self-consistent harmonic approximation (SSCHA) to study NQE and finite temperature on the phase stability and phonons. In order to speed up PIMD and SSCHA calculations, we employ a machine learning potential generated using MACE. This allows us to explore the theoretical LaH_{10} phase diagram over an unprecedentedly wide range of temperatures and pressures. We found that, when quantum effects are included, hydrogen cage symmetrization occurs at lower pressures than in classical simulations, placing the maximum of T_c measured in experiments close to the quantum transition region.

MM 8: Materials for the Storage and Conversion of Energy (joint session MM/KFM)

Lithium-based Materials

Time: Monday 17:15–18:30 Location: H22

MM 8.1 Mon 17:15 H22

Lithium diffusion pathways in modern solid state Li conductors — •Mykhaylo Monchak[1], Volodymyr Baran[2], Stefan Strangmüller[3], and Anatoliy Senyshyn[3] — [1]Institut für Angewandte Materialien, Karlsruhe Institute of Technology, 76344 Eggenstein-Leopoldshafen, Germany — [2]Deutsches Elektronen Synchrotron, 22607 Hamburg, Germany — [3]Heinz Maier-Leibnitz Zentrum, Technical University of Munich, 85748 Garching, Germany

The rapid development of energy storage demands cheaper, more robust electrode and electrolyte materials with improved electrochemical performance. Energy storage and conversion primarily rely on diffusion-based processes, making understanding diffusion pathways crucial. However, determining diffusion pathways in polycrystalline (non-cubic) materials is challenging using bulk or local measurements. Theoretical approaches like molecular dynamics simulations face numerous computational limitations. Alternatively, diffusion processes can be predicted from crystal structures using scattering density maps (electron for X-ray or nuclear for neutrons). These maps analyzed via probability density functions or reconstructed through the maximum entropy method (MEM) are highly reliable. MEM is particularly effective for powder-averaged diffraction data, detecting weak structural disorders. This study applies high-resolution neutron powder diffraction and MEM analysis to explore state-of-the-art lithium conductors considered for application in all-solid-state Li-ion batteries, providing insights into their diffusion pathways and systematics.

MM 8.2 Mon 17:30 H22

"Effortless Embedding": Non-Parametric Solid-State Embedding for NMR Computations using All-Electron DFT — •Federico Civaia[1], Simone S. Köcher[2,1], Karsten Reuter[1], and Christoph Scheurer[1,2] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Institute of Energy Technologies (IET-1), Forschungszentrum Jülich GmbH, Jülich

Solid-state electrolytes are crucial in lithium-ion battery research, because of the pressing need for safe and durable high-energy storage solutions. Understanding Li-ion dynamics in these materials is essential for developing improved battery technologies. Owing to its non-destructive nature and sensitivity to atomic environments, solid-state nuclear magnetic resonance (SS-NMR) spectroscopy has become an invaluable tool for probing diverse Li-ion environments and investigating Li-ion mobility.

To facilitate the interpretation of experimental Li SS-NMR spectra, we are developing a method for computing NMR parameters of diamagnetic Li compounds using the linear-scaling, all-electron, density functional theory code FermiONs++ [1]. To allow the description of both crystalline and disordered materials, we employ a SS embedding method. In this regard, we present a consistent, non-parametric hybrid Quantum Mechanics/Molecular Mechanics (QM/MM) methodology for systematic and reproducible structure generation and SS embedding calculations.

MM 8.3 Mon 17:45 H22

Insights into Li-ion battery cathode redox chemistry via charge transfer multiplet simulations of $LiNi_{1/3}Mn_{1/3}Co_{1/3}O_2$ — •Ruiwen Xie[1], Maximilian Mellin[2], Wolfram Jaegermann[2], Jan. P Hofmann[2], and Hongbin Zhang[1] — [1]Theory of Magnetic Materials Group, Department of Materials and Geosciences, Technical University of Darmstadt — [2]Surface Science Laboratory, Department of Materials and Geosciences, Technical University of Darmstadt

The evolution of electronic structure during discharging and charging processes with Li intercalation and deintercalation in transition metal oxide cathode materials involves changes in oxidation states, non-rigid band behavior, and oxygen's role in charge compensation, which significantly impact cathode performance. To gain deeper insights, we combine experimental x-ray photoelectron spectroscopy (XPS) at various voltages with many-body electronic structure simulations. The electronic structures of Li_xCoO_2 and Li_xNiO_2 were calculated using Density Functional Theory and Dynamical Mean-Field Theory (DFT+DMFT). We found that Li intercalation and deintercalation shift the hybridization between Co/Ni *d* and O *p* orbitals relative to the Fermi energy, altering Co/Ni *d* occupancy. Based on this, we performed XPS calculations using the multiplet ligand-field model in Quanty to revisit the transition metal 2p satellite structure evolution. This study provides crucial insights into the interplay between electronic structure and Li intercalation dynamics for enhancing cathode performance.

MM 8.4 Mon 18:00 H22

Modelling LLZO Grain Boundaries with Amorphous Domains by Adaptively Trained Machine-Learning Interatomic Potentials — •Yuandong Wang, Yute Chan, Hao Wan, Kyeonghyeon Nam, Karsten Reuter, and Christoph Scheurer — Fritz-Haber-Institut der MPG, Berlin

Garnet $Li_7La_3Zr_2O_{12}$ (LLZO) is a highly promising solid state electrolyte (SSE) for lithium batteries. However, its practical application faces challenges, primarily arising from Li dendrite formation and the impact of grain boundaries (GBs) on Li transport and stability. Amorphous LLZO combines several desirable properties like blocking Li dendrite growth, high Li mobility and high electronic impedance. Controlling amorphous domains between crystalline grains could therefore offer an intriguing approach to tune electrolyte performance. For this, an atomistic understanding of the interplay between composition, structure and the properties of LLZO glass-ceramics is crucial.

This study introduces a Machine Learning Interatomic Potential (MLIP) tailored to accurately represent amorphous and GB structures in LLZO. Developed through an iterative training protocol using simulated annealing, this MLIP includes diverse structures in its training set, ensuring comprehensive modeling of complex LLZO phases. The MLIP enables large-scale molecular dynamics simulations, allowing the construction of realistic amorphous and GB models, and providing a foundation for in-depth analysis of LLZO structural and electrochemical behavior.

MM 8.5 Mon 18:15 H22

Early Stage of Li Cluster Nucleation at the Li Anode-Solid Electrolyte Interface in Solid-State Batteries — •Yun An[1,2], Taiping Hu[2], Quanquan Pang[2], and Shenzhen Xu[2] — [1]Fritz-Haber- Institut der MPG, Berlin, Germany — [2]School of Materials Science and Engineering, Peking University, Beijing, China

Li dendrite formation inside all-solid-state lithium batteries (ASSBs) strongly impedes their practical applications. Despite this recognized challenge, a comprehensive understanding of the Li dendrite nucleation mechanism remains elusive. In particular, the initial sites of Li dendrite formation are still ambiguous: do Li clusters form directly at the Li anode surface, or do they nucleate at a distance from the Li metal surface?

Here, based on deep-potential molecular dynamics simulations combined with enhanced sampling techniques, we investigate the atomic-level mechanism of Li cluster nucleation sites in ASSBs. We observe isolated Li clusters initially forming inside the solid electrolyte interphase (SEI), located approximately 1 nm away from the Li anode/SEI boundary, rather than directly connected to the Li anode. The local electronic structure of the spontaneously formed SEI is a key factor enabling the Li cluster formation within SEI. Our work provides atomic-level insights into initial Li-dendrite nucleation sites in ASSBs and could guide future design for developing Li-dendrite-inhibiting strategies.

MM 9: Poster

Time: Monday 18:30–20:30 Location: P1

MM 9.1 Mon 18:30 P1

Well-defined nanostructures synthesized by optimized anodic aluminum oxide template — •Linfeng Su, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

The template method has unique advantages in the design and synthesis of materials with specific nanostructures but with some disadvantages. In recent years, through in-depth research and improvement of its preparation methods, the five shortcomings of the traditional anodic aluminum oxide (AAO) template method, such as short-range order and long-range disorder, insulator, single-set of pores, large dead volume, and limited capability to tune pore shape and arrangement, have been successfully addressed by our group. Large-scale control of the shape, size, spatial configuration, and combination of in-plane and out-of-plane pores of well-defined nanostructures can be achieved, thereby broadening the diversity of nanostructures[1, 2]. In addition, we have improved the mechanical strength of the prepared AAO template, so that it can maintain the stability of the nanostructure under a pressure of 10 MPa[3]. The optimized AAO template method provides practical guidance for the design and preparation of catalysts under complex application conditions. [1] Nat. Commun., 2022, 13(1), 2435; [2] Nat. Nanotechnol., 2017, 12(3), 244; [3] Nat. Commun., 2020, 11(1), 299.

MM 9.2 Mon 18:30 P1

Ferroelectric perovskite oxides: PFM investigations of (001) surface — •Andrzej Jasicki[1], Marta Macyk[1], Llorenç Albons[2], Konrad Szajna[1], Martin Setvin[2], Dominik Wrana[1], and Franciszek Krok[1] — [1]Marian Smoluchowski Institute of Physics, Jagiellonian University, Krakow, Poland — [2]Department of Surface and Plasma Science, Charles University, Prague, Czech Republic

Growing demand for energy from green sources drives development in this sector. Hydrogen, as one of the most promising fuels, is mostly produced with the use of electricity during electrolysis, what lowers the overall efficiency of whole process. To reduce energy costs, one should search for an efficient water-splitting catalyst.

Although ferroelectric perovskite oxides show great potential in photocatalysis, it can be further enhanced via piezo- and pyrocatalysis. In order to understand their role in water-splitting process, a thorough investigation of ferroelectricity manifested at surfaces is necessary. Piezoresponse Force Microscopy (PFM), a method based on inverse piezoelectric effect, provides an opportunity to have a closer look into surface domain structure of such materials.

This poster displays PFM and SEM data obtained by investigations into domain structure on surfaces of single-crystalline, ferroelectric perovskites, namely KNbO3 and BaTiO3. Measurements on both polished and cleaved (001) surfaces were conducted in room temperature and under ambient atmosphere. Influence of different poling voltages and exposure to water is also discussed.

MM 9.3 Mon 18:30 P1

Pressure-induced hybridization changes in elemental silicon at Mbar pressure — Robin Sakrowski[1], Christoph J. Sahle[2], •Gordon Scholz[1], Leonie Tipp[3], Mirco Wahab[3], Sindy Fuhrmann[3], and Christian Sternmann[1] — [1]Fakultät Physik / DELTA, Technische Universität Dortmund, Maria-Goeppert-Mayer-Straße 2, 44221, Dortmund, Germany — [2]ESRF, The European Synchrotron, 71 Avenue des Martyrs, CS40220, 38043 Grenoble Cedex 9, France — [3]Institut für Glas und Glastechnologie, TU Bergakademie Freiberg, Leipziger Straße 28, 09599, Freiberg, Germany

Silicon, a fundamental semiconductor material, undergoes intriguing structural and electronic transformations when subjected to high pressure [1]. These changes are investigated using X-ray Raman scattering (XRS) spectroscopy on pure Si powder loaded into a diamond anvil cell for pressures up to 108 GPa. The XRS spectra of the Si $L_{2,3}$-edge are compared with ab-initio theoretical calculations based on the Bethe-Salpeter equation. Observations include an increase in coordination number from 4-fold to 12-fold and metallization. Additionally, changes in the occupation probability of d-states under pressure are noted, as silicon valence electrons from the 3s and 3p orbitals are transferred.

This work is supported by the BMBF projects 05K22PE2 and 05K22OF1. [1] J.S.Tse et al., J. Phys. Chem. C 118, 1161 (2014)

MM 9.4 Mon 18:30 P1

THz signatures of displacive phase transformation — •Nandita Bajpai[1], Michael Dittler[1], Ahana Bhattacharya[1], Alexander Kunzmann[2], Gabi Schierning[2], and Martin Mittendorff[1] — [1]Department of Physics , University of Duisburg — [2]Institute for energy and material process, University of Duisburg

Phase Change Materials are widely applied in contemporary technological advancements such as sensors, activators, and electronic devices. The Terahertz time-domain spectroscopy (THz-TDS) reflectivity and transmissivity measurements provide valuable insights into carrier dynamics such as mobility and carrier concentration. The temperature-induced phase change results in significant changes in reflectivity and transmissivity that are linked to the presence of free electrons.

Furthermore, the change in the complex conductivity points towards the predicted formation of a charge density wave (CDW) phase, which is a manifestation of periodic modulation of the electron density. This provides more details toward understanding the role of electrons in the phase transformation.

MM 9.5 Mon 18:30 P1

Impact of hyperthermal oxygen on alumina surfaces investigated by molecular dynamics simulations — •Stephen Hocker, Hansjörg Lipp, and Johannes Roth — Institut für Funktionelle Materie und Quantentechnologien, Universität Stuttgart

Oxygen atoms impinging on satellite surfaces in very low earth orbit (VLEO) transfer momentum and energy leading to material degradation as well as drag forces which result in orbital decay of the satellite. The first step in finding solutions to counteract significant drag is to gain understanding of the interaction of atomic oxygen (AO) with material surfaces. We investigate the adsorption rate and the angular distribution of reflected AO on crystalline and amorphous alumina surfaces using molecular dynamics simulations. It is found that the angular distribution depends strongly on the surface structure and the incidence angle. A higher ratio of specular reflection is found in case of smooth surfaces and large incidence angles.

MM 9.6 Mon 18:30 P1

Ultrafast phonon-mediated dephasing of color centers in hexagonal boron nitride probed by electron beams — •Masoud Taleb[1], Mario Hentschel[3], Harald Giessen[3], and Nahid Talebi[1,2] — [1]Institute of Experimental and Applied Physics, Kiel University, 24098 Kiel, Germany — [2]Kiel Nano, Surface and Interface Science KiNSIS, Kiel University, 24118 Kiel, Germany — [3]4th Physics Institute and Research Center SCoPE, University of Stuttgart, 70569 Stuttgart, Germany

Defect centers in hexagonal boron nitride (hBN) have gained significant interest as room-temperature single-photon sources, with strong coupling to phonons evident in their photoluminescence and cathodoluminescence spectra. Despite extensive studies, the electron-phonon coupling dynamics and phonon-mediated dephasing of these centers remain underexplored. In this study we experimentally employed an electron-driven photon source (EDPHS) to generate a coherent superposition of phonon states, with the delay between electron and photon pulses controlled to measure dephasing times. The findings reveal an ultrafast dephasing time of 200 fs and a radiative decay of 585 fs at room temperature, contradicting other optical techniques reporting a decay of a few nanoseconds. This rapid dephasing is attributed to the efficient excitation of coherent phonon-polaritons in hBN by electron beams. The research demonstrates the capability of sequential CL spectroscopy for probing the ultrafast dynamics of single emitters in quantum materials, facilitating future applications in quantum networks and devices.

MM 9.7 Mon 18:30 P1

Raman spectroscopic studies on $NiFe_2O_4$-NiO-Ni and MgO-Steel composites as inert anode materials for aluminium molten salt electrolysis — •Felix Drechsler[1], Ulziikhuu Otgonbayar[2], Cameliu Himcinschi[1], and Jens Kortus[1] — [1]TU Bergakademie Freiberg, Institute of Theoretical Physics, D-09599 Freiberg, Germany — [2]TU Bergakademie Freiberg, Institute of Nonferrous Metallurgy and Purest Materials, D-09599 Freiberg, Germany

The use of inert anodes in aluminium molten salt electrolysis offers positive environmental effects compared to the commercially used graphite anode, especially by avoiding CO, CO_2 and perfluorocarbon (PFC) emissions. Cermet anodes consisting of $NiFe_2O_4$, NiO, and Ni were manufactured by powder metallurgy and sintered at different conditions using the Spark Plasma Sintering (SPS) technique. Furthermore, another type of anode was produced using MgO and steel powder mixture to form metalloceramic composites. These anode materials were investigated by micro-Raman spectroscopy to identify phases formed during the sintering process, such as nickel ferrite spinels. Temperature-dependent Raman measurements were performed to examine the micro-structure behaviour of the anode materials at elevated temperatures.

MM 9.8 Mon 18:30 P1

Influence of the alloying elements on microchemistry and nanostructure of Sm-Co based permanent magnets — •Burçak Ekitli[1], Alex Aubert[1], Fernando Maccari[1], Nikita Polin[2], Xinren Chen[2], Esmaeil Adabifiroozjaei[3], Leopoldo Molina-Luna[3], Baptiste Gault[2], Konstantin Skokov[1], and Oliver Gutfleisch[1] — [1]Functional Materials, TU Darmstadt, 64287 Darmstadt, Germany — [2]Max-Planck-Institut for Sustainable Materials, Düsseldorf 40237, Germany — [3]Advanced Electron Microscopy, TU Darmstadt, 64287 Darmstadt, Germany

Sm-Co 2:17 magnets are high-temperature, high-performance magnets that are commercially available. Their hard magnetic properties are driven by a pinning mechanism, where the complex microstructure and microchemistry play an important role [1]. Since commercial 2:17 magnets consist of five alloying elements and three coherent phases, it is difficult to establish a common understanding of their intrinsic and extrinsic properties. In this study, we continue to investigate the 2:17 magnet system, focusing on a simplified alloy system that we initially introduced [2] by adding Cu to the alloy. Our study focuses on the quaternary Sm(Co,Cu,Zr)6.7 alloy, with four different compositions chosen based on varying Cu concentrations. We investigate the microstructural properties and their influence on the hysteresis of the Sm-Co 2:17 magnet in detail, using advanced characterization techniques such as MOKE, MFM, TEM, and APT. We reveal how Cu concentration influences the microstructure and phase formation, ultimately affecting the magnetic properties.

MM 9.9 Mon 18:30 P1

Bonding changes in solid nitrogen under high pressure — Gordon Scholz[1], Robin Sakrowski[1], Johannes Niskanen[2], Christoph Sahle[3], Leonie Tipp[4], Mirco Wahab[4], Melanie White[5], •Peter Schäfer[1], Ashkan Salamat[5], Sindy Fuhrmann[4], and Christian Sternemann[1] — [1]TU Dortmund, Dortmund, Germany — [2]University of Turku, Turku, Finland — [3]ESRF, Grenoble, France — [4]TU Bergakademie Freiberg, Freiberg, Germany — [5]University of Nevada Las Vegas, Las Vegas, USA

Nitrogen has a complex phase diagram with 15 detected solid molecular phases [1]. In this study, we tracked the electronic and structural changes of nitrogen under high pressure using a novel combined set-up for X-ray Raman scattering (XRS) and X-ray diffraction (XRD) at beamline ID20 at the ESRF exploiting the diamond anvil cell method.

In the pressure regime between ambient conditions and 80 GPa we are able to confirm the δ-phase, ϵ-phase and the ζ-phase with XRD. The corresponding XRS measurements at the nitrogen K-edge show significant changes in the bonding structure. These changes are interpreted via calculated XRS spectra based on molecular dynamic simulations which reveal a hindrance of free rotations of the N_2 molecules in the ϵ-phase.

This work is supported by the BMBF via the projects 05K22PE2 and 05K22OF1.

MM 9.10 Mon 18:30 P1

Grain boundary transformation induced by boron segregation — Xuyang Zhou[1], •Sourabh Kumar[2], Siyuan Zhang[1], Xinren Chen[1], Baptiste Gault[1], Gerhard Dehm[1], Tilmann Hickel[1,2], and Dierk Raabe[1] — [1]Max-Planck-Institut für Eisenforschung, Düsseldorf, 40237, Germany — [2]Bundesanstalt für Materialforschung und -prüfung (BAM), Berlin, 12489, Germany

The segregation of solute atoms at grain boundaries (GBs) critically influences the mechanical properties of materials, including corrosion resistance and fracture toughness. This study examines structural transformations induced by minimal boron concentrations at Σ13 GBs in ferrite thin films. Two sample protocols were investigated: one with carbon as the sole solute and the other with carbon and boron co-segregation. Using ab initio calculations, we meticulously explored the competing Σ13 GB phases coexisting with defects and analyzed the energetics of solute segregation at the GB interface. A defect phase diagram was constructed to illustrate the influence of B concentration on GB structure evolution. We reveal that B segregation transforms the GB structure from flat to zigzag trigonal prisms by forming new chemical bonds, enhancing B-Fe bonding strength by 5%. This transformation doubles steel's fracture resistance and provides valuable insights into solute-driven GB phase evolution, contributing to innovative strategies for designing durable, high-performance steel.

MM 9.11 Mon 18:30 P1

Investigation of spin-crossover iron triazole complexes with carbon nanotubes — •Niloofar Azadegan[1], Marvin Dzinnik[2], Maximilian Kilic[3], Franz Renz[4], and Rolf Haug[5] — [1]Institute of solid state physics, Hannover, Germany — [2]Institute of solid state physics, Hannover, Germany — [3]Institute of inorganic chemistry, Hannover, Germany — [4]Institute of inorganic chemistry, Hannover, Germany — [5]Institute of solid state physics, Hannover, Germany

Iron triazole complexes exhibit spin-crossover (SCO) behavior, transitioning between low-spin and high-spin states under external stimuli, making them suitable for sensing and memory applications.

This study investigates carbon nanotubes (CNTs) decorated with iron triazole to enhance electronic and magnetic properties. Current-voltage measurements were performed on bare and decorated CNTs, followed by cryostat measurements under controlled conditions. Preliminary results suggest interactions between SCO behavior and CNTs, with ongoing analysis to explore their potential in advanced electronics.

MM 9.12 Mon 18:30 P1

Linking Characteristic Length Scale in Nanoporous Gold to Alloy Composition and Dealloying Parameters — •Celina Passig[1,2], Jürgen Markmann[2,1], and Jörg Weissmüller[1,2] — [1]Institute of Materials Physics and Technology, Hamburg University of Technology, Germany — [2]Hybrid Materials Systems, Institute of Hydrogen Technology, Helmholtz-Zentrum Hereon, Geesthacht, Germany

Nanoporous metals display unique material properties due to their high volume-specific surface area and characteristic sizes of pores and ligaments. Although theories of structure formation exist, the process is not yet fully understood. Investigating nanoporous gold as model system will deepen the understanding of the underlying mechanisms, enabling a more precise manipulation of nanoporous structures and their mechanical and functional properties. Therefore, a series of small-angle X-ray scattering (SAXS) data was measured, comparing AuAg alloy compositions subjected to different dealloying potentials, durations, and electrolyte concentrations. Preliminary dependencies were formulated to investigate how these parameters influence the resulting characteristic length scale. This ex-situ and future in-situ analysis of microstructural evolution can be used to identify the underlying mechanisms by validating simulated results of the same dealloying processes, such as those presented by Li et al. [Acta Mater. 222 (2022) 117424.].

MM 9.13 Mon 18:30 P1

Inhomogeneities at different length scales in nanocrystalline Pd-Au prepared by inert gas condensation — Johannes Wild[1], Fabian Andorfer[4], Svetlana Korneychuk[1,2,3], Jules M. Dake[4], Torben Boll[1], Dorothée Vinga Szabó[1,2,3], Stefan Wagner[1], Carl E. Krill III[4], and •Astrid Pundt[1,2] — [1]Institute of Applied Materials (IAM-WK), Karlsruhe Institute of Technology — [2]Institute of Nanotechnology (INT), Karlsruhe Institute of Technology — [3]Karlsruhe Nano Micro Facility (KNMFi), Karlsruhe Institute of Technology — [4]Institute of Functional Nanosystems, Ulm University

Inert gas condensation (IGC) is currently the only viable method to prepare bulk samples of nanocrystalline (NC) palladium-gold (Pd-Au). The raw material is thermally evaporated in a vacuum chamber with a background pressure of 10e-8 mbar that has been backfilled with low-pressure inert gas. On collision with the inert gas, the evaporated material condenses into small particles, which are then collected on a rotating cold finger, scraped off and mechanically compacted into disk-shaped samples.

In this study, we investigate the different types of inhomogeneities in IGC Pd-Au on different length scales and compare them to samples prepared by arc melting. To this end, we apply a variety of methods to accurately characterize the composition, porosity, grain size, grain orientation and grain growth behaviour on multiple length scales. Finally, we attempt to explain the source of the inhomogeneities and verify by probing the IGC experimental setup via various experiments.

MM 9.14 Mon 18:30 P1

Development, Characterization and Catalytic Evaluation of New Nanosized metal complexes — •Tarek El-Dabea — Chemistry Department, Faculty of Science, King Salman International University, Ras Sudr, Sinai 46612, Egypt

A series of novel nano metal complexes involving Pd(II), Cu(II), Fe(III) and Ag(I) ions were synthesized using a Schiff base ligand in a bidentate coordination mode. The structural and molecular characteristics of these complexes were

thoroughly characterized via an array of spectroscopic and analytical techniques, confirming molecular geometry and stoichiometry. Solution stability and stoichiometry of the complexes were systematically evaluated, demonstrating stable metal-ligand coordination. Notably, the Pd(II) complex exhibited unique electronic characteristics, identifying it as a promising candidate for catalytic applications. Based on these results, the Pd(II) complex was tested as a catalyst for synthesizing Different multicomponent reactions. This was achieved through using microwave irradiation. The selection of Pd(II) was informed by its favorable catalytic profile and theoretical insights. Optimization trials demonstrated that the Pd(II) catalyst afforded high yield and efficiency under eco-friendly (H*O/EtOH) solvent conditions. Reusability assessments showed that the catalyst retained high activity for up to five cycles, with minimal performance decline afterward. A mechanistic pathway was proposed, highlighting Pd(II)'s ability for axial coordination, supported by theoretical evidence

MM 9.15 Mon 18:30 P1

Epitaxial Stabilization of Multifunctional Oxide, Oxynitride, and Telluride Thin Films using a Hybrid Pulsed Laser Deposition Technique — Pia Henning, Anna Tschesche, Shagun Thakur, Niklas Kohlrautz, Abhishek Sharma, Laura Pflügl, and •Jasnamol Palakkal — Institute of Materials Physics, Georg-August-University of Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

Materials science uses state-of-the-art thin film techniques, such as pulsed laser deposition (PLD) and molecular beam epitaxy (MBE), to artificially fabricate complex materials [1]. Epitaxial films with controlled defects and orientation are practical for modifying functionalities. We developed a hybrid PLD system attaching molecular beam sources (for elements with high vapor pressure) to fabricate multifunctional oxide, oxynitride, and tellurides. Additionally, gases are provided through a microplasma source. This setup makes a wide range of cation and anion engineering possible in complex materials. In this presentation, we will address challenges in the growth of thin films and how modifications in the defects and structure influence functional properties by taking examples of La_2NiMnO_6 (ordered magnetism and electrocatalysis), Cr_xTe (ferromagnetism and magnetic anisotropy), and $SrNbO_3$ (optical transparency and metallic conduction). Moreover, we will discuss how such a hybrid deposition system can be utilized to grow high-entropy materials and stabilize doping beyond the solubility limit. [1] A. Tschesche, et al., Preprint on Research Square, https://doi.org/10.21203/rs.3.rs-4861088/v1

MM 9.16 Mon 18:30 P1

EXAFS-driven Investigation of ZnO-Mn2O3 and ZnO-Mn2O3-rGO Nanocomposites: Unraveling Structural, Optical, and Electronic Properties — •Shaimaa A. Habib[1], Shehab E. Ali[2], Messaoud Harfouche[3], and Ahmed Awad[4] — [1]1.*Physics Department, Faculty of Science, Damnhour University, Damanhour 22516, Egypt — [2]Materials Science Laboratory, Physics Department, Faculty of Science, Suez Canal University, 41522, Ismailia, Egypt. — [3]SESAME (Synchrotron-light for Experimental Science and Applications in the Middle East), Allan, Jordan — [4]Physics Department, Faculty of Science, Tanta University, Tanta 31527, Egypt

The structural, optical, and electronic properties of ZnO-Mn2O3 and ZnO-Mn2O3-rGO nanocomposites were investigated. The materials, synthesized via sol-gel and self-propagation methods, exhibited porous structures with crystallite sizes of 22-48 nm, as confirmed by XRD and SEM analyses. UV-Vis spectroscopy revealed that rGO incorporation reduced the optical bandgap from 2.63 eV to 1.86 eV and increased the Urbach energy from 1.91 eV to 2.55 eV. The Wemple-DiDomenico model showed a decrease in oscillator resonance energy from 6.64 eV to 6.15 eV and an increase in dispersion energy from 6.47 eV to 13.24 eV. EXAFS and XANES studies at SESAME synchrotron facility provided insights into the coordination environment and electronic structure of the metal centers. This comprehensive characterization establishes a foundation for applying these nanocomposites in optoelectronics, photocatalysis, and energy conversion applications, highlighting rGO's role in enhancing composite performance.

MM 9.17 Mon 18:30 P1

Electrochemical determination of the diffusion coefficient of intercalating species in host metals - conditions of applicability of potential step chronoamperometry — •Magdalena Seiler, Giorgia Guardi, Stefan Wagner, and Astrid Pundt — KIT, Karlsruhe, Deutschland

The diffusion coefficient is generally used to describe the diffusion of intercalating species such as lithium and hydrogen in host metals. It can be determined by a variety of methods, including electrochemical methods. Among these, permeation methods between front and back side of a sample are widely used. On the contrary, in potential step chronoamperometry only one side of the sample needs to be contacted, which is e.g. beneficial for thin film studies. In this work measurements using both methods are performed for hydrogen in palladium and compared to the literature. It is shown that the application of the potential step chronoamperometry approach gives correct results only under very specific restrictions regarding sample thickness and measurement period.

MM 9.18 Mon 18:30 P1

Synthesis, and Characterization of Li/Mn-Excess Cathode Materials for Li-ion Batteries. — •John Karuga[1], Mesfin Kebede[2], and Guido Schmitz[3] — [1]Institute of Materials Science, Department for Material Physics, University of Stuttgart — [2]Institute of Nanotechnology and Water Sustainability, College of Science, Engineering and Technology, University of South Africa — [3]Institute of Materials Science, Department for Material Physics, University of Stuttgart

The study aims to mitigate O2 evolution, spinel phase, and unstable CEI formation common in Li/Mn-excess cathodes. The poster presents preliminary results of the pristine Li/Mn-excess cathodes, which are practical alternatives to LFP, NCA, and Ni-excess materials for high-performance Li-ion batteries. The Li2MnO3 phase in Li/Mn-excess cathodes stabilizes the crystal structure, contributes to the higher discharge capacities >250 mAh/g. Commercialization of Li/Mn-excess materials remains challenging due to undesired transformation from layered to spinel phase, O2 evolution, parasitic reactions with the LiPF6 electrolyte. The Li/Mn excess materials were prepared via solid-state synthesis. Characterization with SEM-EDS, Raman, HR-TEM, and XRD confirmed the development of a material of uniform nano-crystallites with well-layered structure and 0.472 and 0.2 nm interplanar distances, which correspond to the 003 and 104 planes. The CV analysis confirms that the redox reactions (Ni2+/Ni4+; Co3+/Co4+; Mn3+/Mn4+/5+/7+) are highly reversible. The charge transfer resistance is low, indicative of better Li+ diffusion and stable CEI.

MM 9.19 Mon 18:30 P1

Magnetic anisotropy and anomalous Nernst effect in cubic Fe4N films — •Karel Knížek[1], Jakub Vít[1], Mariia Pashchenko[1], Petr Levinský[1], Kyo-Hoon Ahn[1], Jaroslav Kohout[2], and Imants Dirba[3] — [1]Institute of Physics, Czech Academy of Sciences, Prague, Czechia — [2]Faculty of Mathematics and Physics, Charles University, Prague, Czechia — [3]Functional Materials, Institute of Materials Science, Technical University of Darmstadt, Germany

Iron nitrides Fe(x)N are commercially important compounds because of their versatile magnetic, electrical, and mechanical properties. We have studied magnetic and transverse thermoelectric properties of Fe(4)N films prepared by magnetic sputtering. The well-known anisotropic magnetoresistance [1] and rectangular magnetization curves for thin oriented films led us to investigate magnetic anisotropy by rotating the sample in external magnetic field and measuring magnetization along the field. The signal is complex, exhibiting harmonics beyond the expected crystal symmetry. Moreover, the magnetic-field history crucially impacts the anisotropy. The results are quite distinct below and above the metamagnetic phase transition near 50K. The results of the magnetic measurements are compared with anomalous Nernst effect experiments and DFT calculations.

[1] M. Tsunoda et al., Applied Physics Express 2, 083001 (2009).

MM 9.20 Mon 18:30 P1

Thermoelectricity in Bi-directionally Strained $CsSnI_3$ Perovskite — •Michele Reticcioli[1], Mariangela Ruggeri[2], Giovanna D'Angelo[2], and Alessandro Stroppa[1] — [1]CNR-SPIN L'Aquila, Italy — [2]Università degli Studi di Messina, Italy

Thermoelectric materials play a pivotal role in energy sustainability, converting waste heat into electricity without moving parts or emissions. Recent advances spotlight metal halide perovskites, such as $CsSnI_3$, as promising candidates for eco-friendly thermoelectric applications due to their low thermal conductivity and high electrical efficiency. In this work, we explore the influence of bidirectional strain on the orthorhombic gamma-phase of $CsSnI_3$ using density functional theory (DFT), complemented by experimental insights from our collaborators. Strain effects, ubiquitous in thin films grown on mismatched substrates, are known to modify electronic structures and transport properties. Our findings reveal a peculiar dependence of the bandgap on strain direction and intensity. These changes directly impact the thermoelectric properties, including the Seebeck coefficient and figure of merit, emphasizing the interplay between strain-induced electronic modulation and thermoelectric performance. This study contributes to the growing understanding of strain effects in perovskites, offering valuable insights into their potential for thermoelectric applications.

MM 9.21 Mon 18:30 P1

GAP vs. MACE: Efficiency evaluation in a liquid electrolyte system — •Anton Beiersdorfer[1], Lisa Hetzel[1], Carsten Staacke[2], Florian Deissenbeck[2], and Christopher Stein[1] — [1]Technische Universität München, München, Germany — [2]Cellforce Group GmbH, Tübingen, Germany

Machine learning interatomic potentials (MLIP) have transformed molecular simulations, enabling complex materials to be modeled with increasing accuracy and efficiency. As MLIP models evolve, so does the demand for advanced computing architectures, particularly graphics processing units (GPUs), which can accelerate computations compared to traditional central processing unit (CPU) based systems. However, the high cost associated with GPU resources constrain access in both academia and industry, highlighting the relevance of comparing GPU-based and CPU-based MLIPs under real-world conditions.

To this end two popular MLIPs are examined: the GPU-accelerated MACE model and the CPU-based GAP model applied to a test system of a standard

battery electrolyte. The system is selected for its demanding electrostatic interactions in solution, which the MLIPs approximate by learning the local interaction patterns that contribute to the overall electrostatic behavior. Therefore, it represents a significant computational challenge and provides a rigorous benchmark for MLIP accuracy and efficiency. By focusing on these models, the study aims to reveal key differences in computational and numerical performance metrics and resource efficiency as well as in physical performance, particularly through comparisons to experimentally measured properties.

MM 9.22 Mon 18:30 P1

Navigating the Latent Space of Chemical Solid State Reactions in Hybrid Battery Interfaces — •Sina Ziegler, Christoph Scheurer, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin

We explore the potential of rare earth lithium halides as a material-efficient, nanometer-thick cathode coating in contact with thiophosphate electrolytes. Traditional theoretical approaches, such as molecular dynamics (MD) and Monte Carlo (MC) simulations, are computationally intensive for larger systems, posing a challenge in simulating battery interfaces. To identify a suitable halide/thiophosphate combination, it is essential to determine an energetically feasible solid-state reaction pathway within the multidimensional phase diagram of these materials. We employ *ab initio* thermodynamics to assess the thermodynamic stabilities of the resulting solid-state electrolyte (SSE) and halide interfaces by screening the reaction-free enthalpies of potential interface reactions. An end-member analysis is then performed to evaluate possible compositions of interface products and secondary phases, using techniques such as Principal Component Analysis (PCA), t-distributed Stochastic Neighbor Embedding (t-SNE), and autoencoders to identify linked reactions within the chemical latent space.

MM 9.23 Mon 18:30 P1

Structure and transport properties of Li3MCl6 superionic conductors — •Ziyan Zhang[1,2], Peter Müller-Buschbaum[1], and Anatoliy Senyshyn[2] — [1]Chair for Functional Materials,School of Natural Sciences, Technical University of Munich,85748 Garching, Germany — [2]Heinz Maier-Leibnitz Zentrum, Technical University of Munich, 85748 Garching, Germany

Modern society permanently requires more advanced, better performant, safer, and cost-effective energy storage solutions, where the all-solid-state battery (ASSB) concept based on lithium metal is closest to commercialization. Solid electrolytes are a key component of ASSB, defining its lifetime and performance. Halide-based solid electrolytes Li3MCl6 (M = transition metals, rare-earth metals) are emerging as promising materials for all-solid-state batteries due to their high ionic conductivity, electrochemical stability, and compatibility with lithium metal anodes. The current study deals with the systematic characterization of Li3MCl6 solid conductors with M = In, Zr, and Ti transition elements. The focus will be put on the optimization of synthesis routes (between solvent-mediated and mechanochemistry), composition control as well as enhancement of ionic transport. Comprehensive structural characterization, encompassing lab X-ray diffraction (XRD) with Rietveld refinement combined with differential bond-valence estimates of lithium diffusion pathways and differential scanning calorimetry, is performed to reveal the crystallographic details, microstructure, and lithium-ion dynamics.

MM 9.24 Mon 18:30 P1

Processing of non-conductive materials by electroerosion treatment. — •Anton Bespalov — Moscow, Russia

Electroerosion processes process only conductive materials, but it is possible to process non-conductive materials by applying a thin layer of metal to their surface. In this work, based on experiments, the possibility of destruction (processing) of tungsten carbide coated with a layer of 0.01 mm copper with a copper electrode using electric erosion machines is considered. As a result of the experiments, the destruction in the samples corresponding to the shape of the electrode was revealed, which proves the possibility of processing.

MM 9.25 Mon 18:30 P1

Structure formation and phase behavior of amine-water mixtures — •Lena Friedrich[1], Michael Paulus[1], Aurélien Perera[2], Martina Požar[3], Dirk Lützenkirchen-Hecht[4], Nicola Thiering[1], Jaqueline Savelkouls[1], and Christian Sternemann[1] — [1]Fakultät Physik / DELTA, Technische Universität, 44221 Dortmund, Germany — [2]Sorbonne Université, Laboratoire de Physique Théorique de la Matière Condensée, F75252, Paris cedex 05, France; — [3]University of Split, Faculty of Science, 21000 Split, Croatia — [4]Fakultät für Mathematik und Naturwissenschaften, Bergische Universität Wuppertal, 42097 Wuppertal, Germany

Amines are associating liquids that can form transient supramolecular structures via hydrogen bonding [1]. Adding of water can significantly alter the liquids' structure [2] and amine/water mixtures show an interesting phase behavior exhibiting a lower critical solution temperature (LCST) [3]. We studied linear, primary amines mixed with various proportions of water for a variety of temperatures by X-ray diffraction at BL8 and BL9 of DELTA (TU Dortmund). The structure factor prepeak shows a peculiar concentration and temperature dependence which resembles the different phase regimes ranging from disordered nematic via single liquid to two liquid phase. We thank the BMBF for funding via DAAD in the scope of the French-German collaboration PROCOPE 2024-2025 (Project-IDs 57704875 and 50951YA). [1] A. Perera et al., JPC B 44, 128 (2024). [2] L. MM 9.26 Mon 18:30 P1

A Phase Change Material's Journey through its Energy Landscape — •Jakob Ballmaier, Sebastian Walfort, Elias Abele, and Martin Salinga — Universität Münster, Institut für Materialphysik

The concept of energy landscapes is highly successful in explaining structural dynamics of supercooled liquids and glasses. Locally stable configurations correspond to local minima of the total potential energy of the system in the high-dimensional phase space. During physical aging a glass can evolve towards lower local minima through a series of saddle points. Experimental observation of this is challenging, since in large systems several saddle points are passed within the shortest resolvable timescales.

Here, we track paths through the energy landscape of a nanoscopic volume of germanium telluride by following the temporal evolution of its electrical resistance. Two regimes turn out to be especially instructive: fast measurements of the resistance immediately after the formation of the glass as well as slower measurements at low temperatures, where the influence of individual relaxation steps on the resistance can be resolved.

MM 9.27 Mon 18:30 P1

Graphite Composites with Titanium as a Secondary Filler - Microstructure and Electronics — •Hoang Thinh Nguyen, Maria Gaudig, and Ralf Wehrspohn — Martin Luther University Halle-Wittenberg, Institute of Physics, Group μMD, Heinrich-Damerow-Str. 4, 06120 Halle (Saale), Germany

The bipolar plate (BPP) is a crucial component in electrolyzers and fuel cell stacks, serving to separate individual electrochemical cells while ensuring electrical conductivity, water distribution, and mechanical stability. However, the high costs associated with conventional materials like titanium or stainless steel demand the exploration of novel materials and fabrication methods. Graphite-based composites have already emerged as cost-effective alternatives for BPPs. In this work, we developed and characterized an innovative composite material that combines the high electrical conductivity of titanium with the affordability and lamellar structure of graphite to create titaniumgraphite composites. Microstructural analyses using scanning electron microscopy (SEM) and nano X-ray computed tomography revealed that titanium particles integrate gapless into the graphite matrix, enhancing the creation of continuous conductive pathways. Electrical conductivity measurements revealed interesting dependencies on filler composition: depending on the filler ratio, either titanium or graphite becomes the dominant contributor to the overall conductivity. These findings highlight the interrelation between particle morphology, structure, and filler ratio in optimizing the composite matrix for BPP applications.

MM 9.28 Mon 18:30 P1

Mesoporous Ti and TiCu network structures prepared by liquid metal dealloying — •Niklas Österle, Markus Ziehmer, Fabian Andorfer, and Carl E. Krill III — Institute of Functional Nanosystems, Ulm University, Germany

Metallic open-cell foams have emerged as promising functional and structural materials. The use of Ti and TiCu would extend the application of such foams into the medical field, as both materials are highly biocompatible, making them excellent choices for implants and prostheses. Combined with the porous structure of metallic foams, which facilitates the infiltration and adhesion of bone cells, the functionality and performance of prosthetic devices could be significantly improved.

In this work, we present the fabrication of mesoporous Ti and TiCu network structures via liquid metal dealloying. This technique enables the selective removal of Cu from TiCu precursor alloys within a Mg melt to form mesoporous structures. By varying the Mg-to-precursor mass ratio, we show that the chemical composition and morphology of the final network can be tailored. The network structure and morphology were investigated using 2D and 3D imaging, and EDS and XRD were employed for phase analysis. Various morphological structures can be linked to specific compounds in the TiCu phase diagram. Future investigations will focus on post-dealloying thermal coarsening.

MM 9.29 Mon 18:30 P1

Role of trace elements on the GP-Zone formation Al-Cu alloys — •Sandra Müller, Isidor Switalla, Johannes Berlin, and Ferdinand Haider — Chair for Experimental Physics I, University of Augsburg, Universitätsstraße 1, 86159 Augsbur

Both formation and dissolution of Guinier-Preston zones in Al-Cu alloys depend on the presence of excess vacancies. They are quenched in from the high temperature homogenisation treatment but will possibly disappear during the natural aging at ambient temperature. The lifetime of excess vacancies in pure

Aluminium is much shorter than that in Al-Cu alloys, where vacancies presumably are trapped in GP zones. Therefore, a small increase in temperature can lead to drastic changes in the microstructure of these materials by releasing the trapped vacancies. Resistometry is a simple online method to monitor changes in the microstructure of a metallic alloy, complemented by DSC and hardness measurement.In this work we focused on natural and slightly above room temperature artificial ageing of Al-Cu samples containing 2 - 4 wt.% of Cu. DSC gives rather clear evidence that precursor cluster of only very few atoms form before the GP-zones are detected. Those precursors and the GP zones formation can be suppressed or delayed by minor addition of vacancy-binding trace elements like Tin and Indium.

MM 9.30 Mon 18:30 P1

Irradiation Induced Defects in W-Re Alloys Studied by Positron Annihilation Spectroscopy — •Lisa-Marie Krug[1], Danny Russell[1], Maximilian Suhr[1], Leon Chryssos[1], Lucian Mathes[1], Mikhail Zibrov[2], Thomas Schwarz-Selinger[2], and Christoph Hugenschmidt[1] — [1]Heinz Maier-Leibnitz Zentrum (MLZ), Technische Universität München, 85748 Garching, Germany — [2]Max Planck Institute for Plasma Physics, 85748 Garching, Germany

The plasma-facing components in a fusion reactor have to withstand the irradiation of 14 MeV neutrons, which are released in the fusion reaction of deuterium and trithium. Tungsten is considered to be the most suitable plasma-facing material, due to its high melting point, high thermal conductivity and low erosion under fusion reactor operating conditions. In addition to radiation damage, neutron irradiation of tungsten creates transmutation elements such as rhenium. In this work, the effect of rhenium on the defect characteristics in self-ion irradiated tungsten is investigated. Self-ion irradiation is used to mimic the radiation damage caused by 14 MeV neutrons. Positron annihilation spectroscopy is used to provide non destructive, atomic scale resolution measurement of the irradiation damage. Coincidence Doppler broadening spectroscopy of the 511 keV annihilation line is used to provide element sensitive measurements of vacancy type defects. This allows us to test theoretical predictions that rhenium precipitates around voids.

MM 9.31 Mon 18:30 P1

Phases of AlN by machine learning potentials — •Simon Liebing, Oliver Heymer, and Jens Kortus — Institute of Theoretical Physics, TU Bergakademie Freiberg, Germany

AlN is an important wide-band gap semiconductor with e.g. applications in high power electronics. Under high pressure (about 13 GPa) the wurtzite phase transforms to the rocksalt phase. Here, we attempt to simulate this phase transition as function of temperature and pressure by means of machine learned interatomic potentials trained on accurate density functional theory molecular dynamics data. In particular we will utilize use the open-source library FitSNAP [1] for atomistic machine learning in combination with the molecular dynamics code LAMMPS [2]. FitSNAP is used to provide fast interaction potentials with accuracy inherited from DFT. It already provides interfaces for popular open-source codes such as Quantum ESPRESSO[3], PyTorch and LAMMPS and it supports the state-of-the-art atomic cluster expansion (ACE) descriptors [4]. The ACE descriptors transform structural information into machine learning models. This enables us to carry out large-scale classical MD systems of AlN with thou- sands of atoms with DFT accuracy. The results will be compared to earlier works based on small unit cells using density functional theory. [5] References [1] Rohskopf et al., Journal of Open Source Software, 8 (84), 5118 (2023). MM 9.32 Mon 18:30 P1

Brittle to Ductile: Elasticity and Bonding in TiVN Hard Alloys — •Santiago Gómez, Ferenc Tasnadi, Magnus Odén, and Igor A. Abrikosov — Department of Physics, Chemistry and Biology (IFM), Linköping University, Linköping, 58183 Sweden

Hard alloys find extensive applications, such as in coating metal-cutting tools and turbine protective layers, among others. Despite the availability of effective alloys in the market, most remain intrinsically brittle. A critical aspect of alloy engineering is, therefore, the systematic exploration of hard but more ductile alloys with improved fracture toughness.

The low temperature dynamical instability of VN suggest an alloying pathway to improve the ductility of TiN. The idea has been realized by supporting experiments using micro-pillar fracture analysis. In this study, we are searching for novel materials descriptors to gain a better understanding of brittle and ductile behavior, all in an ideal sense suitable for modern data-driven materials science powered by Density Functional Theory (DFT) calculations.

Our findings reveal composition-dependent variations in elastic moduli and anisotropy. Brittle to ductile behavior transition is predicted when a certain composition of Vanadium is reached. Chemical bonding analysis, employing the Quantum Theory of Atoms in Molecules (QTAIM), provide insights into the electronic structure, highlighting trends in bond critical point densities and virial ratios for first-neighbor interactions. These results are contextualized against analogous systems such as $Ti_xAl_{1-x}N$, providing a comparative framework.

MM 9.33 Mon 18:30 P1

Modeling dislocation motion in aluminium alloys by DFT — Inna Plyushchay[1,2], Anna Pliushchai[2,3], Nebahat Bulut[2], Zhengqing Wei[2], and •Sibylle Gemming[2,4] — [1]Natl. Taras Shevchenko University of Kyiv, Ukraine. — [2]Inst. Physics, TU Chemnitz, Germany — [3]Natl. TU of Ukraine, Igor Sikorsky Kyiv Polytechnic Inst., Ukraine — [4]MAIN Center, TU Chemnitz, Germany.

Measured elastic moduli of bulk metals differ from the ideal theoretical values due to the presence of point and line defects as well as grain boundaries, and their joint action has successfully been studied by atomistic simulations. For low-doped alloys with additional elements in small quantities, a plethora of further interactions is obtained, whose classical description is hampered by the lack of suitable potentials for the interaction between different elements. We therefore employ first-principles calculations to determine the dopant-induced electronic structure change in and around the core region of the Shockley partial dislocation in Aluminium as a prototype fcc metal with substitutional Mg, Zr, and Si atoms as dopants. The results indicate that the radius of the first coordination sphere changes within a range of few percent and that all discernible changes in electron density are localized within the first coordination sphere of the impurity. A tendency for the formation of aluminide precipitates is obtained, which may nucleate at 0D, 1D, or 2D defect sites and stabilize local structure motifs which would not be formed in the unperturbed bulk phase.

MM 9.34 Mon 18:30 P1

Generalized susceptibility expressed by Wannier functions — •Dominik Váňa and Jaroslav Hamrle — Faculty of Nuclear Sciences and Physical Engineering, Czech Technical University, Prague

The generalized susceptibility describes the tendency (energy stability) of the cubic phase to become modulated. A typical example is the modulation of Ni_2MnGa [1] which can undergo structural transformation from austenite to a modulated structure. The generalized susceptibility is calculated using occupation probability (Fermi-Dirac distribution), however, this approach omits the dependence which the coupling coefficient of the electron-lattice interaction has on electronic states. The goal of this work is to express generalized susceptibility with calculated coupling coefficients. As the first step, we express generalized susceptibility using Wannier functions, modifying the original approach of Motizuki [2], based on a linear combination of atomic orbitals.

MM 9.35 Mon 18:30 P1

First-principles insight into the role of electronic band filling on thermodynamic stability and mechanical properties of tantalum-diboride-based solid solutions — •Annop Ektarawong[1], Kunpot Mopoung[1], Chayanon Atthapak[1], Thiti Bovornratanaraks[1], and Björn Alling[2] — [1]Chulalongkorn University, Bangkok, Thailand — [2]Linköping University, Linköping, Sweden

Owing to their superior stabilities and mechanical behaviors at high temperature, AlB_2-type metal diborides have increasingly been considered as promising hard and protective coating materials for cutting tools. In this presentation, we theoretically demonstrate how the thermodynamic stability and mechanical properties of metal diborides can feasibly be improved either through the presence of structural defects beyond the dilute limit or through the alloying process, focusing particularly on tantalum diboride. Our first-principles studies reveal the significant enhancement of the stability, stiffness, shear strength, and hardness of the diboride can directly be interpreted in terms of electronic band filling of the bonding and antibonding states of the material.

MM 9.36 Mon 18:30 P1

Unveiling the Origin of the Yield Stress Anomaly in L12 Intermetallics via Atomistic Approaches — •Xiang Xu, Xi Zhang, and Blazej Grabowski — University of Stuttgart, Stuttgart, Germany

We present an approach to studying the yield stress anomaly (YSA) in L12 intermetallics by bridging the electronic scale with large-scale molecular dynamics simulations, using machine-learning-based interatomic potentials. An ab initio database of temperature-dependent Gibbs energy for relevant planar defects in L12 Ni3Al was developed, covering the full temperature range of the YSA. Machine-learning interatomic potentials for Ni3Al, trained through a physically informed active-learning scheme, achieved accuracy comparable to DFT data and successfully modeled key dislocation behaviors in million-atom models. These MD results enabled the development of a phenomenological model that effectively explains YSA characteristics, offering new insights into the high-temperature performance of L12-strengthened high-entropy alloys.

MM 9.37 Mon 18:30 P1

Modelling and Descriptor-based Synthesizability Analysis of High-Entropy Materials — •Chen-Chen Er[1] and Rico Friedrich[1,2,3] — [1]TU Dresden — [2]Helmholtz-Zentrum Dresden-Rossendorf, Dresden — [3]Duke University, Durham, USA

High-entropy materials (HEMs) are single-phase multi-component disordered systems with unique electronic and thermal properties that are promising for applications in the energy and electronics sectors. HEMs include disordered ceramics such as carbides, nitrides, or oxides with ordered anion sublattices and disorder on the cation sites. There are typically five or more cation species to maximize configurational entropy.

Efficient modelling of the disordered systems is conducted based on an ensemble of supercells approach as implemented in the partial occupation algorithm (POCC) [1] within the AFLOW framework [2,3]. Predictive descriptors including the entropy forming ability (EFA) [4] and disordered enthalpy-entropy descriptor (DEED) [5] are crucial to assess synthesizability. Here, we present results for several high-entropy ceramics, including their electronic properties and synthesizability.

An extended two-temperature model for copper — •Simon Kümmel and Johannes Roth — FMQ, University of Stuttgart, Germany

Since its introduction, the two-temperature model (TTM) has been a very powerful tool used to simulate material under strong electronic excitation following strong laser irradiation by coupled heat conduction equations for the electronic and lattice system.

Here, we present an implementation of the TTM, coupled to a molecular dynamics code, in which the heat capacity, the heat conduction, electron-phonon coupling parameter depend on the degree of excitation. We extend this model by also including an interatomic potential that depends on the degree of excitation and is capable of reproducing non-thermal effects predicted by electron temperature-dependent density functional theory calculations.

We investigate the influence and importance of each parameter in a case study applied to copper and compare our findings to experimental investigations.

MM 9.39 Mon 18:30 P1

Exploring Ionic Diffusion and Heat Transport Mechanisms in NASICON Materials: A Molecular Dynamics Study — •Insa F. de Vries and Nikos L. Doltsinis — Institute of Solid State Theory, University of Münster, Wilhelm-Klemm-Straße 10, 48149 Münster

In recent years, sodium-ion batteries have emerged as both a potential replacement and a complement to traditional lithium-ion based energy storage systems [1]. However, ensuring the safety and reliability of any future battery system requires a controlled modelling and a thorough understanding of the thermal conduction characteristics, especially with respect to preventing overheating during operation.

Our study uses molecular dynamics calculations on members of the $Na_{1+x}Zr_2Si_xP_{3-x}O_{12}$ family with different stochiometries (x=2.6, 3.4 and 3.8). For each stochiometry we use different cell geometries characterised by an order parameter. In order to reveal the influence of the sodium ion mobility on the heat transport, we calculate key transport properties, namely the sodium diffusion coefficient and the thermal conductivity. We start from a pre-established interatomic potential [2] and calculate the thermal conductivity using a Green-Kubo approach. We find that it peaks for the compounds with x = 3.4. Increased diffusion caused by small variations in the parameterisation of the sodium-oxygen interaction leads to simultaneous, equally directed changes in the thermal conductivity.

MM 9.40 Mon 18:30 P1

Semiclassical transport in multiple Weyl points — •Ricardo Barbosa, Stuart Parkin, and Annika Johansson — Max Planck Institute of Microstructure Physics, Weinberg 2, 06120 Halle (Saale), Germany

We investigate transport contributions[1,2] in three-dimensional materials exhibiting multiple Weyl nodes[2,3], which are linear band touchings acting as point-like sources and sinks of Berry curvature in momentum space, often referred to as "Weyl-Berry monopoles". Specifically, we analyze the transport properties of CoSi[4,5], a chiral topologically nontrivial semimetal with band-touching points of higher-than-two-fold degeneracy and nonzero Chern numbers. Notably, at the Γ and R points, the band-touching nodes are four- and six-fold degenerate, respectively, with Chern numbers up to ±4. Using the Boltzmann transport equation[6], we investigate how these features give rise to unconventional electronic properties, focusing on the corresponding charge and node conductivities.

A novel technique for measuring 3D thermal conductivity of carbon paper — •Oliver Roser[1], Achour Mahfoudi[1], Cornelius Hahn[1], and Andreas Griesinger[1,2] — [1]Center for Heat Management (ZFW), Stuttgart — [2]Baden-Wuerttemberg Cooperative State University (DHBW), Stuttgart

Gas diffusion layers based on carbon paper are used in various types of fuel cells. They make a significant contribution to dissipating the heat loss generated in the catalyst layers and homogenizing the temperature field. The material structure causes strongly direction-dependent thermal conductivities. It is not possible to determine the direction-dependent thermal conductivity under operating boundary conditions using existing methods. We present a newly developed technique with which thermal conductivity can be determined in all spatial directions. Measurements of thermal conductivity in the sample plane are carried out under steady-state boundary conditions. When measuring thermal conductivity through the sample plane, we use a transient measurement approach. The apparatus developed for this purpose and its components are presented. We show how to set and control the application-related boundary conditions such as temperature, surface pressure, moisture content and filling gas. The thermal measurements and evaluation strategies are presented, and the achievable accuracy of the method is discussed. Finally, we show initial measurement results that demonstrate a significant impact of direction, temperature and moisture content on thermal conductivity of gas diffusion layers, depending on the material structure.

MM 9.42 Mon 18:30 P1

Low-temperature thermal conductivity of $YAlO_3$ and $YbAlO_3$ — Parisa Mokhtari[1,2,3], •Ulrike Stockert[3], Stanislav Nikitin[4], Leonid Vasylechko[5], Manuel Brando[2], and Elena Hassinger[3,2] — [1]Department of Physics, Technical University of Munich, 85748 Garching, Germany — [2]Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany — [3]Faculty of Physics, Technische Universität Dresden, 01062 Dresden, Germany — [4]PSI Center for Neutron and Muon Sciences, 5232 Villigen PSI, Switzerland — [5]Lviv Polytechnic National University, Lviv 79013, Ukraine

$YAlO_3$ is a popular substrate, laser, and scintillator material used at temperatures down to those of liquid helium. A good thermal conductivity is required for many applications for instance to facilitate energy release in lasers or thermal coupling via substrates.

We present for the first time thermal conductivity data on $YAlO_3$ below 80 K, covering the T range from 2 K to 300 K. In addition, we have studied the thermal conductivity of YbAlO3 in the temperature window from 50 K to 300 K. Both materials are very good thermal conductors. The thermal transport in these electrical insulators is phononic and can be fitted by the Callaway model. We discuss our results with respect to the relevance of different scattering processes, the origin of the thermal conductivity anisotropy, and the influence of Y-Yb exchange on the thermal transport. Our results on $YAlO_3$ confirm the suitability of the material for applications requiring a low thermal resistance at temperatures down to liquid He.

MM 9.43 Mon 18:30 P1

(Very) high-temperature physics of selected Planckian metals — •Zuzanna Helena Filipiak[1,2] and Andrew P. Mackenzie[1,2] — [1]Max-Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]Scottish Universities Physics Alliance, School of Physics and Astronomy, University of St Andrews, United Kingdom

Planckian dissipation is the mysterious phenomenon of an almost universal saturation of the electron scattering rate in many condensed matter systems despite their vastly different microscopics and strengths of electron interactions. In crystalline samples, the Planckian temperature dependence of resistivity is referred to as strange metallicity in the low-temperature regime and bad metallicity if the behaviour continues to high temperatures. Despite interest in such materials because of their unique physics, their high-temperature characteristics continues to be understudied. We developed two setups in which resistivity of a metallic sample is measured as a function of temperature (ranging from 2 to 1000 K), magnetic field (up to 12 T) and atmosphere (oxygen-rich, argon, high vacuum). Our results for selected single-crystal and thin-film samples of metallic delafossites, nickelates and ruthenates, incl. ruthenium dioxide, will be presented.

MM 9.44 Mon 18:30 P1

Fitting Tensorial Properties with MACE: a Study of $Li_2Ti_5O_{12}$ Electric Field Gradient Tensors — Elena Gelzinyte[1], Karsten Reuter[1], Christian Carbogno[1], and •Johannes T. Margraf[2] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]University of Bayreuth

Machine learning interatomic potentials, which serve as surrogate models for predicting a structure's energy and forces, have significantly accelerated atomistic simulations. Equivalent approaches have been applied to predict other structural or atomic properties, such as charges, dipole moments, and polarisabilities. One such framework is MACE, a higher-order equivariant neural network [1]. Due to the way its internal features are constructed, the output part of the model may be readily modified to suit the symmetry of the target property. In this presentation, we discuss the required modifications for fitting atomic tensorial quantities and the resulting model's applicability, limitations, and advantages. For illustration, we focus on the prediction of electric field gradient tensors (a per-atom traceless symmetric tensor) using a $Li_2Ti_5O_{12}$ data set [2]. We consider the improvement in fitting the tensorial properties directly, rather than derived scalar properties, and compare the modified MACE's results with those of λ-SOAP [3], discussed in [2].

MM 9.45 Mon 18:30 P1

First-Principles Analysis of Spin-Disorder Resistivity and Its Temperature Dependence — •Fabian Engelke, Felix Schug, Michael Czerner, and Christian Heiliger — Justus-Liebig-Universität, Giessen, Germany

By means of Matthiessen's rule, one can decompose the electrical resistivity of materials into contributions of separate scattering mechanisms. Here, we present ab initio calculations of the electron-magnon scattering contribution to the specific resistivity of ferromagnetic materials within the supercell method. For that purpose, we model the spin disorder with an atomistic spin model described by a Heisenberg Hamiltonian. We then use the Landau-Lifschitz-Gilbert equation to describe the system's dynamics and introduce temperature effects utilizing Langevin dynamics. In the second step, we employ noncollinear density functional theory and the Non-equilibrium-Green's function formalism in a Koringa Kohn Rostocker (KKR) representation to calculate the conductance through slabs of varying thickness derived from the spin-configurations obtained in the first step. Subsequently, we calculate the specific resistivity by averaging over supercells and applying Ohm's Law. First results for Fe show good agreement with experimental data at high temperatures, highlighting the contribution of magnetic short-range order effects to the total temperature dependence of the specific electric resistance in the temperature regime above the Curie-Temperature.

MM 9.46 Mon 18:30 P1

Tuning intrinsic anomalous Hall effect from large to zero in two ferromagnetic states of $SmMn_2Ge_2$ — Mahima Singh[1], Jyotirmoy Sau[1], •Banik Rai[1,2], Arunanshu Panda[1], Manoranjan Kumar[1], and Nitesh Kumar[1] — [1]S N Bose National Centre for Basic Sciences, Salt Lake City, Kolkata 700106, India — [2]Leibniz Institute for Solid State and Materials Research (IFW) Dresden, Helmholtzstraße 20, 01069 Dresden

The intrinsic anomalous Hall conductivity (AHC) in a ferromagnetic metal is determined by its band structure, with spin orientation being a key band structure tuning parameter. We study a layered tetragonal room temperature metallic ferromagnet $SmMn_2Ge_2$, which gives us the opportunity to study magneto-transport properties where both the *c*-axis and *a*-axis can be magnetically easy axes depending on the temperature range we choose. We show a moderately large fully intrinsic AHC up to room temperature when the crystal is magnetized along the *c*-axis. Interestingly, the AHC can be tuned to completely extrinsic with extremely large values when the crystal is magnetized along the *a*-axis, regardless of whether the *a*-axis is magnetically easy or hard. First principles calculations show that nodal line states originate from Mn-*d* orbitals just below the Fermi energy (E_F) in the electronic band structure when the spins are oriented along the *c*-axis. Intrinsic AHC originates from the Berry curvature effect of the gapped nodal lines in the presence of spin-orbit coupling. AHC almost disappears when the spins are aligned along the *a*-axis as the nodal line states shift above E_F and become unoccupied.

MM 9.47 Mon 18:30 P1

Rapid photobleaching of Yb-doped optical fibers exposed to gamma radiation by high energy ns pulsed laser — •Esra Kendir Tekgül and Bülend Ortaç — Bilkent University UNAM, Institute of Materials Science and Nanotechnology, Ankara, 06800, TURKEY

Rare earth-doped optical fibers (OFs) have become one of the new high-power laser and sensor applications. Therefore, it is very important to protect such OFs from being exposed to external effects and to increase their reusability after these effects. Here, Radiation Induced Attenuation (RIA) and the Photo-darkening (PD) processes play an important role. The main source of the problem is the color centers formed in the OF. Preventing or recovering these formations before and after the production of OF is of great importance in both efficient and long-lasting systems.

To determine the behavior of Yb-doped OF, they are exposed to gamma radiation or PD. The important recovery process is photobleaching (PB) for defects due to the gamma radiation. In our study, a rapid and efficient PB process was achieved using a high-energy nanosecond pulse to recover existing and/or revealed color centers in OF that had been irradiated with 10 kGy of gamma radiation. The PB process was analyzed based on the wavelength and energy of the pulsed light source. The highest level was achieved with the 532 nm wavelength laser. The findings indicate that the recovery of color centers can reach up to 96% in a shorter duration (hours) compared to results from studies utilizing continuous lasers.

MM 9.48 Mon 18:30 P1

Design of a setup for conducting experiments synchronized with sample scanning — •Maksim Khasanov — Moscow, Russia

The paper focuses on designing equipment with an electronic drive for compressing samples during experiments, aimed at analyzing their internal structure using computed tomography. The manual compression system previously used prolonged the experiment due to time-consuming data processing. The new electronic system significantly reduces the time required by automating the compression process. The work includes the design of the compression apparatus and its electric drive, providing a more efficient and precise solution for experimental procedures.

MM 9.49 Mon 18:30 P1

Extreme stability of $CoCrFeMnNi_{60}$ multicomponent alloys after severe plastic deformation — •Lukas Musiol[1], Mohan Muralikrishna Garlapati[1], Shabnam Taheriniya[1], Lukasz Rogal[2], Sergiy Divinskiy[1], Harald Rösner[1], and Gerhard Wilde[1] — [1]Institute of Materials Physics, University of Münster, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany — [2]Institute of Metallurgy and Material Science, Polish Academy of Science, Reymonta 25 St., 30-059 Krakow, Poland

Thermal stability of a (CoCrFeMn)Ni60 multicomponent alloy is investigated using in-depth microscopic examination. The specific composition is chosen as a transition one from "high-entropy" to "concentrated alloy" behavior. Such compositional design mimics a conventional alloy design of solutes in the terminal solid solution range but in equiatomic concentrations. Along with the analyses of the homogenized samples, an analysis of compressed and rotary swaged samples was performed to investigate the influence of deformation on the phase stability. The phase stability is investigated at intermediate temperature for prolonged annealing times, which has given an in-depth understanding of the formation and growth of new phases or precipitates. Detailed microscopy analyses were performed to determine the phases and their composition. Overall, the (CoCrFeMn)Ni60 multicomponent alloy has shown a stable microstructure even after extreme deformation and after prolonged heat treatments. The phase stability results, in conjunction with deformation and microstructure, will be correlated and discussed in detail.

MM 9.50 Mon 18:30 P1

Influence of Supercell Size Effects on the Mechanical Properties and Electronic Structure of High-Entropy Transition Metal Diborides ($HETMB_2$) — Inna Plyushchay[2], •Nebahat Bulut[1], Anna Pliushchai[1,3], and Sibylle Gemming[1] — [1]Institute of Physics, TU Chemnitz, Germany — [2]Institute of Physics, National Taras Shevchenko University of Kyiv, Ukraine — [3]National Technical University of Ukraine "Igor Sikorsky Kyiv Polytechnic Institute"

Modeling various supercell sizes for high-entropy transition metal diborides ($HETMB_2$) holds the potential to overcome the computational challenges associated with their unique bonding configurations and complex compositions. First-principles calculations were used to predict the electronic and elastic properties of high-entropy transition-metal diborides after employing supercells with a variety of atomic configurations and complex compositions. We found that larger supercells allowed for clustering of atoms of the same metal type, as evidenced by broadening of the peaks in the histogram of interatomic distances. This, however, had no significant influence on the mechanical properties. The mechanical properties of $HETMB_2$ are determined by the number of electrons, size of atoms or polarizability. However, the average number of *d*-electrons per metal atom was found to be crucial because it affects the Fermi level position relative to the pseudogap, and this impacts the elastic properties strongly in comparison to the binary-TMB_2.

MM 9.51 Mon 18:30 P1

Ab initio calculations of defects in the Mg2Ge intermetallic — •Pavel Papež[1,2], Martin Friák[2], and Martin Zelený[1] — [1]Institute of Materials Science and Engineering, Faculty of Mechanical Engineering, Brno University of Technology, Brno, Czech Republic — [2]Institute of Physics of Materials, Czech Academy of Sciences, v. v. i., Brno, Czech Republic

This work is focused on ab initio calculations of different types of defects in the Mg2Ge intermetallic in order to explain a higher concentration of Mg in exper-

imental samples. Our calculations employed VASP software and include antisite defects and vacancies on both sublattices and furthermore interstitial additions of both Mg and Ge, all in charge neutral state. The calculations were also done with the modified Becke-Johnson potentials to study their influence on the band-structure of this semiconductor. We have calculated their formation energies in regards to Mg rich and Ge rich chemical potential limits. The phonon calculations were done to acquire the defect equillibrium concentration and the evolutiuon of defect formation energies with temperature.

MM 9.52 Mon 18:30 P1

Glass transition and physical aging studies of a gold based Bulk metallic glass by means of flash scanning calorimetry — •Klara Otto[1], Valerio Di Lisio[2], Daniele Cangialosi[2], and Isabella Gallino[1] — [1]Technische University Berlin, Chair for Metallic Materials, Berlin, Germany — [2]DIPC, San Sebastián, Spain

Flash scanning calorimetry is used to study the glass transition of metallic glasses, during direct solidification from the melt [1,2] and by reheating with rates up to thousands of K/s. This enables the access to the supercooled liquid state by avoiding crystallization during the cooling stages.

Glassy materials relax over time when held below the glass transition temperature, to minimize their excess thermodynamic properties. A new methodology to compare the relaxation times related to the atomic mobility with those determined throughout glassy aging of a gold based metallic glass, is presented. Isothermal physical aging was performed to retrieve the temperature dependent timescales of the alpha relaxation. Additionally, the characteristic time of glassy relaxation are retrieved in a wide temperature range [3] complemented with fictive temperature analysis.

The combined data were plotted on an activation diagram, that relates relaxation times to the inverse of temperature. This allowed to investigate relaxation time scales spanning 7 orders of magnitude using a single experimental technique.

MM 9.53 Mon 18:30 P1

Glass Forming Ability, Thermal and Magnetic Properties of the Multicomponent Fe-Mo-P-C-B-Si Metallic Glass for AM Applications — •Alejandro Lejtman Rotberg[1], Amirhossein Ghamivi[2], Lucas M. Ruschel[2], Izzi A. Ahmad[1], Uma Rajput[3], Purbasha Sharangi[3], Paola M. Tiberto[2], Ralf Busch[2], and Isabella Gallino[1] — [1]Technical University of Berlin, Chair for Metallic Materials, Ernst-Reuter-Platz 1, 10587 Berlin, Germany — [2]Saarland University, Chair of Metallic Materials, 66123 Saarbrücken, Germany — [3]INRIM, Strade delle Cacce 91, Torino, Italy

Efficient power-to-work conversion in electric vehicles (EVs) requires soft magnetic materials with low coercivity. Fe-based metallic glasses reduce power losses but struggle achieving casting thicknesses over 1mm due to limited glass-forming ability (GFA). Additive manufacturing (AM), like Laser Powder Bed Fusion (LPBF), provides solutions, with recent studies revisiting Fe-Si-B compositions for processability and performance [1-3]. This study evaluates the alloy Fe74Mo4P10C7.5B2.5Si2. X-ray diffraction (XRD) results of cast plates and ribbons determined the GFA. Thermal properties were analyzed via Differential Scanning Calorimetry (DSC) and Differential Thermal Analysis (DTA), while magnetic properties using Vibrating Sample Magnetometry (VSM). Results suggest the alloy's potential for AM production of soft magnetic components for EVs.[1] Thorsson, L., et al. Selective Laser Melting. Materials & Design.[2] Rodríguez-Sánchez, M., et al. Relating Laser Powder. Materialia.[3] Sadanand, S., et al. Laser Powder Bed Fusion. Journal of Laser Applications.

MM 9.54 Mon 18:30 P1

An atomistic study on the role of size and composition on the structural and thermodynamic properties of Al-Pd bimetallic nanoparticles during melting and solidification. — •Dario Gonzalo Escriba Quispe[1], Justo Alcides Rojas Tapia[1], and Gustavo Cuba Supanta[1,2] — [1]Universidad Nacional Mayor de San Marcos, Lima, Peru — [2]Universidad Privada del Norte, Lima, Peru

Bimetallic nanoparticles (NPs) of Al-Pd exhibit structurally complex phases, as well as quasicrystalline approximants to the Al-Mn-Pd system, which, combined with their controversial and complex phase diagram, makes them an interesting subject of study. In this work, using molecular dynamics, the structural and thermodynamic properties of Al(x)Pd(100-x) NPs at different sizes and compositions are calculated.

The processes of melting and solidification are simulated using the open-source LAMMPS package and a MEAM-type potential. It was found, through the calculation of heat capacity, that the melting temperature and size of AlPd, Al2Pd5, and Al1Pd4 NPs follow a linear behavior, in agreement with the scaling law. Additionally, the RDF graphs of AlPd NPs show that it is an ordered intermetallic compound, with structural parameters such as the crystal structure and lattice parameter matching those reported experimentally. The Al1Pd4 nanoalloy was explored, where it was found that the NP has an icosahedral shape. However, the atoms exhibit internal ordering with regions showing FCC and HCP crystal structures. Finally, other additional results such as MSD, common neighbor analysis (CNA), the Warren-Cowley parameter, excess energy, and phonon dispersion are presented.

MM 9.55 Mon 18:30 P1

An X-ray diffraction study of copper powder for laser-based powder bed fusion — •Eric Schneider[1], Robert Ortmann[2], Julia Frank[3], Fabienne Hellwig[3], Tobias Grimm[2], Michael Blüm[3], Lena Friedrich[1], Michael Paulus[1], Jaqueline Savelkouls[1], Jan T. Sehrt[2], Christian Sternemann[1], and Arne Röttger[3] — [1]Universität TU Dortmund, Maria-Goeppert-Mayer-Straße 2, D-44227 Dortmund — [2]Ruhr-Universität Bochum, Universitätsstraße 150, D-44801 Bochum — [3]Bergische Universität Wuppertal, Bahnhofstraße 15, D-42651 Solingen

Additive manufacturing (AM) of components using laser-based powder bed fusion of metals (PBF-LB/M) has reached market maturity. This layer-by-layer process offers advantages over casting and subtractive methods, especially for producing complex parts with internal cavities and is promising to produce topology-optimized lightweight structures. However, the use of copper powders for PBF-LB/M based AM poses challenges due to its high thermal conductivity and reflectivity. The directed oxidation and reduction of the copper particle surfaces can improve both, the powders processability and reusability. In this study we investigate the oxidation of pre-treated copper powders in air and its controlled reduction using $Ar/2\%H_2$ atmosphere at different temperature conditions up to 350°C by X-ray diffraction at beamline BL9 of DELTA synchrotron radiation source in order to reveal information about induction times and change in Cu, Cu_2O, and CuO phase composition for industrial processing. This research is funded by the DFG via projects RO 4523/9-1, SE 2935/6-1, and STE 1079/9-1.

MM 9.56 Mon 18:30 P1

Linking Process Parameters and Heat Treatment to Microstructural Properties of PBF-LBM 316L Steel for Structural Hydrogen Use — •Tim Haag, •Kai Stefan Lagemann, Stefan Wagner, and Astrid Pundt — Institut für Angewandte Materialien - Werkstoffkunde (IAM-WK), Karlsruher Institut für Technologie (KIT)

Additively manufactured (AM) 316L steel produced by powder bed-based laser melting (PBF-LBM) can be considered for sophisticated applications in hydrogen technology. This project investigates the influence of manufacturing parameters and post-processing treatments, such as heat treatment, on the resulting microstructure and its implications for material properties. The objective is to optimise the manufacturing process in order to achieve components with minimal porosity. The microstructure is comprehensively analysed using advanced techniques, which reveal hierarchical features and a complex interplay of various microstructural elements, including multiscale porosity, varying grain orientations and subgrain dislocation cells. Heat treatments are applied to alter microstructural characteristics and assess their impact on material properties.

MM 9.57 Mon 18:30 P1

Analysis of the Crack Formation in Printed Nanosilver Using In Situ Bending Technique — •Lennart Schwan[1], Michaela Klöcker[1], Michael Feige[1], Laila Bondzio[2], Thomas Kordisch[1], and Sonja Schöning[1] — [1]Bielefeld Institute for Applied Materials Research (BIfAM), Faculty of Engineering and Mathematics, Bielefeld University of Applied Sciences and Arts — [2]Thin Films & Physics of Nanostructures, Bielefeld University, Department of Physics

3D printing is an emerging technology with a wide range of applications. The modern multi-material jetting process, as used in the Nano Dimension Dragonfly Pro LDM, makes it possible to print dielectric and conductive materials in a single process. In addition to electrical circuits such as coils, capacitors, etc., strain gauges can also be printed.

The change in resistance of strain gauges is usually caused by the change in the geometric dimensions of the conductive layer when it is deformed. In the case of the printed material examined in this study, it is also known that the material is permeated by cracks which cause a directional dependence of the electrical conductivity.

The objective of this study is to investigate how these cracks develop during bending and thus also contribute to the change in resistance. For this purpose, a test specimen is loaded under a three-point bending test using a special in situ bending module. In order to investigate the propagation and formation of the cracks, the bending module is positioned in a scanning electron microscope in order to analyze the cracks under loading with a sufficient image resolution.

MM 9.58 Mon 18:30 P1

Atomistic Simulation of Laser-based Powder Bed Fusion of Metals — •Aamir Siddiqui, Simon Kümmel, and Johannes Roth — FMQ, University of Stuttgart, Germany

Additive manufacturing technology applications continue to call for increased reproducibility and quality. The goal is to study the melting and solidification of an AlTi alloy and to create a framework that allows for further studies on arbitrary alloys and metals. Molecular dynamics provides an understanding of

the melting and ablation process, resulting in an understanding of different heat transfer mechanisms. The simulation framework makes it possible to see how changes in scanning speed and laser power affect the melting dynamics.

The melting process of alloys shows that a significant amount of argon gas becomes trapped inside the sample. The simulation of powder beds formed by spheres of varying sizes reveals holes that vanish under vacuum conditions, but persist when the simulation box is filled with protective gas, providing information on the creation of defects. By deforming the sample, the influence of gas pockets on the mechanical properties and the evolution of the lattice structure within the sample can be seen.

MM 9.59 Mon 18:30 P1

Nanoscale characterization of AM316L stainless steel for hydrogen application — •Gabriele Palazzo, •Felix Stierle, Kai Stefan Lagemann, Christian Kübel, Stefan Wagner, and Astrid Pundt — Karlsruhe Institute of Technology, Karlsruhe, Germany

Additive manufactured (AM) austenitic stainless steel 316L prepared by selective laser melting (SLM) is characterized by advanced nanoscale characterization techniques to examine its microstructural features. High-resolution scanning TEM (HR-STEM), selected area diffraction (SAD), and analytical methods such as energy-dispersive X-ray spectroscopy (EDX) as well as electron energy loss spectroscopy (EELS) are employed. Typical SLM printing structures (equiaxial and columnar cellular structure, nano-inclusions) are observed with atomic resolution both for as-built and tensile tested samples. The presence of silicon-manganese oxide nano-inclusions, preferential chromium and molybdenum segregation around them is revealed, as well as iron depletion and chromium enrichment along the cell boundaries. This peculiar multi-scale AM microstructure accounts for the unique mechanical properties of AM316L in terms of resistance and ductile behaviour, if compared to the conventionally manufactured counterpart, allowing to overcome the trade-off between strength and ductility.

MM 9.60 Mon 18:30 P1

Fine-tuning of machine learning interatomic potential for the prediction of phonon properties — •Jonas Grandel, Philipp Benner, and Janine George — Bundesanstalt für Materialforschung und Prüfung, Berlin

Accurate phonon predictions are critical for assessing material stability and thermal behavior, but traditional approaches based on density functional theory (DFT) are computationally expensive, motivating the need for accelerated alternatives. In this work, we investigate the performance of the machine learning interatomic potential MACE-MP-0 for predicting harmonic phonons and thermal properties. The focus is on fine-tuning MACE-MP-0 using various sets of rattled structures and different hyperparameter to identify the most effective strategy for improving model accuracy. We want to develop a general fine-tuning workflow based on the foundational model that can be used to fast and accurately generate phonons to predict both stability and thermal properties. For this purpose, a benchmark dataset was constructed using DFT consisting of a broad range of different crystal systems and mainly of phase change materials and thermoelectric materials. Each fine-tuned model targets one specific material, allowing to improve each material individually. The results demonstrate significant improvements in the prediction of phonon band structures, with a root mean square error (RMSE) reduced from 0.6 THz for the original MACE-MP-0 model to 0.3 THz for the fine-tuned models. In addition, performance in terms of computational speed was improved by up to a factor of 10 compared to traditional DFT-based phonon calculations.

MM 9.61 Mon 18:30 P1

Learning the Reduced Density Matrix Functional from Quantum Processors and Using Density Matrix Embedding Theory to Extend its Universality — •Martin Uttendorfer — Deutsches Zentrum für Luft- und Raumfahrt (DLR), Köln, Deutschland

The advent of quantum computing makes reduced density matrix functional theory (RDMFT) on an exact level viable. By directly applying RDMFT, derived from Levy-Lieb's constrained search, this work leverages quantum processors to overcome some of DFT*s shortcomings, enabling more accurate modeling of quantum chemical and condensed matter systems. The proposed approach incorporates quantum algorithms that utilize variational quantum eigensolvers (VQE), which is viable to be executed on near-term intermediate scale quantum devices (NISQ) in conjunction with machine learning techniques. This work examines the theory*s application to different particle types, including fermions, bosons, and hard-core bosons, highlighting the flexibility of the RDMFT framework. Additionally, density matrix embedding theory (DMET) is incorporated, allowing for a hybrid classical-quantum approach that extends the functional*s universality. This work presents a quantum algorithmic approach to obtain the functional and provides a computational strategy for studying complex many-body systems while keeping the use of limited quantum resources to a minimum.

MM 9.62 Mon 18:30 P1

Integrating Long-Range Interactions into Machine Learning Interatomic Potentials — •Tulga-Erdene Sodjargal[1,2], Egor Rumiantsev[1], Philip Loche[1], and Michele Ceriotti[1] — [1]Laboratory of Computational Science and Modeling (COSMO), Institute of Materials, École Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland — [2]Department of Bio and Brain Engineering, Korea Advanced Institute of Science and Technology (KAIST), 34141 Daejeon, Republic of Korea

Machine learning-based interatomic potentials (MLIPs) often rely on the locality ansatz, calculating atomic energies based on a fixed cutoff radius. While effective for many systems, this nearsightedness can lead to inaccuracies when long-range interactions, such as ionic interactions, dominate. To overcome this limitation, we integrate Particle Mesh Ewald (PME) techniques into existing MLIP frameworks. Our extension is modular and plug-and-play, requiring minimal modifications to incorporate into various models. We demonstrate significant improvements in both simple architectures, such as Behler-Parrinello Neural Networks, and advanced models, including state-of-the-art graph neural networks like the Point Edge Transformer (PET).

MM 9.63 Mon 18:30 P1

pyiron - Automated Workflows for Materials Science — •Jan Janssen[1], Marvin Poul[1], Sarath Menon[1], Tilmann Hickel[2], and Joerg Neugebauer[1] — [1]MPI for Sustainable Materials, Düsseldorf, Germany — [2]BAM Federal Institute for Materials Research and Testing, Berlin, Germany

The pyiron framework, originally developed for atomistic simulations in the field of materials science, has recently been extended beyond the atomistic scale to enable data-driven materials design on all scales and including experiments. As a central interface for materials acceleration platforms (MAP), pyiron couples simulation methods ranging from ab-initio methods of the electronic scale, to the atomistic scale of machine-learned interatomic potentials and up to the continuum scale of crystal plasticity modelling with interfaces for experimental equipment and machine learning.

On our poster, we give a brief overview of the recent developments in the pyiron project and highlight a series of materials science applications. These range from pyiron_workflow, our redesigned graph-based workflow engine, to executorlib for up-scaling workflows for high-performance computing (HPC) and the python workflow definition, a joined standard developed in collaboration with AiiDA and jobflow, the workflow engine of the materials project. At the same time, the poster will provide an opportunity to meet the pyiron developers and discuss ideas and future applications.

Read more about pyiron on our website: https://pyiron.org

Investigating the Impact of Optimization Algorithms on Element-Substitution Based Materials Discovery — •David Greten[1], Konstantin Jakob[1], Karsten Reuter[1], and Johannes T. Margraf[2] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]University of Bayreuth

In this study, we investigate how different optimization algorithms affect the relaxation of inorganic structures using general-purpose machine-learned interatomic potentials (MLIPs) like MACE-MP-0. Assessing computational efficiency and relaxation quality via structural similarity and kernel distance metrics, we find that optimizer choice significantly influences performance and can lead to different equilibrium structures. Analyzing both DFT-relaxed structures from the Materials Project and element-substitution based trial structures, we highlight the optimizer's impact in different scenarios. Our findings emphasize the critical role of optimizer selection in large-scale computational materials science workflows, particularly in the context of element-substitution based materials discovery. This can hopefully guide the community towards choosing appropriate algorithms for efficient and reliable structure relaxations.

MM 9.65 Mon 18:30 P1

The APyT Package: From Raw Data to Three-Dimensional Reconstruction — •Sebastian Eich — Department for Materials Physics, Institute for Materials Science, University of Stuttgart

The APyT package is an advanced, open-source Python framework for evaluating atom probe tomography (APT) data. It offers a suite of modules that automate key steps in APT processing, from mass spectrum calibration to three-dimensional sample reconstruction. Its modular architecture ensures seamless integration with external tools through standardized input/output interfaces, supporting both Linux and Windows environments.

Key features include high efficiency with NumPy and Numba, a low memory footprint, and extensive documentation. The modules are highly automated, requiring minimal user input to achieve accurate results. The package also integrates SQL database management for raw measurement data and corresponding metadata.

The mass spectrum module automatically calibrates and detects peaks, producing high-resolution spectra. The mass spectrum fitting module further refines this by fitting spectra with an analytical function, automatically deconvolving overlapping peaks by incorporating isotope abundances. The recon-

struction module generates a 3D sample reconstruction, including automatic chemical identification and export capabilities. Future enhancements include a PyQt-based GUI to streamline access to all APyT modules in one application.

MM 9.66 Mon 18:30 P1

Relation between the electronic structure and X-ray absorption spectra discussed using multiple-scattering formalism — Hubert Ebert[1], •Sergiy Mankovsky[1], and Jan Minar[2] — [1]LMU of Munich, 81377 Munich, Germany — [2]University of West Bohemia, Pilzen, Czech Republic

Recently, the concept of crystal orbital overlap population (COOP) has been reconsidered [1] based on the finite difference method (FDM), representing the calculated x-ray absorption spectra (XAS) in terms crystal orbital overlap population functions. This allows to reveal the correlation between XAS and the formation of the bonding/antibonding states in solids. Following the idea suggested in Ref. [1], we demonstrate that this relation can be investigated in a very efficient way using the multiple scattering formalism for electronic structure calculations. In this representation, both, the density of states and the x-ray absorption function are determined by the site-diagonal scattering path operator $\tau^{00}(E)$ which can be expressed as $\tau^{00}(E) = t^0 + \sum_n \tau^{0n}(E)\, G^{n0}(E)\, t^0$, in terms of the single-site scattering matrix t^0, the site-off-diagonal operators $\tau^{0n}(E)$, and the structural Green function $G^{n0}(E)$. The second term determines in a pair-wise resolved way the fine structure of the electron density of states (DOS) $n(E)$ as well as the XAS absorption coefficient $\mu(E)$. The DOS and the normalized x-ray absorption coefficient are calculated for several representative systems and discussed in line with the idea of the COOP concept.

MM 9.67 Mon 18:30 P1

Upgrading the Coincidence Doppler Broadening Spectrometer at FRM II — •Danny R Russell, Francesco Guatieri, Leon Chryssos, and Christoph Hugenschmidt — FRM II - Technische Universität München, München, DE

The coincidence Doppler broadening spectrometer (CDBS) at the Forschungs-Neutronenquelle Heinz Maier-Leibnitz (FRM II) provides state-of-the-art, depth dependent detection of defects and chemical composition at the annihilation site. A monoenergetic positron microbeam (50 μm FWHM) is guided onto a sample where positrons annihilate with electrons. The Doppler broadening of the characteristic 511 keV annihilation peak is measured by observing both emitted photons simultaneously.

We present simulations and hardware design for an upgrade to the CDBS which will allow backscattered positron capture. Up to ~ 40 % of the incident positrons are backscattered when they reach the sample surface. The annihilation events occurring when these backscattered positrons return to the sample or annihilate in experimental hardware contribute unwanted signal to the measured spectrum which cannot be removed in data processing.

We use an in-house particle tracking code to design a positron dump that will capture backscattered positrons at an electrode outside detector lines of sight. This will reduce the unwanted signal by up to 50 % and improve the quality of CDBS data. Additionally, we apply the same code to optimize an electrostatic focusing lens, further increasing the spatial resolution of the instrument.

MM 9.68 Mon 18:30 P1

High-entropy alloy pre-screening for lead-free halide double perovskites from material databases — •Marina S. Günthert[1,2], Bernd Meyer[1], and Christoph J. Brabec[2] — [1]Interdisciplinary Center for Molecular Materials and Computer Chemistry Center, FAU Erlangen-Nürnberg — [2]Materials for Electronics and Energy Technology (i-MEET), FAU Erlangen-Nürnberg

Over the last decade, lead-free halide double perovskites with composition $A_2BB'X_6$ have emerged as an interesting class of materials for optoelectronics. Furthermore, it was suggested to introduce different ion ratios on each of the double perovskite sublattices, leading to a vast space of possible compositions.

Two criteria are applied to have a first fast filtering approach to reduce the number of combinations. First, the search is limited to non-toxic and non-f elements for a green chemistry approach. Second, we estimate the thermodynamic stability of the compounds by using a criteria recently proposed by Muzzillo *et al.* [1], which focuses on the entropy stabilization by using several elements on each sublattice. This method can be easily adjusted for halide double perovskites. We applied it first to the Materials Project database but it can also be extended to other databases such as NOMAD and OQMD. In the end, this pre-screening gives an idea, which elements on the different sublattices of the double perovskite are worth further exploration.

Effect of $4f$ occupancy on L_3 edge of Cerium — •Prathibha Chandrashekhar, Patrik Thunström, Felix Sorgenfrei, and Heike Herper — Department of Physics and Astronomy, Uppsala University, Sweden

The valence $4f$ electrons in Cerium exhibit a strong itinerant tendency, allowing them to exist in a mixed-valence regime, between localized and delocalized states. This regime hosts correlated electron phenomena which has profound implications on the material's magnetic, transport, and electronic properties. The shift in $5d$ orbitals to higher energy levels, due to reduced screening from delocalized $4f$ electrons, provides critical insights into electronic properties. We study this shift by probing $2p$ to $5d$ transition using X-ray Absorption Spectra(XAS). However, accurately modeling the light-matter interaction in such systems remains challenging due to the itinerant nature of the $4f$ electrons, strong core-hole effects, multiplet interactions, and hybridization dynamics. In this work, we employ advanced theoretical approach that combines density functional theory (DFT) with multiplet ligand-field theory (MLFT). This method enables computation of $L_{2,3}$-edges by constructing and solving single-impurity Anderson model (SIAM) derived from first-principles calculations. Additionally, we investigate sensitivity of the computed spectra to Slater integrals, hybridization effects, and core-hole relaxation, offering new insights into the intricate electronic behavior of Cerium-based systems. PC acknowledges partial funding from Horizon Europe MSCA Doctoral Network grant n.101073486, EU-SpecLab, funded by European Union.

MM 9.70 Mon 18:30 P1

Stability of AgI Polymorphs and the AgI(0001) Surface Reconstruction — •Angela Rittsteuer[1], Andrea Conti[2], Michael Schmid[2], and Georg Kresse[1] — [1]University of Vienna, Faculty of Physics, 1090 Vienna, Austria — [2]TU Wien, Institute of Applied Physics, 1040 Vienna, Austria

Silver iodide (AgI) is a compound widely used in cloud seeding due to its ability to act as an effective nucleating agent for cloud condensation. Under ambient conditions, AgI crystallizes in hexagonal or cubic close-packed structures, the most prominent polymorphs being the wurtzite and the zincblende structure. A comprehensive understanding of its groundstate structures and phase behavior is essential not only to optimize its role in cloud condensation but also to explore broader applications in solid-state chemistry and catalysis.

To investigate the stability of AgI polymorphs, we perform extensive benchmarking studies across various levels of theory. These include Density Functional Theory with different approximations for the exchange-correlation energy, hybrid Hartree-Fock Density Functionals, and the Random Phase Approximation, offering a hierarchy of accuracy. Building on recent atomic force microscopy studies of the wurtzite AgI(0001) surface, we further provide theoretical insights by developing a machine-learned force field and applying simulated annealing and parallel tempering to study the surface reconstruction.

MM 9.71 Mon 18:30 P1

Investigation of Lloyd's formula at finite electronic temperatures — •Christian Maas[1,2], Michael Czerner[1,2], and Christian Heiliger[1,2] — [1]Institut für Theoretische Physik, Justus-Liebig-Universität Gießen — [2]Center for Materials Research (LaMa), Justus-Liebig-Universität Gießen

In DFT calculations within the Korringa-Kohn-Rostoker (KKR) Green's function formalism the integrated density of states is analytically given by Lloyd's formula. Its better l-convergence can be used for a precise determination of the Fermi energy and a charge density normalization. In the past it has been shown that for finite electronic temperatures the calculation of Lloyd's formula can in principle be done on the same energy mesh that is used for the calculation of the charge density [1]. These calculations require to numerically evaluate the derivative of Lloyd's formula. We show that it is possible to accurately determine the derivative without using additional energy mesh points. This is done by interpolating Lloyd's formula with cubic splines which in turn are used to calculate the derivative. We compare the method to calculations without electronic temperatures and show that the spline interpolation does not lead to a significant accuracy lost.

MM 9.72 Mon 18:30 P1

Fiber composite materials in construction of go-cart. — •Mikhail Brusnikin — Moscow, Russia

Lightweighting any vehicle, especially sports equipment, has always been a pertinent issue, and I aimed to determine how significantly material substitution would affect the mass of the power structure by using modern composite constructions instead of classical steel solutions, with the condition of maintaining the same torsional stiffness as the steel sample.

Fiber composite materials are currently at the forefront of technology in terms of stiffness-to-weight ratio and are sufficiently accessible for my research, which was focused on their application in a sports device such as a go-kart.

The assumptions regarding the weight of the final product, which were proposed at the beginning of the research, turned out to be erroneous. Even in the best-case scenario, the weight reduction of the construction was less than anticipated.

RuNNer 2.0: An Efficient and Modular Program for High-Dimensional Neural Network Potentials — •Alexander L. M. Knoll[1,2], Moritz R. Schäfer[1,2], K. Nikolas Lausch[1,2], Moritz Gubler[3], Jonas A. Finkler[3], Alea Miako Tokita[1,2], Gunnar Schmitz[1,2], Henry Wang[1,2], Richard Springborn[1,2], Marco Eckhoff[4], and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany — [3]Department of Physics, Universität Basel, Switzerland — [4]Laboratorium für Physikalische Chemie, ETH Zürich, Switzerland

Machine learning potentials (MLPs) have become an important tool for atomistic simulations in chemistry and materials science. As methods in this domain grow increasingly complex and mature, the creation of efficient and user-friendly libraries now receives a lot of attention. We introduce the second major release of RuNNer, an open-source, standalone software package designed for constructing and evaluating second-, third-, and fourth-generation high-dimensional neural network potentials (HDNNPs). RuNNer 2.0 integrates the entire workflow into a fully OpenMP- and MPI-parallel program: from generating atomistic descriptors, via training a specific machine learning model, to its application in molecular dynamics simulations.

MM 9.74 Mon 18:30 P1

Hybrid soldering: Interfacial flux-doping of Cobalt nanoparticles hindering the formation and growth of intermetallic compound (IMCs) layers — •Farzad Khodabakhshi[1,2], Irina Wodak[1], Andriy Yakymovych[1], Gerhard Wilde[2], and Golta Khatibi[1] — [1]Vienna University of Technology — [2]University of Münster

The study investigated hybrid nanocomposite soldering of copper components using a lead-free tin-based solder alloy (Sn-3.5 wt% Ag). To suppress the growth of intermetallic compound (IMC) layers, specifically Cu3Sn and Cu6Sn5, at the interface between the solder alloy and the copper substrate during reflow solidification, a modified flux containing cobalt nanoparticles was applied. The research focused on the effects of incorporating cobalt nanoparticles in different fractions, up to 1.0 wt%, on the microstructural development of the soldered joints and the formation of IMC layers. Additionally, the impact of post-soldering aging treatment, conducted at approximately 180°C for extended periods (up to around 20 days), was assessed. The study analyzed how the alloying of cobalt nanoparticles affected the structure of Cu3Sn and Cu6Sn5 IMC layers, as well as the Sn-based solder alloy. This was done using energy-dispersive X-ray spectroscopy (EDS) elemental mapping in conjunction with field emission-scanning electron microscopy (FE-SEM). Furthermore, the microstructural evolutions of the soldered joints, influenced by the contribution of Co-nanoparticles and the aging treatment, were characterized and discussed using electron channeling contrast imaging (ECCI) microscopy.

Understanding the impact of disconnection flow on microstructure evolution — •Marco Salvalaglio — TU Dresden, Dresden 01062, Germany

In polycrystals, which are composed of misoriented grains and grain boundaries (GBs), microstructure evolution primarily occurs through GB migration. It is widely accepted that GB migration is mediated by the flow of line defects with both step and dislocation characters, i.e., disconnections. Numerous phenomena associated with grain boundary (GB) motion can, in fact, be linked to disconnection flow. This presentation discusses novel fundamental aspects regarding how disconnection flow affects overall microstructural changes. First, with a continuum (phase field) model of GBs that accounts for disconnections, we demonstrate that the generation of internal stress (shear coupling) is the primary factor responsible for deviations from classical curvature-driven grain growth observed in recent experiments. The relative impact of other factors is also briefly discussed. Second, through atomistic simulations, a Markov chain model analysis, and an experimental proof of concept, we demonstrate that asymmetric GBs exhibit direction-dependent mobilities and unidirectional motion under oscillatory driving forces or cyclic thermal annealing. This behavior can be attributed to the microscopic structure of GBs affecting the nucleation barriers of disconnections. Additionally, our findings suggest that applying oscillatory driving forces and non-equilibrium thermal fluctuations accelerates grain coarsening in microstructures, a conclusion further supported by numerical simulations.

MM 11: Topical Session: Defects of Defects

Time: Tuesday 10:15–13:00 Location: H10

Topical Talk MM 11.1 Tue 10:15 H10

The role of disconnections in the shear-migration coupling of grain boundaries — •Marc Legros[1], Armin Rajabzadeh[1], Romain Gautier[2], Nicolas Combe[1], and Frédéric Mompiou[1] — [1]CEMES-CNRS, 29 rue Jeanne Marvig, 31055, Toulouse, France — [2]UMET, Université de Lille, Cité scientifique, 59655 Villeneuve d'Ascq

Grain-boundary (GB)-based plasticity is an alternative to classical, dislocation-based deformation. It is supposed to play a significant role in nanocrystalline metals (d<100 nm) for example, that contain a large proportion of GBs but virtually no dislocations. Among all the mechanisms potentially able to generate a permanent (plastic) deformation, the dominant one is the so-called shear-migration coupling. Despite a recent increase in simulations studies, its experimental characterization remains very scarce. Aside from experimental obstacles, the problem is very vast as real grain boundaries possess at least 5 degrees of freedom and contains a potentially infinite number of disconnections, a specific defect that combines step and dislocation characters.

Using both in-situ TEM experiments and molecular dynamic simulations (NEB Nudge Elastic Band), we have shown that shear-migration coupling involves the displacement of these disconnections. As dislocations in the crystal, the properties of these disconnections seem to guide the coupling mechanism of migrating grain boundaries. The overarching question becomes whether we should still consider a given GB as a crystalline defect or a network of its own, which mechanical properties (mobility, shear coupling) are governed by its nature or by its defects?

MM 11.2 Tue 10:45 H10

Atomistic simulation of point defects behavior inside grain boundaries — •Sergei Starikov, Matous Mrovec, and Ralf Drautz — Ruhr University Bochum, ICAMS, 44801 Bochum, Germany

The properties of point defects play a key role in the description of many phenomena within grain boundaries (GBs), such as pre-melting or atomic diffusion. Compared to the bulk, point defects inside GB are characterized by low formation energy and high complexity. Thus, the thermodynamic/kinetic properties of GBs strongly depend on the behavior of point defects. To reveal general aspects of this relationship, we studied behavior of vacancies and self-interstitial atoms inside tilt grain boundaries for several metals (Ni, Al, Fe, Nb, Mo and W) using atomistic modeling. The simulations revealed that the self-diffusion along the tilt GBs at low/moderate temperatures is mostly driven by migration of self-interstitial atoms. However, heating leads to a change in the GB diffusion mechanism to a more complex exchange process, not related to specific defects, but similar to atomic diffusion in a liquid. This change is due to the disordering complexion transition of GBs, which also significantly affects GB mobility.

MM 11.3 Tue 11:00 H10

Impact of grain boundary defects on grain boundary diffusion and segregation of Cr in Ni bicrystal — Shraddha Sevlikar[1], Mohan G. Muralikrishna[1], Daniel Gaertner[1], Sergei Starikov[2], Tobias Brink[3], Daniel Scheiber[4], Daria Smirnova[3], Daniel Irmer[5], Bengü Tas[1], Vladimir A. Esin[5,6], Vsevolod I. Razumovskiy[4], Christian H. Liebscher[3,7], Gerhard Wilde[1], and •Sergiy Divinski[1] — [1]Institute of Materials Physics, University of Münster, Germany — [2]ICAMS, RU Bochum, Germany — [3]MPI for Sustainable Materials, Düsseldorf, Germany — [4]Materials Center Leoben Forschung GmbH, Leoben, Austria — [5]Mines Paris, PSL University, Évry, France — [6]Université de Lorraine, CNRS, Nancy, France — [7]RC FEMS, RU Bochum, Germany

Grain boundary diffusion of Cr in a near Sigma-11 Ni bicrystal is measured using the radiotracer technique. Opposite to expectations, two distinct contributions to short-circuit diffusion along the nominally single interface are distinguished and related to the existence of two macroscopic facets with distinct inclinations and, as a result, distinct structures. The segregation factor of Cr in Ni is found to be about unity, which is fully supported by ab initio calculations. Using classical atomistic simulations, Ni grain boundary self-diffusion rates are cal-

culated for the symmetric and asymmetric facets. An accelerated self-diffusion kinetics along the asymmetric facet is observed and attributed to the presence of disconnection-like defects. A heterogeneous mechanisms governing atomic migration across distinct facets is corroborated.

Topical Talk MM 11.4 Tue 11:30 H10

Grain Boundary Spinodals: Faceting Instability and the Role of Junction Energetics — •Fadi Abdeljawad — Lehigh University, Bethlehem, PA, USA 18015

Interfaces greatly influence the physical properties and stability of materials microstructures. Of particular interest in crystalline solids are phenomena that occur due to anisotropic interfacial properties. In polycrystalline aggregates, several experimental observations revealed that an initially flat GB profile may facet into hill-and-valley morphologies with well-defined planes and junctions connecting them. Dislocation-like defects exist at facet junctions, which in general connect GB facets with different atomic structures and interfacial properties. Based on classical atomistic simulations and mesoscale modeling, we examine GB faceting transitions and subsequent facet coarsening dynamics. Our modeling framework accounts for anisotropic interfacial energies, and it incorporates junction energetics and their non-local interactions. The hallmark of our approach is the ability to independently examine the various factors affecting this interfacial instability. Theoretical and computational studies predict the dominant growth morphologies as a function of GB facet junction energies. Furthermore, atomistic and mesoscale simulations show that when accounting for junction energetics GB faceting and subsequent facet coarsening is akin to spinodal decomposition in bulk materials. In broad terms, our work provides an avenue to account for GB structural transitions in models of microstructural evolution.

MM 11.5 Tue 12:00 H10

Defect Phase Diagrams for Grain Boundaries in Mg: Chemical trends at Finite Temperatures — •Prince Mathews[1], Rebecca Janisch[2], Tilmann Hickel[1,3], and Jörg Neugebauer[1] — [1]Max-Planck-Institut für Nachhaltige Materialien GmbH, Düsseldorf — [2]Interdisciplinary Centre for Advanced Materials Simulation, Ruhr Universität Bochum — [3]Federal Institute for Materials Research and Testing (BAM), Berlin

Lattice defects are known to directly influence the behaviour of materials. The framework of defect phase diagrams (DPDs) offers a powerful and knowledge-based approach for the tailored design of materials by controlling defect phases in competition to bulk phases. Using ab-initio methods and automized workflows, the DPD for the example of Ga segregation to Σ7 [0001] 21.78° (sym. plane 12-30) Mg grain boundary is calculated. It predicts a series of defect phase transformations, which turn out to be in good agreement with transmission electron microscopy experiments. Similar to bulk phases, the stabilities of defect phases can change with temperature. Therefore, different approaches to extend the DPD considering the relevant entropy contributions are discussed. A new sub-lattice model, which is focused on the statistics of grain boundary site column coverages, provides promising insights into temperature-dependent processes of defect phase transformations.

MM 11.6 Tue 12:15 H10

A computationally highly efficient analytical model for the description of defect phase diagrams — •Jing Yang, Mira Todorova, and Jörg Neugebauer — Max Planck Institute for Sustainable Materials, Düsseldorf, D-40237, Germany

In this work, we propose an analytical thermodynamic model for constructing defect and surface phase diagrams. The model is capable of accurately describing the composition-temperature dependence of phase transitions on the surface, including order-disorder ones. It provides a promising alternative to the sublattice model, which is commonly used in the CALPHAD framework to describe solution phases with ordering, as we demonstrate using the system of Mg surface with Ca substitutions. First, as a foundational reference we construct the surface phase transition with grand-canonical Monte Carlo simulation coupled with cluster expansion. The system undergoes a transition from a solid solution (disordered) phase at high temperature, Ca-poor condition to an ordered defect phase with 1/3 Ca coverage. We then show that it is possible to accurately reproduce the critical transition condition with an analytical model assuming a Boltzmann distribution of the phase fractions. Finally, we compare our method with the sublattice model. The proposed method provides a computationally highly efficient and easy-to-parametrize analytical model for constructing defect phase diagrams.

Topical Talk MM 11.7 Tue 12:30 H10

Atomistic structure of fcc-fcc interface in pure iron and in nanomultilayers: insight from atommistic modeling — •Helene Zapolsky[1], Gilles Demange[2], Yuri Borges Gomes Lima[3], Anastasiai Titova[4], and Renaud Patte[5] — [1]GPM, UMR 6634 University of Rouen, France — [2]GPM, UMR 6634 University of Rouen, France — [3]GPM, UMR 6634 University of Rouen, France — [4]GPM, UMR 6634 University of Rouen, France — [5]GPM, UMR 6634 University of Rouen, France

Very great interest in the structure of interphase interfaces between fcc and bcc crystals has historically arisen due to their technological importance in steels. These interfaces also play a crucial role in metallic nanomultilayers (NMLs), where the presence of numerous semi-coherent interfaces leads to a broad spectrum of novel and remarkable properties. One such system, the Cu/Mo NML, holds promise for thermal management applications due to the combination of copper's excellent thermal conductivity and molybdenum's low coefficient of thermal expansion. In these systems, defects at the fcc/bcc interface have a profound impact the thermal properties of the materials. Recently, the Quasiparticle Approach (QA), based on the phase-field methodology, has emerged as a powerful computational tool for modeling and predicting the atomic-scale structure of various interfaces. In this work, we employ atomistic modeling to examine the detailed structure of the fcc/bcc interface, exploring the relationship between this structure and the mode of interface propagation during displacive phase transformations in pure iron and in Cu/Mo NML.

MM 12: Materials for the Storage and Conversion of Energy

Non-Lithiumbased Materials, Characterisation and Simulation Methods

MM 12.1 Tue 10:15 H22

Where Electrons Rest After Dark: Polaron Stability in Opto-Ionic 2D Niobium Titanate — •Christoph Dähn[1], Yang Wang[2], Risov Das[2], Bettina V. Lotsch[2], Karsten Reuter[1], and Christian Carbogno[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]MPI für Festkörperforschung, Stuttgart

Two-dimensional Niobium Titanate in alkaline solution is promising for opto-ionic energy applications, since it can store photo-generated charge carriers over macroscopic time scales. Although experiments suggest polarons to play a key role for charge storage, identifying the atomistic and electronic mechanisms active in this material has so far proved challenging, also due to the intrinsic disorder of this compound. In this work, we shed light on these aspects by performing hybrid density-functional theory calculations. In a first step, we explore the vast amount of possible lattice decorations resulting from the partial occupation of Ti-sites with Nb, from which we identify a representative set of stable configurations for this disordered material. In a second step, we investigate the stability of polarons at different lattice sites in these configurations. To qualitatively rationalize these results, a fuzzy classification scheme [1] is applied to group comparable polarons according to their local environment. This allows us to analyze how the local environment influences polaron stability and, in turn, long-term charge retention and its underlying mechanisms [2].

MM 12.2 Tue 10:30 H22

Beyond Ion Dynamics: Efficient Charge Transport Simula- tions including Polarons at Battery Scales — •Matteo Rinaldi, Karsten Reuter, and Christian Carbogno — Fritz-Haber- Institut der MPG, Berlin

Polarons have long been recognized as fundamental for charge transport in battery materials - be it as charge carrier or as ion-transport enhancer [1]. Nonetheless, a quantitative modeling of polaron dynamics in such materials has, so far, remained elusive. On the one hand, the activated dynamics of polarons requires time and length scales that are inaccessible with first-principles methods. On the other hand, (machine learned) interatomic potentials do not capture electronic charge transport by construction. In this work, we overcome this hurdle by exploiting force-field models that explicitly account for the electronic viz. polaronic degrees of freedom in a semi-classical, adiabatic fashion. We demonstrate the viability of the approach for lithium titanium oxide (LTO), a prototypical anode material for which polaron hopping is known to play a decisive role [1]. To this end, we train an equivariant message-passing model to density-functional theory data obtained with hybrid functionals. By then performing large-scale molecular-dynamics simulations with this force-field, we investigate both ionic and polaronic transport in LTO as well as their dynamic coupling. We show that polarons diffuse orders of magnitude faster than ions and discuss the implications for the design of battery materials.

MM 12.3 Tue 10:45 H22

Tuning electronic structure of CoNi LDHs via surface Fe doping for achieving effective oxygen evolution reaction — •Yunli Shi[1,2], Huaping Zhao[1], Junqi Li[2], and Yong Lei[1] — [1]Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany — [2]School of Materials Science and Engineering, Shaanxi University of Science and Technology, Xian 710021, China

Cobalt and nickel-based layered double hydroxides (LDHs) are promising oxygen evolution reaction (OER) catalysts, but their performance is limited by poor conductivity and low intrinsic catalytic activity. In this study, CoNi LDHs were used as a matrix, with iron sites introduced onto the surface via cation replacement (Fe-CoNi LDHs). Unlike ternary Fe-CoNi LDHs synthesized through conventional one-step methods, the iron sites in Fe-CoNi LDHs are primarily located on the surface and edges of nanosheets, ensuring abundant exposure of reactive sites. Surface doping was found to optimize the coordination environment and electronic structure, reducing the binding energy between reactants and active sites. As a result, Fe-CoNi LDHs exhibit an overpotential of only 260 mV at 10 mA cm-2, demonstrating superior OER performance. This study elucidates the electronic structure and mechanism of enhanced activity, highlighting the potential of surface doping to advance electrocatalytic applications.

MM 12.4 Tue 11:00 H22

Ferromagnetic chiral hybrid organic-inorganic perovskites — •Muskan Nabi and Alessandro Stroppa — CNR - Institute for SuPerconductors, INnovative materials, and devices Italy

In recent years, chiral hybrid organic-inorganic perovskites where the organic cations are the *source* of chirality, have received great attention from the physics and chemistry community. Their functional properties enable the control of light, charge, and electron spins in the same materials. Here, we discuss the intriguing *chirality transfer mechanism* in newly synthesized ferromagnetic chiral hybrid inorganic perovskite and their interplay with magnetism. Although the organic cations are chiral and polar molecules, their arrangement in the crystal structure results in a chiral non-polar space-group P212121. Moreover, we discuss a new chirality order parameter such as the electronic chirality measure (ECM) aiming at quantify the molecular cation chirality taking into account ionic and electronic degrees of freedoms simultaneously. Also, the relation of ECM to physical properties of chiral hybrid perovskites will be discussed.

MM 12.5 Tue 11:15 H22

Enhanced Supercapacitor Performance of Sr-Doped Barium Stannate (BaSnO3) Nanostructures: Synthesis, Characterization, and Electrochemical Insights — Alaa Farid[1,2], •Diaa El-Rahman Rayan[1,3], Moataz Fayed[4], Saad Mohamed[4], Abdel Hakim Kandil[2], Mohamed Abd El-Nasser[2], and Mohamed Rashad[1] — [1]Central Metallurgical Research and Development Institute (CMRDI), P.O. Box: 87 Helwan, 11421, Egypt — [2]Chemistry Department, Faculty of Science, Helwan University, Cairo, Egypt — [3]Department of Physics, Deraya University, New Minia, Minya, Egypt — [4]Mining and Metallurgy Engineering Department, Tabbin Institute for Metallurgical Studies, (TIMS), Tabbin, Helwan, Cairo Egypt

This study investigates the structural, morphological, thermal, and electrochemical properties of Sr-doped barium stannate. The annealing of undoped BaSnO3 at various temperatures leads to the formation of cubic BaSnO3 phase predominating at 1100 ˚C. The increasing Sr ion doping induces lattice strain, with slight shifts in the (110) peak. HR-TEM analysis confirms high crystallinity with a significant reduction in particle size from 125.3 to 22.6 nm due to Sr doping. Electrochemical performance tests in a three-electrode configuration show that Sr doping significantly enhances charge storage capacity, with Ba0.8Sr0.2SnO3 achieving a maximum specific capacitance of 1902 F.g-1 at 1 A.g-1. Additionally, the device demonstrated an impressive energy density of 65.6 Wh.kg-1 at a power density of 1633.54 W.kg-1.

MM 12.6 Tue 11:45 H22

Advanced Electron Energy Loss Spectroscopy techniques in catalyst analysis — •Daniela Ramermann, Michael Poschmann, Christoph Göbel, Wenchao Wan, Elisabeth H. Wolf, Saskia Heumann, Holger Ruland, and Walid Hetaba — Max-Planck-Institut für Chemische Energiekonversion, Mülheim an der Ruhr

Electron energy loss spectroscopy (EELS) is a powerful technique that gives access to the electronic structure of the sample, enabling analysis of elemental composition, chemical bonding and oxidation states. Combined with the high spatial resolution of a scanning transmission electron microscope, detailed analysis of a catalyst can be carried out, to gain knowledge about the structure-function relationship. In addition to spatially resolved oxidation state analysis, accessing spectra at higher energy losses than commonly used was recently reported.

We apply these techniques to investigate the oxidation states of a CuZn-based MeOH catalyst system spatially resolved, using self-measured standards. Furthermore, we give examples of the utilization of EELS at high energy losses on a Co-based ammonia decomposition catalyst.

MM 12.7 Tue 12:00 H22

Rapid Identification of Ion Migration in Solid-State Ion Conductors from Machine-Learning Raman Spectroscopy — Manuel Grumet[1], Takeru Miyagawa[1], Karin S. Thalmann[2], Tomáš Bučko[3,4], •Waldemar Kaiser[1], and David A. Egger[1] — [1]TUM School of Natural Sciences, Technical University of Munich — [2]Institute of Physics, University of Freiburg — [3]Faculty of Natural Sciences, Comenius University of Bratislava — [4]Institute of Inorganic Chemistry, Slovak Academy of Sciences

Raman spectroscopy is a rapid, non-invasive, and widely available technique that provides a fingerprint of atomic vibrations within solid-state materials. In this work, we demonstrate evidence of Raman signatures that arise from the migration of ions within solid-state ion conductors. We use a rapid computational framework, which consists of machine-learning molecular dynamics simulations [1] and machine-learned polarizability tensors [2], to predict finite-temperature Raman spectra of two classes of superionic conductors, i.e. AgI [3] and Na_3PnS_4 (Pn=P,Sb) [4]. Our simulation results indicate pronounced and broad low-energy Raman intensities due to the host lattice that are correlated with the diffusion of cations. These insights can open novel synergies with experiments to rapidly screen novel compounds for future battery materials. [1] Miyagawa, et al. J. Mater. Chem. A. 12, 11344-11361 (2024) [2] Grumet, et al. J. Phys. Chem. C, 128, 15, 6464-6470 (2024) [3] Brenner, et al. Phys. Rev. Mater. 4, 115402 (2020) [4] Brenner, et al. J. Phys. Chem. MM 12.8 Tue 12:15 H22

Ion Dynamics in Li-Garnet Electrolytes from Machine-Learning Molecular Dynamics and Raman Spectroscopy — •Takeru Miyagawa[1], Hyunwon Chu[2], Willis O'Leary[2], Manuel Grumet[1], Jennifer L.M. Rupp[1,2], Waldemar Kaiser[1], and David A. Egger[1] — [1]TUM School of Natural Sciences, Technical University of Munich — [2]Department of Materials Science and Engineering, Massachusetts Institute of Technology

Lithium lanthanum zirconate (LLZO) is a promising electrolyte compound for solid-state batteries. Despite subtle differences in the structural properties, its cubic phase, often stabilized by doping, strongly exceeds the tetragonal counterpart in its ionic conductivity. Here, we study the interplay of Li ion migration and host lattice dynamics in tetragonal and cubic LLZO, and compare the ion dynamics to Ta-doped LLZO, using machine-learning molecular dynamics benchmarked in our previous study [1]. We observe a strongly correlated Li-ion migration in the undoped cubic LLZO at increased temperatures, whereas the tetragonal phase showed no Li ion conduction. In contrast, Li ion hopping is the dominant mechanism in Ta-doped cubic LLZO. Additionally, we compute finite-temperature Raman spectra [2] of the LLZO materials and correlate them to experiments. Our predicted Raman results accurately align with measured Raman spectra, allowing us to reveal concrete vibrational motifs that may be utilized to screen LLZO films for the presence of the conductive cubic phase. [1] Miyagawa, et al. J. Mater. Chem. A 12, 11344 (2024) [2] Thomas, et al. Phys. Chem. Chem. Phys. 15, 6608-6622 (2013)

MM 12.9 Tue 12:30 H22

Extracting Gibbs free energies from local composition fluctuations in atom probe data — •Parisha Diwan, Jianshu Zheng, Rüya Duran, Guido Schmitz, and Sebastian M. Eich — University of Sttugart

In this work, thermodynamic fluctuation theory which is traditionally used for liquids has been extended to solids by incorporating an additional elastic work component to account for local composition variations, which is not present in liquids. In solids, composition fluctuations are quantified through the relative variance of the composition histogram, which is influenced by the evaluation volume size and interface effects. These fluctuations are key to determining the Gibbs free energy of mixing in solid alloys. The technique most suitable for identifying local composition fluctuations is Atom Probe Tomography (APT), which provides high-resolution, 3D spatial chemical information at the atomic level. This allows for the detection of local composition variations in solid materials, making it an ideal tool for the evaluation of the extended fluctuation theory. The study applies this theory to a Cu-Ni alloy, using experimental APT data and spatial frequency distribution analysis. By comparing the results with existing phase diagram data, the method demonstrates its effectiveness in extracting the Gibbs free energy of mixing from local composition fluctuations in solids. The comparison with the latest CALPHAD depiction of the miscibility gap further supports the reliability of the method, showing that the proposed approach can accurately predict thermodynamic properties in solid alloys based on atomic-scale data.

MM 12.10 Tue 12:45 H22

Nanoscopic Bubble Formation during Hydrogen Desorption: Insight from Simulations and Neutron Scattering at the Nanometer Scale and its Impact on Hydrogen Storage Performance — •Arnab Majumdar[1], Neslihan Aslan[1], Martin Müller[1,2], and Sebastian Busch[1] — [1]GEMS at MLZ, Helmholtz-Zentrum Hereon — [2]Kiel University

Chemical hydrogen storage using complex hydrides is promising; characterizing the process at various length scales is crucial for optimizing this approach. At the nanometer length scale and below, neutron scattering is a powerful non-destructive technique, in particular because of hydrogen's significant scattering interaction with neutrons. Additionally, neutrons scatter differently depending on the isotope, allowing deuterium to be used in place of hydrogen.

Small Angle Neutron Scattering (SANS) is suited for characterizing structures at the nanometer length scale. In situ measurements confirmed the occurrence of the hydrogen storage process but the measurements alone could not provide complete details about the processes.

Computer simulations were performed; the most suitable model described the nanoscopic structure using the probability distribution of different compounds. The evolution of initial to final probability distribution was modelled according to different chemical kinetic models. This approach qualitatively reproduces the experimental data, suggesting the presence of trapped gas at the nanometer scale during desorption. This key insight enables an estimate of volumetric performance at the engineering scale, which shows a good match with experiments.

MM 13: Topical Session: Defects of Defects

Dynamics of dislocations and grain boundaries during recrystallization of metal nanoparticles — •Eugen Rabkin and Jonathan Zimmerman — Department of Materials Science and Engineering, Technion - Israel Institute of Technology, Haifa, Israel

Recrystallization of bulk metals plays a central role in materials processing, yet it has not been utilized so far for the synthesis of metal nanoparticles. In this work we describe the kinetics of recrystallization and related annealing phenomena in Pt nanoparticles. We uniaxially deformed the particles, annealed them both in-situ and ex-situ, and characterized their morphology and microstructure. Our findings reveal that new grains often nucleate within the parent particle, only to be rapidly reabsorbed back into it, with a strong correlation between this phenomenon and particle size. We propose a model that combines recrystallization and recovery through dislocation annihilation at the particle surface, predicting a critical size for recrystallization in nanoparticles. Finally, we propose a set of rules for nanoparticle recrystallization, mirroring the rules of recrystallization in bulk materials.

MM 13.2 Tue 14:30 H10

Hierarchy of defects in near-Σ5 tilt grain boundaries in copper studied by length-scale bridging electron microscopy — •Hui Ding[1], Anoosheh Akbari[2], Enze Chen[3], Harald Rösner[2], Timofey Frolov[4], Sergiy Divinski[2], Gerhard Wilde[2], and Christian H. Liebscher[5] — [1]Max Planck Institute for Sustainable Materials, Düsseldorf, Germany — [2]University of M\"unster, Institute of Materials Physics, Münster, Germany — [3]Department of Materials Science and Engineering, Stanford University, Stanford, CA 94305, USA — [4]{Materials Science Division, Lawrence Livermore National Laboratory, Livermore, CA 94550, USA — [5]Faculty of Physics and Astronomy, Ruhr University Bochum, Bochum, Germany

Grain boundaries (GBs) are material imperfections that significantly impact material properties. In this study, we utilized aberration-corrected scanning transmission electron microscopy to examine the structure of a series of near-Σ5(310)[001] tilt grain boundaries in copper. Globally, the GB appears flat with no noticeable defects. On the atomic-scale, however, various types of GB defects are observed. When a slight deviation in the misorientation is introduced, a patterning emerges featuring characteristic structural units from the Σ5 (310) [001] and Σ5 (210) [001] tilt boundaries. The structural landscape of the GB becomes more complex when GB plane inclination is also present, such as a wavy morphology or staircase-like architecture. Our investigation into GB structure, particularly its inherent defects, is a prerequisite towards gaining atomic-scale insights into their potential impact on material properties.

MM 13.3 Tue 14:45 H10

Data-driven modelling of vacancy segregation to grain-boundaries — •Christoph Dösinger, Oliver Renk, and Lorenz Romaner — Montanuniversität Leoben, Department of Materials Science, Roseggerstraße 12, A-8700 Leoben, Austria

Both vacancies and grain-boundaries (GB) are important defects in materials. The vacancies can interact with the GBs which might lead to a formation of voids, as a result this might start the formation of pores or cracks. From atomistic simulations it is known that vacancies can be attracted to GBs, which indeed may act as sinks for the vacancies. However, such simulations, especially if performed using ab-initio, methods can be tedious and costly. In this work we apply machine learning (ML) methods to predict the segregation energies of vacancies to GBs, which give a measure how strongly a vacancy is attracted to specific sites at different GBs. For this ML approach each segregation site is described by its local environment which can be encoded by using for example Steinhardt or SOAP parameters. Together with the site-specific segregation energies a regression model, in our case a Gaussian Process, is trained. Previously we have shown that this approach can be used to predict the segregation of solutes to grain-boundaries. This method for prediction the segregation of vacancies is tested and applied to GBs in tungsten, for which a complete data-set is available for 15 different GBs (Σ3 – Σ43). By using this diverse set of GBs, it will be possible to predict the GB segregation of vacancies for general GBs or polycrystalline materials.

MM 13.4 Tue 15:00 H10

A high-throughput ab initio segregation study of light elements at Ni grain boundaries and their effects on cohesion — •Han Lin Mai[1], Jörg Neugebauer[1], and Tilmann Hickel[2] — [1]Max-Planck-Institut for Nachhaltige Materialien GmbH, Dusseldorf, Germany — [2]Bundesanstalt für Materialforschung und -prüfung, Berlin, Germany

Segregation of alloying/tramp elements to grain boundaries (GBs) can drastically affect the properties of metallic alloys. We present a high-throughput density-functional theory-based study on the segregation of smaller elements, H, B, C, N, O, P, S, in a variety of FCC Ni GBs and their effects on cohesion. To support GB engineering efforts, we investigate the thermodynamics of segregation and calculate its effects on interface cohesion. These elements often play a significant role in engineering alloys, but their positioning at GBs is ambiguous and challenging to study. The study utilizes efficient and highly automated workflows using the integrated development environment pyiron. We discuss chemical and structural trends for segregation and cohesion at GBs for these elements. In order of segregation binding strength at GBs, the trend is approximately O > B, S > P > N = C = H. Elemental trends for maximum segregation binding strength across various GB models are largely consistent, enabling qualitative cross-element comparisons through small GB sets. However, conventional metrics, such as GB energy, are insufficient for predicting segregation strength or quantity for these elements.

MM 13.5 Tue 15:15 H10

Mechanistic Influence of Interstitial Solutes on Hydrogen Trapping at Σ5 GB in γ-Fe — •Poulami Chakraborty, Mauricio Rincon Bonilla, and Elena Akhmatskaya — Basque Centre for Applied Mathematics, Bilbao, Spain

The local variation of grain boundary atomic structures and chemistry caused by segregation of impurities influences the macroscopic properties of polycrystalline materials. Here, the effect of co-segregation of carbon and boron on hydrogen segregation at a Σ5 (210) [001] tilt grain boundary in γ-Fe phase is studied by density functional theory. The grain boundary structure predominantly features kite-like motifs, which are disrupted by atomic-scale defects. First-principles calculations indicate that carbon and boron exhibit the strongest segregation tendency. Their interaction with aluminum is notably repulsive, leading to aluminum depletion at the grain boundary. Subsequently, the effect of boron and carbon co-segregation is studied with the introduction of H at the GB. Our comprehensive investigation provides valuable insight in the interaction of interstitial impurities with substitutional solutes, which, strongly influences grain boundary composition and the properties of the interface.

MM 14.1 Tue 14:00 H22

Multiscale defective interfaces for realizing Na-CO2 batteries with ultralong lifespan — •changfan xu, tzuchin huang, and yong lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

The cycling capability of Na-CO2 batteries has been impeded by limitations in the kinetics of cathodic CO2 reduction/evolution reaction (CO2RR/CO2ER) as well as the challenging process of depositing/stripping metallic Na during cycling.[1-3] Herein, a "two-in-one" electrode with multiscale defective FeCu interfaces (CP@FeCu) is presented, improving the kinetics of CO2RR/CO2ER and modulating sodium deposition behavior.[4] The enhancement of sodiophilicity and catalytic properties is attributed to multiscale defective FeCu interfaces, as revealed by experimental and theoretical investigations. The defect and valence oscillation effects originate in multiscale defective FeCu interfaces, effectively facilitating reactant adsorption and Na2CO3 decomposition during CO2RR/CO2ER processes, along with exceptional cycling stability of 2400 cycles (4800 h) at 5 μA cm*2. Meanwhile, the CP@FeCu with high sodium affinity creates a uniform electric field and strong Na adsorption, promoting favorable nucleation sites for dendrite-resistant and durable anodes. This work provides scientific insights into the design of "two-in-one" electrodes, which are crucial for addressing challenges in sodium anodes and CO2 cathodes.

MM 14.2 Tue 14:15 H22

Electro-chemo-mechanical behavior of a layered cathode material upon cycling — •Robert Löser[1], Yug Joshi[2], Roham Talei[1], and Guido Schmitz[1] — [1]University of Stuttgart, Stuttgart, Germany — [2]Max-Planck-Institut für Nachhaltige Materialien GmbH, Düsseldorf, Germany

The mechanical properties of lithium-ion cathode materials play a critical role in determining battery performance such as cycle life, durability, and safety, especially when the battery is under external pressure which is typical for all-solid-state batteries. This research investigates LiCoO2 (LCO), a prevalent hexagonal layer-structured cathode material, and explores its mechanical responses during de-/lithiation using sputter-deposited thin films and nanoindentation. The values of the experimental Young*s modulus in pure (101) and (003) lattice orientations are quantified to 337.1 * 8.7 GPa and 267.9 * 7.2 GPa, respectively, in the fully lithiated state. Furthermore, a substantial texture-dependent decrease in Young*s modulus upon lithium deintercalation is demonstrated, probably due to modification of the bonding interactions between the cobalt oxide layers. Delithiation also elevates the relative contribution of plastic deformation, indicating that dislocation glide becomes easier in deintercalated states. By extensive cycling, the Young*s modulus in higher lithiated charge-states decreases considerably which is most-likely due to irreversibility of phase transitions. The work provides valuable insight on the dynamic changes of the mechanical properties during electrochemical cycling of LiCoO2, which paves the way for all other layered cathode materials.

MM 14.3 Tue 14:30 H22

$MnTiO_3$ as a Carbon-Free Cathode for Rechargeable Li-oxygen Batteries — Doaa Ahmed[1,2], Wernfried Mayr-Schmölzer[1], Mustafa Çelik[3,4], Abdulkadir Kizilaslan[3,4], and •Gregor Vonbun-Feldbauer[1,2] — [1]Institute of Advanced Ceramics, TU Hamburg, Germany — [2]Institute of Soft Matter Modeling, TU Hamburg, Germany — [3]Research, Development and Application Center (SARGEM), Sakarya University, Turkey — [4]Department of Metallurgical and Materials Engineering, Engineering Faculty, Sakarya University, Turkey

Lithium-oxygen batteries (LOB) are promising energy storage systems due to their high theoretical energy density. However, their main challenges are the sluggish kinetics of oxygen reduction and evolution reactions (ORR/OER) and high charge overpotentials. To overcome these challenges, the development of a suitable catalyst is crucial. Here, $MnTiO_3$ was investigated as a carbon-free cathode catalyst using density functional theory (DFT) calculations and experimental approaches. DFT calculations revealed the coexistence of Mn and Ti energy levels near the Fermi level of $MnTiO_3$, which facilitates ORR/OER. This feature endows MnTiO3 with a bifunctional role in promoting battery performance. Our DFT-based investigation further elucidates the surface stability and catalytic properties of $MnTiO_3$. In addition, experiments confirm that the electrochemical reactions on $MnTiO_3$ follow a two-electron pathway. LOBs with $MnTiO_3$ exhibit a total overpotential of 1.18 V and 1.55 V from DFT and electrochemical measurements, respectively, and current densities up to 1 A/g.

MM 14.4 Tue 14:45 H22

Modeling and optical characterization of Lithium deposition on Copper current collectors — •Len Kimms[1], Tjark Ingber[2], Diddo Diddens[1,2], and Andreas Heuer[1] — [1]Institut für physikalische Chemie, Universität Münster — [2]Helmholtz Institute Münster (IEK-12), Forschungszentrum Jülich GmbH

In this contribution, we will present modeling results of the initial deposition of lithium metal on a copper current collector combined with experimental insights. Zero–excess lithium–metal batteries (ZELMBs) may offer higher energy densities, better safety, and reduced cost by reducing the amount of lithium employed in the cell. Instead of an excess of lithium as electrode, the anode is formed in situ during charging. When charging the battery, lithium is plated on the current collector directly. However, the lifespan of ZELBMs in practical applications is still limited by irreversible loss of active lithium. The loss is induced by the high reactivity of lithium which causes parasitic side reactions and dendrite growth during charging cycles. To uncover the mechanisms at play, the initial deposition of lithium metal has been experimentally investigated by plating varying amounts on a copper surface with different current densities. The deposits have been characterized by scanning electron microscopy (SEM) and laser scanning microscopy (LSM) in an automated way. Numerical simulations of a simple geometric model were employed to uncover the relevant mechanisms which govern the growth over different stages. Combining the experimental and numerical results, an effective description of the deposition has been found.

MM 14.5 Tue 15:00 H22

Preparation of Prussian blue analogue materials and their application to potassium-ion batteries — •Ping Hong, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Prussian blue (PB) and its analogs (PBAs), with their unique open framework structure and chemical stability, have emerged as promising cathode materials for potassium-ion batteries (PIBs). PB and PBAs feature three-dimensional channels, facilitating rapid potassium-ion intercalation and de-intercalation, thus delivering excellent rate performance. Furthermore, its low-cost synthesis and environmentally friendly properties provide a strong foundation for potential commercial applications. Despite these advantages, the practical application of PBAs is hindered by challenges such as their high solubility in electrolytes and limited cycle stability and life. To overcome these limitations, we optimized synthesis techniques (by simple adjustment of the co-precipitation method) and structural design, leading to significant improvements in material performance. In addition, a series of adjustments were made to the binder, electrolyte, and voltage range used in the batteries. The improved PBA cathode exhibited remarkable cycling stability, showing almost no capacity decay after 500 cycles at a current density of 100 mA/g within the voltage range of 2.0-4.0 V. It maintained excellent cycling performance even under high current conditions, providing strong support for the advancement of high-performance PIBs.

MM 15: Invited Talk. C. Scheu

Invited Talk MM 15.1 Wed 9:30 H10

Grain Boundary Defect Phases in Thermoelectric Materials: Impact on physical properties — •Christina Scheu[1], Ruben Bueno Villoro[1], Siyuan Zhang[1], Baptiste Gault[1], Duncan Zavanelli[2], and Gerald Jeffrey Snyder[2] — [1]Max-Planck-Institute for Sustainable Materials, Max-Planck-Str. 1, 40627 Düsseldorf, Germany — [2]Northwestern University, Clark Street 633, 60208, Evanston, USA

Grain boundary defect phases are known since more than three decades, but mostly the impact on mechanical properties was investigated. In our work we were able to correlate the atomic structure and chemical composition of grain boundary defect phases in different thermoelectric materials to the electrical and thermal properties. For example, we were able to show by atom probe tomography and scanning transmission electron microscopy that grain boundaries in p-type Ti(Co,Fe)Sb Half-Heusler thermoelectric materials possess a signifi-

cant Fe segregation and Co depletion compared to the bulk. Atomic column resolved scanning transmission electron microscopy images reveal that the grain boundary phase has a hexagonal close packed stacking compared to the face centered cubic stacking of the bulk with lattice distances differing from those of any known bulk phase. The grain boundary defect phase acts as fast charge carrier pathway providing a high electrical conductivity while simultaneously reducing the thermal conduc

MM 16: Topical Session: Thermophysical Properties of Bulk Metallic Glasses and Bulk Metallic Glass-forming Liquids

Time: Wednesday 10:15–13:00 Location: H10

Topical Talk MM 16.1 Wed 10:15 H10

Microstructure and transport in model isotropic amorphous solids — •Peter Derlet — Condensed Matter Theory Group, Paul Scherrer Institut, Switzerland

Amorphous solids lack long range order, however structural heterogeneity can exist over intermediate length scales suggesting the notion of a glassy microstructure. Such spatial variations, whatever they may be, can also be related to variations in thermally driven structural fluctuation time scales. In this talk, I will present atomistic simulations of model isotropic (metallic) binary glass systems spanning the microsecond timescale, and discuss the resulting amorphous structure in terms of bond frustration, demonstrating that despite the strong disorder, a percolative region containing strong medium range order emerges that fundamentally affects transport and dissipation. Particular focus will be given to how such simulations can give insight into experiments probing arrested colloidal glasses obtained through isotropic compression, and structural decorrelation in a metallic glass probed by long-time x-ray photon correlation measurements.

MM 16.2 Wed 10:45 H10

Liquid-like versus Stress-Driven Dynamics in a Metallic Glass Former Observed by Temperature Scanning XPCS — •Maximilian Frey[1], Ralf Busch[1], and Eloi Pineda[2] — [1]Chair of Metallic Materials, Saarland University, Campus C6.3, 66123 Saarbrücken, Germany — [2]Department of Physics, Institute of Energy Technologies, Universitat Politècnica de Catalunya - BarcelonaTech, 08019 Barcelona, Spain

Using high flux synchrotron radiation (ESRF, ID10), we study a Pt-based metallic glass former via X-ray photon correlation spectroscopy (XPCS) upon temperature scanning through the glass, glass transition and supercooled liquid (SCL). In the equilibrium SCL, the obtained intensity autocorrelation functions are well-described by a conventional Kohlrausch-William-Watts (KWW) model. Yet, in the glass and especially the glass transition region, this approach fails. Instead, we demonstrate that a multiplication of two KWW functions allows to describe the complex decay shape. Within the glass transition region, the fit parameters of the two separate KWW fits decouple massively. While one KWW component models the compressed shape of glass-typical non-equilibrium dynamics, the other fit maintains stretched liquid-like characteristics. We demonstrate that the compressed decay can be likely addressed to ballistic-like atomic motions while the stretched component apparently reflects (sub-)diffusive atomic motions, which are both superimposed in the non-equilibrium.

MM 16.3 Wed 11:00 H10

Non-monotonic hydrodynamic relaxations in a nanochannel — •Linnea Heitmeier[1,2], Thomas Voigtmann[1,2], and Jesper Schmidt Hansen[3] — [1]Institut für Materialphysik im Weltraum, Deutsches Zentrum für Luft- und Raumfahrt (DLR), Köln, 51170 — [2]Heinrich Heine University, Universitätsstraße 1, Düsseldorf — [3]DNRF Center Glass and Time, IMFUFA, Department of Science, Systems and Models, Roskilde University, DK-4000 Roskilde

Nanotechnology is an active research field with applications in the everyday-life, electronics and medicine.

In my talk, I will present results of Molecular-Dynamics Simulations of a glass-forming liquid, which is confined in a nanochannel and excited with a sinusoidal force in order to probe the velocity relaxation on different lengthscales.

I show that the velocity relaxation behavior in different regions of the channel depends non-monotonically on the position of the fluid.

To explain the results, I will make use of the Maxwell-model for fluids, which states that a fluid behaves like an elastic solid on small timescales and like a viscous fluid on large timescales.

The simulation results can be recovered by this model, when using generalizations of this model:

On the one hand, a two-mode-Maxwell-model captures the contributions from the short-time dynamics and the slow structural relaxation to the viscosity. On the other hand, a spatially non-local generalization of the Maxwell-model allows to capture the velocity relaxation in the channel depending on different positions.

MM 16.4 Wed 11:15 H10

Structural Complexity and Atomic-Scale Dynamics in Metallic Glasses — •Emel Gurbuz and Elif Ertekin — University of Illinois Urbana-Champaign

Metallic glasses (MG) become prominent for their exceptional mechanical strength, corrosion resistance, and versatile processing capabilities, all strongly linked to their amorphous atomic structures. Despite extensive research, the interplay between structural motifs, their connectivity, and the resulting dynamic behavior during glass formation remains insufficiently understood.

This study uses molecular dynamics simulations to explore the dynamics of glass formation in MG systems with varying compositions (Fe_xZr_{100-x}, Co_xZr_{100-x}, Cu_xZr_{100-x}). By analyzing melt-quench trajectories, we identify key structural motifs, such as five-fold icosahedra, and examine their role in the "freezing in" process. Regions with rapid solidification and liquid-like behavior are characterized by tracking atomic diffusivity distributions over time. Remarkably, sequences of connected icosahedra persist as liquid-like regions even at low temperatures, facilitating ionic transport.

Our findings reveal critical insights into the mechanisms governing structural and dynamic complexity in MGs, advancing the understanding of their formation and potential for designing functionally optimized materials.

Topical Talk MM 16.5 Wed 11:45 H10

Structural relaxation and deformation of bulk metallic glasses — •Gerhard Wilde — Institute of Materials Physics, University of Münster, Germany

In metallic glasses, relaxation is discussed in the context of shear transformation zones, viscous flow, structural medium-range order (MRO) and even crystal nucleation. However, the structural origin of different relaxation modes and how these structures change during relaxation, rejuvenation or deformation is rather unclear. In order to address some of these related aspects, calorimetric measurements have been performed together with TEM-based analyses of the local medium range order structures before and after plastic deformation as well as after controlled thermal relaxation. The combined results of macroscopically averaging and spatially resolved analyses are discussed with respect of the correlations between relaxation, deformation and modifications of the MRO structure.

MM 16.6 Wed 12:15 H10

Tracing the Roots of Elastic Heterogeneity in Metallic Glass — •Reza Rashidi[1,2], Birte Riechers[1], and Robert Maass[1,2,3] — [1]Federal Institute of Materials Research and Testing (BAM), Unter den Eichen 87, 12205 Berlin, Germany — [2]Department of Materials Engineering, Technical University of Munich, 85748 Garchingen, Germany — [3]Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign, Urbana, IL 61801, USA

Metallic glasses (MGs) show structural and temporal heterogeneities over a broad range of time and length scales. With the aid of atomistic simulations, we can explain these dynamic and structural fluctuations at the nanometer scale. Here, our focus shifts to the larger length scale of property variations and the ongoing exploration of their origin. In past work, we suggested that cooling constraints during solidification could lead to elastic heterogeneities and therefor an elastic microstructure on the scale of ~100 nm (Materials & Design 229 (2023) 111929). In this presentation, we further support this idea by examining various casting geometries and thermal histories, tracking how elastic decorrelation lengths change with sample size and position within the MG. We also find that thermal annealing reduces decorrelation length-scale gradients and smooths out fluctuations in modulus values (Scripta Materialia 255 (2025)116380). In concert with the nano-elastic property assessment, we leverage spatially-resolved scanning nanobeam diffraction in the search for a structural origin of elastic microstructure.

MM 16.7 Wed 12:30 H10

Yield surfaces of glass-forming fluids — •Stephan Domann[1,2] and Thomas Voigtmann[1,2] — [1]Institut für Materialphysik im Weltraum, DLR Köln — [2]Heinrich-Heine-Universität

The yielding of amorphous solids depends in principle on the geometry of the deformation applied to the solid. This defines a ”static” yield surface in the state of principal stresses that is typically described by empirical models (such as von Mises, Tresca, Drucker-Prager etc). In a similar vein, approaching the glass transition from the fluid side, the flow stresses approach a dynamical yield stress,

defining the dynamical yield surface as the geometry of the flow is varied. Owing to the difficulty of imposing arbitrary steady deformation geometries, both experiment and simulation data are scarce.

We will discuss an approach to model yield surfaces that is rooted in a first-principle theory originally developed by Fuchs and Cates, the combination of mode-coupling theory of the glass transition with the integration-through transients framework (ITT-MCT). Using suitable simplifications, we recover some of the well-known empirical yield surface descriptions as limiting cases. It also sheds light on the qualitative differences arising between models of the upper-convected and the lower-convected type. We also performed non-equilibrium molecular-dynamics simulations of a model glass former to determine the dynamical yield surface. Surprisingly, this attains a shape that is in qualitative agreement with the lower-convected model, although common expectation is that upper-convected models are more canonical in emerging from microscopic descriptions of glass forming fluids.

MM 16.8 Wed 12:45 H10

Unveiling the Asymmetry in Density within the Shear Bands of Metallic Glasses — •Harald Rösner[1], Arabinda Bera[2], and Alessio Zaccone[2] — [1]Universität Münster, Institut für Materialphysik, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany — [2]University of Milan, Department of Physics "A. Pontremoli", via Celoria 16, 20133 Milan, Italy

Plastic deformation in metallic glasses at room temperature leads to the development of shear bands due to shear localization. In many experiments, shear bands have shown local density variations along their path, with a distinct imbalance in magnitude between local densification and dilation. However, a comprehensive mechanistic understanding or theory to explain this asymmetry has been lacking until now. Here, we introduce a new model [1] that consists of a sequential arrangement of alternating topological charges, generating a dipolar field. The resulting microscopic displacement field, when integrated into the deformation gradient tensor, provides an accurate analytical solution for the observed imbalances in the density variations. The implications of this model are discussed, highlighting the potential to elucidate a broader range of observations in shear bands.

MM 17: Development of Calculation Methods

Machine Learning, DFT

Time: Wednesday 10:15–12:45 Location: H22

MM 17.1 Wed 10:15 H22

Premature Convergence, It's Nothing to be Embarrassed About: Solving Performance Issues with Swarm-Based Global Optimization to Generate Pt Nanoparticle Ensembles — •Julian Holland[1], Malgorzata Makos[3], Difan Zhang[4], Mal-Soon Lee[3], Roger Rousseau[3], Chris-Kriton Skylaris[2], and Vanda Glezakou[3] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]University of Southampton, Southampton, UK — [3]Oak Ridge National Laboratory, Oak Ridge, USA — [4]Pacific Northwest National Laboratory, Three Cities, USA

Swarm-based global optimisation (GO) algorithms have proven successful in exploring potential energy surfaces (PESs) of chemical systems. However, they are often limited by their serial implementation. Our GO software, pyGlobOpt, uses an asynchronously parallel artificial bee colony (ABC) methodology, mitigating this limitation. We enhance pyGlobOpt further by tuning parameters against a new, general, ensemble generation assessment criterion. Using this criterion, we were also able to demonstrate how to overcome premature convergence, an issue pervading the use of the ABC algorithm for some systems, using a clustering-based methodology. We demonstrate that using the clustering algorithm alongside tuned pyGlobOpt parameters can lead to a 5-fold increase in the number of unique low-energy structures found as well as more than halving the average energetic distance from the global minimum. We produce ensembles of thermodynamically relevant Pt nanoparticles with varying hydrogenation using our enhanced software and compare to experimental results.

MM 17.2 Wed 10:30 H22

Charge Equilibration in Machine Learning Potentials — •Martin Vondrak[1,2], Johannes Margraf[1], and Karsten Reuter[2] — [1]Bayreuth University, Bayreuth, Germany — [2]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany

Machine learning (ML) techniques have recently been shown to bridge the gap between accurate first-principles methods and computationally cheap empirical potentials. This is achieved by learning a mapping between a system's structure and its physical properties. To this end, state-of-the-art models typically represent chemical structures in terms of local atomic environments. This inevitably leads to the neglect of long-range interactions (most prominently electrostatics) and non-local phenomena (e.g. charge transfer), resulting in significant errors in the description of e.g. polar molecules or materials in non-isotropic environments. To overcome these issues, we are developing ML frameworks for predicting charge distributions in molecules based on Charge Equilibration (QEq). Here, atomic charges are derived from a physical model using environment-dependent atomic electronegativities. In this presentation, we will demonstrate strategies for creating long-range interatomic potentials on the example of Kernel Charge Equilibration (kQEq) models combined with local Gaussian Approximation Potentials (GAP). An alternative approach, incorporating QEq into the equivariant MACE neural network scheme will also be discussed.

MM 17.3 Wed 10:45 H22

Development of on-the-fly kinetic Monte Carlo framework with neural network potentials for surface chemistry — •Tomoko Yokaichiya, Tatsushi Ikeda, Koki Muraoka, and Akira Nakayama — The University of Tokyo, Tokyo, Japan

It is established that adsorbate-adsorbate lateral interactions in heterogeneous catalysis significantly influence adsorption and activation energies. To further our understanding of the degree to which such lateral interactions affect catalytic properties, we develop an "on-the-fly" adaptive kinetic Monte Carlo (kMC) simulation scheme. The scheme proceeds by energetically evaluating each configuration, including its local adsorbate-rich environment, using a neural-network potential then stores them to a database for efficient reuse in later kMC iterations. We apply this scheme to the industry-relevant interactions of H adsorption and diffusion on Pd and Pt surfaces as well as CO oxidation on Pt surfaces. With this scheme, we are able to elicit the extent lateral adsorbate-adsorbate interactions influence surface reactions and diffusion.

MM 17.4 Wed 11:00 H22

DECAF: An Open Source Local Atomic Environment Classifier — •King Chun Lai, Sebastian Matera, Christoph Scheurer, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin

Classification of local atomic environments (LAEs) is an inevitable task in most atomic-scale modeling and simulation. The reason is trivial, atoms' characteristics are predominantly determined by neighbors within a limited radius. The task itself, however, is abstract and error-prone due to the diversity of structures and the often ambiguous relationship between geometry and atomic behaviors. To address these issues, we have developed the open-source package DECAF during the last years [1]. DECAF automatically identifies equivalence groups within atomic structure datasets on the basis of the LAEs. We showcase the usage of the DECAF package on a set of nanotructures. We explain the theoretical background as well as the influence of different options to control the outcome. A particular feature is DECAF's ability for out-of-sample classification, identifying LAEs that differ from any groups in the training set. We provide examples where this has been exploited such as automatic process exploration [2] or active learning.

MM 17.5 Wed 11:15 H22

Accurate TDDFT Excited-State Spectra Across the Full Spectral Range — •Matthias Kick and Troy Van Voorhis — Massachusetts Institute of Technology, Cambridge, MA, USA

Theoretically, electronic excitations can be obtained by analyzing the frequency components of the time-dependent dipole moment obtained from real-time time-dependent density functional theory (RT-TDDFT) simulations. Yet, an exact treatment of electronic excitations in large systems with TDDFT is computational prohibitive. Super-resolution techniques such as compressed sensing typically fail due to the presence of a quasi-continuum of electronic excitations. We present a new approach where we combine exact short-time dynamics with approximate frequency space methods. As a prototypical test system, we use an organic dye-molecule adsorbed on a semi-conductor quantum-dot surface. We calculate the entire electronic absorption spectrum of this system and find that our approach can accurately capture narrow features and a quasi-continuum of states at the same time. We see a reduction of the required amount of data points up to a factor of 20 compared to standard Fourier analysis. By doing so, our

method allows us to study electronic properties of large systems in ways that are not currently possible.

MM 17.6 Wed 11:45 H22

Beyond-DFT Machine-Learning Interatomic Potentials and Applications to Covalent-Organic Frameworks — •Yuji Ikeda, Axel Forslund, and Blazej Grabowski — University of Stuttgart, Germany

Covalent-organic frameworks (COFs) are nanoporous crystalline materials composed of covalent organic secondary building units (SBUs), primarily composed of light elements such as C, N, O, and H. Many COFs exhibit a quasi-two-dimensional layered structure, stabilized by van der Waals (vdW) interactions. Machine-learning interatomic potentials (MLIPs) offer an exciting opportunity to explore COFs, enabling access to extended time and length scales in molecular dynamics (MD) simulations. To accurately model vdW interactions, MLIPs must be trained on datasets that include these effects, often derived from vdW-DFT functionals. However, vdW-DFT methods are essentially semi-empirical, with parameters calibrated for experimental agreement, raising concerns about their transferability. Instead, we propose generating training data from post-Hartree-Fock methods, such as coupled-cluster (CC) calculations, which are non-empirical and provide beyond-DFT accuracy. By utilizing MLIPs trained on these high-accuracy datasets, we aim to investigate the structural properties of COFs in unprecedented detail.

MM 17.7 Wed 12:00 H22

Performance and limits of finite-temperature DFT for SiO2 — •Axel Forslund, Jong Hyun Jung, Blazej Grabowski, and Yuji Ikeda — Institute for Materials Science, University of Stuttgart, Germany

Silicon dioxide (SiO2) is a widely studied compound, yet far from fully understood. It exists in a variety of different phases, several of which are dynamically stabilized. These structures require dynamic vibrations of the atoms to not transform, and pose a challenge from an atomistic modeling point of view. Even in recent publications where state-of-the-art machine-learning interatomic potentials (MLIPs) have been used, the predictions differ significantly from experiments. For example, the transition between the two dynamically stabilized phases beta-quartz and cristobalite is very sensitive, and a single meV/atom shift can change the transition by 100 K. Not only the accuracy of the MLIP and the method for free-energy calculations matters, but also the underlying ab initio data play a crucial role. We demonstrate this sensitivity, and provide a simplified, yet precise method of estimating the quartz-cristobalite transition temperature. This approach is accurate enough to closely estimate the transition temperature using new density-functional-theory (DFT) functionals, and we demonstrate this for several functionals and on-top corrections. Our method is also efficient enough for using the random-phase approximation (RPA), which provides a transition temperature in very good agreement with the average CALPHAD value, and thus serves as a benchmark for the development of improved DFT functionals.

MM 17.8 Wed 12:15 H22

DSKO: Dancing through DFTB Parametrization — •Artem Samtsevych, Yihua Song, Christoph Scheurer, Karsten Reuter, and Chiara Panosetti — Fritz Haber Institute of the Max Planck Society, Berlin, Germany

Density Functional Tight-Binding (DFTB) offers a computationally efficient alternative to *ab initio* methods, bridging between the accuracy of DFT and the speed of semiempirical models. The approximate nature of DFTB makes its reliability highly dependent on parameter quality. While recent advancements have significantly improved the parametrization of the so-called repulsive potential, the parametrization of the so-called electronic part of the DFTB interaction remains relatively simplistic and underdeveloped.

Here, we present our in-house DFTB Slater-Koster Optimizer (`DSKO`), a novel DFTB parametrization framework that aims at producing highly accurate and transferable electronic parameter sets, under rigorous physical constraints. By incorporating robust optimization algorithms and physics-informed loss functions, `DSKO` generates parameters that align well with high-level DFT references, particularly in predicting electronic properties like density of states (DOS) and band gaps. The versatility of `DSKO` facilitates the application of DFTB to a wide spectrum of materials science challenges, from catalysis to energy storage, paving the way for routine high-fidelity semiempirical simulations.

MM 17.9 Wed 12:30 H22

A Fundamental Study of Slater-Koster Tables in Density Functional Tight-binding within Trial Nickel Oxides Systems — •Yihua Song, Artem Samtsevich, Christoph Scheurer, Karsten Reuter, and Chiara Panosetti — Fritz Haber Institut

Density-Functional Tight Binding (DFTB), a semiempirical approximation to Density Functional Theory (DFT), is widely used thanks to its undoubtful computational efficiency, which allows to access large scale systems out of reach for DFT, while keeping adequate accuracy and direct electronic structure information. To be mentioned, even with non-spin polarized and non +U reference, the optimized parameters are able to be highly transferable to spin-polarized, DFTB+U and large scale calculations without any pain. The speed advantage in DFTB originates from precalculating distance dependent two-center interaction integrals for each atomic species pair, following the Slater-Koster (SK) principle[1]. In a fundamental study of the prototypical system Ni/NiOx, we test the hypothesis of adapting the SK integrals depending on the local environment. Considering a trial structure containing Ni in different oxidation states simultaneously, we find that assigning to each Ni "type" its optimal SK parametrization significantly improves the description of the band structure and density of states. Generalizing this concept opens a promising way towards adaptive, reliable, machine-learnable SK parameters.
