INTERNATIONAL YEAR OF Quantum Science and Technology

Image designed by Freepik and DPG/Carstensen

Supported by

WILHELM UND ELSE HERAEUS-STIFTUNG

quantum2025.de

www.dpg-physik.de

Dear participants,

Welcome to the DPG Spring Meeting of the Condensed Matter Section on the campus of the University of Regensburg.

Our Spring Meetings are the DPG's flagship events for promoting scientific exchange — both for internal communication within the DPG and for exchange with researchers from all over the world. We expect a total of up to 10,000 guests at our Spring Meetings, which will once again make the DPG conferences the largest platform for scientific exchange in the field of physics in Europe this year. The comprehensive inclusion of presentations by young scientists in the conference program is also a unique selling point at both national and international level. This is by no means a matter of course: on the one hand, this is due to the well-coordinated cooperation of our many committed conference organisers in the DPG and the support of our DPG office in Bad Honnef. On the other hand, it is thanks to the generous support of the universities that are excellent hosts for our conferences. For a whole week, the universities are almost entirely dedicated to physics and thus become internationally visible "beacons" of physics research.

We are also working on making our conferences even more international, in the spirit of „Science bridges cultures." I am therefore very pleased that the DPG communication programme, which enables young scientists to actively participate in DPG conferences at the earliest possible stage of their scientific training, has been expanded thanks to the generous support of the Wilhelm und Else Heraeus-Stiftung: by awarding additional scholarships to young scientists from the countries supporting the electron storage ring "SESAME" in the Middle East as well as from Central and Eastern European countries to participate in our conferences. Strengthening and fostering international scientific exchange cannot be overestimated — especially in these times!

As the world's largest physics society, the DPG is also one of the main initiators of this year's "International Year of Quantum Science and Technology" (IYQ). The DPG is taking the lead in implementing the IYQ proclaimed by the UN in Germany. The formulation of quantum mechanics in 1925 created a lasting foundation for our physical understanding of nature. Quantum technologies have changed our daily lives and have become pillars of our prosperity, which is why we are celebrating their successes and highlighting future prospects. Under the motto "Quantum2025 — 100 years is just the beginning..." within the framework of IYQ, a wide variety of events and activities are being organized and coordinated by DPG (see *quantum2025.de*). I would like to thank all those who are contributing to the success of the quantum year!

The success of this Spring Meeting is only possible with the greatest commitment. I would like to express my sincere thanks to everyone involved. First of all, I would like to thank the University of Regensburg for their hospitality and support. Many thanks also to the Wilhelm und Else Heraeus Stiftung for generously supporting all DPG Spring Meetings. I would also like to thank the participating DPG Divisions and Working Groups for organising the scientific programme. My special thanks also go to the local organising committee at the University of Regensburg and its head, Prof. Christoph Strunk, Institute of Experimental and Applied Physics.

Finally, I would like to thank the DPG Head Office for its support of all Spring Meetings.

I wish you a great DPG Spring Meeting at the University of Regensburg with many new insights and excellent discussions!

Prof. Dr. Klaus Richter

Programme

The scientific programme consists of **3,849** contributions:

11	Plenary Talks
1	Evening Talk
8	Prize Talks
1	Ceremonial Talk
5	Lunch Talks
215	Invited Talks
32	Topical Talks
2,368	Contributed Talks
14	Tutorials
1,192	Posters
2	Discussions

The programme stated in this document corresponds to the status from January 30, 2025. You will find the updated programme using the DPG App and at

www.dpg-verhandlungen.de/year/2025/conference/regensburg

Information for Participants

The conference will be held March 16 – 21, 2025

Conference Information

Conference Venue
University of Regensburg
Universitätsstraße 31
93053 Regensburg

The central activities will take place in the Main Lecture Hall (Audimax) of the University of Regensburg, Universitätsstraße 31, 93053 Regensburg. A detailed map of the campus and the buildings can be found at the end of this book. The location of the lecture halls on the Campus can be found in the DPG-App.

For visitors with reduced mobility and visitors with pushchairs, a detailed map with barrier-free routes and information on lifts, car parks and toilets is available: go.ur.de/barrier-free

Transportation
By car, train, plane or bus?
You will always find up-to-date directions for your journey on the website of the University of Regensburg as follows:

- Travel information of the University of Regensburg: go.ur.de/directions
- Parking at the University of Regensburg: go.ur.de/parking
- Further information and maps of the University of Regensburg: go.ur.de/maps

Conference Office / Information Desk
The conference office and information desk are located in the foyer of the Main Lecture Hall (foyer Audimax). The opening hours are:

		Registration	**Information Desk**
Sunday	March 16	15:00 – 19:00	12:00 – 20:00
Monday	March 17	07:30 – 18:00	07:30 – 22:00
Tuesday	March 18	08:00 – 17:00	08:00 – 20:00
Wednesday	March 19	08:00 – 17:00	08:00 – 22:00
Thursday	March 20	08:00 – 17:00	08:00 – 22:00
Friday	March 21	08:00 – 12:00	08:00 – 15:00

To contact the information desk during the opening hours call +49 (0)941-943 2530.

You will receive a receipt for your conference fee, the printed short programme, vouchers for food and drinks for the welcome evening, and your name tag at the conference office. **The name tag must be worn visibly during the entire conference**. Please note that the conference fee does not include a ticket for local public transport in Regensburg.

The organisers, the staff of the conference desk, and the student assistants will be identifiable by name tags and Φ-T-shirts in a uniform colour. Please contact them if you have any questions.

Do not hesitate to inquire about all necessary information concerning the conference, orientation in Regensburg, accommodation, restaurants, going out, and cultural events at the information desk located in the foyer of the Main Lecture Hall.

Allocation of the Lecture Halls

H1-H10, H22, H23	Main Lecture Hall Building
H11-H17	Law and Economy Building
H18-H20	Multi-purpose Building
H24-H25	Vielberth-Building
H31, H32	Mathematics Building
H33-H36	Physics Building
H37-H38	Pre-clinical Medicine Building
H43-H47	Chemistry and Pharmacy Building
Plenary talks, joint Symposia	H1 (Audimax), H2
Lunch Talks	H1, H2, H3, H4
Prize Ceremony, Evening Talk	H1 (Audimax)

Job Market	Kunsthalle (Foyer Audimax, 1st floor)
Registration Desk	Foyer Audimax (Main Lecture Hall)
Information Desk	Foyer Audimax (Main Lecture Hall)
Einstein Slam	H1 (Audimax)

WIFI & LAN

The University of Regensburg is member of the eduroam-network. Users from eduroam institutions, who have registered for eduroam, can use WIFI at the University of Regensburg without local registration in Regensburg. Please ask the computer center/network administration of your home institution for eduroam-registration. Eduroam in Regensburg is possible with WLAN SSID eduroam.

In addition to eduroam WIFI BayernWLAN is offered without prior registration. Furthermore you will have access with "StudiWLAN". Login required:
"RZ Account": dpg2025
"RZ Password": dpg2025

A few workstations for guests are available in the central library for emergencies. Please sign up directly at the information desk of the central library at th University of Regensburg! Opening hours: Mo-Fr 10:00 — 14:00.

Printing service

The „Print Gallery" printing company (Monday to Friday 10:00 — 18:00, Carl-Maria-von-Weber-Straße 6, 93053 Regensburg) offers prints up to DIN A0 format. You are welcome to send the data in PDF format with the exact details by email to: *info@printgallery.de*
It is not possible to print posters in DIN A0 format directly at the shop – the printing service needs 1 day in advance! The copy shop on the university forum has been closed unfortunately.

Presentations

Scientific presentations will be held either as oral presentations or posters. Presentations are held in English (preferred) or German.

Usually, presentations will have the following durations:

- For contributed talks a total of 15 minutes including discussion time and speaker change (12 min talk + 3 min discussion/speaker change).
- For invited talks a total of 30 minutes including discussion time and speaker change (25 min talk + 5 min discussion/speaker change).
- For plenary talks 45 minutes without discussion.

For further information on the language or length of the presentation, please contact the division or working group in which you have submitted your presentation.

PCs/laptops will be available in all lecture halls. **Therefore, the presentation should be recorded onto an USB stick as back-up in PDF and power point format.** Of course, you can also use your own laptop – please consider to bring your own adapter if required. All lecture rooms are equipped with projectors. The projectors mainly display in the 4:3 format. However they are compatible with the 16:9, limited to the display width. Some newer systems also work directly with 16:9. A majority of lecture halls offers radio microphone amplifiers as well. Overhead-Projectors are not available. Presenters and/or laser pointers will be available in all lecture rooms.

All lecture rooms will be opened, at the latest, 30 minutes prior to the lecture. Speakers must be in the lecture room at least 20 minutes before the sessions starts. They must report to the chairperson and the technical staff. They will receive an equipment introduction.

Poster Presentations

Sites for poster sessions are named and located as follows:

Poster area P1	Sammelgebäude (Multi-purpose Building)
Poster area P2	Physik (Physics)
Poster area P3	Exhibition tent in front of the Physics Building
Poster area P4	Chemie (Chemistry and Pharmacy)

The poster boards will be marked with the number according to the scientific programme. As there will be several different poster sessions at the poster sites every day, **authors are asked to mount their poster max. 1 hour before their session.** Each poster should display the number according to the scientific programme. Each poster should be no larger than 85 cm x 120 cm (A0 portrait format).

For the mounting of the poster please use the prepared "poster strips" (P1, P2, P4) or magnets (P3) at the poster frame (residue-free removing). You are also welcome to contact the student assistants on site.

Presenters are requested to be available at their poster for at least half of the length of their poster session. Please provide the information when you will be available at the poster. **The posters have to be removed after the session. Any posters remaining on display walls will be removed and disposed without requesting your permission.** The conference management accepts no liability for the posters.

Notice Board

The programme stated in this document is current as of 30 January 2025 and will not be updated!

All changes to the conference programme (i.e. cancellation of presentations, change of rooms, etc.) will be continuously updated on the notice board of the conference website. The information is identical to the programme updates of the scientific programme and is also available there in other formats (sorted by publication date, filterable by conference parts and as an rss-feed). Please use the form *regensburg25.dpg-tagungen.de/programm/notice-board* to notify changes or cancellations.

Cloakroom

Participants are asked to carefully watch their clothes, valuables, laptops, and other belongings. The organisers decline any liability. You will find a cloakroom in the basement of the Main Lecture Hall (Audimax). Please note that there is only limited possibility to store luggage! The opening hours are:

Sunday	March 16	14:00 — 19:30
Monday	March 17	07:00 — 22:30
Tuesday	March 18	07:30 — 19:00
Wednesday	March 19	07:30 — 21:00
Thursday	March 20	07:30 — 21:00
Friday	March 21	07:30 — 15:00

Lost and Found Property

Take your found items to the information desk in the foyer of the Audimax. You can also claim your lost property there.

Wilhelm and Else Heraeus Communication Programme

Important notes for participants who apply for a grant in the WEH Communication Programme:
At the beginning of the conference you will receive an identification form at the conference office. Your participation in the conference must be certified at the conference office. At the end of the conference, you may leave this certificate with DPG staff members at the conference office (preferably) or submit it to the DPG head office (DPG-Geschäftsstelle, Hauptstr. 5, 53604 Bad Honnef, Germany) by **April 18, 2025 at the latest.** For more detailed information refer to *weh.dpg-physik.de*.

The Deutsche Physikalische Gesellschaft thanks the Wilhelm und Else Heraeus-Stiftung for the generous financial support of young academic talents. We hope that young physicists will continue to benefit from the offered opportunity for active scientific communication at DPG meetings. A total of about 41,900 young academics were supported by this programme so far.

SAY CHEESE!

The DPG Spring Meetings are basically public to the press. Please note: On behalf of DPG, photos and videos will be recorded during the Spring Meetings. In the context of public relations, a selection of this footage will be published on our website, in social media or within printed materials of the DPG for example.

Tactfulness

All participants are requested to contribute to a successful and enjoyable conference through respect- and tactful behaviour. Please contact the conference office or the local conference organisers in the event of disturbances. §§ 9 and 12 of the DPG's Statutes are applicable.

CO_2 Compensation for the DPG Conferences

By decision of its council, the DPG will compensate for fossil CO_2 emissions resulting from mobility for DPG conferences and committee meetings.

Bei den Angeboten von „Physik und Beruf“ sind alle Tagungsteilnehmende herzlich willkommen!

Acknowledgement
The Deutsche Physikalische Gesellschaft (DPG) and the local organisers want to thank the following institutions for supporting the conference:

- the Wilhelm and Else Heraeus Foundation, Hanau
- the University of Regensburg
- all industrial sponsors of the DPG-Frühjahrstagung (refer to page 18)
- and all staff, who make the success of the conference possible.

Disclaimer of liability
Participants are asked to look carefully after their wardrobe, valuables, laptops, and other belongings. The organisers decline any liability.

Catering
Free coffee, tea and water will be provided to all registered participants of the conference at DPG-coffee corners located near all exhibition and poster areas. All locations are displayed in the map of the campus at the end of this booklet. Please wear your name tag visibly during the entire conference.

Refreshments and snacks are also available in the cafeterias in the Multi-purpose Building and in the Buildings of Chemistry, Physics, Philosophy and Law (Monday-Friday). Please pay by your debit oder credit card. Cash Payment is not possible!

Mensa:
Lunch will be supplied in the Mensa of the University (Monday-Friday: 11:00 – 14:00). Prices: about 12.00 € including the meal, one drink and one dessert. Please pay by your EC- oder credit card. Cash Payment is not possible!

Tent
In the exhibition and poster tent in front of the physics department focaccia is offered by the Pizzeria UNIKAT at lunchtime (also vegetarian and vegan!).

Food-Truck:
In addition to the Mensa and the cafeterias, a Food truck ("Tommy's Mutzbraten") will offer hearty (= non-vegetarian) grilled food in front of the Physics Building (outside). Cash only!

Uni-Pizzeria:
The Pizzeria UNIKAT offers freshly made food. Reservation recommended!

Campus' Grocery Store
The Campus' Grocery Store "Hechtbauer" at the Forum offers food, beverages and convenience goods (Monday-Friday: 08:00 – 18:00).

Social Events

Tutorials
On Sunday, March 16, 16:00 – 18:15, there will be Tutorials on current scientific topics for interested conference participants, in particular for students and young scientists. All conference participants are welcome.

The topics of the Tutorials are:

- Hands-on Tutorial: AI Fundamentals for Research
- How to Use NOMAD's Workflow Utilities to Improve Data Management and Facilitate Discovery in Materials Science
- Into the Third (and Fourth) Dimension: Imaging Methods for 3D Nanomagnetism
- Do it Yourself Guide for Simulating Complex Magnetism: From Theoretical Foundations to Hands-on Spin-dynamics
- Automated Workflows

Welcome Evening
Sunday, March 16, 18:30 – 21:30, Mensa
On Sunday evening, a Bavarian Welcome Evening will be held in the Mensa of the University of Regensburg to which all registered participants are kindly invited. Snacks and drinks will be served. "Vieraloa" (Bavarian Brass Music) will entertain you with music.

Do not miss the opportunity to register in the conference office (15:00 – 19:00) for the conference before the Welcome Evening as well as the official beginning of the conference. During check-in at the conference you will receive your badge and **food and drink vouchers** for the Welcome Evening (you will find these in the conference bag!). Please note that the cloakroom in the lecture hall basement closes on Sunday at 19:30!

Welcome Address
A short welcome address will be given by the chair of the Condensed Matter Section (SKM) on Monday, March 17 from 8:25 until 8:30 in lecture hall H1 (Audimax).

Einstein Slam
Monday, March 17, 20:00, H1 (Audimax)
Einstein Slam is the competitive art of making complex science accessible to a broad audience. There are just 10 minutes for every attendee to present his/her self-made performance. The event will finish with a public poll in order to evaluate if a particular contribution was either instructive and amusing or rather should have never been performed. All presentations will be given in English. For more information please refer to *www.einstein-slam.de*.

Climate Lounge
Tuesday, March 18, 14:00 – 16:00, H7
Following the lunchtime lecture PSV III '*The human task of climate change and the DPG: founding the Climate Working Group*', there will be the opportunity to exchange views on the topic in the 'Climate Lounge' with talks, questions and discussions.

Special Plenary Session with Award Ceremony
On Tuesday, March 18, at 16:00 the Ceremonial Session with Award Ceremony will take place in H1 (Audimax). The programme is as follows:

Music

Welcome
Prof. Dr. Christoph Strunk, Universität Regensburg
Local Organiser

Prof. Dr. Udo Hebel
President of the Universität Regensburg

Speech
Prof. Dr. Klaus Richter
President of the Deutsche Physikalische Gesellschaft

Music

Award Ceremony

Walter-Schottky-Prize 2025
to Dr. Libor Šmejkal, JGU Mainz / MPI für Physik komplexer Systeme, Dresden

Gaede-Prize 2025
to PD Dr. Wouter Jolie, Universität zu Köln

Dissertation Prize of the Condensed Matter Section 2025
(The Laureate will be announced at the award ceremony)

Ceremonial Lecture

Prof. Dr. Petra Schwille, Max-Planck-Institut für Biochemie, Martinsried
„How to build a biological cell from scratch" (PSV IV)

Prize Talks
The following prize talks will be given during the conference (in chronological order):

Gustav-Hertz-Prize 2025
Monday, March 17, 13:15 — 13:45, H2,
Dr. Anna Seiler, ETH Zürich, Switzerland
„Correlated phases in the vicinity of tunable van Hove singularities in Bernal bilayer graphene“ (PRV I)

Gustav-Hertz-Prize 2025
Tuesday, March 18, 13:15 — 13:45, H2,
Dr. Lisanne Sellies, IBM Research Europe — Zurich
„Single-molecule electron spin resonance by means of atomic force microscopy“ (PRV II)

Gentner-Kastler-Prize 2025
Wednesday, March 19, 13:15 — 13:45, H2
Prof. Dr. Regine von Klitzing, Technische Universität Darmstadt
„Complex liquids under confinement“ (PRV III)

Max-Born-Prize 2025
Wednesday, March 19, 13:15 — 13:45, H4
Prof. Michael Johnston, University of Oxford, United Kingdom
„Nanowire-based THz polarimetry“ (PVR IV)

Gaede-Prize 2025
Wednesday, March 19, 13:15 — 13:45, H4
PD Dr. Wouter Jolie, Universität zu Köln
„Confining strongly correlated quasiparticles in 2D semiconductors“ (PRV VI)

Walter-Schottky-Prize 2025
Thursday, March 20, 13:15 — 13:45, H2
Dr. Libor Šmejkal, JGU Mainz / MPI für Physik komplexer Systeme, Dresden
„Altermagnetism and spin symmetries“ (PRV V)

Georg-Simon-Ohm-Prize 2025
Thursday, March 20, 11:15, H15
Annika Janssen, Technische Hochschule Nürnberg
„Development and Application of Computational Simulations to Optimize Organic Photovoltaic Modules“

Physik: Erkenntnisse und Perspektiven — A Publication for Everyone (in German)!

The title “Physik: Erkenntnisse und Perspektiven” (Physics: Insights and Perspectives) refers to a publication, which was produced on a voluntary basis by almost 200 authors. It provides a detailed exploration of the fundamentals of physics, current research and future developments. The book offers readers an engaging and inspiring insight into the world of physics! The publication is also available at www.physik-erkenntnisse-perspektiven.de – along with exclusive video interviews. Printed copies can also be ordered by covering the shipping costs.

For interested readers: Experience the brand-new book live!
Join us for the book launch on Wednesday, 19 March 2025, from 13:15 to 13:45 (H3). You will have the opportunity to pick up a free copy – as long as stocks last!

Public Evening Lecture *(in German language)*
Wednesday, March 19, 19:00 – 20:15, Audimax (H1)
Prof. Dr. Thomas Jung, Alfred Wegener Institut, Bremerhaven, will speak about *„Leben in einer wärmer werdenden Welt: Wie der Klimawandel unser Leben beeinflusst”*.

The Public Evening Lecture is open for all conference participants and interested public. The entrance is free.

Job Market
During the conference, various companies and organisations will present their working fields and career opportunities to all interested participants. The presentations will last for about 30 minutes plus discussion and will take place in the Kunsthalle (Foyer Audimax, 1st floor). The Programme is as follows:

Tuesday, March 18

11:00 –12:00	**d-fine GmbH** *„Als Physiker:in in die Unternehmensberatung? Der Einsatz von MINT-Know-how zur Lösung komplexer Probleme in der Praxis bei d-fine.“*
13:00 – 14:00	**Carl Zeiss AG** *„Karrierechancen bei Carl Zeiss AG.“*
15:00 – 16:00	**ritzenhoefer & company** *„Transformation Consulting.“*

Wednesday, March 19

11:00 – 12:00	**Basycon Unternehmensberatung GmbH** *„Aus der Wissenschaft in die Beratung.“*

Thursday, March 20

11:00 – 12:30	**BCG – The Boston Consulting Group GmbH** *„Als Physiker:in in die Strategieberatung “*

Exhibition of Scientific Instruments and Literature

From Tuesday to Thursday there will be an exhibition of scientific instruments and literature in the Main Lecture Hall Foyer (A – Main Lecture Hall Foyer), in the Economy Building (E – “Wirtschaft und Recht”), and one tent (T – Tent in front of the Physics Building). Almost 100 companies (see list of exhibitors at the end of this booklet) will present their products. Opening hours are from 09:00 to 18:00. All conference participants are welcome to attend the exhibition. The entrance is free.

City Tours „Regensburg – Experience a Historic City“

Walking Tour
“Regensburg – Experience a Historic City“ (90 min; 14,00 € per person)
Meeting point: in front of the Tourist Information in the Old Town Hall of Regensburg
in German: daily 10:30, Tuesday March, 18 also at 16:30
in English: only on Tuesday, March 18, 16:30
Please register via e-mail *tourismus@regensburg.de*

Bus trip „CityTour“
Information and booking at *www.city-tour.info/en/regensburg/tour*

jDPG Pub Crawl

Tuesday, 18 March, 19:00 – 22:00

Meeting Point: “Kugel” (sculpture) at the Audimax (Albertus-Magnus-Straße 5)
In case you need some time to take a rest in the middle of the conference and you are looking for conversations beyond physics, the local group of the Young DPG cordially invites you to a pub crawl through the nightlife in Regensburg.

Members‘ Assemblies of the Divisions and Working Groups

During the DPG Spring Meeting, Members‘ Assemblies of the divisions and working groups take place. Please refer to the scientific programme for the time and place of the meetings.

Deutsche Physikalische Gesellschaft DPG

2nd DPG Fall Meeting

of the Deutsche Physikalische Gesellschaft

Quantum Physics

Topics:

- **Quantum Physics in Research and Technology**
- **The Path to the Modern Quantum World**
- **Applications of Quantum Technologies**

Joint Meeting of the

- **Atomic, Molecular, Quantum Optics and Photonics Section (SAMOP)**
- **Condensed Matter Section (SKM)**
- **Matter and Cosmos Section (SMuK)**

100 years ago, Göttingen played a central role in creating quantum physics as we know it today. In 1925 Werner Heisenberg, then an assistant at the Göttingen Institute for Theoretical Physics, published his famous article "Quantum-Theoretical Re-Interpretation of Kinematic and Mechanical Relations". This article marks the beginning of quantum mechanics and therefore the United Nations, the German Physical Society (DPG) and numerous Physical Societies around the world will celebrate 2025 as the "Year of Quantum Science and Technology".

The activities of the Quantum Year 2025 in Germany will culminate in an international conference in Göttingen (2nd DPG Fall Meeting, Sept. 8-12, 2025). The meeting will cover the present status and perspectives of all fields of modern physics reigned by quantum mechanics (condensed matter physics, atomic and molecular physics, quantum optics, elementary particle physics, quantum information and computing, and many others) as well as the historical roots of quantum mechanics and conceptual questions that still challenge us today.

Apart from high profile speakers covering all fields of modern physics there will be contributed sessions, all together creating a unique opportunity to look across the boundaries of individual research topics under the umbrella of quantum physics.

Save the Date!
8-12 Sep 2025

Synopsis of the Daily Programme

Sunday, March 16, 2025

TUT

			Sessions
16:00	H2	TUT 1	**Hands-on Tutorial: AI Fundamentals for Research**
16:00	H2	TUT 1.1	Introduction •Janine Graser
16:40	H2	TUT 1.2	Hands-On Session 1 – Function Approximation •Jan Bürger
17:30	H2	TUT 1.3	Hands-On Session 2 – Classification and More •Robin Msiska
16:00	H3	TUT 2	**Tutorial: How to Use NOMAD's Workflow Utilities to Improve Data Management and Facilitate Discovery in Materials Science**
16:00	H3	TUT 2.1	FAIR-data management with the NOMAD infrastructure: Core functionalities •Joseph F. Rudzinski
16:30	H3	TUT 2.2	Using NOMAD's API for project management •Nathan Daelman
17:00	H3	TUT 2.3	Creating custom entries in NOMAD using yaml schema and ELN integration •Andrea Albino
17:30	H3	TUT 2.4	Creating custom workflow entries in NOMAD to link multiple uploads •Bernadette Mohr
16:00	H4	TUT 3	**Tutorial: Into the Third (and Fourth) Dimension: Imaging Methods for 3D Nanomagnetism**
16:00	H4	TUT 3.1	3D Magnetic Imaging: Utilizing Synchrotron X-Ray Coherence for Nanometric Resolution in Thick Samples •Marisel Di Pietro Martinez
16:45	H4	TUT 3.2	Nanoscale Mapping of Magnetic Textures in 3D Using Vector Field Electron Tomography •Axel Lubk
17:30	H4	TUT 3.3	3D magnetic imaging: an experimental window to study 3D magnetization at the nanoscale •Aurelio Hierro-Rodriguez
16:00	H10	TUT 4	**Tutorial: Do it Yourself Guide for Simulating Complex Magnetism: From Theoretical Foundations to Hands-on Spin-dynamics**
16:00	H10	TUT 4.1	Derivation of the spin-lattice Hamiltonian: Heisenberg, beyond Heisenberg, DMI, nematic exchange •Hiroshi Katsumoto
16:45	H10	TUT 4.2	Computing magnetic exchange interactions using DFT •Manuel dos Santos Dias
17:30	H10	TUT 4.3	Hands-on atomistic spin-dynamics simulations with Spirit •Thorben Pürling
16:00	H15	TUT 5	**Tutorial: Automated Workflows**
16:00	H15	TUT 5.1	Hands-on Tutorial: Automated Workflows and Machine Learning for Materials Science Simulations •Jörg Neugebauer

18:30	Mensa	**Welcome Evening** (for registered participants)

Monday, March 17, 2025

08:25	H1		**Welcome Address**

			Plenary Talks
08:30	H1	PLV I	Seeing dents in the atom •Franz Giessibl
14:00	H1	PLV II	High-power semiconductor lasers based on Hermitian and non-Hermitian control in photonic crystals •Susumu Noda
14:00	H2	PLV III	Physics informed artificial intelligence and data-driven design of materials •Jörg Neugebauer
			Prize Talk
13:15	H2	PRV I	Correlated phases in the vicinity of tunable van Hove singularities in Bernal bilayer graphene •Anna Seiler (Laureate of the Gustav-Hertz-Prize 2025)
			Discussion
13:15	H1	PSV I	Karriere auf Zeit: Perspektiven auf befristete Arbeitsverträge in der Wissenschaft •Carolin Wagner, •Axel Dürkop, •Raja Hoffmann

SYED

			Invited Talks
09:30	H1	SYED 1.1	Emergent crystalline order in a developing epithelium •Frank Jülicher
10:00	H1	SYED 1.2	A tissue rigidity phase transition shapes morphogen gradients •Nicoletta Petridou
10:30	H1	SYED 1.3	Building quantitative dynamical landscapes of developmental cell fate decisions •David Rand
11:15	H1	SYED 1.4	Control of lumen geometry and topology by the interplay between pressure and cell proliferation rate •Anne Grapin-Botton
11:45	H1	SYED 1.5	Chromosomes as active communication and memory machines •Leonid A. Mirny
			Session
09:30	H1	SYED 1	Physics of Embryonic Development Across Scales: From DNA to Organisms

SYMD

			Invited Talks
15:00	H1	SYMD 1.1	Learning physically constrained microscopic interaction models of functional materials •Boris Kozinsky
15:30	H1	SYMD 1.2	GRACE universal interatomic potential for materials discovery and design •Ralf Drautz
16:00	H1	SYMD 1.3	Multiscale Modelling & Machine Learning Algorithms for Catalyst Materials: Insights from the Oxygen Evolution Reaction •Nong Artrith
16:45	H1	SYMD 1.4	Inverse Design of Materials •Hongbin Zhang
17:15	H1	SYMD 1.5	Data-Driven Materials Science •Miguel Marques
			Session
15:00	H1	SYMD 1	AI-driven Materials Design: Recent Developments, Challenges and Perspectives

Monday, March 17, 2025

SYSD

Invited Talks

09:30	H2	SYSD 1.1	Nanoscale Chemical Analysis of Ferroic Materials and Phenomena •Kasper Aas Hunnestad
10:00	H2	SYSD 1.2	Advanced Excitation Schemes for Semiconductor Quantum Dots •Yusuf Karli
10:30	H2	SYSD 1.3	Aspects and Probes of Strongly Correlated Electrons in Two-Dimensional Semiconductors •Clemens Kuhlenkamp
11:00	H2	SYSD 1.4	Mean back relaxation and mechanical fingerprints: simplifying the study of active intracellular mechanics •Till Münker
11:30	H2	SYSD 1.5	Coherent Dynamics of Atomic Spins on a Surface •Lukas Veldman

Session

09:30	H2	SYSD 1	SKM Dissertation Prize Symposium

BP

Invited Talks

11:15	H44	BP 3.7	Killing to survive – how protein-lipid interactions drive programmed cell death •Kristyna Pluhackova
09:30	H46	BP 4.1	Spatiotemporal organization of bacterial biofilm formation and functions •Knut Drescher
15:00	H44	BP 7.1	Single-molecule dynamic structural biology with Graphene Energy Transfer •Philip Tinnefeld
16:15	H46	BP 8.6	In situ control of cells and multicellular structures at the microscale by two-photon lithography •Christine Selhuber-Unkel

Sessions

09:30	H37	BP 2	Active Matter I
09:30	H44	BP 3	Computational Biophysics I
09:30	H46	BP 4	Bacterial Biophysics
11:30	H46	BP 5	Membranes and Vesicles I
15:00	H37	BP 6	Active Matter II
15:00	H44	BP 7	Single Molecule Biophysics
15:00	H46	BP 8	Biomaterials, Biopolymers and Bioinspired Functional Materials I
17:00	H46	BP 9	Biomaterials, Biopolymers and Bioinspired Functional Materials II

CPP

Invited Talks

09:30	H34	CPP 1.1	Impact of smallest loops and composition Fluctuations on the structure of end-linked polymer model networks •Michael Lang
11:30	H38	CPP 5.1	Theoretical characterization of sulfur/carbon copolymer cathodes for next-generation batteries via ab initio spectroscopy simulations •Daniel Sebastiani
15:00	H38	CPP 8.1	The Nanoscale Photovoltaics Laboratory on a Tip •Stefan Weber

Sessions

09:30	H34	CPP 1	Gels, Polymers Networks and Elastomers I
09:30	H37	CPP 2	Active Matter I
09:30	H38	CPP 3	Organic Electronics and Photovoltaics I
11:30	H34	CPP 4	Crystallization, Nucleation and Self-Assembly I
11:30	H38	CPP 5	Composites and Functional Polymer Hybrids
15:00	H34	CPP 6	Gels, Polymers Networks and Elastomers II

Monday, March 17, 2025

CPP

15:00	H37	CPP 7	Active Matter II
15:00	H38	CPP 8	Hybrid and Perovskite Photovoltaics I
15:00	H46	CPP 9	Biomaterials and Biopolymers
16:15	H34	CPP 10	Wetting, Fluidics and Liquids at Interfaces and Surfaces I
16:15	H38	CPP 11	Hybrid and Perovskite Photovoltaics II
17:00	H46	CPP 12	Biomaterials, Biopolymers and Bioinspired Functional Materials I
17:15	H38	CPP 13	Molecular Electronics and Excited State Properties I
17:30	H34	CPP 14	Wetting, Fluidics and Liquids at Interfaces and Surfaces II
19:00	P4	CPP 15	Poster Session I

DS

Sessions

09:30	H3	DS 1	Thin Film Properties
09:30	H14	DS 2	Layer Deposition
15:00	H3	DS 3	2D Materials and their Heterostructures I

DY

Invited Talks

10:45	H37	DY 3.6	Collective behavior of photoactive macroscopic particles •Iker Zuriguel
09:45	H43	DY 4.2	Physical application of infinite ergodic theory •Eli Barkai
11:30	H43	DY 4.7	Modelling the movements of organisms: Movement ecology meets active particles and anomalous diffusion •Rainer Klages
15:00	H43	DY 8.1	Spatio-temporal pattern formation in time-delayed optical systems •Svetlana Gurevich
16:45	H43	DY 8.6	Nonlinear dynamics and time delays in metal cutting •Andreas Otto
16:00	H47	DY 9.5	Large-deviation simulations of non-equilibrium stochastic processes •Alexander K. Hartmann

Sessions

09:30	H31	DY 2	Nonequilibrium Quantum Systems
09:30	H37	DY 3	Active Matter I
09:30	H43	DY 4	Focus Session: Nonlinear Dynamics and Stochastic Processes – Advances in Theory and Applications I
09:30	H47	DY 5	Statistical Physics: General
11:30	H47	DY 6	Critical Phenomena and Phase Transitions
15:00	H37	DY 7	Active Matter II
15:00	H43	DY 8	Focus Session: Nonlinear Dynamics and Stochastic Processes – Advances in Theory and Applications II
15:00	H47	DY 9	Statistical Physics far from Thermal Equilibrium
16:15	H34	DY 10	Wetting, Fluidics and Liquids at Interfaces and Surfaces I
17:30	H34	DY 11	Wetting, Fluidics and Liquids at Interfaces and Surfaces II

HL

Invited Talks

09:30	H17	HL 3.1	Alexandria Database – Improving machine-learning models in materials science through large datasets •Jonathan Schmidt
10:00	H17	HL 3.2	Generative Models on the Rise – Which one shall I pick for my Inverse Design Problem? •Hanna Türk
10:30	H17	HL 3.3	Machine-learning accelerated prediction of two-dimensional conventional superconductors •Haichen Wang

Monday, March 17, 2025

HL

11:15	H17	HL 3.4	Machine Learning for Design, Understanding, and Discovery of (Semiconducting) Materials •Pascal Friederich
11:45	H17	HL 3.5	OptiMate: Artificial intelligence for optical spectra •Malte Grunert
			Sessions
09:30	H13	HL 1	Perovskite and Photovoltaics I
09:30	H15	HL 2	2D Semiconductors and van der Waals Heterostructures I
09:30	H17	HL 3	Focus Session: Machine Learning of semiconductor properties and spectra
15:00	H3	HL 4	2D Materials and their Heterostructures I
15:00	H11	HL 5	2D Materials Beyond Graphene: Growth, Structure and Substrate Interaction
15:00	H13	HL 6	Materials and Devices for Quantum Technology I
15:00	H14	HL 7	Semiconductor Lasers
15:00	H15	HL 8	2D Semiconductors and van der Waals Heterostructures II
15:00	H17	HL 9	Oxide Semiconductors I
15:00	H19	HL 10	Spin-Dependent Phenomena in 2D
16:00	H14	HL 11	Ultra-fast Phenomena I
16:45	H15	HL 12	Quantum Transport and Quantum Hall Effects
16:45	H17	HL 13	Heterostructures, Interfaces and Surfaces

KFM

			Invited Talk
09:30	H9	KFM 1.1	Epitaxial films of layered perovskite-based ferroelectrics: phase stability, polarization enhancement, and pathways to polar metallicity •Elzbieta Gradauskaite
			Sessions
09:30	H9	KFM 1	(Multi)ferroic States: From Fundamentals to Applications (I)
09:30	H13	KFM 2	Perovskite and Photovoltaics I
09:30	H16	KFM 3	Multiferroics and Magnetoelectric Coupling
11:30	H9	KFM 4	(Multi)ferroic States: From Fundamentals to Applications (II)
15:00	H9	KFM 5	Instrumentation, Microscopy and Tomography with X-ray Photons, Electrons, Ions and Positrons
15:00	H10	KFM 6	Invited Talk: X. Fang
17:15	H22	KFM 7	Materials for the Storage and Conversion of Energy

MA

			Invited Talks
09:30	H20	MA 5.1	Driving Coherent Phonon-Phonon Angular Momentum Transfer via Lattice Anharmonicity •Sebastian Maehrlein
10:00	H20	MA 5.2	Chiral phonons, phono-magnetism, and spin-rotation coupling •Matthias Geilhufe
10:30	H20	MA 5.3	Geometry of temporal chiral structures and photoinduced chirality-spin coupling •Olga Smirnova
11:15	H20	MA 5.4	Phonon thermal Hall effect •Kamran Behnia
11:45	H20	MA 5.5	Giant effective magnetic moment of chiral phonons •Swati Chaudhary
15:00	H16	MA 6.1	Magnetization dynamics of chiral helimagnetic insulators •Aisha Aqeel
15:00	H18	MA 7.1	Realizing Reservoir Computing with skyrmions in geometrical confinements tuned by ion irradiation •Grischa Beneke
15:20	H18	MA 7.2	Low-energy spin excitations of the Kitaev candidate material $Na_2Co_2TeO_6$ probed by high-field/high-frequency electron spin resonance spectroscopy •Luca Bischof

MA

15:40	H18	MA 7.3	Tailoring the first-order magnetostructural phase transition in Ni-Mn-Sn for caloric applications by microstructure •Johannes Puy
16:15	H18	MA 7.4	Tuning the properties of two-dimensional magnetic heterostructures via interface engineering with molecular and inorganic van der Waals crystals. •Carla Boix-Constant
16:40	H18	MA 7.5	Theoretical Prediction for Probing Magnon Topology •Robin R. Neumann
17:05	H18	MA 7.6	Multiphysics-Multiscale Simulation of Additively Manufactured Functional Materials •Yangyiwei Yang

Sessions

09:30	H16	MA 2	Multiferroics and Magnetoelectric Coupling
09:30	H18	MA 3	Magnonics I
09:30	H19	MA 4	Electron Theory of Magnetism and Correlations
09:30	H20	MA 5	Focus Session: Magnetic Phenomena from Phonon Chirality and Angular Momentum I
15:00	H16	MA 6	Skyrmions I
15:00	H18	MA 7	INNOMAG e.V. Prizes 2025 (Diplom-/Master and Ph.D. Thesis)
15:00	H19	MA 8	Spin-Dependent Phenomena in 2D
15:00	H20	MA 9	Altermagnets I

MM

Invited Talks

09:30	H10	MM 2.1	Probing Ion Migration in ABX_3 Perovskite Compounds: Five Fallacies of Simulations •Roger De Souza
15:00	H10	MM 5.1	Room-temperature dislocations in oxide ceramics: from understanding to active engineering •Xufei Fang

Sessions

09:30	H10	MM 2	Invited Talk: R. de Souza
10:15	H10	MM 3	Data-driven Materials Science: Big Data and Worksflows
10:15	H22	MM 4	Materials for the Storage and Conversion of Energy
15:00	H10	MM 5	Invited Talk: X. Fang
15:45	H10	MM 6	Phase Transformations
15:45	H22	MM 7	Materials for the Storage and Conversion of Energy
17:15	H22	MM 8	Materials for the Storage and Conversion of Energy
18:30	P1	MM 9	Poster

O

Invited Talks, Topical Talk

09:30	H24	O 3.1	Insights in real and electronic structure of interfaces by electron microscopy •Kerstin Volz
11:15	H11	O 7.4	Nanoimaging the electronic, plasmonic, and phononic structure and dynamics of 2D materials •Sarah King
10:30	H24	O 8.1	Chiral reactions at surfaces elucidated by machine learning and enhanced sampling •Daniele Passerone
15:00	H2	O 10.1	Probing coherent optical emission processes with ultrafast scanning electron microscopy •Albert Polman
16:15	H2	O 10.5	Ultrafast exciton dynamics in momentum space •Ralph Ernstorfer

Monday, March 17, 2025

O

15:00	H24	O 15.1	Kondo and Yu-Shiba-Rusinov resonances: transport and coupling •Laëtitia Farinacci
15:30	H24	O 15.2	Electron delocalization in a 2D Mott insulator •Amadeo L. Vazquez de Parga
16:00	H24	O 15.3	Kondo or no Kondo, that is the question •Alexander Weismann
16:30	H24	O 15.4	Evidence for spinarons in Co atoms on noble metal (111) surfaces •Artem Odobesko
17:00	H24	O 15.5	Spinarons: A new view on emerging spin-driven many-body phenomena in nanostructures •Samir Lounis

Sessions

09:30	H24	O 3	Overview Talk Kerstin Volz
10:30	H4	O 4	Solid-Liquid Interfaces: Structure
10:30	H6	O 5	Scanning Probe Microscopy: Light-Matter Interactions at the Atomic Scale I
10:30	H8	O 6	Oxides and Insulator Surfaces: Structure, Epitaxy and Growth
10:30	H11	O 7	Focus Session Ultrafast Electron Microscopy at the Space-Time Limit I
10:30	H24	O 8	Focus Session Molecular Nanostructures on Surfaces: On-Surface Synthesis and Single-Molecule Manipulation I
10:30	H25	O 9	Surface Reactions
15:00	H2	O 10	Focus Session Ultrafast Electron Microscopy at the Space-Time Limit II
15:00	H4	O 11	Electronic Structure of Surfaces: Spectroscopy, Surface States I
15:00	H6	O 12	Nanostructures at Surfaces I
15:00	H8	O 13	Organic Molecules on Inorganic Substrates: Adsorption and Growth
15:00	H11	O 14	2D Materials Beyond Graphene: Growth, Structure and Substrate Interaction
15:00	H24	O 15	Focus Session Many-Body Phenomena in Nanomagnets: Kondo, Spinons, Spinarons and Beyond
15:00	H25	O 16	Scanning Probe Techniques: Method Development
18:00	P2	O 17	Poster Focus Session Molecular Nanostructures on Surfaces: On-Surface Synthesis and Single-Molecule Manipulation
18:00	P2	O 18	Poster Focus Session Ultrafast Electron Microscopy at the Space-Time Limit
18:00	P2	O 19	Poster Surface Magnetism
18:00	P2	O 20	Poster Scanning Probe Microscopy: Light-Matter Interactions at the Atomic Scale
18:00	P2	O 21	Poster Heterogeneous Catalysis
18:00	P2	O 22	Poster Surface Reactions
18:00	P2	O 23	Poster Ultrafast Electron Dynamics
18:00	P2	O 24	Poster Scanning Probe Techniques: Method Development

SOE

Prize Talk, Invited Talk

15:00	H45	SOE 1.1	Interplay between multiscaling and rough volatility •Tiziana Di Matteo
16:30	H45	SOE 2.1	Higher-order network science •Federico Battiston (Laureate of the Young Scientist Award for Socio- and Econophysics2025)

Sessions

15:00	H45	SOE 1	Econophysics
16:15	H45	SOE 2	Award Session: Young Scientist Award for Socio- and Econophysics (YSA)
17:30	P4	SOE 3	Poster

TT

Sessions

09:30	H20	TT 1	Focus Session: Magnetic Phenomena from Phonon Chirality and Angular Momentum I
09:30	H31	TT 2	Nonequilibrium Quantum Systems

Monday, March 17, 2025

O

09:30	H32	TT 3	Correlated Magnetism – General
09:30	H33	TT 4	Topological Insulators
09:30	H36	TT 5	Superconductivity: Properties and Electronic Structure I
15:00	H24	TT 6	Focus Session Many-Body Phenomena in Nanomagnets: Kondo, Spinons, Spinarons and Beyond
15:00	H31	TT 7	Correlated Electrons: Electronic Structure Calculations
15:00	H32	TT 8	Measurement Technology and Cryogenics
15:00	H33	TT 9	Correlated Magnetism – Low-Dimensional Systems
15:00	H36	TT 10	Topological Semimetals
15:00	P4	TT 11	Superconductivity: Poster
16:45	H15	TT 12	Quantum Transport and Quantum Hall Effects

20:00	H1		**Einstein Slam**

Tuesday, March 18, 2025

Plenary Talk

08:30	H1	PLV IV	Some new aspects of unconventional superconductivity in layered materials •Irina Grigorieva

Prize Talk

13:15	H2	PRV II	Single-molecule electron spin resonance by means of atomic force microscopy •Lisanne Sellies (Laureate of the Gustav-Hertz-Prize 2025)

Lunch Talks

13:15	H1	PSV II	Research Funding by the DFG – Funding of Coordinated Programmes •Christian Hahn
13:15	H4	PSV III	Menschheitsaufgabe Klimawandel und die DPG: Gründung der AG Klima •Gregor Schaumann

Ceremonial Session with Award Ceremony and Ceremonial Talk

16:00	H1	PSV IV	How to build a biological cell from scratch •Petra Schwille

SYIS

Invited Talks

09:30	H1	SYIS 1.1	Electron-phonon and exciton-phonon coupling in advanced materials •Claudia Draxl
10:00	H1	SYIS 1.2	Exciton-phonon dynamics from first principles •Enrico Perfetto
10:30	H1	SYIS 1.3	Polarons and exciton polarons from first principles •Feliciano Giustino
11:15	H1	SYIS 1.4	Wannier-Function-Based First-principle Approach to Coupled Exciton-Phonon-Photon Dynamics in Two-Dimensional Semiconductors •Alexander Steinhoff
11:45	H1	SYIS 1.5	Phonon influence on (cooperative) photon emission from quantum dots •Erik Gauger

Session

09:30	H1	SYIS 1	Progress and Challenges in Modelling Electron-Phonon Interaction in Solids

BP

Invited Talks

09:30	H44	BP 11.1	Network connectivity determines the mechanisms responsible for cytoskeletal elasticity •Martin Lenz
11:45	H44	BP 15.1	Does Oncology Need Physics of Cancer? •Josef Käs

Sessions

09:30	H43	BP 10	Focus Session: Nonlinear Dynamics in Biological Systems I
09:30	H44	BP 11	Cytoskeleton
09:30	H46	BP 12	Biomaterials, Biopolymers and Bioinspired Functional Materials III
09:30	H47	BP 13	Active Matter III
10:00	P3	BP 14	Poster Session I
11:45	H44	BP 15	Cell Mechanics I
14:00	H43	BP 16	Focus Session: Nonlinear Dynamics in Biological Systems II
18:00	P4	BP 17	Poster Session II

Tuesday, March 18, 2025

CPP

Invited Talks

09:30	H34	CPP 16.1	Multifunctional structural batteries •Göran Lindbergh
09:30	H38	CPP 17.1	Continuum models for water's peculiar behavior on the nanoscale •Alexander Schlaich
09:30	H46	CPP 18.1	Hybrid materials from colloidally stable nanocellulose and nanoparticles – scattering techniques are needed for characterization •Eva Malmström
11:30	H38	CPP 20.1	Tailored polymer thin films enabled by initiated chemical vapor deposition (iCVD): From fundamentals to functional applications •Stefan Schröder

Sessions

09:30	H34	CPP 16	Energy Storage and Batteries I
09:30	H38	CPP 17	Modeling and Simulation of Soft Matter I
09:30	H46	CPP 18	Biomaterials, Biopolymers and Bioinspired Functional Materials II
09:30	H47	CPP 19	Active Matter III
11:30	H38	CPP 20	Interfaces and Thin Films I
14:00	H34	CPP 21	Modeling and Simulation of Soft Matter II
14:00	H38	CPP 22	Organic Electronics and Photovoltaics II

DS

Invited Talk

09:30	H3	DS 4.1	Graphene-based epitaxial 2D heterosystems: making graphene great again •Christoph Tegenkamp

Sessions

09:30	H3	DS 4	2D Materials and their Heterostructures II
14:00	H3	DS 5	Thin Oxides and Oxide Layers

DY

Invited Talks

09:30	H43	DY 14.1	Robust signal amplification and information integration via self-tuned proximity to bifurcation points •Isabella Graf
11:30	H43	DY 14.7	Beyond the connectionist view: (De-)synchronizing neural networks via cell-intrinsic dynamics •Susanne Schreiber
10:45	H47	DY 15.6	Beyond spheres – active matter in new shapes •Juliane Simmchen
12:30	H47	DY 15.11	Emergent correlations and boundary fluctuations in epithelial cell sheets •Silke Henkes
14:00	H43	DY 17.1	Mechanistic origins of temperature scaling in the early embryonic cell cycle •Lendert Gelens

Sessions

09:30	H31	DY 12	Quantum Coherence and Quantum Information Systems
09:30	H37	DY 13	Many-body Quantum Dynamics I
09:30	H43	DY 14	Focus Session: Nonlinear Dynamics in Biological Systems I
09:30	H47	DY 15	Active Matter III
14:00	H37	DY 16	Many-body Systems: Equilibration, Chaos, and Localization
14:00	H43	DY 17	Focus Session: Nonlinear Dynamics in Biological Systems II
14:00	H47	DY 18	Pattern Formation

Tuesday, March 18, 2025

HL

Invited Talks

09:30	H17	HL 18.1	Ultrafast Nano-Spectroscopy of Photo-Induced Dynamics in Low-Dimensional Materials •Takashi Kumagai
10:00	H17	HL 18.2	Landau level Nanoscopy of charge and heat transport in low-dimensional heterostructures •Mengkun Liu
10:30	H17	HL 18.3	Real space mapping of electrically tunable anisotropic THz plasmon polaritons in hBN encapsulated black phosphorus •Eva Pogna
11:15	H17	HL 18.4	Ultra-confined THz hyperbolic phonon polaritons in a transition metal dichalcogenide •Alexander Paarmann
11:45	H17	HL 18.5	Programmable polariton nanophotonics using phase-change materials •Thomas Taubner

Sessions

09:30	H3	HL 14	2D Materials and their Heterostructures II
09:30	H13	HL 15	Quantum Dots and Wires: Growth and Properties
09:30	H14	HL 16	Organic Semiconductors
09:30	H15	HL 17	2D Semiconductors and van der Waals Heterostructures III
09:30	H17	HL 18	Focus Session: Nanoscale Light-matter Interaction I
09:30	H36	HL 19	Focus Session: Strongly Correlated Quantum States in Moire Heterostructures
10:00	P3	HL 20	Poster I
10:30	H6	HL 21	Graphene: Electronic Structure and Excitations
10:30	H8	HL 22	2D Materials: Electronic Structure and Exitations I
11:15	H13	HL 23	Quantum Dots and Wires: Transport
12:15	H14	HL 24	Thermal Properties
13:30	P3	HL 25	Poster 2D Materials: Electronic Structure and Exitations
13:30	P3	HL 26	Poster 2D Materials Beyond Graphene: Growth, Structure and Substrate Interaction
13:30	P3	HL 27	Poster 2D Materials: Stacking and Heterostructures
14:00	H16	HL 28	Topological Insulators
18:00	P1	HL 29	Poster II

KFM

Invited Talk

09:30	H9	KFM 8.1	Ferrolectric bubble currents •Hugo Aramberri

Sessions

09:30	H9	KFM 8	(Multi)ferroic States: From Fundamentals to Applications (III)
11:45	H9	KFM 9	(Multi)ferroic States: From Fundamentals to Applications (IV)
14:00	H22	KFM 10	Materials for the Storage and Conversion of Energy

MA

Sessions

09:30	H16	MA 10	Focus Session: Magnetic Phenomena from Phonon Chirality and Angular Momentum II
09:30	H18	MA 11	Spin Transport and Orbitronics, Spin-Hall Effects I
09:30	H19	MA 12	Magnetization Dynamics and Damping
09:30	H20	MA 13	Altermagnets II
09:30	H36	MA 14	Focus Session: Strongly Correlated Quantum States in Moire Heterostructures
10:00	P1	MA 15	Poster I
14:00	H16	MA 16	Topological Insulators
14:00	H18	MA 17	Micro- and Nanostructured Magnetic Materials
14:00	H19	MA 18	Functional Antiferromagnetism
14:00	H20	MA 19	Magnetic Imaging and Sensors

Tuesday, March 18, 2025

MM

Topical Talks

09:30	H10	MM 10.1	Understanding the impact of disconnection flow on microstructure evolution •Marco Salvalaglio
10:15	H10	MM 11.1	The role of disconnections in the shear-migration coupling of grain boundaries •Marc Legros
11:30	H10	MM 11.4	Grain Boundary Spinodals: Faceting Instability and the Role of Junction Energetics •Fadi Abdeljawad
12:30	H10	MM 11.7	Atomistic structure of fcc-fcc interface in pure iron and in nanomultilayers: insight from atommistic modeling •Helene Zapolsky
14:00	H10	MM 13.1	Dynamics of dislocations and grain boundaries during recrystallization of metal nanoparticles •Eugen Rabkin

Sessions

09:30	H10	MM 10	Topical Talk: M. Salvalaglio
10:15	H10	MM 11	Topical Session: Defects of Defects
10:15	H22	MM 12	Materials for the Storage and Conversion of Energy
14:00	H10	MM 13	Topical Session: Defects of Defects
14:00	H22	MM 14	Materials for the Storage and Conversion of Energy

O

Invited Talks, Topical Talk

09:30	H24	O 25.1	Exploring quantum physics with scanning probe methods •Jörg Kröger
10:30	H2	O 26.1	Attosecond Electron Microscopy •Peter Baum
12:00	H4	O 27.7	Ultrafast electrochemistry beyond the RC time constant •Yujin Tong
11:30	H11	O 30.5	Resonant molecular transitions in femtosecond second harmonic generation spectroscopy of Fe-porphyrin/Cu(001) •Andrea Eschenlohr
11:00	H24	O 31.3	Single molecule machines on surface •Francesca Moresco

Sessions

09:30	H24	O 25	Overview Talk Jörg Kröger
10:30	H2	O 26	Focus Session Ultrafast Electron Microscopy at the Space-Time Limit III
10:30	H4	O 27	Solid-Liquid Interfaces: Reactions and Electrochemistry I
10:30	H6	O 28	Graphene: Electronic Structure and Excitations
10:30	H8	O 29	2D Materials: Electronic Structure and Exitations I
10:30	H11	O 30	Surface Magnetism
10:30	H24	O 31	Focus Session Molecular Nanostructures on Surfaces: On-Surface Synthesis and Single-Molecule Manipulation II
10:30	H25	O 32	Heterogeneous Catalysis I
13:30	P3	O 33	Poster Graphene: Electronic Structure and Excitations
13:30	P3	O 34	Poster Solid-Liquid Interfaces: Reactions and Electrochemistry
13:30	P3	O 35	Poster Solid-Liquid Interfaces: Structure
13:30	P3	O 36	Poster 2D Materials: Electronic Structure and Exitations
13:30	P3	O 37	Poster 2D Materials Beyond Graphene: Growth, Structure and Substrate Interaction
13:30	P3	O 38	Poster 2D Materials: Stacking and Heterostructures
14:00	H4	O 39	Oxides and Insulator Surfaces: Adsorption and Reaction of Small Molecules I
14:00	H6	O 40	Surface Dynamics
14:00	H8	O 41	Heterogeneous Catalysis II
14:00	H11	O 42	Electron-driven Processes
14:00	H24	O 43	Scanning Probe Microscopy: Light-Matter Interactions at the Atomic Scale II
18:00	P2	O 44	Poster Oxides and Insulator Surfaces: Structure, Epitaxy and Growth

Tuesday, March 18, 2025

O

18:00	P2	O 45	Poster Spins on Surfaces at the Atomic Scale
18:00	P2	O 46	Poster Organic Molecules on Inorganic Substrates: Electronic, Optical and Other Properties
18:00	P2	O 47	Poster Electron-driven Processes
18:00	P2	O 48	Poster Surface Dynamics
18:00	P2	O 49	Poster Nanostructures at Surfaces
18:00	P2	O 50	Poster Organic Molecules on Inorganic Substrates: Adsorption and Growth
18:00	P2	O 51	Poster Electronic Structure of Surfaces: Spectroscopy, Surface States
18:00	P2	O 52	New Methods: Experiment
18:00	P2	O 53	Poster Electronic Structure Theory
18:00	P2	O 54	Poster New Methods: Theory
18:00	P2	O 55	Poster Topology and Symmetry-protected Materials

SOE

Invited Talks

09:30	H45	SOE 4.1	Urban scaling and conflicting goals •Diego Rybski
14:00	H45	SOE 6.1	Analyzing Political Regime Stability Through the Diffusion Equation: Insights from V-Dem Data (1900-2021) •Karoline Wiesner

Sessions

09:30	H45	SOE 4	Urban systems, Scaling, and Social Systems
12:15	H45	SOE 5	Agent-Based Modeling
14:00	H45	SOE 6	Political Systems and Conflicts

TT

Invited Talk, Topical Talks

09:30	H31	TT 15.1	Solving Many-Body Problems on Quantum Computers •Benedikt Fauseweh
09:30	H36	TT 18.1	The Thermoelectric Effect and Its Natural Heavy Fermion Explanation in Twisted Bilayer and Trilayer Graphene •Bogdan Andrei Bernevig
10:00	H36	TT 18.2	Angle-Tuned Chiral Phase Transition in Twisted Bilayer Graphene •Laura Classen
10:30	H36	TT 18.3	Quantum Optics of Semiconductor Moire Materials •Atac Imamoglu
11:15	H36	TT 18.4	Probing the Band Structures of Multilayer Graphene Using the Quantum Twisting Microscope •Martin Lee
11:45	H36	TT 18.5	Gate-Tunable Bose-Fermi Mixture in a Strongly Correlated Moiré Bilayer Electron System •Nathan Wilson

Sessions

09:30	H16	TT 13	Focus Session: Magnetic Phenomena from Phonon Chirality and Angular Momentum II
09:30	H18	TT 14	Spin Transport and Orbitronics, Spin-Hall Effects I
09:30	H31	TT 15	Quantum Coherence and Quantum Information Systems
09:30	H32	TT 16	Superconductivity: Properties and Electronic Structure II
09:30	H33	TT 17	Correlated Electrons: Method Development
09:30	H36	TT 18	Focus Session: Strongly Correlated Quantum States in Moiré Heterostructures
09:30	H37	TT 19	Many-body Quantum Dynamics I
10:30	H8	TT 20	2D Materials: Electronic Structure and Exitations I
11:15	H13	TT 21	Quantum Dots and Wires: Transport
14:00	H37	TT 22	Many-body Systems: Equilibration, Chaos, and Localization
14:15	H33	TT 23	Members' Assembly

Tuesday, March 18, 2025

AKPIK

			Invited Talks
11:00	H5	AKPIK 3.1	3D Integration Towards Autonomous Optical Neural Networks •Adrià Grabulosa
14:00	H5	AKPIK 4.1	The Scaling of Intelligence: From Transformers to Agentic AI •Oliver Mey
14:30	H5	AKPIK 4.2	Inverse Design in Electromagnetics with Artificial Intelligence •Willie Padilla
15:00	H5	AKPIK 4.3	Inverse design of lateral hybrid metasurfaces with machine learning •Rui Fang
			Sessions
09:30	H5	AKPIK 2	Machine Learning Prediction and Optimization Tasks
11:00	H5	AKPIK 3	Research with AI: Hardware, Software, Tools
14:00	H5	AKPIK 4	Focus: Applications of Deep Neural Networks

09:00	Foyer Audimax, H6, Economy Bldg., Tent	**Exhibition of Scientific Instruments and Literature** (free entrance)

		Job Market
11:00	Kunsthalle	d-fine GmbH: *"Von der Kosmologie in die Beratung"*
13:00	Kunsthalle	Carl Zeiss AG: *„Karrierechancen bei Carl Zeiss AG"*
15:00	Kunsthalle	ritzenhoefer & company: *"Transformation Consulting"*

19:00	"Kugel" am Audimax	**jDPG Pub Crawl**

Wednesday, March 19, 2025

Plenary Talks

08:30	H1	PLV V	Ultrafast magnetism – terra incognita beyond the classical approximations •Alexey Kimel
14:00	H1	PLV VI	Topological spin-textures – from domain walls to Hopfions: Current innovations and future challenges •Stefan Blügel
14:00	H2	PLV VII	Variance sum rule for dissipative systems •Felix Ritort

Prize Talks

13:15	H2	PRV III	Complex liquids under confinement •Regine von Klitzing (Laureate of the Gentner-Kastler-Prize 2025)
13:15	H4	PRV IV	Nanowire-based THz polarimetry •Michael Johnston (Laureate of the Max-Born-Prize 2025)

Lunch Talk, Discussion

13:15	H1	PSV V	Career Paths: Academia or Industry? •Adelind Elshani, •Jan Wilhelm, •Valentin Kahl
13:15	H3	PSV VI	Book Launch – Physik: Erkenntnisse und Perspektiven (in German) •Sarah Köster, •Lutz Schröter

SYFD

Invited Talks

09:30	H1	SYFD 1.1	Pushing the Boundaries of Fair Data Practices for Condensed Matter Insight •Astrid Schneidwind
10:00	H1	SYFD 1.2	Establishing Workflows of Experimental Solar Cell Data into NOMAD •Eva Unger
10:30	H1	SYFD 1.3	Building up the EOSC Federation •Ute Gunsenheimer
11:15	H1	SYFD 1.4	Data-Driven Materials Science for Energy-Sustainable Applications •Jacqueline Cole
11:45	H1	SYFD 1.5	Machine Learning and FAIR Data in X-ray Surface Science •Stefan Kowarik

Session

09:30	H1	SYFD 1	Pushing the Boundaries of Fair Data Practices for Condensed Matter Insights

SYMS

Invited Talks

15:00	H1	SYMS 1.1	Exploring the Non-Perturbative Magnetic Resonance Drive Regime with spin selection rules in a π-Conjugated Polymer •Christoph Boehme
15:30	H1	SYMS 1.2	The puzzle of spin and charge transport in the chirality induced spin selectivity effect •Bart van Wees
16:00	H1	SYMS 1.3	Nano- and Microscale NMR spectroscopy with spin qubits in diamond •Nabeel Aslam
16:45	H1	SYMS 1.4	Spin effects in adsorbed organometallic complexes •Richard Berndt
17:15	H1	SYMS 1.5	Quantum Computing with Molecules •Mario Ruben

Session

15:00	H1	SYMS 1	Spins in Molecular Systems: Strategies and Effects of Hyperpolarization

Wednesday, March 19, 2025

BP

Invited Talks

09:30	H44	BP 18.1	Mechanical Imprints of Cell Competition •Benoit Ladoux
11:30	H46	BP 19.8	Rolling vesicles: From confined rotational flows to surface-enabled motion •Laura R. Arriaga
16:30	H44	BP 20.6	Centrosome positioning in cell migration and immune response •Heiko Rieger
15:00	H46	BP 22.1	From DNA Nanotechnology to biomedical insight: Towards single-molecule spatial omics •Ralf Jungmann

Sessions

09:30	H44	BP 18	Tissue Mechanics
09:30	H46	BP 19	Membranes and Vesicles II
15:00	H44	BP 20	Statistical Physics of Biological Systems I
15:00	H45	BP 21	Networks, From Topology to Dynamics
15:00	H46	BP 22	Bioimaging
18:00	P2	BP 23	Poster Focus Session Chemical Imaging for the Elucidation of Molecular Structure
18:15	H46	BP 24	Members' Assembly

CPP

Invited Talks

09:30	H34	CPP 23.1	Advanced combined rheometer setups to in-situ correlate molecular dynamics and molecular structure formation with mechanical properties •Manfred Wilhelm
11:30	H34	CPP 26.1	Polyelectrolytes in the confined space of mesopores for transport regulation •Annette Andrieu-Brunsen
16:15	H34	CPP 30.1	Challenges and Opportunities in Bringing Machine Learning to a Synchrotron •Alexander Hexemer
16:15	H38	CPP 31.1	Moving with minimum effort – Optimal work protocols for systems with memory •Sarah Loos

Sessions

09:30	H34	CPP 23	Polymer and Molecular Dynamics, Friction and Rheology
09:30	H38	CPP 24	Hybrid and Perovskite Photovoltaics III
10:00	P3	CPP 25	Poster: Active Matter, Soft Matter, Fluids
11:30	H34	CPP 26	Nanostructures, Nanostructuring and Nanosized Soft Matter I
11:30	H38	CPP 27	Molecular Electronics and Excited State Properties II
15:00	H34	CPP 28	Modeling and Simulation of Soft Matter III
15:00	H38	CPP 29	Organic Electronics and Photovoltaics III
16:15	H34	CPP 30	Emerging Topics in Chemical and Polymer Physics, New Instruments and Methods I
16:15	H38	CPP 31	Responsive and Adaptive Polymers

DS

Invited Talk

09:30	H14	DS 7.1	Enhancing Organic Spin Valves Through Spinterface Engineering •Shuaishuai Ding

Sessions

09:30	H3	DS 6	Thin Film Application
09:30	H14	DS 7	Spins in Molecular Systems: Strategies and Effects of Hyperpolarization
12:00	H3	DS 8	Optical Analysis of Thin Films I

DY

Invited Talks

15:00	H43	DY 24.1	Dynamics of odd and chiral active systems •Hartmut Löwen

DY

16:45	H43	DY 24.7	Odd dynamics and universal flows of passive objects in a chiral active fluid •Cory Hargus
18:00	H43	DY 24.11	How to model frictional contacts in sheared and active colloids •Friederike Schmid

Sessions

09:30	H17	DY 19	Focus Session: Quantum Emission from Chaotic Microcavities
09:30	H37	DY 20	Many-body Quantum Dynamics II
09:30	H43	DY 21	Granular Matter
10:00	P3	DY 22	Poster: Statistical Physics
10:00	P3	DY 23	Poster: Active Matter, Soft Matter, Fluids
15:00	H43	DY 24	Focus Session: Broken Symmetries in Statistical Physics – Dynamics of Odd Systems
15:00	H44	DY 25	Statistical Physics of Biological Systems I
15:00	H45	DY 26	Networks, From Topology to Dynamics
15:00	P4	DY 27	Poster: Nonlinear Dynamics, Pattern Formation, Granular Matter
15:00	P4	DY 28	Poster: Machine Learning, Data Science
15:00	P4	DY 29	Poster: Quantum Dynamics and Many-body Systems

HL

Invited Talks

09:30	H13	HL 30.1	Exploring semiconducting epigraphene grown by polymer-assisted sublimation growth •Teresa Tschirner
10:00	H13	HL 30.2	Huge Enhancement of the Giant Negative Magnetoresistance with Decreasing Electron Density •Lina Bockhorn
10:30	H13	HL 30.3	Ultrafast quantum optics with single-photon emitters in 2D materials •Steffen Michaelis de Vasconcellos
11:15	H13	HL 30.4	Realistic simulation of quantum emitter dynamics made easy •Moritz Cygorek
11:45	H13	HL 30.5	Data-driven Design of Next Generation 2D Materials and Their Heterostructures •Rico Friedrich
09:30	H17	HL 34.1	From complex internal dynamics to emission characteristics control in quantum billiards •Martina Hentschel
10:00	H17	HL 34.2	Positioning of microcavities around single emitters •Tobias Huber-Loyola
10:30	H17	HL 34.3	Exploring Wave Chaos and Non-Hermitian Physics: Future Prospects for Quantum Emission from Chaotic Microcavities •Jan Wiersig
11:15	H17	HL 34.4	Correlations and statistics in cavity embedded quantum dot sources of quantum light •Ana Predojevic
11:45	H17	HL 34.5	Nonlinear Phenomena in Exciton-Polaritons from Bound States in the Continuum •Dario Ballarini
16:45	H17	HL 42.1	Quantum key distribution with single photons from quantum dots •Jingzhong Yang

Sessions

09:30	H13	HL 30	Focus Session: Young Semiconductor Forum
12:15	H13	HL 31	Focus Session: Young Semiconductor Forum Poster
09:30	H15	HL 32	Nitrides: Preparation and Characterization I
11:15	H15	HL 33	Nitrides: Devices
09:30	H17	HL 34	Focus Session: Quantum Emission from Chaotic Microcavities
10:30	H11	HL 35	2D Materials: Electronic Structure and Exitations II
15:00	H13	HL 36	Materials and Devices for Quantum Technology II

Wednesday, March 19, 2025

HL

15:00	H15	HL 37	Focus Session: Physics of the van der Waals Magnetic Semiconductor CrSBr I
15:00	H17	HL 38	Nanomechanical systems
15:00	P3	HL 39	Poster III
15:30	H15	HL 40	2D Semiconductors and van der Waals Heterostructures IV
15:45	H17	HL 41	Spin Phenomena in Semiconductors
16:45	H17	HL 42	Quantum Dots and Wires: Optics I
17:00	H31	HL 43	Twisted Materials / Systems
18:00	H13	HL 44	Focus Session: Quantum Technologies in Deployed Systems I

KFM

Invited Talks

09:30	H9	KFM 11.1	Towards 3D nanoscale chemical mapping with atom probe tomography •Kasper Hunnestad
11:00	H9	KFM 12.1	Model-assisted Insight into Degradation of Li-Ion Batteries during Thermal Abuse •Ulrike Krewer

Sessions

09:30	H9	KFM 11	(Multi)ferroic States: From Fundamentals to Applications (V)
11:00	H9	KFM 12	Holistic Structural and Safety Assessment of Lithium-ion and Post-Lithium Cells and their Materials (Modelling of Battery Materials and Degradation)
15:00	H9	KFM 13	Holistic Structural and Safety Assessment of Lithium-ion and Post-Lithium Cells and their Materials (Experimental Characterisation and Safety Testing)
17:00	P1	KFM 14	Poster

MA

Invited Talks

09:30	H20	MA 23.1	Magneto-transport effects in crystalline magnetic films •Sebastian T. B. Goennenwein
10:00	H20	MA 23.2	Cubic magneto-optic Kerr effect in thin films depending on structural domain twinning and crystal orientation •Robin Silber
11:15	H20	MA 23.5	electrical and optical detection of the multipolar structure in the magnetization space •Dazhi Hou
12:30	H20	MA 23.9	Ultrafast Néel order dynamics detected by time-resolved magneto-optical Voigt effect •Haibin Zhao
16:00	H18	MA 30.1	Boosting Coercivity in Additively Manufactured Magnets Through Nano-Functionalization of NdFeB Powder •Anna Ziefuss

Sessions

09:30	H16	MA 20	Magnonics II
09:30	H18	MA 21	Frustrated Magnets I
09:30	H19	MA 22	Caloric Effects in Ferromagnetic Materials
09:30	H20	MA 23	Focus Session: Magneto-Transport and Magneto-Optics of Higher Orders in Magnetization I
09:30	H36	MA 24	Focus Session: Nonlinear Spectroscopy of Collective Excitations in Quantum Magnets
15:00	H15	MA 25	Focus Session: Physics of the van der Waals Magnetic Semiconductor CrSBr I
15:00	H16	MA 26	Ultrafast Magnetization Effects I
15:00	H18	MA 27	Focus Session: Magneto-Transport and Magneto-Optics of Higher Orders in Magnetization II
15:00	H19	MA 28	Cooperative Phenomena: Spin Structures and Magnetic Phase Transitions
15:00	H20	MA 29	Skyrmions II
16:00	H18	MA 30	Bulk Materials: Soft and Hard Permanent Magnets
17:00	P1	MA 31	Poster II
17:30	H19	MA 32	Spin Transport and Orbitronics, Spin-Hall Effects II

Wednesday, March 19, 2025

MM

Invited Talks, Topical Talks

09:30	H10	MM 15.1	Grain Boundary Defect Phases in Thermoelectric Materials: Impact on physical properties •Christina Scheu
10:15	H10	MM 16.1	Microstructure and transport in model isotropic amorphous solids •Peter Derlet
11:45	H10	MM 16.5	Structural relaxation and deformation of bulk metallic glasses •Gerhard Wilde
15:00	H10	MM 19.1	Structure, interfacial segregation and transformations of solid-state precipitates in aluminium alloys •Laure Bourgeois
15:45	H10	MM 20.1	Magnetic properties of Fe-based amorphous alloys produced by melt-spinning and selective laser melting •Paola Tiberto
17:15	H10	MM 20.5	Diffusion and nucleation in Al-Ni melts using machine-learned MD simulations •Thomas Voigtmann
18:00	H10	MM 20.7	The effect of composition on the thermodynamics, structure, mechanical properties and atomic motion of (Pd-Pt)42.5Cu27Ni9.5P21 alloys •Ralf Busch

Sessions

09:30	H10	MM 15	Invited Talk: C. Scheu
10:15	H10	MM 16	Topical Session: Thermophysical Properties of Bulk Metallic Glasses and Bulk Metallic Glass-forming Liquids
10:15	H22	MM 17	Development of Calculation Methods
10:15	H23	MM 18	SYMD contributed
15:00	H10	MM 19	Invited Talk: L. Bourgeois
15:45	H10	MM 20	Topical Session: Thermophysical Properties of Bulk Metallic Glasses and Bulk Metallic Glass-forming Liquids
15:45	H22	MM 21	Interface Controlled Properties, Nanomaterials and Microstructure Design
15:45	H23	MM 22	Materials for the Storage and Conversion of Energy
17:15	H23	MM 23	Phase Transformations
18:45	H10	MM 24	Members' Assembly

O

Invited Talks, Topical Talk

09:30	H24	O 56.1	trends and perspectives in on-surfece UHV synthesis •Pavel Jelínek
11:00	H2	O 57.3	Floquet engineering in black phosphorus •Changhua Bao
11:00	H11	O 61.3	Polaritons in two-dimensional materials and hybrids probed by electron beams •Nahid Talebi
11:30	H24	O 62.5	On-Surface Synthesis with Hydrogen Atoms •Szymon Godlewski
15:00	H2	O 64.1	Topological spin structures in two-dimensional van der Waals magnets and heterostructures •Stefan Heinze
15:30	H2	O 64.2	Ferromagnetic Order in 2D Layers of Transition Metal Dichlorides •Martina Corso
16:00	H2	O 64.3	Tailoring spin lattice in van der Waals monolayer crystals •Ying-Shuang Fu
16:30	H2	O 64.4	Spin excitations in 2D heterostructures from realistic fermionic models •António Costa
15:00	H8	O 66.1	Unveiling the crucial role of kinetic modeling of gas flows in vacuum and fusion technologies •Christos Tantos

Wednesday, March 19, 2025

O

15:30	H8	O 66.2	Advances in traceable vacuum and outgassing rate measurements •Matthias Bernien
17:00	H24	O 68.9	On-Surface Synthesis of Porphyrins and BN-Substituted Carbon Scaffolds •Willi Auwärter

Sessions

09:30	H24	O 56	Overview Talk Pavel Jelinek
10:30	H2	O 57	Ultrafast Electron Dynamics I
10:30	H4	O 58	Solid-Liquid Interfaces: Reactions and Electrochemistry II
10:30	H6	O 59	Spins on Surfaces at the Atomic Scale I
10:30	H8	O 60	Plasmonics and Nanooptics: Fabrication, Characterization and Applications I
10:30	H11	O 61	2D Materials: Electronic Structure and Exitations II
10:30	H24	O 62	Focus Session Molecular Nanostructures on Surfaces: On-Surface Synthesis and Single-Molecule Manipulation III
10:30	H25	O 63	Oxides and Insulator Surfaces: Adsorption and Reaction of Small Molecules II
15:00	H2	O 64	Focus Session Atomic Scale Investigation of Magnetic 2D Materials
15:00	H6	O 65	Solid-Liquid Interfaces: Reactions and Electrochemistry III
15:00	H8	O 66	Vacuum Science Technology: Theory and Applications
15:00	H11	O 67	Ultrafast Electron Dynamics II
15:00	H24	O 68	Focus Session Molecular Nanostructures on Surfaces: On-Surface Synthesis and Single-Molecule Manipulation IV
15:00	H25	O 69	Nanostructures at Surfaces II
18:00	P2	O 70	Poster Oxides and Insulator Surfaces: Adsorption and Reaction of Small Molecules
18:00	P2	O 71	Poster Plasmonics and Nanooptics: Fabrication, Characterization and Applications
18:00	P2	O 72	Poster Plasmonics and Nanooptics: Light-Matter Interaction, Spectroscopy
18:00	P2	O 73	Poster Metal and Semiconductor Substrates: Adsorption and Reactions of Small Molecules
18:00	P2	O 74	Poster Metal and Semiconductor Substrates: Structure, Epitaxy and Growth
18:00	P2	O 75	Poster Focus Session Chemical Imaging for the Elucidation of Molecular Structure
18:00	P2	O 76	Poster Focus Session Atomic Scale Investigation of Magnetic 2D Materials
18:00	P2	O 77	Poster Vacuum Science Technology: Theory and Applications

SOE

Invited Talk, Topical Talk

09:30	H45	SOE 7.1	When networks can think: The meaning of self-regulation in the presence of humans •Alina Herderich
11:15	H45	SOE 7.6	Self-organization in neural systems •Philipp Hövel

Sessions

09:30	H45	SOE 7	Focus Session: Self-Regulating and Learning Systems: from Neural to Social Networks
15:00	H45	SOE 8	Networks, From Topology to Dynamics
18:00	H45	SOE 9	Members' Assembly

TT

Invited Talks, Topical Talks

09:30	H31	TT 24.1	Possible Origin of High-Field Reentrant Superconductivity in UTe_2 •Toni Helm
11:30	H31	TT 24.7	Unconventional Superconductivity in Epitaxial $KTaO_3$-Based Heterostructures •Denis Maryenko
09:30	H36	TT 27.1	Detecting Anyons Using Nonlinear Pump-Probe Spectroscopy •Max McGinley

Wednesday, March 19, 2025

TT

10:00	H36	TT 27.2	Two-Dimensional Nonlinear Dynamic Response of Frustrated Magnets •Wolfram Brenig
10:30	H36	TT 27.3	Imaging Magnetization Dynamics and Collective Spin Excitations in Compensated Magnets on Ultrafast Timescales •Benjamin Stadtmüller
11:15	H36	TT 27.4	Revealing Dynamics of Hidden Sectors with Nonlinear Spectroscopy •Yoshito Watanabe
11:45	H36	TT 27.5	Theory of Nonlinear Spectroscopy of Quantum Magnets •Stefan Birnkammer
15:00	H31	TT 31.1	Quantum Skyrmion Hall Effect •Ashley Cook
17:00	H33	TT 33.8	Emergent Dynamical Gauge Fields in Generic Kitaev Spin Liquids: From Monolayer to Multilayers •Aprem Joy

Sessions

09:30	H31	TT 24	Unconventional Superconductors
09:30	H32	TT 25	Superconductivity: Supercurrent Diode Effect
09:30	H33	TT 26	Correlated Magnetism – Frustrated Systems
09:30	H36	TT 27	Focus Session: Nonlinear Spectroscopy of Collective Excitations in Quantum Magnets
09:30	H37	TT 28	Many-body Quantum Dynamics II
10:30	H11	TT 29	2D Materials: Electronic Structure and Exitations II
15:00	H17	TT 30	Nanomechanical systems
15:00	H31	TT 31	Topology: Quantum Hall Systems
15:00	H32	TT 32	Superconductivity: Yu-Shiba-Rusinov and Andreev Physics
15:00	H33	TT 33	Correlated Magnetism – Spin Liquids
15:00	H36	TT 34	Superconductivity: Theory
15:00	P3	TT 35	Topology: Poster
15:00	P3	TT 36	Nanotubes, BEC, Cryocoolers: Poster
15:00	P4	TT 37	Correlated Electrons: Poster
16:45	H32	TT 38	Superconducting Electronics: SQUIDs, Qubits, Circuit QED I
17:00	H31	TT 39	Twisted Materials / Systems
17:30	H19	TT 40	Spin Transport and Orbitronics, Spin-Hall Effects II

AIW

Sessions

14:00	H4	AIW 1	Quantencomputing
15:55	H4	AIW 2	Quantenkommunikation
17:20	H4	AIW 3	Get Together bei Bier und Brezeln

09:00	Foyer Audimax, H6, Economy Bldg., Tent	**Exhibition of Scientific Instruments and Literature** (free entrance)

Job Market

11:00	Kunsthalle	Basycon Unternehmensberatung GmbH: *"Aus der Wissenschaft in die Beratung"*

Public Evening Talk (free entrance)

19:00	H1	PSV VII	Leben in einer wärmer werdenden Welt: Wie der Klimawandel unser Leben beeinflusst •Thomas Jung

AIW Verbunden durch Physik

Deutsche Physikalische Gesellschaft DPG

Industrietag 2025

Quantentechnologien in Wirtschaft und Gesellschaft

Der Industrietag, an dem rund 200 Personen (meist Studierende und Promovierende) teilnehmen, wird durch den Arbeitskreis Industrie und Wirtschaft (AIW) der Deutschen Physikalischen Gesellschaft (DPG) organisiert und durchgeführt. Ziel der Veranstaltungen ist es, Studierende und Promovierende für Berufe in Wirtschaft und Industrie zu begeistern.

Ablauf der Veranstaltung

14:00 Uhr Willkommen und Grußwort durch AIW und AKPIK
Dr. Hans-Georg Grothues, Dr. John Kettler, Dr. Tim Ruhe

Themenblock 1 Quantencomputing

14:10 Uhr Von Quantenwinter bis Quantensprung – Wo stehen Quantentechnologien heute?
Carina Kiessling, Roland Berger

14:30 Uhr Der Weg zum praktischen Quantencomputing – Potenziale und Use-Cases
Dr. Nico Piatkowski – Fraunhofer-Institut für Intelligente Analyse- und Informationssysteme

14:50 Uhr Wie verbinden wir die Quanten- mit unserer klassischen Welt?
Dr. Claudius Riek – Zurich Instruments Germany

15:10 Uhr Podiumsdiskussion: Quantencomputing – Perspektiven für die Industrie

15:30 Uhr Kaffeepause

15:55 Uhr Finde deinen Weg: Berufliche Orientierung und Unterstützung durch die DPG
Gabriele Becker – Referentin des Vorstandes der DPG

Themenblock 2 Quantenkommunikation

16:00 Uhr Introduction to quantum cryptography and related use-cases
Dr. Mathieu Bozzio – Universität Wien

16:20 Uhr Quantenkommunikation in der Raumfahrt
Dr. Stephan Seidel – Airbus Defense & Space

16:40 Uhr Small is beautiful: Leading innovation in miniaturizing quantum sensors
Dr. Binh Tran – Bosch Quantum Sensing

17:00 Uhr Podiumsdiskussion: Quantenkommunikation – Chancen für globale Anwendungen

17:20 Uhr Get-Together bei Bier und Brezeln bis 18:30 Uhr

Veranstaltungsort:
Universität Regensburg
Zentrales Hörsaalgebäude, H4
Universitätsstr. 31
93053 Regensburg

Datum und Uhrzeit:
19.03.2025
14:00 Uhr – 18:30 Uhr

Thursday, March 20, 2025

			Plenary Talks
08:30	H1	PLV VIII	Learning how biomolecules move and undergo chemical reactions •Frauke Gräter
14:00	H1	PLV IX	Tunable Ultrafast Dynamics of Antiferromagnetic Vortices in Nanoscale Dots •Jelena Klinovaja
14:00	H2	PLV X	Process-directed formation of nonequilibrium structures in copolymer materials •Marcus Müller
			Prize Talks
13:15	H2	PRV V	Altermagnetism and spin symmetries •Libor Šmejkal (Laureate of the Walter-Schottky-Prize 2025)
13:15	H4	PRV VI	Confining strongly correlated quasiparticles in 2D semiconductors •Wouter Jolie (Laureate of the Gaede-Prize 2025)
			Lunch Talks
13:15	H1	PSV VIII	Let's talk about science communication! •Nicolas Wöhrl
13:15	H3	PSV IX	From PhD to Head of Product Management at a Biotech Company •Judith Stolwijk

SYAI

			Invited Talks
09:30	H1	SYAI 1.1	Predicting interaction partners and generating new protein sequences using protein language models •Anne-Florence Bitbol
10:00	H1	SYAI 1.2	Realizing Schrödinger's dream with AI-enabled molecular dynamics •Alexandre Tkatchenko
10:30	H1	SYAI 1.3	Emergent behavior of artificial intelligence •Steffen Rulands
11:15	H1	SYAI 1.4	AI in medical research – navigating complexity with AI •Daniel Truhn
11:45	H1	SYAI 1.5	Computational Modelling of Morphogenesis •Dagmar Iber
			Session
09:30	H1	SYAI 1	AI in (Bio-)Physics

SYQS

			Invited Talks
15:00	H1	SYQS 1.1	Active quantum flocks •Markus Heyl
15:30	H1	SYQS 1.2	Robust dynamics and function in stochastic topological systems •Evelyn Tang
16:00	H1	SYQS 1.3	Nonequilibrium Dynamics of Disorder-Driven Ultracold Fermi Gases •Artur Widera
16:45	H1	SYQS 1.4	Topological classification of driven-dissipative nonlinear systems •Oded Zilberberg
17:15	H1	SYQS 1.5	Learning dynamical behaviors in physical systems •Vincenzo Vitelli
			Session
15:00	H1	SYQS 1	Nonequilibrium Collective Behavior in Open Classical and Quantum Systems

Thursday, March 20, 2025

BP

Invited Talks

09:30	H44	BP 25.1	Oncogenic signaling and stiffness sensing •Johanna Ivaska
11:00	H46	BP 26.6	Theory for sequence selection via phase separation and oligomerization •Christoph Weber
15:00	H44	BP 29.1	Community-driven software and data training for computational biology •Toby Hodges
16:00	H46	BP 30.5	Topology in biological matter – are there double knots in proteins or maybe even more complicated knots? Prediction and in vitro verification. •Joanna I Sulkowska

Sessions

09:30	H44	BP 25	Cell Mechanics II
09:30	H46	BP 26	Synthetic life-like systems and Origins of Life
15:00	H24	BP 27	Focus Session Chemical Imaging for the Elucidation of Molecular Structure I
15:00	H37	BP 28	Microswimmers and Microfluidics
15:00	H44	BP 29	Focus Session: Innovations in Research Software Engineering
15:00	H46	BP 30	Protein Structure and Dynamics

CPP

Invited Talks

15:00	H34	CPP 34.1	Understanding Nanocellulose-Water Interactions to Engineer Advanced Functional Materials •Valentina Guccini
16:15	H34	CPP 37.1	Modelling Hygroexpansion of Compression and Opposite Wood of Conifer Branches: Bridging the Gap between Molecular and Cell Wall Level •Malin Wohlert
16:15	H38	CPP 38.1	Adsorption and Interaction of Amino Acids on Titanium Oxide Photocatalyst •Heshmat Noei

Sessions

09:30	P3	CPP 32	Poster Session II
11:45	H34	CPP 33	Modeling and Simulation of Soft Matter IV
15:00	H34	CPP 34	Focus Session: Interactions Between Water and Cellulose I
15:00	H37	CPP 35	Microswimmers and Microfluidics
15:00	H38	CPP 36	Organic Electronics and Photovoltaics IV
16:15	H34	CPP 37	Focus Session: Interactions Between Water and Cellulose II
16:15	H38	CPP 38	Interfaces and Thin Films II
18:00	H38	CPP 39	Members' Assembly

DS

Invited Talks

09:30	H3	DS 9.1	Inverse Problems and Uncertainty Quantification for the analysis of thin films and nanostructured surfaces •Sebastian Heidenreich
10:00	H3	DS 9.2	Metrological spectroscopic and imaging Mueller matrix ellipsometry for the analysis of thin films and nanostructured surfaces •Bernd Bodermann
16:15	H3	DS 12.1	Probing the Electronic Structure of Halide Perovskites •Selina Olthof
16:45	H3	DS 12.2	Quantum Science with Single Atoms and Molecules on Surfaces •Philip Willke
17:30	H3	DS 12.3	Gallium Nitride Technology – the second pillar of microelectronics •Andreas Waag
18:00	H3	DS 12.4	Ultrafast X-ray photoelectron spectroscopy and photoelectron diffraction •Philip Hofmann

Thursday, March 20, 2025

DS

Sessions

09:30	H3	DS 9	Optical Analysis of Thin Films II
11:30	H14	DS 10	Transport Properties
15:00	H3	DS 11	Thermoelectric and Phase Change Materials
16:15	H3	DS 12	Gaede-Jubiläumssitzung
18:00	P1	DS 13	Poster
18:30	H3	DS 14	Members' Assembly

DY

Invited Talks

10:45	H37	DY 31.6	Strong coupling and coherence in quantum thermodynamics •Janet Anders
09:30	H43	DY 32.1	Fluctuation-Response Relations for Non-equilibrium Systems •Benjamin Lindner
15:00	H37	DY 36.1	Light-Driven Manipulation of Passive and Active Microparticles •Svetlana Santer

Sessions

09:30	H31	DY 30	Quantum-Critical Phenomena
09:30	H37	DY 31	Focus Session: Nonequilibrium Collective Behavior in Open Classical and Quantum Systems
09:30	H43	DY 32	Nonlinear Stochastic Systems
09:30	H47	DY 33	Machine Learning in Dynamics and Statistical Physics I
11:30	H43	DY 34	Nonlinear Dynamics, Synchronization, and Chaos
15:00	H31	DY 35	Fluctuations, Noise and Other Transport Topics
15:00	H37	DY 36	Microswimmers and Microfluidics
15:00	H43	DY 37	Brownian Motion and Anomalous Diffusion
15:00	H44	DY 38	Focus Session: Innovations in Research Software Engineering
15:00	H47	DY 39	Machine Learning in Dynamics and Statistical Physics II
18:00	H43	DY 40	Members' Assembly

HL

Prize Talk, Invited Talks

09:30	H15	HL 46.1	Exploring Auto-Oscillations in Semiconductor Electron-Nuclear Spin System •Alex Greilich
11:15	H15	HL 46.6	Development and Application of Computational Simulations to Optimize Organic Photovoltaic Modules •Annika Janssen (Laureate of the Georg-Simon-Ohm-Prize 2025)
09:30	H17	HL 47.1	Quantum-Dot Quantum Light Sources in Deployed Systems •Peter Michler
10:00	H17	HL 47.2	Field test of semiconductor quantum light sources •Fei Ding
10:30	H17	HL 47.3	Quantum dot based quantum communication in urban networks •Rinaldo Trotta
11:15	H17	HL 47.4	Quantum communication protocols over a 14-km urban fiber link •Jürgen Eschner

Sessions

09:30	H13	HL 45	Perovskite and Photovoltaics II
09:30	H15	HL 46	Optical Properties
09:30	H17	HL 47	Focus Session: Quantum Technologies in Deployed Systems II
09:30	H36	HL 48	Focus Session: Ising Superconductivity in Monolayer Transition Metal Dichalcogenides
10:30	H11	HL 49	2D Materials: Electronic Structure and Exitations III
15:00	H6	HL 50	2D Materials: Stacking and Heterostructures

Thursday, March 20, 2025

HL

15:00	H13	HL 51	Transport Properties
15:00	H14	HL 52	Oxide Semiconductors II
15:00	H15	HL 53	2D Semiconductors and van der Waals Heterostructures V
15:00	H17	HL 54	Ultra-fast Phenomena II
15:00	H33	HL 55	Graphene and 2D Materials
17:30	H17	HL 56	Members' Assembly

KFM

Invited Talks

09:30	H9	KFM 15.1	Is CVD diamond now ready to become an electronic material? •Philippe Bergonzo
15:30	H9	KFM 18.1	Domain gratings of sub-micrometer period for quantum technologies •Carlota Canalias

Sessions

09:30	H9	KFM 15	Crystal Structure Defects / Real Structure / Microstructure
09:30	H13	KFM 16	Perovskite and Photovoltaics II
11:45	H23	KFM 17	Functional Materials: Performance, Reliability and Degradation; and Complex Materials
15:30	H9	KFM 18	Materials Research in Polar Oxides: Perspectives for Optics & Electronics
18:00	H9	KFM 19	Members' Assembly

MA

Invited Talks

09:35	H20	MA 35.1	Artificial Intelligence for Materials Science: Critical Importance of Rare Events, Active Learning, and Uncertainties •Matthias Scheffler
10:05	H20	MA 35.2	Physics meets data: decoding magnetic inhomogeneities through latent analysis •Karin Everschor-Sitte
10:35	H20	MA 35.3	AI used for micromagnetic simulations •Thomas Schrefl
11:15	H20	MA 35.4	Future method for estimating parameters in magnetic films using machine learning •Kenji Tanabe
15:00	H18	MA 38.1	Liquid-mediated surface-surface interactions investigated by close-to-surface magnetic particle transport •Rico Huhnstock
15:00	H19	MA 39.1	Voltage control of magnetism using hydrogen •Markus Gößler

Sessions

09:30	H16	MA 33	Non-Skyrmonic Magnetic Textures I
09:30	H18	MA 34	Molecular Magnetism
09:30	H20	MA 35	PhD Focus Session: Using Artificial Intelligence Tools in Magnetism
09:30	H36	MA 36	Focus Session: Ising Superconductivity in Monolayer Transition Metal Dichalcogenides
15:00	H16	MA 37	Magnetic Imaging Techniques
15:00	H18	MA 38	Magnetic Particles / Clusters & Biomagnetism
15:00	H19	MA 39	Magnetic Thin Films
15:00	H20	MA 40	Frustrated Magnets II
15:00	P3	MA 41	Poster III
18:00	H20	MA 42	Members' Assembly

MM

Invited Talk

09:30	H10	MM 25.1	Transformation-induced plasticity in zirconia ceramics: neural network simulations and in-situ experiments •David Rodney

Thursday, March 20, 2025

MM

Sessions

09:30	H10	MM 25	Invited Talk: D. Rodney
10:15	H10	MM 26	Topical Session: Thermophysical Properties of Bulk Metallic Glasses and Bulk Metallic Glass-forming Liquids
10:15	H22	MM 27	Transport in Materials: Diffusion, Charge or Heat Conduction
10:15	H23	MM 28	Mechanical properties
12:00	H10	MM 29	Liquid and Amorphous Materials
11:45	H23	MM 30	Functional Materials: Performance, Reliability and Degradation; and Complex Materials
15:00	H10	MM 31	Data-driven Materials Science: Big Data and Worksflows
15:00	H22	MM 32	Transport in Materials: Diffusion, Charge or Heat Conduction

O

Invited Talks, Topical Talk

09:30	H24	O 78.1	Imaging Electronic and Atomic Motion in Molecules •Manish Garg
15:00	H24	O 91.1	Infrared Nanoscopy and Tomography of Intracellular Structures •Emmanuel Pfitzner
15:30	H24	O 91.2	Coherent Raman Imaging •Michael Schmitt
16:00	H24	O 91.3	Sum Frequency Generation Microscopy of Electrochemical Interfaces •Steven Baldelli

Sessions

09:30	H24	O 78	Overview Talk Manish Garg
10:30	H2	O 79	Ultrafast Electron Dynamics III
10:30	H4	O 80	Organic Molecules on Inorganic Substrates: Electronic, Optical and Other Properties I
10:30	H6	O 81	Heterogeneous Catalysis III
10:30	H8	O 82	Plasmonics and Nanooptics: Fabrication, Characterization and Applications II
10:30	H11	O 83	2D Materials: Electronic Structure and Exitations III
10:30	H24	O 84	Gerhard Ertl Young Investigator Award Competition
10:30	H25	O 85	New Methods: Theory
15:00	H2	O 86	Electronic Structure of Surfaces: Spectroscopy, Surface States II
15:00	H4	O 87	Plasmonics and Nanooptics: Light-Matter Interaction, Spectroscopy I
15:00	H6	O 88	2D Materials: Stacking and Heterostructures
15:00	H8	O 89	Metal and Semiconductor Substrates: Structure, Epitaxy and Growth
15:00	H11	O 90	Spins on Surfaces at the Atomic Scale II
15:00	H24	O 91	Focus Session Chemical Imaging for the Elucidation of Molecular Structure I
15:00	H25	O 92	Electronic Structure Theory
19:00	H1	O 93	Members' Assembly
19:30	H1	O 94	Post Deadline Session

SOE

Invited Talk

15:00	H45	SOE 10.1	Emergent Behaviors in LLMs-Populated Societies •Giordano De Marzo

Session

15:00	H45	SOE 10	Focus Session: Large Language Models, Social Dynamics, and Assessment of Complex Systems

TT

Invited Talk, Topical Talks

09:30	H36	TT 44.1	Evidence of Unconventional Superconductivity in Monolayer and Bulk van der Waals Material TaS_2 •Somesh Chandra Ganguli

Thursday, March 20, 2025

TT

10:00	H36	TT 44.2	Signatures of Unconventional Superconductivity in Transition Metal Dichalcogenides •Miguel Ugeda
10:30	H36	TT 44.3	Friedel Oscillations and Chiral Superconductivity in Monolayer $NbSe_2$ •Magdalena Marganska
11:15	H36	TT 44.4	Unconventional Pairing in Ising Superconductors •Andreas Kreisel
11:45	H36	TT 44.5	High-Field Study of Ising Superconductivity in TMDs •Oleksandr Zheliuk

Plenary Talks

Plenary Talk PLV I Mon 8:30 H1

Seeing dents in the atom — •Franz Giessibl — Exp. and Appl. Phys., University of Regensburg, 93053 Regensburg, Germany

Explaining the emission spectra of atoms was a giant early success of quantum mechanics. Directly seeing atoms remained elusive, though. When Binnig and Rohrer imaged the atoms of the silicon 7x7 reconstructed surface with the scanning tunneling microscope (STM), it came as a surprise. STM relies on a quantum effect, electron tunneling. In 1986, Binnig, Gerber and Quate introduced atomic force microscopy (AFM), a method that also images samples by probing it with, ideally, the single front atom of a sharp tip. Feynman quoted the atomic hypothesis (attracting each other when they are a little distance apart, but repelling upon being squeezed into one another) in chapter 1 of his Lectures on Physics. The AFM uses exactly those forces between atoms to create images line by line. The force sensor needs to probe forces small enough such that neither the tips front atom nor the sample are displaced. AFM passed its acid test when it resolved the silicon 7x7 surface in a non-contact mode using the frequency shift of an oscillating cantilever. The qPlus sensor, a self-sensing quartz cantilever oscillating at sub-A amplitudes resolves molecules with a CO tip. Today, AFM even resolves structures within single atoms. The quantum corral, introduced by Crommie, Lutz and Eigler in 1993, was revisited by AFM, showing that this 2D artificial atom interacts similar with AFM tips as a natural atom. A qPlus sensor with a metal tip reunites STM with AFM and it enables us to do surface science of insulators on the atomic level.

Plenary Talk PLV II Mon 14:00 H1

High-power semiconductor lasers based on Hermitian and non-Hermitian control in photonic crystals — •Susumu Noda — Department of Electronic Science and Engineering, Kyoto University, Kyoto 615-8510, Japan

Realizing single-mode, high-power, high-beam-quality semiconductor lasers, which rival (or even replace) bulky gas and solid-state lasers, is one of the ultimate goals of photonics and laser physics. Conventional high-power semiconductor lasers, however, inevitably suffer from poor beam quality owing to the onset of many-mode oscillation. In this conference, I will review the recent progress, in which these challenges have been surmounted by developing large-scale photonic-crystal surface-emitting lasers (PCSELs) with controlled Hermitian and non-Hermitian couplings inside the photonic crystal. A CW output power exceeding 50W with purely single-mode oscillation and an exceptionally narrow divergence of 0.05˚has been achieved for PCSELs with a diameter of 3mm. The brightness, a figure of merit encapsulating both output power and beam quality, exceeds 1GWcm-2sr-1, which is over ten times larger than those of conventional semiconductor lasers and rivals those of existing bulky lasers. I will also discuss our recent efforts towards realizing even 1-kW-class PCSELs with expanded resonant diameters of 10mm and finely tuned Hermitian and non-Hermitian couplings. Such PCSELs are expected to replace conventional, bulkier lasers in the near future. Finally, I will refer to the high functionalities of PCSELs including the emission of arbitrary beam patterns, and high-peak-power short-pulse generation.

Plenary Talk PLV III Mon 14:00 H2

Physics informed artificial intelligence and data-driven design of materials — •Jörg Neugebauer — MPI für Nachhaltige Materialien, Düsseldorf, Germany

Recent advances in materials science have introduced novel compositionally and structurally complex materials, opening up a vast configuration space for discovery. These innovative materials promise to revolutionize industries related to energy storage, transportation, and medicine. However, traditional methodologies fall short in dealing with the high-dimensional configuration spaces involved. This presentation addresses the application of physics-informed artificial intelligence (PIAI) and data-driven strategies as an emerging solution. PIAI uses physical laws and advanced simulation techniques to improve the predictability of AI models, while automated digital workflows facilitate efficient exploration and material discovery. This synergy accelerates the design pipeline and effectively supports navigation of the newly opened vast material space. Real-world case studies will illustrate the potential of these methodologies.

Plenary Talk PLV IV Tue 8:30 H1

Some new aspects of unconventional superconductivity in layered materials — •Irina Grigorieva — University of Manchester, Manchester, UK

I will overview our recent work on layered superconductors where signatures of unconventional superconductivity are revealed or sometimes promoted by their response to magnetic fields. Magnetic correlations and superconductivity are usually antagonistic. However, in some situations external magnetic fields can be helpful in bringing to light new superconducting properties. One example is magnetic field induced multiphase superconductivity in an anisotropic superconductor with strong spin-orbit coupling, PdBi2. Another is an unconventional response of surface superconductivity to the applied magnetic field due to the presence of topological surface states in In2Bi. Yet another is proximity superconductivity surviving in the quantum Hall regime in Josephson junctions based on twisted bilayer graphene. I will discuss the underlying mechanisms and their relation to unconventional topology of these materials.

Plenary Talk PLV V Wed 8:30 H1

Ultrafast magnetism- terra incognita beyond the classical approximations — •Alexey Kimel — Radboud University, Nijmegen, The Netherlands

While the conventionally accepted Curie-Neumann's principle states that "the symmetries of the causes are to be found in the effects" [1], in ultrafast magnetism the principle fails and magnetization dynamics becomes counter-intuitive. We will demonstrate that ultrafast (sub-100 ps) heating with the help of ultrashort laser pulses causes magnetization reversal without any magnetic fields [2], laser-induced spin dynamics is strongly non-linear, where new channels of spin-lattice interaction open-up [3,4], the principle of superposition fails i.e. 1+1>2 [5] and the approximation of macrospin is no longer adequate [6].

Plenary Talk PLV VI Wed 14:00 H1

Topological spin-textures – from domain walls to Hopfions: Current innovations and future challenges — •Stefan Blügel — Peter Grünberg Institute, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany

Topological spin- and magnetization textures, generally associated with Skyrmions, is a very exciting, timely and multidisciplinary field, where mathematicians, theoretical and computational physicists meet with experts on film and multilayer growth, on high-resolution magnetization and electronic structure characterization, transport and dynamics, and on device concepts and devices in order to integrate these particles into the field of spintronics. It is very fascinating to observe that simple spin models, which can be determined for real materials by density functional theory calculations, lead to micromagnetic equations whose solutions are localized topological textures in an homogeneous solid, which can now be studied by experimental methods, e.g. by means of quantitative off-axis electron holography or x-ray ptychography. Drawing a line between the first solitary wave discovered by John Scott Russel and Heisenberg's question of how countable particles can appear in continuous fields, I will give an elementary overview of the field, introduce the core objects and the primary interactions, discuss their nonlinear behavior which can be useful for neuromorphic spintronics, discuss their electric detection and magnetic hopfions, a new type of solitonic structure in three dimensions shaped as bounded knots, and their recent discovery stabilized by a skyrmion filament.

Work is supported by the ERC Grant 856538 - 3D MAGiC.

Plenary Talk PLV VII Wed 14:00 H2

Variance sum rule for dissipative systems — •Felix Ritort — Small Biosystems Lab, Condensed Matter Physics Department, University of Barcelona, C/ Marti i Franques, 1, 08028 Barcelona (Spain)

Nonequilibrium pervades nature, from the expanding universe to climate dynamics, living cells, and molecular machines. Key to nonequilibrium states is the entropy production rate σ at which energy is dissipated to the environment. Despite its importance, σ remains challenging to measure, especially in nanoscale systems with limited access to microscopic variables. I present a recently introduced variance sum rule for displacement and force variances that permits measuring σ by constraining energetics through modeling [1,2]. We apply it to measure the first heat map of human red blood cells in experiments with laser optical tweezers and ultrafast life-imaging microscopy. The variance sum rule sets a new resource for energy inference in nonequilibrium systems [3], from measuring entropy production in active and living matter to identifying hidden sources of energy and dissipation.

ance sum rule: proofs and solvable models. New Journal of Physics, 26, 063013. [3] Roldán, É. (2024). Thermodynamic probes of life. Science, 383(6686), 952-953.

Plenary Talk PLV VIII Thu 8:30 H1

Learning how biomolecules move and undergo chemical reactions — •Frauke Gräter — Max Planck Institute for Polymer Research, Mainz, Germany

Life is biochemistry in action. While molecular simulations of systems as complex as whole cells are now within reach, predicting chemical reactivity on relevant time and length scales remains a challenge. I will present our recent work towards bringing action * here: chemistry * to classical atomistic simulations and molecular design through machine learning.

We substitute costly quantum mechanical calculations with a graph neural network-based emulator which predicts reaction rates without explicitly modelling the reaction. To deal with the chemistries arising from the such reactions, we have developed a framework to parametrize a classical force field. GRAPPA leverages graph attention, is highly accurate, and can be easily fine-tuned. Our ML-based simulations can predict cascades of chemical reactions amidst the 'jiggling and wiggling' of biomolecules at an efficiency close to classical simulations.

Finally, I will demonstrate how we harness a flow-matching model based on geometric algebra and trained on Molecular Dynamics simulations to design novel proteins with tailored flexibilities. Our method generates conformational ensembles of unseen proteins without the need to run costly Molecular Dynamics simulations, and paves the way for generating novel proteins with biochemical functions that rely on molecular motions.

Plenary Talk PLV IX Thu 14:00 H1

Tunable Ultrafast Dynamics of Antiferromagnetic Vortices in Nanoscale Dots — •Jelena Klinovaja[1], Ji Zho[1], Even Thingstad[1], Se Kwon Kim[2], and Daniel Loss[1] — [1]Department of Physics University of Basel Klingelbergstrasse 82 4056 Basel, Switzerland — [2]Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon 34141, Republic of Korea

Topological vortex textures in magnetic disks have garnered great attention due to their interesting physics and diverse applications. However, up to now, the vortex state has mainly been studied in microsize ferromagnetic disks, which have oscillation frequencies confined to the GHz range. We propose an experimentally feasible ultrasmall and ultrafast vortex state in an antiferromagnetic nanodot surrounded by a heavy metal, which is further harnessed to construct a highly tunable vortex network. We theoretically demonstrate that, interestingly, the interfacial Dzyaloshinskii-Moriya interaction (iDMI) induced by the heavy metal at the boundary of the dot acts as an effective chemical potential for the vortices in the interior. Mimicking the creation of a superfluid vortex by rotation, we show that a magnetic vortex state can be stabilized by this iDMI. Subjecting the system to an electric current can trigger vortex oscillations via spin-transfer torque, which reside in the THz regime and can be further modulated by external magnetic fields. Coherent coupling between vortices in different nanodisks can be achieved via an antiferromagnetic link. Remarkably, this interaction depends on the vortex polarity and topological charge and is also exceptionally tunable through the vortex resonance frequency.

Plenary Talk PLV X Thu 14:00 H2

Process-directed formation of nonequilibrium structures in copolymer materials — •Marcus Müller — Georg-August-Universität, Göttingen, Germany

Macromolecular systems often become trapped in metastable structures rather than reaching true equilibrium, offering opportunities to fabricate structures with unique properties. Process-directed structure formation refers to reproducibly trapping the kinetics of structure transformation into a desired (meta)stable target structure after a quench of the thermodynamic state, such as solvent evaporation or light-stimulated chemical conversions. This strategy leverages several unique advantages of copolymer systems, including a comprehensive knowledge of equilibrium properties and a clear separation of timescales between the quench of thermodynamic variables, the system's spontaneous relaxation toward the nearest metastable structure, and its thermally activated escape toward equilibrium. Both highly coarse-grained particle-based and continuum models will be discussed, highlighting challenges for quantitatively predicting copolymer material processing at the molecular scale.

Plenary Talk PLV XI Fri 8:30 H1

Exploring correlated phases and topology in van der Waals platforms — •Roser Valenti — Institute of Theoretical Physics, Goethe University Frankfurt

In recent years a plethora of new correlated states have been observed by stacking, twisting and straining two dimensional van der Waals materials of different kind. Some prominent examples are twisted bilayer graphene, bilayer heterostructures of graphene with the spin-orbit assisted Mott insulator α-RuCl3 -a candidate for Kitaev spin physics-, or bilayer heterostructures of the Mott insulator 1T-TaS2 with the metal 1H-TaS2. Unique to these bilayer structures is the possible emergence of phases not foreseable from the single layers alone, such as heavy fermions, Kondo insulators, quantum spin liquids, correlated metals, or topological superconductors.

In this talk I will discuss the microscopic modelling of such heterostructures by a combination of first-principles calculations, effective-model considerations, many-body techniques and statistical/ machine learning methods and will present exemplary cases on the emerging correlated electronic and magnetic properties[1-5] and will compare with experimental results.

Prize Talk PRV I Mon 13:15 H2

Correlated phases in the vicinity of tunable van Hove singularities in Bernal bilayer graphene — •Anna Seiler — ETH Zürich — University of Göttingen — Laureate of the Gustav-Hertz-Prize 2025

The band structure of naturally occurring Bernal bilayer graphene features four linearly dispersed Dirac cones [1] but undergoes significant changes under the application of large electric displacement fields across the two layers. In this regime, tunable van Hove singularities give rise to complex correlated states. Our experiments reveal signatures consistent with various interaction-driven phases, including fractional metals of the Stoner type [2, 3]. More strikingly, we identify competing nontrivial insulating phases at both hole [2] and electron doping [3]. These phases exhibit intriguing temperature dependence and nonlinear I-V characteristics at zero magnetic field, consistent with sliding Wigner crystals of both trivial and nontrivial topology [2-4].

Prize Talk PRV II Tue 13:15 H2

Single-molecule electron spin resonance by means of atomic force microscopy — •Lisanne Sellies — University of Regensburg, Regensburg, Germany — IBM Research Europe - Zurich, Rüschlikon, Switzerland — Laureate of the Gustav-Hertz-Prize 2025

Recently, we combined the high energy resolution of electron spin resonance (ESR) with the spatial resolution offered by atomic force microscopy (AFM) [1]. This ESR-AFM technique relies on driving electron spin transitions between the non-equilibrium triplet state levels of a single molecule. Since these triplet states typically have different lifetimes, driving such transitions modifies the overall triplet lifetime [1,2], which can be detected by an electronic pump-probe scheme [3].

In this talk, an introduction to ESR-AFM will be given. It will be shown that the ESR-AFM spectra feature a sub-nanoelectronvolt energy resolution. Thereby, molecules only differing in their isotopic configuration can be distinguished. Moreover, due to the minimally invasive nature of the ESR-AFM technique, the electron spins of pentacene can be coherently manipulated over tens of microseconds [4]. The high energy resolution and long spin coherence represent a leap forward for local studies of future artificial quantum systems and fundamental local quantum-sensing experiments.

Prize Talk PRV III Wed 13:15 H2

Complex liquids under confinement — •Regine von Klitzing[1,2], Michael Ludwig[1], Thomas Tilger[1], and Larissa Braun[1] — [1]Institute for Condensed Matter Physics, Hochschulstrasse 8, 64289 TU Darmstadt — [2]Laureate of the Gentner-Kastler-Prize 2025

Complex liquids are widely used in many applications, from industrial painting processes to personal care products. Despite their numerous applications, they are still actively discussed in basic research, e.g. their structural behaviour under confinement. In the present study, colloidal dispersions (e.g. nanoparticle suspensions, micellar solutions) are confined between two surfaces in a Colloidal Probe Atomic Force Microscope (CP-AFM) or in a Thin Film Pressure Balance (TFPB). When approaching the surface, the depletion of the dispersion from the thin film leads to oscillations of the interaction force between the confining surfaces. The structure of the confined colloidal dispersions is compared with their bulk structure, which is analysed by small-angle neutron or X-ray scattering (SANS, SAXS). The results show that the softness and the charge of the particles have a strong influence on the scaling law for the particle distance and the correlation length of the particle distribution, which is not yet fully understood. Another open question is when a charged object can be considered as an ion contributing to the electrostatic screening between two confining surfaces and when it behaves like a charged particle, where the jellium approach could provide a suitable model to describe the experimental data.

Prize Talk PRV IV Wed 13:15 H4

Nanowire-based THz polarimetry — •Michael Johnston — Department of Physics, University of Oxford, Oxford, UK. — Laureate of the Max-Born-Prize 2025

Semiconductor nanowires show extreme polarization selectivity for both visible and terahertz photons. We are utilising an in-depth knowledge of ultrafast charge-carrier dynamics in nanowires to develop unique devices for THz polarimetry. Our photoconductive THz sensors based on a hash-nanowire architecture are compact and recover the full polarisation state of THz pulses. These nanowire-based devices are showing promise in areas including semiconductor characterisation and the development of metamaterials for THz polarisation manipulation.

Prize Talk PRV V Thu 13:15 H2

Altermagnetism and spin symmetries — •Libor Šmejkal — Max Planck Institute for the Physics of Complex Systems — Laureate of the Walter-Schottky-Prize 2025

Since the 1930s, magnetism had been divided into two main branches: ferromagnetism and antiferromagnetism. Recently, we have identified a new branch, altermagnetism, characterized by a d-, g-, or i-wave spin order [1]. Our discovery emerged from our systematic spin symmetry classification [1], analogous to the well-established classifications in the fields of superconductors, superfluids, or the Standard Model.

In this talk, we will outline our decade-long journey to uncover altermagnets, including the prediction of the anomalous Hall effect and unconventional electronic structure in compensated collinear magnets [2,3]. We will present our systematic classification that revealed beside the even-partial wave altermagnets also odd-partial wave unconventional magnets [4]. Additionally, we will highlight experimental observation of altermagnetism using photoemission spectroscopy [5] and nanoscale X-ray microscopy [6]. Finally, we will explore emerging research directions [7], more than 300 material candidates, and potential applications of altermagnets across and beyond solid-state physics [8], e.g. in ultrafast and low power nanoelectronics.

Prize Talk PRV VI Thu 13:15 H4

Confining strongly correlated quasiparticles in 2D semiconductors — •Wouter Jolie — II. Physikalisches Institut, Universität zu Köln, Germany — Laureate of the Gaede-Prize 2025

Electrons are prone to strong correlations when confined into one-dimensional (1D) or 0D cavities. Many exotic ground states can emerge, depending on the type of interactions at play. Examples are Peierls transitions, Tomonaga-Luttinger liquids or Anderson impurities.

An ideal experimental testbed for the observation of correlated electronic behaviour are metallic mirror twin boundaries (MTBs) in the two-dimensional semiconductor MoS_2. These MTBs have well-defined structural and electronic properties, are only weakly coupled to the environment and accessible to spatially resolved spectroscopic techniques such as scanning tunnelling microscopy.

In my talk I will show that the confined quasiparticles within finite MoS_2 MTBs transform into spin and charge excitations as described by the Tomonaga-Luttinger liquid theory of strongly interacting 1D electrons. In addition, a Kondo resonance emerges when the highest occupied state is filled by a single electron, in quantitative agreement with the Anderson impurity model. Lastly, I will outline possible ways to create and manipulate new types of correlated states in this system.

Ceremonial, Lunch, Evening Talks and Discussions

Discussion PSV I Mon 13:15 H1

Karriere auf Zeit: Perspektiven auf befristete Arbeitsverträge in der Wissenschaft — •Carolin Wagner[1], •Axel Dürkop[2], •Raja Hoffmann[3,4], Pauleo Nimtz[4], David Smolinski[4], Susanne Liese[5] und Alexander Schlaich[5] — [1]Mitglied der Bundestags, Ausschuss für Bildung, Forschung und Technikfolgenabschätzung — [2]Universität Regenburg, Konvent der wissenschaftlichen und künstlerischen Mitarbeiterinnen und Mitarbeiter — [3]Universität Jena — [4]jDPG — [5]AGyouLeaP

Befristete Arbeitsverträge prägen den Alltag vieler Wissenschaftlerinnen und Wissenschaftler. Die Diskussionsrunde beleuchtet die Herausforderungen und Chancen dieser Beschäftigungsform aus der Perspektive von Expert:innen aus Wissenschaft und Politik. Wie lassen sich Planungssicherheit, Innovation und wissenschaftliche Freiheit vereinbaren? Gemeinsam suchen wir nach Wegen für faire und zukunftsfähige Karrierewege in der Wissenschaft.

AGyouLeaP und jDPG freuen sich auf eine spannende Diskussion mit Dr. Carolin Wagner, Prof. Dr. Axel Dürkop und Raja Hoffmann.

Lunch Talk PSV II Tue 13:15 H1

Research Funding by the DFG - Funding of Coordinated Programmes — •Christian Hahn[1], Mario Bomers[1], Joanna Kowalska[1], Michael Mössle[1], and Uwe Bovensiepen[2] — [1]German Research Foundation (DFG), Bonn — [2]Fakultät für Physik, Universität Duisburg-Essen and CENIDE, Duisburg

The German Research Foundation (DFG) is the central research funding organization in Germany. It is self-governed by the scientific community, supports research projects and funds cooperation between researchers. The DFG offers a broad range of funding opportunities from individual grants to larger coordinated programmes. This talk will focus on the DFG funding lines for coordinated projects, such as Collaborative Research Centres, Priority Programmes or Research Units. These programmes promote cooperation and structural innovation by fostering national and international collaboration in areas of current relevance. Also, we will give some first-hand insights into the review and decision process for the coordinated programmes from the perspective of the DFG head office and a current review board member.

Lunch Talk PSV III Tue 13:15 H4

Menschheitsaufgabe Klimawandel und die DPG: Gründung der AG Klima — •Gregor Schaumann — JMU Würzburg

Der menschengemachte Klimawandel mit allen humanitären Folgen ist ein physikalischer Fakt. Wie gehen wir als einzelne Wissenschaftler:in, beziehungsweise im Verband wie der DPG mit dem Befund um? Worin besteht die Verantwortung der Wissenschaft in dem Kontext? Seit einem Jahr gründet sich innerhalb der DPG die AG Klima, die das Thema als Querschnittthema in der DPG begreift. Im Vortrag werden das Selbstverständnis und die Aktivitäten der AG Klima vorgestellt. Im Anschluss gibt es in der Klima-Lounge die Möglichkeit zum Austausch und Einbringen Ihres Standpunkts.

PSV IV: Ceremonial Session with Award Ceremony

Time: Tuesday 16:00–18:00 Location: H1

Ceremonial Talk PSV IV H1

How to build a biological cell from scratch — •Petra Schwille — MPI of Biochemistry, Martinsried

Researchers at the interface of biology with the quantitative sciences, like physics and chemistry, have in the past years been pursuing a new approach towards a fundamental understanding of living systems, termed "bottom-up synthetic biology". The underlying idea is that only a radical simplification and abstraction of a biological cell will allow us to decipher the distinctive features of life, because even the simplest life forms on earth have accumulated a huge degree of redundancy, in order to remain viable in a hostile and competitive environment. Thus, in order to arrive at a self-sustaining minimal reaction system with the ability to replicate and evolve - a minimal living system - we likely need to build it from scratch. I will show how the bottom-up assembly of a minimal functional machinery accomplishes the spontaneous division of a vesicle-based artificial cell. Important functions that we have successfully reconstituted in a minimal model system include autonomous assembly, positioning, and contraction of a minimal division ring.

Discussion PSV V Wed 13:15 H1

Career Paths: Academia or Industry? — •Adelind Elshani[1], •Jan Wilhelm[2], •Valentin Kahl[3], Hans-Georg Grothues[4], Pauleo Nimtz[5], and Susanne Liese[6] — [1]RWTH Aachen — [2]University of Regensburg — [3]ibidi GmbH, Munich — [4]Arbeitskreis Industrie und Wirtschaft — [5]jDPG — [6]AGyouLeaP

After completing your undergraduate studies, your PhD, or, at the latest, your first postdoc, you may ask yourself the question: Do I want to stay at a research institution or work in industry? In this panel discussion, we would like to talk about this question with experts from different areas of science and industry representing different varieties of career paths. We are looking forward to a diverse panel discussion with Adelind Elshani RWTH Aachen, Dr. Jan Wilhelm, University of Regensburg, and Dr. Valentin Kahl, ibidi GmbH, Munich.

Lunch Talk PSV VI Wed 13:15 H3

Book Launch – Physik: Erkenntnisse und Perspektiven (in German) — Joachim Ullrich[1], Ulrich Bleyer[1], •Sarah Köster[2], Claus Lämmerzahl[3], Dieter Meschede[4] und •Lutz Schröter[1] — [1]Deutsche Physikalische Gesellschaft e. V., Bad Honnef — [2]Universität Göttingen, Institut für Röntgenphysik, Göttingen — [3]Universität Bremen, Weltraumwissenschaft ZARM, Bremen — [4]Universität Bonn, Institut für Angewandte Physik, Bonn

Join us for the book launch of the new DPG publication. You will have the opportunity to pick up a free copy – while stocks last!

The title "Physik: Erkenntnisse und Perspektiven" (Physics: Insights and Perspectives) refers to a publication, which was produced on a voluntary basis by almost 200 authors. It provides a detailed exploration of the fundamentals of physics, current research and future developments. The book offers readers an engaging and inspiring insight into the world of physics! The publication is also available at www.physik-erkenntnisse-perspektiven.de – along with exclusive video interviews. Printed copies can also be ordered by covering the shipping costs.

Evening Talk PSV VII Wed 19:00 H1

Leben in einer wärmer werdenden Welt: Wie der Klimawandel unser Leben beeinflusst — •Thomas Jung — Alfred Wegener Institut, Bremerhaven, Deutschand

In seinem Vortrag erklärt Professor Thomas Jung vom Alfred-Wegener-Institut, wie der Klimawandel unser Leben auf lokaler Ebene beeinflusst. Mit Hilfe von Beobachtungsdaten und modernen Klimamodellen zeigt er, wie sich eine wärmere Welt auf unser Wetter auswirkt, von häufigeren Extremwetterereignissen bis hin zu Veränderungen in den Jahreszeiten. Gleichzeitig veranschaulicht er, wie das heutige Wetter unter den Bedingungen eines vorindustriellen Klimas ausgesehen hätte. Professor Jung präsentiert dabei neue Ergebnisse aus der Klimaforschung, die durch hochauflösende Klimasimulationen und sogenannte Storyline-Verfahren gewonnen wurden. Diese innovativen Methoden ermöglichen es, den Klimawandel und dessen Auswirkungen greifbar zu machen. Dabei möchte er nicht nur die Herausforderungen des Klimawandels aufzeigen, sondern auch Perspektiven für positive Veränderungen entwickeln, die uns alle zum Handeln inspirieren können.

Lunch Talk PSV VIII Thu 13:15 H1

Let's talk about science communication! — •Nicolas Wöhrl and Peter Kohl — University Duisburg-Essen, Lotharstr. 1, 47057 Duisburg

Trust in science is essential – not as blind acceptance, but as informed trust based on an understanding of how the scientific method works. At a time when social issues are increasingly politicized and overshadowed by desinformation, the ability to critically assess data, distinguish between fact and fiction and develop evidence-based arguments makes researchers indispensable voices. Trust in science is not solely built on reliable data and conclusions; it also hinges on the transparency of the scientific process itself. The public should be familiar with how science works and how knowledge is generated to be able to make societal decisions that are based on facts.. Trust in science is not only gained through excellent research, but also by getting to know the actual people that stand behind the results. This is a communication challenge that, in principle, all researchers

can take on. They can convey, how the scientific method makes an evidence-based world view possible.

Some topics, addressed in this talk: Why do we need communicating scientists alongside press offices and science journalism? How can science communication be done despite all other tasks in research and teaching? What role can it play in a scientific career? Do I have talent for outreach and how do I find out which formats are best for me?

Lunch Talk PSV IX Thu 13:15 H3

From PhD to Head of Product Management at a Biotech Company — •Judith Stolwijk — ibidi GmbH

ibidi is a leading supplier for functional cell-based assays and advanced products for cellular microscopy. ibidi is located in Gräfelfing, Germany, close to Munich. In 2001, ibidi was founded by three physics PhD students and their group leader as a spin-off from the Technische Universität München (TUM) and the Center for Nanoscience (CeNS) at the University of Munich (LMU). Today, a close-knit team of physicists, biologists, and engineers work together to develop ground-breaking products.

Tutorials

TUT 1: Hands-on Tutorial: AI Fundamentals for Research (joint session BP/TUT/DY/AKPIK)

Artificial intelligence (AI) has become an essential tool in modern physics, enabling new approaches to data analysis, modeling, and prediction. This hands-on tutorial provides an accessible introduction to key AI concepts, emphasizing their practical applications in physics research.

Please bring your laptop. There will be limited power outlets in the room, so come with a fully charged battery.

Materials will be made available from 10.03.2025, accessible via the following options:

GitHub repository:
https://github.com/RedMechanism/DPG-SKM-2025-Tutorial-AI-Fundamentals-for-Research

ZIP file download:
https://jlubox.uni-giessen.de/getlink/fiAGRzcGTiCL3GZxk8WAjom4/

Participants are encouraged to download them ahead of time.

Organized by Jan Bürger (Aachen), Janine Graser (Duisburg), Robin Msiska (Duisburg/Ghent), and Arash Rahimi-Iman (Gießen), with support from Stefan Klumpp (Göttingen) and Tim Ruhe (Dortmund).

Time: Sunday 16:00–18:15 Location: H2

Tutorial TUT 1.1 Sun 16:00 H2

Introduction — Jan Bürger[1], •Janine Graser[2], Robin Msiska[2,3], and Arash Rahimi-Iman[4] — [1]ErUM-Data-Hub, RWTH Aachen University, Aachen, Germany — [2]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Duisburg, Germany — [3]Department of Solid State Sciences, Ghent University, Ghent, Belgium — [4]I. Physikalisches Institut and Center for Materials Research, Justus-Liebig-University Gießen, Gießen, Germany

The session begins with an overview of essential AI concepts, including neural networks, training methodologies, and key distinctions between AI models. Participants will gain a foundational understanding of AI principles and how these tools can be leveraged for various research challenges.

5 min. break

Tutorial TUT 1.2 Sun 16:40 H2

Hands-On Session 1 – Function Approximation — •Jan Bürger[1], Janine Graser[2], Robin Msiska[2,3], and Arash Rahimi-Iman[4] — [1]ErUM-Data-Hub, RWTH Aachen University, Aachen, Germany — [2]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Duisburg, Germany — [3]Department of Solid State Sciences, Ghent University, Ghent, Belgium — [4]I. Physikalisches Institut and Center for Materials Research, Justus-Liebig-University Gießen, Gießen, Germany

In the first half of the interactive session, participants will work with Jupyter Notebooks to explore practical applications of machine learning. They will train simple neural networks to predict a mathematical function, gaining hands-on experience in tuning key parameters. Since neural networks can typically be considered universal function approximators, this concept is effectively illustrated using a one-dimensional function, making it easy to visualize and understand.

5 min. break

Tutorial TUT 1.3 Sun 17:30 H2

Hands-On Session 2 – Classification and More — Jan Bürger[1], Janine Graser[2], •Robin Msiska[2,3], and Arash Rahimi-Iman[4] — [1]ErUM-Data-Hub, RWTH Aachen University, Aachen, Germany — [2]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Duisburg, Germany — [3]Department of Solid State Sciences, Ghent University, Ghent, Belgium — [4]I. Physikalisches Institut and Center for Materials Research, Justus-Liebig-University Gießen, Gießen, Germany

The session demonstrates how pre-trained models can simplify tasks such as classification, making them readily applicable to research. Typical examples include recognizing handwritten digits, which showcase the power of pretrained models in solving common challenges. As a preview of advanced topics, the tutorial concludes with brief examples of large language models (LLMs) and generative AI.

TUT 2: Tutorial: How to Use NOMAD's Workflow Utilities to Improve Data Management and Facilitate Discovery in Materials Science (joint session O/TUT)

NOMAD (nomad-lab.eu) [1] is an open-source, community-driven data infrastructure, that supports automated (meta)data extraction from a wide range of simulations, including ab initio and advanced many-body calculations as well as molecular dynamics simulations. NOMAD allows users to store both standardized and custom complex simulation workflows, which not only streamlines data provenance and analysis but also facilitates the curation of AI-ready datasets. This tutorial will focus on recently developed workflow functionalities and utilities within the NOMAD infrastructure. These advances enable high-throughput interfacing with the NOMAD repository, opening improved discovery pipelines by leveraging the benefits of NOMAD's comprehensive and FAIR-compliant data management system [2].

[1] Scheidgen, M. et al., JOSS 8, 5388 (2023).

[2] Scheffler, M. et al., Nature 604, 635-642 (2022).

Time: Sunday 16:00–18:00 Location: H3

Tutorial TUT 2.1 Sun 16:00 H3

FAIR-data management with the NOMAD infrastructure: Core functionalities — •Joseph F. Rudzinski — Physics Department and CSMB Adlershof, Humboldt-Universität zu Berlin, Germany

In this first part of the tutorial series, an overview of the NOMAD infrastructure will be provided. Attendees will learn how NOMAD processes raw data and stores it within a generalized data structure, and the corresponding GUI features that allow users to comfortably browse data. An example scenario will also be set up for use throughout the remainder of the tutorial series: *A researcher with a variety of data obtained within a project workflow would like to upload this data to NOMAD in order to link it to their manuscript while exposing the details of their (meta)data and retaining the scientifically relevant connections between the individual project tasks.*

Tutorial TUT 2.2 Sun 16:30 H3

Using NOMAD's API for project management — •Nathan Daelman — Physics Department and CSMB Adlershof, Humboldt-Universität zu Berlin, Germany

In this part of the tutorial series, you will learn how to interface with NOMAD programmatically using a Python module built to simplify the API (application programming interface). Functionalities for uploading data, editing metadata of uploads, creating datasets with multiple uploads, and publishing data will be covered. Attendees will use these functionalities to manage a portion of the data from the example project workflow, in particular, the subset of data that is automatically recognized and processed by one of NOMAD's existing parsers. *(For attendees without any Python experience, an alternative route to upload via the GUI will also be demonstrated!)*

Tutorial TUT 2.3 Sun 17:00 H3

Creating custom entries in NOMAD using yaml schema and ELN integration — •Andrea Albino — Physics Department and CSMB Adlershof, Humboldt-Universität zu Berlin, Germany

In this part of the tutorial series, attendees will learn how to create custom entries to store data that is not already supported by one of NOMAD's parsers. The basics of writing a schema, using NOMAD's ELN (electronic lab notebook) integration, and how to create simple plots of your data to visualize in the GUI will be covered. Attendees will then use this knowledge to manage the remainder of the data from the example project workflow, which is not automatically recognized by NOMAD.

Tutorial TUT 2.4 Sun 17:30 H3

Creating custom workflow entries in NOMAD to link multiple uploads — •Bernadette Mohr — Physics Department and CSMB Adlershof, Humboldt-Universität zu Berlin, Germany

In this last part of the tutorial series, attendees will complete the example project workflow storage by creating a custom workflow entry in NOMAD that connects all the uploaded tasks. The basics of the schema for defining custom workflows will be covered, followed by a demonstration of the straightforward creation of the required workflow file using the same workflow utility Python module as in the first part of the tutorial series. Finally, attendees will navigate NOMAD's interactive workflow graph visualizations to investigate the uploaded data, and learn how to obtain a DOI for their workflow.

TUT 3: Tutorial: Into the Third (and Fourth) Dimension: Imaging Methods for 3D Nanomagnetism (joint session MA/TUT)

Nanostructured magnetic materials have found several applications in everyday objects, such as data storage devices, sensors, and biomedical devices. When one brings these materials to the third dimension, a variety of new physics, and opportunities for applications appear. However, until recently, the vast majority of experimental investigations have primarily been focused on 2D planar geometries, as 3D systems provide a set of experimental challenges that still needs to be overcome. This tutorial seeks to provide a comprehensive overview for both experts and non-experts in the field of 3D imaging to gain a deeper understanding of the recent advances and experimental challenges connected to the investigation of 3D magnetic systems.

Organized by Claire Donnelly (MPI-CPFS, Dresden, Germany) and Simone Finizio (Paul Scherrer Institut, Villigen, Switzerland).

Time: Sunday 16:00–18:15 Location: H4

Tutorial TUT 3.1 Sun 16:00 H4

3D Magnetic Imaging: Utilizing Synchrotron X-Ray Coherence for Nanometric Resolution in Thick Samples — •Marisel Di Pietro Martinez — Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany — International Institute for Sustainability with Knotted Chiral Meta Matter (WPI-SKCM2)

In recent years, there has been a growing interest from the magnetism community in expanding to three-dimensional magnetic systems - from exploring new geometries to revealing complex magnetic textures arising in micrometer-thick samples. A key aspect of this exploration is the ability to visualize the magnetization vector field at the nanoscale throughout the entire sample, made possible by the development of 3D magnetic imaging. This technique can achieve nanometric spatial resolution in micrometer-thick samples by leveraging the penetration depth and coherence of synchrotron X-rays. Furthermore, the coherence of the X-ray beam provides magnetic contrast not only in the absorption of the transmitted wave, but also in the phase. This phase contrast enables the investigation of micron-sizes magnets, even with soft X-rays, while minimizing the sample damage. In this tutorial, I will introduce how to exploit these advantages using coherence-based techniques, such as Fourier transform holography and ptychography, to perform 3D magnetic imaging. Visualizing the magnetization vector field with nanometer spatial resolution in micrometer thick samples opens the door to studying magnetic textures in higher dimensions, offering insights into fundamental physical phenomena as well as promising new applications in information storage and processing.

Tutorial TUT 3.2 Sun 16:45 H4

Nanoscale Mapping of Magnetic Textures in 3D Using Vector Field Electron Tomography — •Axel Lubk[1,2] and Daniel Wolf[1] — [1]Leibniz Institute for Solid State and Materials Research, Dresden, Germany — [2]Institute of Solid State and Materials Physics, TU Dresden, Germany

Vector field Electron Tomography (VFET) combines Electron Holography and Electron Tomography in the Transmission Electron Microscope (TEM) to reconstruct magnetic induction vector fields in 3D down to several nanometer resolution. In this tutorial we discuss the foundations of the technique, the practical workflow including pitfalls, and application to topical examples in nanomagnetism including domain walls in nanowires and skyrmion strings.

Tutorial TUT 3.3 Sun 17:30 H4

3D magnetic imaging: an experimental window to study 3D magnetization at the nanoscale — •Aurelio Hierro-Rodriguez — Department of Physics, University of Oviedo,33007, Oviedo, Spain — CINN (CSIC-University of Oviedo) , 33940, El Entrego, Spain

The synergetic confluence of technological and scientific developments in nanofabrication and characterization techniques is paving the way towards the advance in Three-Dimensional Nanomagnetism, fuelled by the richness of phenomena and technological potential of the exploitation of the magnetization vector field in their natural dimensionality: three dimensions. In this lecture, a broad picture of the importance of the topic, in the framework of the novel physics that can be explored and exploited will be given, with a brief description of the methods that allow to fabricate almost any 3D magnetic geometry with nanometer resolution. The core of the lecture will deal with the advanced magnetic imaging techniques, which are opening a window towards the characterization of the full three-dimensional magnetization vector. Specifically, X-ray based magnetic vector tomography will be described and exemplified, showing the capabilities of the technique to volume resolve the magnetization vector field in arbitrary systems with nanometer resolution. These developments in vector magnetic imaging are making possible a change in the actual paradigm on how magnetization is characterized and studied at the nanoscale, by bringing a direct experimental probe to realize experimental micromagnetism.

TUT 4: Tutorial: Do it Yourself Guide for Simulating Complex Magnetism: From Theoretical Foundations to Hands-on Spin-dynamics (joint session O/TUT)

This tutorial is designed for students, early-career researchers, and anyone interested in the foundational principles and practical methods for simulating magnetic materials. The journey begins with an introduction to the fundamentals of spin lattice Hamiltonians and their various forms, including a detailed discussion of their derivation (Lecture 1). Next, we explore state-of-the-art techniques for extracting magnetic exchange interactions from first-principles calculations through an engaging overview (Lecture 2). The final session (Lecture 3) delves into atomistic spin-dynamics simulations using the SPIRIT code, a versatile tool compatible with both smartphones and laptops. Throughout, we will emphasize the theoretical framework underpinning these approaches. The participants will have the freedom to explore a large range of phenomena, such as domain walls, skyrmions, and their dynamics under applied currents or torques.

Time: Sunday 16:00–18:15 Location: H10

Tutorial TUT 4.1 Sun 16:00 H10

Derivation of the spin-lattice Hamiltonian: Heisenberg, beyond Heisenberg, DMI, nematic exchange — •Hiroshi Katsumoto — Peter Grünberg Institut, Forschungszentrum Jülich and JARA, 52428 Jülich, Germany

Magnetization textures, such as domain walls, skyrmions, or hopfions, are very active areas of condensed matter physics. These magnetic textures are usually explained based on the Heisenberg and the relativistic Dzyaloshinskii-Moriya interaction (DMI). Comparisons with experiments have shown that, in many cases, these interactions are insufficient, and a whole range (sometimes called a zoo) of higher-order symmetric and antisymmetric interactions have been proposed. In this tutorial, based on four elemental ingredients: Coulomb interaction, indistinguishability of electrons, spin, and spin-orbit interaction (SOI), I present a framework for systematically constructing exact spin-lattice models containing all spin Hamiltonians, including higher-order terms dependent on spin quantum numbers and lattice size. Examples of spin Hamiltonians for spin-1/2 and spin-1 systems up to four lattice sites are discussed. The tutorial also explores higher-order relativistic exchange interactions derived from SOI. I consider perturbations up to the 2^{nd} order of SOI and organize (anti)symmetric interactions. Finally, the classicalization of quantum spin relevant to magnetism in solids is discussed, culminating in a spin-lattice model that provides a theoretical framework for extracting material-dependent exchange interactions via numerical calculations and enables the modeling of magnetic textures. – DFG supports the work through SPP-2137 Skyrmionics.

Tutorial TUT 4.2 Sun 16:45 H10

Computing magnetic exchange interactions using DFT — •Manuel dos Santos Dias — Scientific Computing Department, STFC Daresbury Laboratory, United Kingdom

Magnetic materials are an unending source of fascinating physical behaviour which have fundamental appeal but also important technological applications. In order to understand, quantify and predict the properties of magnetic materials, we need information about the magnetic exchange interactions (introduced in the preceding tutorial), which control how the different magnetic atoms interact with each other and respond to external stimuli. This tutorial will give an overview on first-principles approaches to the calculation of magnetic exchange interactions using density functional theory (DFT). First I will outline how the properties of magnetic materials can be computed with and what capabilities are offered by different DFT codes. Next I will discuss how to map DFT calculations to spin models and when such a mapping is expected to work, followed by a discussion of the two main approaches to compute magnetic exchange interactions: the infinitesimal rotation method and the spin cluster expansion. Lastly, I will explain how to obtain simple information from the computed magnetic exchange interactions, such as the magnetic ground state and the spin wave spectrum, and how to connect to atomistic spin dynamics (for instance using the Spirit code covered in the next tutorial), Monte Carlo and micromagnetic simulations.

Tutorial TUT 4.3 Sun 17:30 H10

Hands-on atomistic spin-dynamics simulations with Spirit — •Thorben Pürling[1,2] and Moritz Sallermann[1,2,3] — [1]Peter Grünberg Institute, Forschungszentrum Jülich, D-52425 Jülich — [2]Physics Department, RWTH-Aachen University, D-52062 Aachen — [3]University of Iceland

Atomistic spin-dynamics is a powerful, fascinating and educational simulation approach to studying the stability and dynamics of mesoscopic spin-textures such as skyrmions on the basis of atomistic spin-models. It can be used as digital twin to experiments.In this tutorial, participants will be introduced to the atomistic spin model and learn interactively how to perform atomistic spin simulations using the Spirit code [1]. We will cover common computational methods employed in atomistic spin simulations, emphasizing their practical application through the Spirit software framework [2]. The majority of the session will be dedicated to engaging exercises, where participants will work through example problems using Jupyter notebooks that interface directly with Spirit. Participants are encouraged to come with basic knowledge of Python and bring their charged laptops to fully engage in the tutorial. We provide a website [3] to keep you updated such that you arrive at the tutorial prepared for a hands-on experience.
We acknowledge funding from the ERC grant 856538 (project "3D MAGIC").

[1] Gideon P. Müller *et al.*, 10.5281/zenodo.7746551 (2024)

[3] https://spirit-code.github.io/dpg-regensburg2025

TUT 5: Tutorial: Automated Worksflows (joint session MM/TUT)

Participants in the tutorial will be able to run all the examples shown in the presentation interactively on their own laptops. There is no need to install any code, just a standard web browser to explore the applications interactively.

Time: Sunday 16:00–18:15 Location: H15

Tutorial TUT 5.1 Sun 16:00 H15

Hands-on Tutorial: Automated Workflows and Machine Learning for Materials Science Simulations — •Jörg Neugebauer[1], Tilmann Hickel[2], and Ralf Drautz[3] — [1]MPI für Nachhaltige Materialien, Düsseldorf, Germany — [2]BAM, Berlin, Germany — [3]ICAMS, Ruhr-Universität Bochum, Germany

Machine learning techniques in physics and materials science have revolutionized simulations and experimental analysis. Using these techniques to accurately predict, for example, material properties requires the manipulation and use of vast amounts of data. Manual processing and analysis quickly become impractical and error-prone, so the availability of automated workflows is critical to their efficient, reliable, and consistent application.

In this hands-on tutorial, we provide an interactive, practical introduction to workflow management using Pyiron (www.pyiron.org). Pyiron is an integrated materials science development environment based on Python and Jupyter notebooks that can be used for a wide range of simulation tasks, including rapid prototyping, coupling with experiments, and high-performance computing. The tutorial gives a general introduction to the use of Pyiron with a focus on atomistic simulation tasks. As a practical example, all steps of the workflow for the construction of ab initio phase diagrams will be performed interactively by all participants, e.g. the generation of DFT datasets, the training and validation of machine learning potentials as well as the construction of the phase diagram.

Symposium AI in (Bio-)Physics (SYAI)

jointly organised by
the Biological Physics Division (BP),
the Chemical and Polymer Physics Division (CPP),
the Dynamics and Statistical Physics Division (DY), and
the Physics of Socio-economic Systems Division (SOE)

Jona Kayser
Max-Planck-Zentrum für Physik und Medizin
Kussmaulallee 2
91054 Erlangen
jona.kayser@mpl.mpg.de

Alexander Schug
Forschungszentrum Jülich
Wilhelm-Johnen-Straße
52428 Jülich
al.schug@fz-juelich.de

Artificial intelligence is revolutionizing scientific research, including the study of biophysical systems. The symposium will explore how AI and machine learning can enhance biophysics research, with applications ranging from predictive modeling of biomolecular interactions and high-throughput data analysis to the development of machine-learned force fields and artificial scientific discovery. The goal of this symposium is to create a dynamic forum for scientific exchange in this rapidly developing field, providing novices with a valuable head start while helping experts stay at the forefront of cutting-edge developments. The conceptual nature of AI-powered research approaches will make the discussed topics highly relevant to a broad audience.

Overview of Invited Talks and Sessions

(Lecture hall H1)

Invited Talks

SYAI 1.1	Thu	9:30–10:00	H1	**Predicting interaction partners and generating new protein sequences using protein language models** — •Anne-Florence Bitbol
SYAI 1.2	Thu	10:00–10:30	H1	**Realizing Schrödinger's dream with AI-enabled molecular dynamics** — •Alexandre Tkatchenko
SYAI 1.3	Thu	10:30–11:00	H1	**Emergent behavior of artificial intelligence** — •Steffen Rulands
SYAI 1.4	Thu	11:15–11:45	H1	**AI in medical research - navigating complexity with AI** — •Daniel Truhn
SYAI 1.5	Thu	11:45–12:15	H1	**Computational Modelling of Morphogenesis** — •Dagmar Iber

SYAI 1: AI in (Bio-)Physics

Time: Thursday 9:30–12:15 Location: H1

Invited Talk SYAI 1.1 Thu 9:30 H1

Predicting interaction partners and generating new protein sequences using protein language models — •Anne-Florence Bitbol — École Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland

Protein sequences are shaped by functional optimization on the one hand and by evolutionary history, i.e. phylogeny, on the other hand. A multiple sequence alignment of homologous proteins contains sequences which evolved from the same ancestral sequence and have similar structure and function. In such an alignment, statistical patterns in amino-acid usage at different sites encode structural and functional constraints.

Protein language models trained on multiple sequence alignments capture coevolution between sites and structural contacts, but also phylogenetic relationships. I will discuss a method we recently proposed that leverages these models to predict which proteins interact among the paralogs of two protein families, and improves the prediction of the structure of some protein complexes. Next, I will show that these models can be used to generate new protein sequences from given protein families.

While multiple sequence alignments are very useful, their construction is imperfect. To address these limitations, we developed ProtMamba, a homology-aware but alignment-free protein language model based on the Mamba architecture, which efficiently uses long contexts. I will show that ProtMamba has promising generative properties, and is able to predict fitness.

Invited Talk SYAI 1.2 Thu 10:00 H1

Realizing Schrödinger's dream with AI-enabled molecular dynamics — •Alexandre Tkatchenko — Department of Physics and Materials Science, University of Luxembourg

The convergence between accurate quantum-mechanical (QM) models (and codes) with efficient machine learning (ML) methods seem to promise a paradigm shift in molecular simulations. Many challenging applications are now being tackled by increasingly powerful QM/ML methodologies. These include modeling covalent materials, molecules, molecular crystals, surfaces, and even whole proteins in explicit water (https://www.science.org/doi/abs/10.1126/sciadv.adn4397). In this talk, I attempt to provide a reality check on these recent advances.

In particular, I will introduce the recently developed SO3LR force field (https://doi.org/10.26434/chemrxiv-2024-bdfr0), trained on a diverse set of 4 million neutral and charged molecular complexes computed at the PBE0+MBD level of quantum mechanics, ensuring a comprehensive coverage of covalent and non-covalent interactions. SO3LR is characterized by computational and data efficiency, scalability to 200 thousand atoms on a single GPU, and reasonable to high accuracy across the chemical space of organic (bio)molecules. SO3LR is applied to study units of four major biomolecule types, polypeptide folding, and nanosecond dynamics of larger systems such as a protein, a glycoprotein, and a lipid bilayer, all in explicit solvent. Finally, I discuss the future challenges toward truly general molecular simulations by combining ML force fields with traditional atomistic models.

Invited Talk SYAI 1.3 Thu 10:30 H1

Emergent behavior of artificial intelligence — •Steffen Rulands — Arnold-Sommerfeld Center for Theoretical Physics, LMU München, Theresienstr. 37, 80333 München

Can artificially intelligent systems show emergent behavior that does not originate from the data they are trained on? This question is relevant for understanding the potential dangers and possibilities of powerful AI systems. In this talk, I will address this question from two different perspectives drawing on ideas from theoretical biophysics. First, I will show that neural networks exhibit an instability that gives rise to the emergent formation of structures independent of the training data. I will show how these structures aid the interpretation of data. In the second part of my talk, I will then draw on the biophysics of subcellular compartments and insect societies to demonstrate ways in which emergent behavior of artificially intelligent systems can facilitate and jeopardize deep learning.

Invited Talk SYAI 1.4 Thu 11:15 H1

AI in medical research - navigating complexity with AI — •Daniel Truhn — University Hospital Aachen, Germany

Modern artificial intelligence (AI) systems, including Large Language Models (LLMs) and advanced multimodal vision systems, are transforming clinical practice and medical research. This talk outlines how these technologies navigate complex medical challenges and enhance clinician efficiency. By showcasing practical applications, I demonstrate how AI empowers healthcare professionals to make better and faster decisions, ultimately improving patient outcomes.

Invited Talk SYAI 1.5 Thu 11:45 H1

Computational Modelling of Morphogenesis — •Dagmar Iber — Department of Biosystems Science and Engineering, ETH Zürich, Switzerland

Epithelia are fundamental building blocks of life, playing pivotal roles in morphogenesis and are at the origin of most cancers. This talk will explore epithelial organization across scales, from individual cell geometry to tissue-level architecture. I will introduce theoretical work that sheds light on long-standing, unexplained phenomena in epithelial cell organization, enabling the development of advanced 2D and 3D simulation tools. These tools allow for data-driven simulations of epithelial dynamics, advancing our understanding of both development and disease. Additionally, I will examine how chemical gradients drive precise epithelial patterning during development and demonstrate how their interplay with geometric and mechanical constraints shapes epithelial morphogenesis. Case studies include neural tube formation, lung branching morphogenesis, nephrogenesis, and bladder cancer progression. By integrating experimental insights with computational approaches, this work offers a comprehensive view of the mechanisms driving epithelial morphogenesis in health and disease.

Symposium Physics of Embryonic Development Across Scales: From DNA to Organisms (SYED)

jointly organised by

fbrauns@ucsb.edu

The development of a single fertilized cell into a fully functional embryo is a prime example of non-equilibrium self-organization. While biological research on development has focussed on molecular aspects, recent progress has brought into the spotlight the underlying physical phenomena across scales in space and time. This includes polymer physics of DNA organization, dynamical systems and information theory of gene regulation, signaling and pattern formation, and the active mechanics of cells and tissues. Development therefore presents tantalizing challenges at the interface between physics and biology, experiment and theory. Addressing these challenges requires an integrative approach that bridges scales and disciplines. This symposium will bring together researchers from diverse backgrounds and provide an overview of the exciting recent advances in experiment and theory and highlight future challenges.

SYED 1: Physics of Embryonic Development Across Scales: From DNA to Organisms

Time: Monday 9:30–12:15 Location: H1

Invited Talk SYED 1.1 Mon 9:30 H1

Emergent crystalline order in a developing epithelium — Kartik Chhajed[1], Natalie Dye[2], Marko Popović[1], and •Frank Jülicher[1] — [1]Max Planck Institute for the Physics of Complex Systems, Nöthnitzerstrasse 38, 01187 Dresden, Germany — [2]Cluster of Excellence Physics of Life, TU Dresden, Arnoldstrasse 18, 01307 Dresden, Germany

A fundamental question in Biology is to understand how patterns and shapes emerge from the collective interplay of large numbers of cells. Cells forming two-dimensional epithelial tissues behave as active materials that can undergo remodeling and spontaneous shape changes. Focussing on the fly wing as a model system, we will discuss the physics underlying the emergence of crystalline order in the wing epithelium during the pupal phase of morphogenesis. Using a vertex model of epithelial tissue, we demonstrate that when cell size heterogeneity exceeds a critical value, cellular packing remains disordered, whereas reducing heterogeneity below this value induces a phase transition to crystalline packing. Combining these results with analysis of experimental data reveals that cell size heterogeneity controls crystallization in the developing fly wing. Shear flows facilitate this process but are not the main driver of the disorder-to-order transition. Our work reveals how order can emerge during morphogenesis by the dynamic remodeling of tissues.

Invited Talk SYED 1.2 Mon 10:00 H1

A tissue rigidity phase transition shapes morphogen gradients — Camilla Autorino[1], Diana Khoromskaia[2], Bernat Corominas-Murtra[3], Zena Hadjivasiliou[2], and •Nicoletta Petridou[1] — [1]EMBL Heidelberg, Germany — [2]Francis Crick Institute, UK — [3]University of Graz, Austria

Transitions between solid-like and fluid-like tissue material states are essential for morphogenesis. However, if phase transitions instruct cell function is still unknown. Here, we show that tissue rigidification impacts cell signalling by regulating the length-scales and time-scales of morphogen gradients. By combining rigidity percolation theory, reaction-diffusion modelling, quantitative imaging, genetics and optogenetics in zebrafish germ layer formation we uncover that a tissue rigidity phase transition defines the dynamics of fate specification by restricting Nodal morphogen transport and facilitating its signalling dynamics. This is a self-generated mechanism where Nodal, besides triggering cell fate specification, increases cell adhesion via regulating planar cell polarity genes. Once adhesion strength reaches a critical point it triggers a rigidity transition which sharply minimises tissue porosity and induces the formation of tricellular contacts. The resulted tissue reorganisation negatively feeds back to Nodal signalling by sealing the interstitial paths of Nodal diffusion and restricting it close to the source, and by speeding up its degradation. This leads to prompt expression of its inhibitor resulting in robust pattern formation. Overall, we reveal how phase transitions shape morphogen gradients and uncover macroscopic mechanisms of positional information.

Invited Talk SYED 1.3 Mon 10:30 H1

Building quantitative dynamical landscapes of developmental cell fate decisions — •David Rand — University of Warwick, Coventry CV4 7AL, UK

I will discuss the dynamics of decision-making in the early embryo. As cells proliferate and assemble into tissues, their molecular identity changes in discrete step-like transitions to produce diverging sequences of distinct cell states that culminate in the differentiation of specific functional cell types. Hence, cellular development can be viewed as sets of branching cell lineages generating increasing diversity and comprising increasingly specialised cell types. I will outline an approach to understanding this that relies on geometry and dynamics, and I will illustrate this with recent work on the early development of the nervous system. New methods for the analysis of single-cell temporal data combined with ideas from dynamical systems can be used to deduce the topology of the branching network, the dynamical nature of the branching transitions and a quantitative model of the underlying dynamics that reproduces the data.

15 min. break

Invited Talk SYED 1.4 Mon 11:15 H1

Control of lumen geometry and topology by the interplay between pressure and cell proliferation rate — •Anne Grapin-Botton[1], Byung Ho Lee[1], Masaki Sano[2,5], Daniel Riveline[3], Kana Fuji[2], and Tetsuya Hiraiwa[2,4] — [1]Max Planck Institute of Molecular Cell Biology and Genetics Dresden — [2]The University of Tokyo — [3]IGBMC, Strasbourg — [4]Academia Sinica, Taipei — [5]Shanghai Jiao Tong University

Many organs in multicellular organisms comprise epithelia which enclose fluid-filled cavities referred to as lumens. Their formation is regulated by a wide range of processes, including polarization, secretion, exocytosis and actomyosin contractility. While these mechanisms have shed light on lumen growth, what controls lumen morphology remains enigmatic. Here we use organoids to explore how lumens acquire either a spherical shape or a branched topology. We develop a multicellular phase field model with the following basic components: conditions for the timing and volume of cell division, lumen nucleation rules, and lumenal pressure. Combining computational simulations with experimental measurements we reveal that lumen morphology arises from the balance between the cell cycle duration and lumen pressure, with more complex lumen at low pressure and fast proliferation rates. Moreover, the perturbation of proliferation and lumen pressure in silico and in vitro is sufficient to alter and reverse the morphological trajectories of the lumens. We further show that low pressure depends on epithelial permeability enabling complex lumen shapes.

Invited Talk SYED 1.5 Mon 11:45 H1

Chromosomes as active communication and memory machines — •Leonid A. Mirny — Institute for Medical Engineering and Science, and Department of Physics, Massachusetts Institute of Technology, Cambridge, MA, USA

Chromosomes are long polymers of genomic DNA decorated by myriads of proteins. We are interested in understanding how cells fold them to read, write, and process genetic and epigenetic information. Can the way chromosomes are folded carry information itself?

Recent work from my group and others has shown that chromosomes are active polymers. First, we found that chromosomes are folded by the active (ATP-dependent) process of loop extrusion, where molecular motors form progressively larger loops. The collective action of these nanometer-sized motors shapes micron-sized chromosomes. This active mechanism also enables long-range communication between the *regulatory genome* and protein-coding genes.

Second, we found that chromosome folding can help store *epigenetic memory* patterns of chemical marks along the genome. Such marks are lost and spread by enzymes, yet when marks influence genome folding, the pattern of marks can be preserved for hundreds of cell divisions. We further identified a parallel between this mechanism of epigenetic memory and associative memory in a neural network, suggesting that this system may perform more complex information processing tasks.

The next generation of quantum technologies will utilize microscopic properties without classical counterparts, often encoded in the quantum-mechanical wave function phase. These properties unify phenomena like noncollinear magnetism, multiferroicity, and superconductivity. Noncollinear magnets create emergent electromagnetic fields driving novel transport effects for spintronics, while superconductors enable dissipationless supercurrents and working qubits for quantum computers. Combining magnetic and superconducting materials can produce quantum entities like Majorana states, relevant to topological quantum computing. In this context, exciting developments based on ab-initio methods will be discussed at the symposium, providing an ideal platform for fostering collaboration among experts, students, and early-career researchers.

SYES 1: Electronic Structure Theory for Quantum Technology

Time: Friday 9:30–12:15 Location: H1

Invited Talk SYES 1.1 Fri 9:30 H1

Ab-initio Design of superconductors — •Lilia Boeri — Physics Department, Sapienza University, Rome, Italy

Over the last ten years, ab-initio methods for superconductivity and crystal structure prediction have seen a substantial advancement, opening the concrete possibility of designing new conventional superconductors completely in silico. The most spectacular demonstration of the power of this approach is the prediction of high-temperature conventional superconductivity in compressed sulfur hydride, which started the so-called hydride rush towards room-temperature superconductivity.[1] However spectacular these discoveries might be, bridging the gap with applications requires devising new strategies to realize high-Tc at more accessible pressures [2], and understanding the origin of superconductivity in seemingly simple materials, like Hg and NbTi. Finally, I will addressed the challenges that the community needs to address after recent reputation breaches due to false claims of room-temperature superconductivity [3].

Invited Talk SYES 1.2 Fri 10:00 H1

Topological superconductivity from first principles — Bendegúz Nyári[1,2], András Lászlóffy[3], Levente Rózsa[3,2], Gábor Csire[4], Balázs Újfalussy[3], and •László Szunyogh[2,1] — [1]HUN-REN BME Condensed Matter Research Group, Budapest, Hungary — [2]Budapest University of Technology and Economics, Budapest, Hungary — [3]HUN-REN Wigner Research Centre for Physics, Budapest, Hungary — [4]Materials Center Leoben Forschung GmbH, Leoben, Austria

Magnetic chains manufactured on superconductors are possible candidates for fault tolerant quantum computing architectures. Due to the interplay of magnetism and superconductivity these systems are suitable to host topological zero-energy end states, the so-called Majorana Zero Modes (MZM). In this talk we present a first-principles approach suitable to study atomic chains by employing an embedding technique within the Multiple Scattering Theory, combined with the solution of the Bogoliubov–de Gennes equations. In case of Fe chains on an Au monolayer on Nb(110) we show that the formation of MZMs is supported in a broad range of spin-spiral states. Through computer experiments we also demonstrate the emergence of topological fragmentation and simulate the shifting of MZMs within the nanowire. Our computational method allows for calculating the one-dimensional band structure of infinite chains which provides a clear picture to analyze the topological properties of Shiba bands. The band structure is calculated and compared with the quasiparticle interference spectrum for Mn chains on Nb(110) and Ta(110).

Invited Talk SYES 1.3 Fri 10:30 H1

First-principles study and mesoscopic modeling of two-dimensional spin and orbital fluctuations in FeSe — •Myrta Grüning[1,2], Abyay Ghosh[1], and Piotr Chudzinski[1,3] — [1]Centre for Quantum Materials and Technologies, Queen's University Belfast, Belfast, Northern Ireland (UK) — [2]European Theoretical Spectroscopy Facility — [3]Institute of Fundamental Technological Research, Polish Academy of Sciences, Warsaw, Poland

FeSe is the simplest quasi-two-dimensional iron chalcogenide superconductor, yet its phase diagram exhibits exotic phases like superconductivity, spin density wave, and nematicity, which are intensely studied in condensed matter physics. Understanding the interaction of orbital and spin degrees of freedom is key to explaining FeSe's diverse phases. Using density-functional theory within the generalized gradient approximation, we calculated the structural, electronic, and magnetic properties of FeSe in its tetragonal phase. First, we explored how the d-band bandwidths at the Fermi energy evolve with corrections and long-range magnetic orders. Introducing striped or staggered dimer antiferromagnetic order significantly reduced the bandwidth overestimation seen at the generalized gradient approximation level, aligning more closely with experimental data. Next, we examined the magnetic formation energy for ferromagnetic and antiferromagnetic orders, under pressures up to 6 GPa and derived bilinear and biquadratic spin-exchange energies. We uncovered non-trivial spin-exchange behavior dependent on magnetization and proposed a field-theory model linking this to strong two-dimensional spin-orbital fluctuations.

15 min. break

Invited Talk SYES 1.4 Fri 11:15 H1

Non-collinear magnetism in 2D materials from first principles: Multiferroic order and magnetoelectric effects. — •Thomas Olsen — Department of Physics, Technical University of Denmark

We present a systematic classification of the magnetic ground states in hundreds of two-dimensional (2D) materials. Non-collinear order is shown to be abundant and may typically be represented by planar spin spiral ground states. We discuss a range of physical effects associated with non-collinear order and take specific materials as examples. The $Ni(Cl,Br,I)_2$ compounds exhibit type II multiferroic order where the spontaneous polarization is induced by spiral order and we discuss the subtleties associated with the calculation of the polarization from first principles. The breathing Kagomé compounds $Nb_3(Cl,Br,I)_8$ are pyroelectric and have spiral ground states with ordering vectors that couple strongly to out-of-plane external electric fields. Finally we discuss a set of 2D altermagnets and analyse the important role of spin-orbit coupling with respect to the band structure, magnons and non-collinearity.

Invited Talk SYES 1.5 Fri 11:45 H1

Spin-phonon and magnon-phonon interactions from first principles — •Marco Bernardi — Caltech

Electron-phonon interactions have become a major research focus in first-principles electronic structure calculations. This talk discusses our recent efforts to include the spin degree of freedom in this framework.

First, I will present precise predictions of spin-phonon interactions and electron spin relaxation using a new approach that unifies the description of spin-flip and precession mechanisms. Second, I will describe an approach to compute magnon-phonon interactions and the associated magnon relaxation times and mean-free paths, focusing on results for 2D ferromagnetic materials. Our calculations shed light on which phonon modes couple more strongly with free spins and magnons and limit their transport, providing valuable microscopic insight for applications in spintronics and spin-based quantum technologies.

To conclude, I will highlight new frontiers of this research, including data-driven compression of electron-phonon and spin-phonon interactions and extending these methods to the strong spin-phonon coupling regime. Advances in the Perturbo code enabling these calculations will also be discussed.

Symposium Pushing the Boundaries of Fair Data Practices for Condensed Matter Insights: From Workflows to Machine Learning (SYFD)

jointly organised by
the Surface Science Division (O),
the Chemical and Polymer Physics Division (CPP),
the Thin Films Division (DS), and
the Magnetism Division (MA)

This symposium will highlight best practice in FAIR data and the development of streamlined workflows for open data and machine learning techniques. To be jointly organised by DAPHNE4NFDI and FAIRmat, topics will cover optimizing data collection methodologies and workflows, implementing electronic lab notebooks for efficient data recording, and integrating on-the-fly analysis techniques to enhance experimental outcomes. Moreover, the seminar will showcase cutting-edge advancements in data analysis methodologies, with a particular focus on on-the-fly analysis and machine learning techniques tailored to synchrotron and neutron data. Participants will discuss the integration of machine learning algorithms for data processing, analysis, and interpretation, thereby unlocking new avenues for scientific discovery and innovation. Furthermore, the DPG symposium will address the challenges associated with the storage and management of big data generated by modern data collection techniques and in particular, for condensed matter at synchrotron and neutron facilities. The symposium will provide the international state-of-the-art of the different disciplines and technology and give a platform to discuss future challenges and develop common solutions.

SYFD 1: Pushing the Boundaries of Fair Data Practices for Condensed Matter Insights

Time: Wednesday 9:30–12:15 Location: H1

Invited Talk SYFD 1.1 Wed 9:30 H1

Pushing the Boundaries of Fair Data Practices for Condensed Matter Insight — •Astrid Schneidwind — JCNS at MLZ Garching, FZ Jülich, Germany

The scientific impact of experiments using neutron, synchrotron and free-electron X-ray sources is drastically increasing, not least related to recent experimental and technical developments, which increase the demand for experiments, too. In parallel, new opportunities attract new researchers with less experience. The request for advanced computing opportunities - from data collection to robotics and AI-assisted experiments to the re-use of data and reproducible data analysis - is increasing accordingly. Adopting FAIR practices [1] opens further space for efficient, extended usage of the highly valuable data. Within the DAHNE4NFDI [2] initiative such workflows along the whole data pipeline are exemplarily developed, provided within use cases and systematically connected to prior and subsequent laboratory work. Standards are agreed on European level, as well as data repositories and reference data bases. ML-compatible data formats link the data to theoretical and computational approaches - closing the loop for increasing the efficiency of the experiments and exciting new outcomes.

Invited Talk SYFD 1.2 Wed 10:00 H1

Establishing Workflows of Experimental Solar Cell Data into NOMAD — Edgar Nandayapa[1], Paolo Graniero[1], Jose Marquez[2], Michael Götte[1], and •Eva Unger[1,3] — [1]Helmholtz-Zentrum Berlin für Materialen und Energie GmbH, HySPRINT Innovation Lab, Kekuléstraße 5, 12489 Berlin, Germany — [2]Humboldt University Berlin, FAIRmat Project, Zum Großen Windkanal 2, 12489 Berlin, Germany — [3]Humboldt University Berlin, Department of Chemistry and CSMB, Zum Großen Windkanal 2, 12489 Berlin, Germany

Materials for solar energy conversion are key enablers for the green energy transition. Perovskite Solar Cells (PSCs) are an excellent example of an emerging technology, where an intense and world-wide R&D activities has enabled a very fast improvement in the reported power conversion efficiencies. The monthly output of new reports in the peer-reviewed literature is in the hundreds to thousands and it is at this point neither effective nor possible to still make effcient use of the research results reported. Considering data reported in the peer-reviewed literature, this just represent the "tip of the iceberg" of research data that is actually being measured in labs around the world.

Out of desparation, our team started a fairly manual "data digging" initiative in 2019 to compile data from the then published data in the peer-reviewed literature into a single database based on a very rudimentary and single-metric representation of the actual research data resulting in the Perovskite Database (www.perovskitedatabase.com). In close collaboration with the FAIRmat project, we are now taking steps towards transferring the literature dataset into NOMAD and are creating NOMAD platforms to capture, store, analyse and share the actual experimental research data within and beyond our research community. The goal is to, both, initiate community driven data sharing platforms that can be used to directly share and disseminate experimental datasets to adhere to FAIR data principles, and make photovoltaic research data AI-ready to enable the utilization of modern ML-tools to facilitate a further acceleration of the technological exploitation of new materials.

Invited Talk SYFD 1.3 Wed 10:30 H1

Building up the EOSC Federation — •Ute Gunsenheimer — EOSC Association

The European Open Science Cloud (EOSC) envisions a unified system in Europe to enable researchers to store, share, process, and reuse FAIR data and services across disciplines and borders. Central to this vision is the EOSC Federation, a network of interconnected nodes, that will provide seamless access to scientific data and resources. With the public launch of the EOSC EU Node in October 2024, the development of the EOSC Federation has gained significant momentum. To realise its full potential, the EOSC Federation requires the enrolment of additional EOSC Nodes. The nodes will act as entry points to the Federation.

To enable the establishment of such a distributed system, many questions remain to be addressed, including defining minimum requirements for EOSC Nodes, establishing enrolment rules, ensuring effective governance, and developing financial mechanisms to support resource sharing. Answering these questions is critical to building a robust, distributed infrastructure that drives Open Science and innovation in Europe.

By the time of the conference, the first wave of EOSC Nodes will have been identified, representing a diverse range of thematic and national communities across Europe. At the same time, active work on the enrolment process will have been kicked-off.

This talk will explore the progress, challenges, and future steps in shaping the EOSC Federation.

15 min. break

Invited Talk SYFD 1.4 Wed 11:15 H1

Data-Driven Materials Science for Energy-Sustainable Applications — •Jacqueline Cole — Cavendish Laboratory, University of Cambridge, Cambridge, UK

Data-driven materials discovery is coming of age, given the rise of 'big data' and machine-learning (ML) methods. However, the most sophisticated ML methods need a lot of data to train them. Such data may be custom materials databases that comprise chemical names and their cognate properties for a given functional application; or data may comprise a large corpus of text to train a language model. This talk showcases our home-grown open-source software tools that have been developed to auto-generate custom materials databases for a given application. The presentation will also demonstrate how domain-specific language models can now be used as interactive engines for data-driven materials science. The talk illustrates the application of these data-science methods using case studies from the energy sector. The talk concludes with a forecast of how this 'paradigm shift' away from the use of static databases will likely evolve materials science.

Invited Talk SYFD 1.5 Wed 11:45 H1

Machine Learning and FAIR Data in X-ray Surface Science — •Stefan Kowarik — Phys. Chemistry, Univ. of Graz, Austria

Synchrotrons are among the world's largest producers of scientific data, yet many experiments fail to contribute adequately to databases. Publishing raw data without comprehensive metadata fails to align with the "Findable" and "Reusable" principles of FAIR data, which are essential to unlocking the full potential of these datasets.ML not only benefits from large FAIR datasets but also facilitates their creation. Our recent work highlights live ML-based analysis of X-ray reflectometry (XRR) for thin-film characterization, enabling adaptive experimentation with a fourfold increase in speed. Additionally, we demonstrate automated crystal structure solutions from grazing-incidence X-ray diffraction (GIXD) of thin films. These advancements lay the foundation for self-driving laboratories, where integrated ML algorithms can control thin-film deposition processes, enhancing precision and throughput.Importantly, live ML analysis generates metadata, such as unit cell parameters in textured thin films, improving data findability and reusability. While XRR requires standardized structural model formats*efforts championed by groups like ORSO*GIXD leverages established crystallographic formats for database integration.*In the future, these advancements could culminate in expansive, standardized databases for surface science, encompassing thin-film crystal structures, surface reconstructions, and thin film material properties, analogous to established bulk crystallographic databases.

Symposium Progress and Challenges in Modelling Electron-Phonon Interaction in Solids (SYIS)

Electron-phonon interaction is crucial to predict and explain material behaviour under a variety of equilibrium and non-equilibrium conditions. Though recent developments in theoretical and computational methods have significantly advanced our capability, significant challenges still remain to be addressed. An accurate description of electron-phonon interactions in complex materials, including e.g., disordered perovskites, correlated oxides, superconductors, interfaces, and heterostructures, is often beyond the capability of existing methodologies. This symposium will bridge different communities working on electron-phonon interactions in solids and pinpoint common problems and open challenges in the field.

SYIS 1: Progress and Challenges in Modelling Electron-Phonon Interaction in Solids

Time: Tuesday 9:30–12:15 Location: H1

Invited Talk SYIS 1.1 Tue 9:30 H1

Electron-phonon and exciton-phonon coupling in advanced materials — •Claudia Draxl — Humboldt-Universität zu Berlin, Berlin, Germany

Treating various excitations in materials on equal footing allows us not only to achieve excellent agreement with experiment, but, importantly, to gain a deeper understanding of complex processes and materials. Prominent examples are organic-inorganic hybrid systems whose building blocks are very different in nature. I will discuss the critical role of both the mutual dynamical screening of the constituents and electron-phonon coupling (EPC) [1] to obtain the correct ground state and excitation spectra. Many-body perturbation theory (MBPT) is the state-of-the-art methodology for such problems. In particular, the Bethe-Salpeter equation (BSE) is the method of choice for computing optical excitations. For polar materials, the dielectric screening of both the electronic and vibrational degrees of freedom must be considered to obtain correct exciton binding energies and spectral features [2]. Finally, I will show, how the BSE together with EPC matrix elements can be used to treat exciton-phonon coupling and thus geometry relaxation in the excited state [3], giving a handle to the description of photoluminescence and exciton dynamics.

Invited Talk SYIS 1.2 Tue 10:00 H1

Exciton-phonon dynamics from first principles — •Enrico Perfetto — Physics Department University of Rome Tor Vergata

Exciton dynamics, encompassing ultrafast photogeneration, diffusion, and thermalization, plays a fundamental role in optoelectronic, photovoltaic, and photocatalytic processes. In this talk we discuss a novel many-body approach to describe exciton dynamics from first-principles. We show that the introduction of an auxiliary exciton species, termed 'irreducible exciton', is crucial to formulate a theory free from overscreening of the electron-phonon interaction. The resulting Excitonic Bloch Equations, while having the same computational cost as the well-known Excitonic Boltzmann Equations, enable a comprehensive description of the temporal evolution of coherent, irreducible, and incoherent excitons during and after the optical excitation.

Within this framework, we explore the real-time dynamics of exciton formation, elucidating the mechanism by which quasi-free electron-hole pairs, generated by above-gap photoexcitation, are dynamically converted into bound excitons.

Invited Talk SYIS 1.3 Tue 10:30 H1

Polarons and exciton polarons from first principles — •Feliciano Giustino — The University of Texas at Austin

Polarons are quasiparticles formed when a charge carrier interacts with lattice vibrations. In materials with strong electron-phonon couplings, this phenomenon results in self-trapped polarons. Similarly, excitons, which are composite quasiparticles formed by the binding of an electron and a hole, can polarize the surrounding crystal lattice through spatial fluctuations in their charge density. This polarization, in turn, can promote the spatial localization of the exciton, leading to the formation of exciton polarons or even self-trapped excitons in the presence of strong exciton-phonon couplings. First-principles calculations of these effects are challenging because they require large supercells potentially involving hundreds or thousands of atoms. In this talk, I will discuss recent methodological developments that combine density-functional perturbation theory and the Bethe-Salpeter approach to compute polarons and exciton polarons from first principles. The main advantage of the present approach is that it does not require supercells, and all necessary information is generated via calculations in the crystal unit cell. To illustrate these developments, I will report on two recent applications: (i) the discovery of topological polarons in halide perovskites, wherein the distortion of the atomic lattice describes a vector field with definite topological invariants; and (ii) the discovery of large polarons and exciton polarons in rutile and anatase titanium dioxide, which provide a natural explanation for why anatase exhibits diffusive carrier transport while rutile supports thermally-activated transport.

Invited Talk SYIS 1.4 Tue 11:15 H1

Wannier-Function-Based First-principle Approach to Coupled Exciton-Phonon-Photon Dynamics in Two-Dimensional Semiconductors — •Alexander Steinhoff[1], Matthias Florian[2], and Frank Jahnke[1] — [1]Institut für Theoretische Physik, Universität Bremen, Bremen, Germany — [2]Department of Electrical Engineering and Computer Science, University of Michigan, Ann Arbor, USA

Marrying the predictive power of ab initio calculations with many-body effects of ever increasing complexity remains a challenging task. In particular, for van der Waals materials, understanding carrier-phonon interaction from first principles is a field of growing interest. Here, we present a many-body theory for coupled free-carrier, exciton, phonon and photon dynamics based on carrier-carrier and carrier-phonon interaction matrix elements obtained from first principles via projection on Wannier orbitals. We demonstrate the impact of carrier-two-phonon scattering processes on optical spectra and coupled nonequilibrium carrier-phonon kinetics in monolayer $MoSe_2$. Our studies open a perspective to advance the material-realistic description of nonequilibrium physics in two- dimensional nanostructures to new many-body levels.

Invited Talk SYIS 1.5 Tue 11:45 H1

Phonon influence on (cooperative) photon emission from quantum dots — •Erik Gauger[1], Julian Wiercinski[1], and Moritz Cygorek[2] — [1]Institute of Photonics and Quantum Sciences, Heriot Watt University — [2]Technische Universität Dortmund

Semiconductor quantum dots (QDs) provide an established on-demand single-photon source platform. Integrating such sources into quantum networks comes with the requirement of producing fundamentally indistinguishable photons, and the ability to generate and preserve coherence between different emitters.

The leading source of decoherence of solid state emitters such as quantum dots is typically their coupling to longitudinal acoustic lattice vibrations, as can be observed under coherent control experiments such as Rabi oscillations as well as in their emission resonance spectrum.

In this presentation, I will give an overview of our theoretical work on modelling, understanding, and mitigating the interaction between solid-state emitters and their vibrational environment, and how this interaction manifests in measurable signatures such as photon statistics and spectral properties.

With a view towards scaling up to networks of coupled emitters, a particular focus of this presentation will be our recent progress in understanding the interplay between collective light-matter coupling and phonon decoherence, by utilising intuitive and interpretable master equation approaches as well as state-of-the-art numerical process tensor methods. I will also make connections to experimental data for up to five quantum dots displaying signatures of cooperative behaviour.

Symposium AI-driven Materials Design: Recent Developments, Challenges and Perspectives (SYMD)

In a surprisingly short time, AI (artificial intelligence) has demonstrated its transformative potential in materials science by integrating machine learning algorithms and generative models to predict and optimize material properties. High-throughput computational frameworks powered by AI enable rapid screening of vast chemical spaces, significantly reducing the time and cost associated with traditional experimental approaches and providing new physical insights. By leveraging large data sets and sophisticated algorithms, researchers have successfully uncovered hidden patterns and relationships in material behavior, leading to the discovery of novel materials with superior mechanical, electrical, magnetic, or catalytic properties.
The interdivisional symposium highlights the latest advances and success stories in AI and data-driven materials design, focusing on both machine learning and generative approaches. Leading experts in the field present the latest methods in AI used to predict material properties, optimize manufacturing processes, and accelerate the discovery of new materials. Key topics include the development and application of machine learning models, highthroughput computational techniques, and the integration of AI with experimental and theoretical methods, as well as current challenges and future perspectives.

SYMD 1: AI-driven Materials Design: Recent Developments, Challenges and Perspectives

Time: Monday 15:00–17:45 Location: H1

Invited Talk SYMD 1.1 Mon 15:00 H1

Learning physically constrained microscopic interaction models of functional materials — •Boris Kozinsky — Harvard University, Cambridge MA, USA — Bosch Research, Watertown MA, uSA

Discovery and understanding of next-generation materials requires a challenging combination of the high accuracy of first-principles calculations with the ability to reach large size and time scales. We pursue a multi-tier development strategy in which machine learning algorithms are combined with exact physical symmetries and constraints to significantly accelerate computations of electronic structure and atomistic dynamics. First, current DFT approximations fall short of the required accuracy and efficiency for predictive calculations of defect properties, band gaps, stability and electrochemical potentials of materials for energy storage and conversion. To advance the capability of DFT we introduce nonlocal charge density descriptors that satisfy exact scaling constraints and learn exchange functionals called CIDER. These models are orders of magnitude faster in self-consistent calculations for solids than hybrid functionals but similar in accuracy. On a different level, we accelerate MD simulations by using machine learning to construct generalized potential and free energy functions with arbitrary nonlinear dependence on external fields and temperature. This framework enables learning and prediction of dielectric and vibrational response properties and coarse-grained free energies. We demonstrate these methods via first principles ML MD simulations of dynamics of phase transformations, heterogeneous reactions, ferroelectric transitions, nuclear quantum effects, and soft materials.

Invited Talk SYMD 1.2 Mon 15:30 H1

GRACE universal interatomic potential for materials discovery and design — •Ralf Drautz — ICAMS, Ruhr-Universität Bochum, Germany

Universal interatomic potentials parameterize the interaction between all chemical elements in the periodic table simultaneously. In my talk I will introduce the Graph Atomic Cluster Expansion (GRACE). GRACE builds on a complete set of graph basis functions and generalizes equivariant message passing neural networks and other machine learning interatomic potentials. Next, I will discuss the parameterization of GRACE across the periodic table and compare the performance of universal GRACE to element-specific potentials.

The ability to simulate thousands or millions of atoms with complex chemistries for extended time scales opens completely new routes for materials discovery and design. I will demonstrate usage scenarios for widely different materials, chemistries and applications.

Finally, I will focus on limitations of current universal interatomic potentials and suggest steps to overcome these.

Invited Talk SYMD 1.3 Mon 16:00 H1

Multiscale Modelling & Machine Learning Algorithms for Catalyst Materials: Insights from the Oxygen Evolution Reaction — •Nong Artrith — Debye Institute for Nanomaterials Science, Utrecht University, NL

Machine learning (ML) has emerged as a powerful tool to accelerate the discovery of catalytic materials by integrating information from computation and experiment. While ML excels at pattern detection in large, uniform datasets, many catalyst studies rely on small, experimentally measured datasets. Our approach combines ML and first-principles calculations to extract insights from such small experimental datasets by training a complex ML model on a large computational library of transition-state energies and combining it with simple linear regression models fitted to experimental data. We use this approach to explore the catalytic activity of monolayer bimetallic catalysts for ethanol reforming, identifying key reactions and predicting promising catalyst compositions. For the explicit modeling of catalytic reactions, we performed ML-driven molecular dynamics and metadynamics simulations of the oxygen evolution reaction (OER) over oxide materials. Using a neural network potential, trained using transfer learning, we captured the dynamic mechanistic details of OER, elucidating the impact of nickel doping on the catalytic activity of $BaTiO_3$, a perovskite oxide synthesized from earth-abundant precursors. The combined insights from these case studies illustrate the versatility of ML in guiding the design of efficient and sustainable catalysts, ranging from ethanol reforming to water-splitting reactions.

Invited Talk SYMD 1.4 Mon 16:45 H1

Inverse Design of Materials — •Hongbin Zhang — Institute of Materials Science, TU Darmstadt, 64287 Darmstadt, Germany

Machine learning has been widely applied to obtain statistical understanding and rational design of advanced materials to map out the processing-(micro-)structure-property-performance relationships, mostly in the forward manner. In this work, focusing on the structure-property relationships, I am going to introduce the concept of inverse design and to showcase how it can be carried out based on Bayesian optimization and generative deep learning. To explore a well-defined and possibly vast design space efficiently, Bayesian optimization can be applied for reliable recommendations, either based on ranking schemas balancing exploration and exploitation or by using proper sampling strategies. This leads to a closed loop adaptive design strategy, which can be integrated with theoretical scale-bridging simulations and experimental synthesis and characterization, resulting in a domain expertise- and physics-informed active learning paradigm. Furthermore, to go beyond the known design space, generative deep learning (such as GAN, VAE, and diffusion models) can be applied. I will demonstrate such a strategy for the polycrystalline microstructure-property mapping, with the physical properties constrained based on an integrated ControlNet in stable diffusion models.

Invited Talk SYMD 1.5 Mon 17:15 H1

Data-Driven Materials Science — •Miguel Marques — Ruhr University Bochum, Germany

We summarize our recent attempts to discover, characterize, and understand inorganic compounds using novel machine learning approaches. We start by motivating why the search for new materials is nowadays one of the most pressing technological problems. Then we summarize our recent work in using crystal-graph attention neural networks for the prediction of materials properties. To train these networks, we developed a dataset of over 5 million density-functional calculations with consistent calculation parameters. Combining the data and the newly developed networks we have already scanned thousands of structural prototypes spanning a space of several billion materials and identified tens of thousands of theoretically stable compounds. We then discuss how these techniques can be used to discover new materials with tailored properties, using as an example the transition temperature of conventional superconductors. Finally, we speculate which role data-driven research will have in the future of materials science.

Spin hyperpolarization in molecular systems describes the transient electronic or nuclear spin order that surpasses the Boltzmann distribution. There is an enormously increasing interest in the fundamental aspects of building-up, transport and relaxation of spin hyperpolarization. Strategies that have been tested for building-up spin hyperpolarization include the controlled realization of molecule-based interfaces, spin pumping, spin injection, intersystem crossing or the chiral induced spin selectivity in molecular solids, thin films or devices. On the other hand, significant efforts are being made on the experimental and theoretical side to understand the mechanisms of transport of spin hyperpolarization and the related relaxation processes. This interdisciplinary symposium brings together experts working on various experimental and theoretical aspects of thin films, magnetism, surface science as well as device physics, aiming to identify common mechanisms involved in different hyperpolarization strategies in order to push synergistic advances in this field.

Time: Wednesday 15:00–17:45 Location: H1

Invited Talk SYMS 1.1 Wed 15:00 H1

Exploring the Non-Perturbative Magnetic Resonance Drive Regime with spin selection rules in a π-Conjugated Polymer — •Christoph Boehme — Department of Physics & Astronomy, University of Utah, Salt Lake City, UT 84112, USA

Spin-dependent charge carrier recombination currents in π-conjugated polymers can be governed by radical pair physics, reflecting the spin-permutation symmetry of electron-hole spin-pair states, rather than spin-polarization states. This effect can be used to detect magnetic resonance under conditions unsuitable for conventional spectroscopy, such as low spin polarization or thin-film systems containing small spin ensembles (Frankevich et al., Phys. Rev. B, 1992, 46, 9320; Roundy and Raikh, Phys. Rev. B, 2013, 88, 125206). Recent work has demonstrated this mechanism's utility for studying strong-drive, non-perturbative magnetic resonance, where magnetic radiation amplitudes comparable to the static Zeeman field create hybrid spin-light states. This results in non-linear behaviors like spin-collectivity (Waters et al., Nat. Phys., 2015, 11, 910-914), multi-photon transitions, and fractional g-factor effects (Jamali et al., Nat. Commun., 2021, 12, 465; Jamali et al., Nano Lett., 2017, 17, 4648-4653; Ashton et al., 2020). Experimental confirmations include monochromatic multi-photon transitions, angular dependence of resonance shifts, and hybrid light-matter states, promising advancements in high-fidelity sensing qubits with long coherence times [S. I. Atwood et al., Phys. Rev. B 110, 195304 (2024); S. I. Atwood et al., Phys. Rev. B 110, L060103 (2024)].

Invited Talk SYMS 1.2 Wed 15:30 H1

The puzzle of spin and charge transport in the chirality induced spin selectivity effect — •Bart van Wees — Zernike Institute for Advanced Materials, University of Groningen, The Netherlands

I will present an overview of the current understanding of the chirality induced spin selectivity effect [1], as measured as a magnetoresistance in electronic devices and scanning probe geometries. I will describe the principles of chirality induced coupling of spin and charge currents, and show that this indeed allows to observe the specific chirality in non-linear transport experiments [2,3]. However, experiments at low bias, in the linear transport regime, show that Onsager's reciprocity relations are not obeyed. This, together with the large magnetoresistances which are observed, (sometimes exceeding 90% or more) are not compatible with descriptions in terms of spin (polarized) transport. I will discuss alternative mechanisms, which are based on the modification of the electrostatic potential profile, which depend on the interplay between chirality and magnetisation. These lead to a magnetoresistance due to a modification of the charge transport, not the spin transport. I will point out that open questions remain for these alternative mechanisms, and propose experimental stategies to address these.

Invited Talk SYMS 1.3 Wed 16:00 H1

Nano- and Microscale NMR spectroscopy with spin qubits in diamond — •Nabeel Aslam — Leipzig University

Expanding nuclear magnetic resonance (NMR) spectroscopy to the micro- and nanoscale holds significant potential to advance research across disciplines. Potential applications include the chemical analysis of mass-limited samples, single-cell metabolomics for disease diagnostics, and the detection and characterization of individual proteins, such as functional membrane proteins.

In this talk, I will introduce a novel approach to nano- and microscale NMR using nitrogen-vacancy (NV) centers in diamond. These quantum defects can be optically polarized and read out, enabling highly sensitive detection of nuclear spins with exceptional spatial resolution. This capability is further enhanced through hyperpolarization techniques. I will provide an overview of the state-of-the-art in the field, including advancements in detecting nuclear spins on surfaces, integrating NV-based NMR with microfluidic technologies for high-throughput applications, and employing diffusion NMR to study molecular transport at the nanoscale.

Furthermore, I will discuss how nuclear spins in diamond can serve as quantum memories, enhancing the performance and versatility of NV-based sensing. This highly sensitive and versatile method has the potential to uncover new insights into complex systems in chemistry, biology, and material science.

15 min. break

Invited Talk SYMS 1.4 Wed 16:45 H1

Spin effects in adsorbed organometallic complexes — •Richard Berndt — Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel

By adsorbing organometallic complexes onto surfaces, high densities can be achieved and the molecules can be probed individually with a scanning tunneling microscope. This approach has enabled experiments on molecular spin switches and their interactions in artificial arrays. New insights have been gained into spin-crossover molecules, electrostatic interactions and their effect on spin states, and the role of orbital magnetic moments. The talk will highlight some results from this field as well as some of the challenges.

Invited Talk SYMS 1.5 Wed 17:15 H1

Quantum Computing with Molecules — •Mario Ruben — KIT, IQMT, 76344 Leopolshafen-Eggenstein — CESQ, Université Strasbourg, France

Nuclear spin states in molecules act as quantum registers for quantum operations. We report on the implementation of metal complexes into nanometer-sized spintronic devices by a combination of bottom-up self-assembly and top-down lithography techniques. The controlled generation of magnetic molecular nanostructures will be shown and persistence of their magnetic properties under confinement Molecular Quantum Devices will be proven. The Hilbert space spanned by the nuclear spins will be engineered synthetically and addressed both electrically and optically, partially at the single molecule level. Finally, Grovers quantum search algorithm will be implemented on the nuclear spin register of a TbPc2 Qudit.

Nonequilibrium classical and quantum systems coupled to thermal or (driven) non-equilibrium environments have recently been shown to exhibit rich collective phenomena and phase transitions without equilibrium counterparts. From the classical side, intriguing examples are flocking and phase separation in active matter, but also patterns and bifurcations in driven-diffusive systems and spontaneous parity-time symmetry breaking in systems involving nonreciprocal couplings. From the quantum side much interest has been devoted, e.g., to ordering and phase transitions in non-equilibrium steady states, the formation of time crystals, superradiance, as well as phase transitions or critical behavior in time. The symposium and the accompanying focus session is devoted to connections between the quantum and the classical realms, as they have been explored recently both in theory and experiment.

SYQS 1: Nonequilibrium Collective Behavior in Open Classical and Quantum Systems

Time: Thursday 15:00–17:45 Location: H1

Invited Talk SYQS 1.1 Thu 15:00 H1

Active quantum flocks — Reyhaneh Khasseh[1,2], Sascha Wald[3], Roderich Moessner[2], Christoph Weber[1,2], and •Markus Heyl[1,2] — [1]Theoretical Physics III, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, D-86135 Augsburg, Germany — [2]Max-Planck-Institut für Physik komplexer Systeme, 01187 Dresden, Germany — [3]Statistical Physics Group, Centre for Fluid and Complex Systems, Coventry University, Coventry, England

Flocks of animals represent a fascinating archetype of collective behavior in the macroscopic classical world, where the constituents, such as birds, concertedly perform motions and actions as if being one single entity. Here, we address the outstanding question of whether flocks can also form in the microscopic world at the quantum level. For that purpose, we introduce the concept of active quantum matter by formulating a class of models of active quantum particles on a one-dimensional lattice. We provide both analytical and large-scale numerical evidence that these systems can give rise to quantum flocks. A key finding is that these flocks, unlike classical ones, exhibit distinct quantum properties by developing strong quantum coherence over long distances. We propose that quantum flocks could be experimentally observed in Rydberg atom arrays. Our work paves the way towards realizing the intriguing collective behaviors of biological active particles in quantum matter systems. We expect that this opens up a path towards a yet totally unexplored class of nonequilibrium quantum many-body systems with unique properties.

Invited Talk SYQS 1.2 Thu 15:30 H1

Robust dynamics and function in stochastic topological systems — •Evelyn Tang — Rice University, Houston, TX

Living systems exhibit various robust dynamics and cycles during system regulation, growth, and motility. However, how robustness emerges from stochastic components remains unclear. Towards understanding this, I develop topological theories that support robust edge currents and localization, effectively reducing the system function to a lower-dimensional subspace. I will introduce stochastic networks in molecular reaction space that model long and stable time scales, such as the circadian rhythm. More generally, we prove that unlike their quantum counterparts, stochastic topological systems require driving or nonequilibrium for edge states and strong localization. I will close by discussing experimental platforms for the detection and use of edge currents for self-assembly and replication in living systems.

Invited Talk SYQS 1.3 Thu 16:00 H1

Nonequilibrium Dynamics of Disorder-Driven Ultracold Fermi Gases — •Artur Widera — University of Kaiserslautern-Landau, Department of Physics and state-research center OPTIMAS, 67663 Kaiserslautern, Germany

Ultracold quantum gases provide a unique platform to experimentally study many-body dynamics under precisely controlled external potentials and driving forces. In this talk, I will present recent results on the dynamics of an ultracold gas of spin-polarized fermionic lithium atoms subjected to a time-dependent disorder potential. For static disorder, we observe signatures of the well-known Anderson localization. In contrast, time-varying disorder with finite correlation time is expected to disrupt localization. Specifically, for weak disorder, we find that time-dependent disorder induces a transition in the transport behavior of the gas from normal diffusion to superdiffusion and eventually ballistic motion as the correlation time of the disorder decreases. This enhanced diffusion is well described by a stochastic Fermi acceleration model, where randomly fluctuating force fields drive the system. Interestingly, for strong disorder, normal diffusion persists over a broad range of disorder correlation times despite the time-varying potential. We attribute this resilience to the continued presence of destructive interference as quantified by the localized fraction of atoms, which remains intact even under the influence of time-dependent disorder. These results point toward a nonequilibrium phase transition between localized and diffusive regimes in this driven system.

Invited Talk SYQS 1.4 Thu 16:45 H1

Topological classification of driven-dissipative nonlinear systems — •Oded Zilberberg[1], Greta Villa[1], Kilian Seibold[1], Vincent Dumont[2], Gianluca Rastelli[3], Mateusz Michałek[4], Alexander Eichler[2], and Javier del Pino[1] — [1]Department of Physics, University of Konstanz, Universitätsstraße 10, 78464 Konstanz, Germany — [2]Laboratory for Solid State Physics, ETH Zurich, CH-8093 Zürich, Switzerland — [3]Pitaevskii BEC Center, CNR-INO and Dipartimento di Fisica, Università di Trento, I-38123, Trento, Italy — [4]Dept. of Mathematics and Statistics, University of Konstanz, Universitätsstraße 10, 78464 Konstanz, Germany

Topological classification of matter has become crucial for understanding the linear response of (meta-)materials, with associated quantized bulk phenomena and robust topological boundary effects. Moving to nonlinear systems, we develop an approach that harnesses the topology of structurally stable vector flows, and thus propose a new topological graph invariant to characterize out-of-equilibrium dynamical systems. We exemplify our approach on the ubiquitous model of a dissipative bosonic Kerr cavity, subject both to one- and two-photon drives. Using our classification, we can identify the topological origin of phase transitions in the system, as well as explain the robustness of a multicritical point in the phase diagram. We, furthermore, identify that the invariant distinguishes population inversion transitions in the system in similitude to a Z2 index. Our approach spans across the classical-to-quantum regimes, and extensions to coupled nonlinear cavities are postulated.

Invited Talk SYQS 1.5 Thu 17:15 H1

Learning dynamical behaviors in physical systems — •Vincenzo Vitelli — University of Chicago, Chicago, USA

Physical learning is an emerging paradigm in science and engineering whereby (meta)materials acquire desired macroscopic behaviors by exposure to examples. So far, it has been applied to static properties such as elastic moduli and self-assembled structures encoded in minima of an energy landscape. Here, we extend this paradigm to dynamic functionalities, such as motion and shape change, that are instead encoded in limit cycles or pathways of a dynamical system. We identify the two ingredients needed to learn time-dependent behaviors irrespective of experimental platforms: (i) learning rules with time delays and (ii) exposure to examples that break time-reversal symmetry during training. After providing a hands-on demonstration of these requirements using programmable LEGO toys, we elucidate how they emerge from physico-chemical processes involving the causal propagation of fields. Our trainable particles can self-assemble into structures that move or change shape on demand, either by retrieving the dynamic behavior previously seen during training. This phenomenology is captured by a non-reciprocal Hopfield spin model amenable to analytical treatment. The principles illustrated here provide a step towards von Neumann's dream of engineering synthetic living systems that adapt to the environment.

Symposium SKM Dissertation Prize 2025 (SYSD)

jointly organised by
all divisions of the Condensed Matter Section of the DPG

Elke Scheer
Department of Physics, University of Konstanz
Universitätsstraße 10
78464 Konstanz
elke.scheer@uni-konstanz.de

The divisions belonging to the Condensed Matter Section (SKM) of the DPG annually award the SKM Dissertation Prize. The prize acknowledges outstanding research during the doctoral studies in the research areas of the SKM completed in 2023 or 2024, and its excellent oral presentation. Based on nominations, a jury consisting of the chair persons of all SKM divisions has selected five finalists to present their work in this symposium. The winner will be selected after the symposium and publicly announced Tuesday, March 18, 2025 in the afternoon during the ceremonial sessionn (Lecture hall H1 (Audimax) starting at 16:00).

SYSD 1: SKM Dissertation Prize Symposium

Time: Monday 9:30–12:00 Location: H2

Invited Talk SYSD 1.1 Mon 9:30 H2

Nanoscale Chemical Analysis of Ferroic Materials and Phenomena — •Kasper Aas Hunnestad — Department of Materials Science and Engineering, Norwegian University of Science and Technology, Trondheim, Norway

The discovery of new physical phenomena in materials is closely linked to the progress in characterization, and is propelled by the ability to observe and study physical processes occurring at the atomic level. In this talk, I will present how atom probe tomography (APT) can be incorporated into the toolkit of nanoscale research to study ferroelectric oxide materials. The aim is to demonstrate its feasibility and power to unravel correlations between the local chemical composition and emergent functional properties.

A range of systems with fundamental importance to ferroelectrics are investigated, including solute dopants in bulk, naturally occurring interfaces in ferroelectrics, such as grain boundaries and domain walls, and artificially grown interfaces in heterostructures. Using a correlative microscopy approach, a complex and diverse defect chemistry is revealed in 3D, which further clarify the origin of anomalous electronic properties. The work presented demonstrates the outstanding potential and general feasibility of applying APT to study ferroelectric oxide systems. Correlations between defect chemistry and ferroic phenomena can be experimentally probed with nanoscale spatial resolution, opening an avenue to obtain a deeper understanding of ferroic materials.

Invited Talk SYSD 1.2 Mon 10:00 H2

Advanced Excitation Schemes for Semiconductor Quantum Dots — •Yusuf Karli — Cavendish Laboratory, University of Cambridge, Cambridge, UK — Institut für Experimentalphysik, Universität Innsbruck, 6020, Innsbruck, Austria

Semiconductor quantum dots are nanometer-scale structures that confine electrons in three dimensions, creating discrete energy levels similar to those in atoms. This unique property makes them an excellent platform for generating high-quality single photons with high purity and indistinguishability. As such, they are critical for advancing quantum technologies, serving as essential building blocks for quantum communication, quantum computing, and photonic quantum networks.

In this talk, I address practical challenges associated with traditional excitation methods for semiconductor quantum dots by introducing innovative approaches. These include below-bandgap excitation (the SUPER scheme), a two-pulse technique (Stimulated TPE), and Adiabatic Rapid Passage (ARP). These methods enhance robustness, improve photon indistinguishability, and enable efficient population transfer, positioning semiconductor quantum dots as reliable and scalable sources for quantum photonic systems.

Invited Talk SYSD 1.3 Mon 10:30 H2

Aspects and Probes of Strongly Correlated Electrons in Two-Dimensional Semiconductors — •Clemens Kuhlenkamp — Harvard University, Cambridge, USA

Due to their high level of control two-dimensional (2D) materials are emerging as fascinating platforms to explore correlated electronic phases of matter. In this talk, I will discuss opportunities to control, prepare, and probe exotic states in structures of transition metal dichalcogenides (TMDs), a class of 2D semiconductors. Remarkably, already a single TMD layer can reach an interaction-dominated regime upon doping electrons. By analyzing the optical response of the material, we directly reveal the formation and properties of an electronic Wigner crystal—a state where electrons break translational symmetry by arranging in a triangular lattice. Moving on to multi-layer TMDs, I will demonstrate how Moiré patterns—arising from misalignments between the layers—can realize highly tunable, frustrated Hubbard models in the presence of large magnetic fields. Our theoretical analysis predicts that such materials can exhibit exotic insulator-to-insulator transitions and give rise to exceptionally robust spin liquid phases in the Mott insulating limit. I will conclude with an outlook on future directions, particularly highlighting opportunities to realize unconventional superconductivity.

Invited Talk SYSD 1.4 Mon 11:00 H2

Mean back relaxation and mechanical fingerprints: simplifying the study of active intracellular mechanics — •Till Münker — Third Institute of Physics - Biophysics, University of Göttingen, 37077 Göttingen

Vital cellular functions rely on the interplay between the viscoelastic mechanical properties of the cytoplasm and the active force generated by the consumption of metabolic energy. However, quantifying these properties poses significant challenges due to the complexity of the physical quantities and the elaborate, low-throughput experimental methods required for their investigation. We propose two techniques to meet these challenges. Firstly, we introduce a mechanical fingerprint that reduces the complexity of intracellular active mechanical properties to six parameters. We demonstrate how the fingerprint captures changes in mechanics upon disrupting cytoskeletal components and enables identification of individual cells through their unique fingerprint. By introducing a phase space of resistance, activity, and fluidity, we observe how position in phase space correlates with expected cell function. Secondly, we introduce the Mean Back Relaxation (MBR) as a novel statistical tool to determine the breaking of detailed balance in confined systems. In living cells, we observe surprising relations between the MBR and intracellular activity. Strikingly, by deploying this relation, we determined the mechanical properties of MDCK cells by purely passive observations. Together, these techniques simplify the quantification of intracellular mechanics, reducing experimental complexity while enhancing throughput.

Invited Talk SYSD 1.5 Mon 11:30 H2

Coherent Dynamics of Atomic Spins on a Surface — •Lukas Veldman — TU Delft, Department of Quantum Nanoscience, Delft, The Netherlands — University of Stuttgart, Institute for Functional Matter and Quantum Technologies, 70569 Stuttgart, Germany

Studying dynamical interactions between individual spins is vital for understanding exotic magnetic materials as well as for development of applications that require control over solid state spins like spintronics and quantum computation. Here, we introduce the possibility to inject a single spin flip with atomic precision into a magnetic nanostructure and trace the resulting coherent spin dynamics. We achieve this by combining electron spin resonance (ESR) and DC pump-probe techniques with scanning tunneling microscopy (STM). In our first proof-of-concept measurement, we apply this method to two coupled Ti atoms and resolve the resulting coherent flip-flop oscillations between their electron spins [1]. Next, we investigate larger structures up to 6 spins and study magnon dynamics in the few-atom limit [2]. Lastly, we resolve the magnetic dynamics between an electron and a nucleus within a single atom [3,4], further expanding the potential of this new measurement scheme to nuclear spins. These experiments add to the understanding of the microscopic mechanism behind magnetic interactions and open the door to detailed control of individual spins on surfaces for quantum coherent applications. BP 1: Hands-on Tutorial: AI Fundamentals for Research (joint session BP/TUT/DY/AKPIK)

Artificial intelligence (AI) has become an essential tool in modern physics, enabling new approaches to data analysis, modeling, and prediction. This hands-on tutorial provides an accessible introduction to key AI concepts, emphasizing their practical applications in physics research.

Please bring your laptop. There will be limited power outlets in the room, so come with a fully charged battery.

Materials will be made available from 10.03.2025, accessible via the following options:

GitHub repository:
https://github.com/RedMechanism/DPG-SKM-2025-Tutorial-AI-Fundamentals-for-Research

ZIP file download:
https://jlubox.uni-giessen.de/getlink/fiAGRzcGTiCL3GZxk8WAjom4/

Participants are encouraged to download them ahead of time.

Organized by Jan Bürger (Aachen), Janine Graser (Duisburg), Robin Msiska (Duisburg/Ghent), and Arash Rahimi-Iman (Gießen), with support from Stefan Klumpp (Göttingen) and Tim Ruhe (Dortmund).

Time: Sunday 16:00–18:15 Location: H2

Tutorial BP 1.1 Sun 16:00 H2

Introduction — Jan Bürger[1], •Janine Graser[2], Robin Msiska[2,3], and Arash Rahimi-Iman[4] — [1]ErUM-Data-Hub, RWTH Aachen University, Aachen, Germany — [2]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Duisburg, Germany — [3]Department of Solid State Sciences, Ghent University, Ghent, Belgium — [4]I. Physikalisches Institut and Center for Materials Research, Justus-Liebig-University Gießen, Gießen, Germany

The session begins with an overview of essential AI concepts, including neural networks, training methodologies, and key distinctions between AI models. Participants will gain a foundational understanding of AI principles and how these tools can be leveraged for various research challenges.

5 min. break

Tutorial BP 1.2 Sun 16:40 H2

Hands-On Session 1 – Function Approximation — •Jan Bürger[1], Janine Graser[2], Robin Msiska[2,3], and Arash Rahimi-Iman[4] — [1]ErUM-Data-Hub, RWTH Aachen University, Aachen, Germany — [2]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Duisburg, Germany — [3]Department of Solid State Sciences, Ghent University, Ghent, Belgium — [4]I. Physikalisches Institut and Center for Materials Research, Justus-Liebig-University Gießen, Gießen, Germany

In the first half of the interactive session, participants will work with Jupyter Notebooks to explore practical applications of machine learning. They will train simple neural networks to predict a mathematical function, gaining hands-on experience in tuning key parameters. Since neural networks can typically be considered universal function approximators, this concept is effectively illustrated using a one-dimensional function, making it easy to visualize and understand.

5 min. break

Tutorial BP 1.3 Sun 17:30 H2

Hands-On Session 2 – Classification and More — Jan Bürger[1], Janine Graser[2], •Robin Msiska[2,3], and Arash Rahimi-Iman[4] — [1]ErUM-Data-Hub, RWTH Aachen University, Aachen, Germany — [2]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Duisburg, Germany — [3]Department of Solid State Sciences, Ghent University, Ghent, Belgium — [4]I. Physikalisches Institut and Center for Materials Research, Justus-Liebig-University Gießen, Gießen, Germany

The session demonstrates how pre-trained models can simplify tasks such as classification, making them readily applicable to research. Typical examples include recognizing handwritten digits, which showcase the power of pretrained models in solving common challenges. As a preview of advanced topics, the tutorial concludes with brief examples of large language models (LLMs) and generative AI.

BP 2: Active Matter I (joint session DY/BP/CPP)

Time: Monday 9:30–12:45 Location: H37

BP 2.1 Mon 9:30 H37

Odd dynamics and pattern formation in mixtures of magnetic spinners and passive colloids — •Dennis Schorn[1], Stijn van der Ham[2], Hanumantha Rao Vutukuri[2], and Benno Liebchen[1] — [1]Technische Universität Darmstadt, 64289 Darmstadt, Germany — [2]MESA+ Institute, University of Twente, 7500 AE Enschede, The Netherlands

Starfish embryos aggregate into chiral crystals exhibiting odd elasticity (Tan *et al.* Nature **607**, 287 (2022)). Similar structures have been recently observed in externally driven magnetic colloids. In this talk, I present experiments and simulations of binary mixtures of magnetic spinners and passive colloids. We develop a model to predict the phase diagram of the system, which comprises four distinct phases that can be systematically reproduced in experiments. In particular, our simulations and experiments show a phase where the passive particles form a gel-like network featuring significant holes filled with self-organized rotating chiral clusters made of spinners. This phase can be reversed by changing the system's composition and magnetic field strength, featuring a system spanning spinner phase with embedded counter-rotating chiral clusters made of passive colloids. Our system may open the route towards a new type of viscoelastic active chiral matter involving nonreciprocal interactions between both species.

BP 2.2 Mon 9:45 H37

Symmetry breaking in active non-reciprocal systems — •Kim L. Kreienkamp and Sabine H. L. Klapp — TU Berlin, Germany

Non-reciprocity significantly impacts the dynamical behavior in mixtures. One of its particularly striking consequences is the spontaneous emergence of time-dependent phases that break parity-time symmetry [1-3]. Here, we study a paradigmatic model of a non-reciprocal polar active mixture with completely symmetric repulsion [4,5]. Using a combination of field theory and particle-based simulations, we identify two qualitatively distinct regimes of non-reciprocity-induced dynamics. In the regime of weak intra-species alignment, non-reciprocity leads to asymmetric clustering in which only one of the two species forms clusters. Notably, the asymmetric density dynamics is driven alone by non-reciprocal orientational couplings [4,5]. In contrast, in the strongly coupled regime, the corresponding field theory exhibits exceptional points that have been associated with the emergence of chiral phases where the polarization direction rotates over time [2]. Our simulations confirm that spontaneous chirality arises at the particle level. In particular, we observe chimera-like states with co-existing locally synchronized and disordered regions. At the coupling strengths associated with exceptional points, the spontaneous chirality peaks.

Emergent phases in a discrete flocking model with non-reciprocal interaction — •Swarnajit Chatterjee, Matthieu Mangeat, and Heiko Rieger — Center for Biophysics & Department for Theoretical Physics, Saarland University, 66123 Saarbrücken, Germany

Non-reciprocal interactions arise in systems that seemingly violate Newton's third law "actio=reactio". They are ubiquitous in active and living systems that break detailed balance at the microscale, from social forces to antagonistic interspecies interactions in bacteria. Non-reciprocity affects non-equilibrium phase transitions and pattern formation in active matter and represents a rapidly growing research focus in the field. In this work, we have undertaken a comprehensive study of the non-reciprocal two-species active Ising model (NRTSAIM), a non-reciprocal discrete-symmetry flocking model. Our study uncovers a distinctive *run-and-chase* dynamical state that emerges under significant non-reciprocal frustration. In this state, A-particles chase B-particles to align with them, while B-particles avoid A-particles, resulting in B-particle accumulation at the opposite end of the advancing A-band. This run-and-chase state represents a non-reciprocal discrete-symmetry analog of the chiral phase seen in the non-reciprocal Vicsek model. Additionally, we find that self-propulsion destroys the oscillatory state obtained for the non-motile case, and all the NRTSAIM steady-states are metastable due to spontaneous droplet excitation and exhibit motility-induced interface pinning. A hydrodynamic theory supports our simulations and confirms the reported phase diagrams.

BP 2.4 Mon 10:15 H37

Emergent phases in a discrete flocking model with reciprocal interaction — •Matthieu Mangeat[1], Swarnajit Chatterjee[1], Jae Dong Noh[2], and Heiko Rieger[1] — [1]Saarland University, Saarbrücken, Germany — [2]University of Seoul, Seoul, Korea

We have undertaken a comprehensive study of the two-species active Ising model (TSAIM), a discrete-symmetry counterpart of the continuous-symmetry two-species Vicsek model, motivated by recent interest in the impact of complex and heterogeneous interactions on active matter systems. In the TSAIM, two species of self-propelled particles undergo biased diffusion in two dimensions, interacting via local intraspecies alignment and reciprocal interspecies anti-alignment, along with the possibility of species interconversion. We observe a liquid-gas phase transition, exhibiting macrophase-separated bands, and the emergence of a high-density parallel flocking state, a feature not seen in previous flocking models. With species interconversion (species-flip dynamics), the TSAIM corresponds to an active extension of the Ashkin-Teller model and exhibits a broader range of steady-state phases, including microphase-separated bands that further enrich the coexistence region. We also find that the system is metastable due to droplet excitation and exhibits spontaneous motility-induced interface pinning, preventing the system from reaching long-range order at sufficiently low noise. A hydrodynamic theory complements our computer simulations of the microscopic model and confirms the reported phase diagrams.

BP 2.5 Mon 10:30 H37

Emergent collective behavior from cohesion and alignment — •Jeanine Shea and Holger Stark — Technische Universität Berlin, Institut für Theoretische Physik, Hardenbergstr. 36, 10623 Berlin, Germany.

Collective behavior is all around us, from flocks of birds to schools of fish. These systems are immensely complex. To explore their basic characteristics, we introduce a minimal model for cohesive and aligning self-propelled particles in which group cohesion is established through additive, non-reciprocal torques [1]. These torques cause constituents to effectively turn towards one another, while an additional alignment torque competes in the same spatial range. By changing the strength and range of these torque interactions, we uncover six states which we distinguish via their static and dynamic properties. These states range from disperse particles to closely packed worm-like formations. A number of the states generated by this model exhibit collective dynamics which are reminiscent of those seen in nature.

Invited Talk BP 2.6 Mon 10:45 H37

Collective behavior of photoactive macroscopic particles — •Iker Zuriguel — University of Navarra, Pamplona, Spain

Active matter refers to systems of interacting, self-propelled agents that convert energy into mechanical motion, representing a nice example of out-of-equilibrium systems. In this work, a novel type of active particles is introduced. These are active granular (i.e. they interact solely through physical contacts) and photoactive, meaning that they self-propel using energy from light. Therefore, by means of a programmable LED panel, we are able to change the illumination pattern and, consequently, the particle activity in space and time, allowing a precise exploration of a variety of scenarios related to collective behavior. This possibility has been exploited in microscopic systems but is genuinely new in macroscopic ones.

First, we will present the clustering behavior of these agents under homogeneous illumination. By varying the illumination intensities and changing the population size, we observed a power-law-like distribution for both the cluster sizes and durations. We identified a transition from unstable to stable clusters, as indicated by the divergence of average cluster durations. Higher particle activities and smaller populations led to the creation of small unstable clusters, while lower particle activities and larger populations result in big, stable clusters that persist over time. This transition is explained with the help of a simple model capturing the most important processes involved in cluster dynamics. In the last part of the talk, the collective behavior under inhomogeneous illumination patterns will be introduced.

Swarming model with minority interaction exhibits temporal and spatial scale-free correlations — •Simon Syga[1], Chandraniva Guha Ray[2,3,4], Josué Manik Nava Sedeño[5], Fernando Peruani[6,7], and Andreas Deutsch[1] — [1]Technische Universität Dresden — [2]Max Planck Institute for the Physics of Complex Systems — [3]Max Planck Institute of Molecular Cell Biology and Genetics — [4]Center for Systems Biology Dresden — [5]Universidad Nacional Autónoma de México — [6]Université Côte d'Azur, Nice — [7]CY Cergy Paris Université

Collective motion is a widespread phenomenon in social organisms, from bird flocks and fish schools to human crowds and cell groups. Swarms of birds and fish are particularly fascinating for their coordinated behavior and rapid escape maneuvers during predator attacks. Critical motion is hypothesized as an optimal trade-off between cohesive group behavior and responsiveness to well-informed individuals. However, traditional models only show criticality at the phase transition between ordered and unordered motion. Here, we extend the Vicsek model with a minority interaction, where individuals primarily follow neighbors but can switch to follow a defector moving against a well-aligned group. This triggers cascades of defections, leading to rich dynamics, including large-scale fluctuations, scale-free velocity distributions, and a scale-free return time distribution of the order parameter. Our model underscores the biological importance of minority interactions in swarming and their role in critical behavior.

BP 2.8 Mon 11:45 H37

'Predator-prey' driven swarmalator systems — •Ginger E. Lau, Mario U. Gaimann, and Miriam Klopotek — Stuttgart Center for Simulation Science (SimTech), Cluster of Excellence EXC 2075, University of Stuttgart, Germany

Swarmalators are an active matter system of oscillators which exhibit swarming and collective motion in physical space, as well as synchronization behavior in an additional phase variable space, originally introduced by O'Keeffe *et al.* (*Nat. Commun.* 8(1), 1504, 2017). Such systems with bidirectional couplings in space and phase can be observed in nature, such as in the chorusing behavior of Japanese tree frogs characterized by Aihara *et al.* (*Sci. Rep.* 4(1), 3891, 2014). The interplay between attraction, repulsion, and phase synchronization provides several distinct regimes of self-organizational behavior. Akin to biological swarm systems responding to predator interactions, swarmalators can respond collectively to external perturbations by a repulsive driver. In previous work, driving was realized with a mobile 'pacemaker' by Xu *et al.* (*Chaos* 34(11), 113103, 2024). The present study introduces a new 'predator-prey' driven swarmalator model showing rich adaptive behavior. This could have a wide variety of potential future applications, from biological physics to swarm robotics to nature-inspired learning algorithms and methods of inference.

Inertial active matter governed by Coulomb friction — •Alexander Antonov[1], Lorenzo Caprini[2], and Hartmut Löwen[1] — [1]Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany — [2]University of Rome La Sapenzia, Rome, Italy

Coulomb, or dry friction, is a common phenomenon that can be encountered in various systems, such as granular matter or Brownian motors. The Coulomb friction force resists the motion and, unlike the friction in wet systems, is almost independent of the relative velocity. We show that this characteristic feature of Coulomb friction leads to emergence of dynamical states when subjected to active, or self-propelled motion [1]. At low activity levels, the dynamics resembles Brownian motion, while at greater activity, a dynamic Stop & Go regime emerges, marked by continuous switching between diffusion and accelerated motion. At even higher activity levels, a super-mobile regime arises, characterized by fully accelerated motion and an anomalous scaling of the diffusion coefficient with activity. Near the transition between the Stop & Go and super-mobile regimes, we reveal a novel activity-induced phase separation in collective behavior [2]. Our theoretical findings have been also demonstrated in experiments, where

vibrobots on a horizontal surface are activated by vertical oscillations generated using an electromagnetic shaker.

Active nematic turbulence with substrate friction — •Peter A. E. Hampshire[1,2] and Ricard Alert[1,2,3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Center for Systems Biology Dresden, Dresden, Germany — [3]Cluster of Excellence Physics of Life, Dresden, Germany

Active nematics with high activity exhibit turbulent-like flows, characterized by vortices, spatio-temporal chaos and power laws in the energy spectra [1-3]. Continuum models have been successfully used to predict the scaling of the energy spectra with the wavevector. Most theoretical work has focused on free-standing, active nematic films. However, in several experimental realisations, such as bacterial colonies and epithelial monolayers, the active nematic is in contact with a solid substrate. We generalised a 2D, incompressible active nematic model to include substrate friction, and studied its impact on the transition to turbulence and the energy spectra of the turbulent-like flows. We find a variety of dynamic states including flow in lanes, stable vortices and both isotropic and anisotropic turbulence. At high activity and moderate friction, we found a power-law scaling in the kinetic energy spectrum $E(q) \sim q^3$, where q is the wavevector, at low wavevectors. The exponent of 3 can be justified with a power-counting argument. Overall, we have developed a model for active nematic turbulence on a substrate that can be compared to biological systems. [1] L. Giomi, *Phys. Rev. X* **5**, 031003 (2015). [2] R. Alert, J.-F. Joanny, J. Casademunt, *Nat. Phys.* **16**, 682-688 (2020). [3] B. Martínez-Prat*, R. Alert*, et al., *Phys. Rev. Self-sustained patchy turbulence in shear-thinning active fluids — •Henning Reinken and Andreas M. Menzel — Otto-von-Guericke-Universität Magdeburg

Bacterial suspensions and other active fluids are known to develop highly dynamical vortex states, denoted as active or mesoscale turbulence. We reveal the pronounced effect of non-Newtonian rheology of the carrier fluid on these turbulent states, concentrating on shear thinning. As a consequence, a self-sustained heterogeneous state of coexisting turbulent and quiescent areas develops, which results in anomalous velocity statistics. The heterogeneous state emerges in a hysteretic transition under varying activity. We provide an extensive numerical analysis and find indirect evidence for a directed percolation transition. Our results are important, for instance, when addressing active objects in biological media with complex rheological properties.

RNA plasticity emerges as an evolutionary response to fluctuating environments — •Paula García-Galindo[1] and Sebastian E. Ahnert[1,2] — [1]Department of Chemical Engineering and Biotechnology, University of Cambridge, Philippa Fawcett Drive, Cambridge CB3 0AS United Kingdom — [2]The Alan Turing Institute, 96 Euston Road, London NW1 2DB, UK

Phenotypic plasticity, the ability of a single genotype to produce multiple distinct phenotypes, can be studied effectively using RNA. RNA is a dynamic macromolecule that probabilistically shifts its structure due to thermal fluctuations at the molecular scale. To model the evolution of RNA plasticity, we use the RNA sequence-to-structure non-deterministic mapping, a computationally tractable genotype-phenotype (GP) map where probabilistic phenotypes are derived from the Boltzmann distribution of structures for each RNA sequence. Through evolutionary simulations with periodic environmental switching on the GP map, we observe that RNA phenotypes adapt to these fluctuations by evolving toward optimal plasticity. These optimal phenotypes are defined by nearly equal Boltzmann probabilities for distinct structures, each representing the most advantageous configuration for alternating environments. Our findings demonstrate that phenotypic plasticity, a widespread biological phenomenon, is a fundamental evolutionary adaptation to fluctuating environments.

BP 3.2 Mon 9:45 H44

Symmetry of loop extrusion by dimeric SMC complexes is DNA-tension-dependent — Biswajit Pradhan[1], •Adrian John Pinto[2], Peter Virnau[2], and Eugene Kim[1] — [1]Max Planck Institute of Biophysics, 60438 Frankfurt am Main, Germany — [2]Institut für Physik, Staudingerweg 9, Johannes Gutenberg-Universität Mainz, 55128 Mainz, Germany

Structural maintenance of chromosome (SMC) complexes are involved in genome organization and regulation via DNA loop extrusion. During extrusion SMC proteins reel DNA from one or both sides and a loop forms and increases. At low DNA tension (< 0.1pN), Smc5/6 and Wadjet extrude DNA from both sides of the loop. At higher tension, however, they transition to a behavior akin to one-sided extruders, yet still capable of extruding from one or the other side thereby switching the direction of extrusion [1]. In order to model this process in simulations, we propose a coarse-grained model for DNA loop extrusion using a Kratky-Porod chain as a basis for DNA and a handcuff for SMC proteins. By matching stalling forces, we are able to simulate loop extrusion on experimental time and length scales. We find that the observed switching from two- to one-sided behavior does not require a change in motor activity, but can be explained as a complex interplay of extrusion, stalling and thermal fluctuations.

[1] Pradhan, B., Pinto, A., Kanno, T., et al. (2024). Symmetry of loop extrusion by dimeric SMC complexes is DNA-tension-dependent. bioRxiv. https://doi.org/10.1101/2024.09.12.612694

BP 3.3 Mon 10:00 H44

NucleoSeeker - Precision filtering of RNA databases to curate high-quality datasets — •Utkarsh Upadhyay[1], Fabrizio Pucci[2], Julian Herold[3], and Alexander Schug[1,4] — [1]Jülich Supercomputing Centre, Germany — [2]Universite Libre de Bruxelles, Belgium — [3]Karlsruhe Institute for Technology, Germany — [4]University of Duisburg- Essen, Germany

The structural prediction of biomolecules via computational methods complements the often involved wet-lab experiments. Unlike protein structure prediction, RNA structure prediction remains a significant challenge in bioinformatics, primarily due to the scarcity of RNA structure data and its varying quality. Many methods have used this limited data to train deep learning models but redundancy, data leakage and bad data quality hampers their performance. In this work, we present NucleoSeeker, a tool designed to curate high-quality, tailored datasets from the Protein Data Bank (PDB) database. It is a unified framework that combines multiple tools and streamlines an otherwise complicated process of data curation. It offers multiple filters at structure, sequence and annotation levels, giving researchers full control over data curation. Further, we present several use cases. In particular, we demonstrate how NucleoSeeker allows the creation of a non-redundant RNA structure dataset to assess AlphaFold3's performance for RNA structure prediction. This demonstrates NucleoSeeker's effectiveness in curating valuable non-redundant tailored datasets to both train novel and judge existing methods. NucleoSeeker is very easy to use, highly flexible and can significantly increase the quality of RNA structure datasets.

Uncovering the Non-Canonical RNA Binding site on the Immune Sensor OAS2 by combining AI, MD simulations and experiments. — •Adrian F. Schnell[1], Veronika Merold[2], Indra Bekere[2], Carina C. de Oliveira Mann[2], and Nadine Schwierz[1] — [1]Institute of Physics, University of Augsburg — [2]Department of Bioscience, Technical University of Munich

Molecular dynamics (MD) simulations and machine learning provide powerful tools to predict protein-RNA interactions, but their predictions require experimental verification. In this talk, we showcase an advancement in understanding the immune sensor 2'-5'-oligoadenylate synthetase 2 (OAS2) by combining AlphaFold 3, MD simulations, cryo-electron microscopy (cryo-EM), and cellular assays. Although the structure of the OAS2 has been resolved through cryo-EM, the precise mechanisms underlying its activation and the RNA binding site remained elusive.

To fill this gap, we combined all-atom MD simulations based on cryo-EM structures and AlphaFold 3 predictions to identify non-canonical RNA binding interfaces on the catalytically deficient OAS2 domain. By integrating mutagenesis studies and contact data from MD simulations, we uncovered critical structural details of RNA binding and OAS2 activation. Importantly, our findings reveal how OAS2 domains discriminate RNA length, providing new insights into its function and regulatory mechanisms. These results enhance our understanding of OAS2's antiviral immune role and offer a foundation for developing antiviral strategies targeting the OAS-RNase L pathway.

BP 3.5 Mon 10:30 H44

Computational bridging between sequence design and network-level behaviour of programmable DNA-nanomotifs — •Aaron Gadzekpo[1] and Lennart Hilbert[1,2] — [1]Karlsruhe Institute of Technology, Institute of Biological and Chemical Systems — [2]Karlsruhe Institute of Technology, Zoological Institute

DNA can serve as a programmable material, by using the DNA sequence to control the 3D-structure of building blocks at the nanometre-scale. In our work, we construct X-shaped particles, or "nanomotifs", from four single-stranded DNA-oligomers, each 46 nucleotides in length. The X-motifs' four arms selectively and transiently hybridize, linking into large, dynamic networks guided by DNA sequence complementarity. We present our scale-bridging computational methods to predict how DNA-oligomer sequences translate into physical properties of X-motifs and the emergent behaviour of networks. In particular, we leverage machine learning to transition from base-pair resolution simulations of single X-motifs and linked pairs to coarse-grained molecular dynamics simulations of networks at increased time and length scales. These simulations are used to explore how nanomotif design at nucleotide level influences emergent behaviour, including liquid-liquid phase separation and condensation on target DNA strands with complementary binding motifs. We connect our observation to corresponding experiments, showcasing model-aided design of DNA-based materials.

BP 3.6 Mon 10:45 H44

Ionizable cationic lipids and helper lipids synergistically contribute to RNA packing and protection in lipid-based nanomaterials — •David Noel Zimmer[1,2], Friederike Schmid[1], and Giovanni Settanni[1,2] — [1]Physics Department Johannes Gutenberg University Mainz — [2]Faculty of Physics and Astronomy Ruhr University Bochum

Lipid-based nanomaterials are used as a common delivery vehicle for RNA therapeutics. They typically include a formulation containing ionizable cationic lipids, cholesterol, phospholipids, and a small molar fraction of PEGylated lipids. The ionizable cationic lipids are considered a crucial element of the formulation for the way they mediate interactions with the anionic RNA as a function of pH. Here[1], we show, by means of molecular dynamics simulation of lipid formulations containing two different ionizable cationic lipids (DLinDMA and DLinDAP), that the direct interactions of those lipids with RNA, taken alone, may not be sufficient to determine the level of protection and packaging of mRNA. Our simulations help and highlight how the collective behavior of the lipids in the formulation, which determines the ability to envelop the RNA, and the level of hydration of the lipid-RNA interface may also play a significant role. This allows the drawing of a hypothesis about the experimentally observed differences in the transfection efficiency of the two ionizable cationic lipids.

Killing to survive - how protein-lipid interactions drive programmed cell death — •Kristyna Pluhackova — University of Stuttgart, Stuttgart, Germany

Programmed cell death is an essential process of eukaryotic life, enabling e.g., embryonic development, regeneration, or fighting pathogens. Depending on the needs of an organism, diverse molecular mechanisms of cell death exist, determining among others the speed of cell death, its extent and the impact on surrounding cells. Not surprisingly, dysregulation of cell death culminates in diverse diseases, the most prominent of all being cancer.

Here, I reveal molecular details of protein-lipid interactions in programmed cell death by multiscaling molecular dynamics simulations. First, I unveil how lipids unplug medium-sized membrane pores formed by a pyroptotic agent gasdermin and reveal astonishing adaptability of the pore shape. Next, I demonstrate how the gasdermin species and the lipid composition determine the process of gasdermin pore formation. At last, I resolve the mechanism through which ninjurin-1 disrupts membranes during plasma membrane rupture, the terminal event of many cell-death processes.

Integrative Modeling of Cellular Dynamics: Applications to Viruses and Neurotransmission — •Mohsen Sadeghi — Freie Universität Berlin, Berlin, Germany

A comprehensive understanding of cellular processes requires a quantitative analysis of biomembrane dynamics in interaction with protein populations, within a model that integrates kinetics and protein structural information. This is crucial for deciphering and potentially manipulating complex biological pathways. In this work, we introduce a dynamic framework for modeling membranes and proteins [1-5], showcasing its large-scale applications. These include the first computational model of the human cytomegalovirus [6] and the simulation of synaptic vesicle docking. We highlight how large-scale mesoscopic simulations provide unprecedented insights into complex cellular dynamics, capturing spatiotemporal scales that are directly relevant to cell biology.

Hepatitis C Virus Infection Alters NK Cell Receptor Expression: A High-Dimensional Analysis — •Andrea Schneider — Heirich-Heine Universität Düsseldorf

Hepatitis C virus (HCV) infection influences the expression of receptors on natural killer (NK) cells, a crucial component of the innate immune system. Using fluorescent markers for flow cytometry measurements, receptor expression can be analyzed to identify differences between healthy individuals, recovered patients, and those with chronic infections. Due to the possibility of using many markers simultaneously in one measurement, algorithms for dimension reduction are necessary for the evaluation of flow cytometry data. These findings could provide a potential starting point for novel therapeutic approaches. A key focus of the talk is the application of t-SNE, a dimensionality reduction algorithm that visualizes high-dimensional data in two-dimensional scatterplots while preserving high-dimensional clustering. The analysis offers valuable insights into the cellular differences among the three patient groups and opens new perspectives for immunological research.

BP 3.10 Mon 12:15 H44

Activity enhanced shear-thinning of flexible linear polar polymers — •Arindam Panda[1], Roland G. Winkler[2], and Sunil P Singh[1] — [1]Indian Institute Of Science Education and Research, Bhopal, Madhya Pradesh, India — [2]Institute for Advanced Simulation, Forschungszentrum Jülich, Jülich, Germany

The rheological behavior of tangentially propelled flexible polymers in linear shear flow is investigated through computer simulations and compared with analytical predictions. Our study reveals a significant interplay between nonequilibrium active forces and shear-induced effects on the polymer's structural and dynamical properties. Polar activity enhances the shear-induced stretching along the flow direction while inducing compression in the transverse direction. This coupling leads to a pronounced shear-thinning response, where the viscosity decreases with increasing shear rate. In the high activity and shear limit, the polymer's behavior becomes largely independent of the active forces, with the shear flow predominantly driving the system's response. At asymptotically high shear rates, the system transitions to a regime where the polymer exhibits characteristics akin to passive polymers, with shear forces entirely overshadowing the influence of activity.

BP 3.11 Mon 12:30 H44

Patchy Particle Model for Biomolecular Condensates — •Devika Magan[1,2,3], Alena Taskina[1,4], Simon Dannenberg[1], and Stefan Klumpp[1,4] — [1]Institute for the Dynamics of Complex Systems, University of Goettingen, Friedrich-Hund-Platz 1, 37077 Goettingen, Germany — [2]Indian Institute of Science Education and Research Mohali, India — [3]Institute for Theoretical Physics, Heidelberg University, 69120 Heidelberg, Germany — [4]Max Planck School Matter to Life

Biomolecular condensates are formed via liquid-liquid phase separation (LLPS) of proteins and nucleic acids, driven by interactions between low-affinity binding sites. Computational studies of biomolecular condensates often use coarse-grained patchy particle models, representing proteins with a repulsive core and directional attractive patches. However, these simulations are typically limited by slow dynamics and struggle to capture the full range of material properties of fluid-like condensates. We present an enhanced patchy particle model to study the formation and dynamics of biomolecular condensates. By incorporating flexible patches and weak isotropic attractions between cores, our model preserves key equilibrium characteristics, including phase behavior and local structure, while significantly accelerating system dynamics. These modifications enable the simulation of larger, more complex systems previously inaccessible due to prohibitive relaxation times and provide a versatile tool for studying condensate dynamics.

BP 3.12 Mon 12:45 H44

Co-translational (polysome-protein) condensation — •Zhouyi He, Jens-Uwe Sommer, and Tyler Harmon — Leibniz Institute of Polymer Research , 01069, Dresden, Germany

Biomolecular condensates are ubiquitous in cells and play crucial roles in cellular regulation. These condensates typically form via liquid-liquid phase separation, where protein-protein interactions are crucial. However, how condensates interact with protein translation machinery is poorly studied. During translation, multiple ribosomes are simultaneously translating each mRNA forming a poly-ribosome structure (polysome), which resembles beads packed on a string. On one end of the mRNA, the ribosomes have only extruded the start of the nascent protein, and on the other end the ribosomes have a nearly finished pro-

tein. Nascent proteins from translating polysomes can interact with the finished proteins that make up the condensate (co-translational condensation). Using coarse-grained simulations, we show that the architecture of encoded proteins determines whether the polysome is adsorbed to the condensate surface or remains in the cytoplasm. Furthermore, we employ a reaction-diffusion model to analyze the time scales relevant to this process. Additionally, we model the potential cellular advantages of this phenomenon, including enhanced cellular response times, reduced noise in protein concentration, and facilitation of post-translational modifications. This work establishes a theoretical framework for co-translational condensation and highlights new functions for condensates in cells and offers promising directions for experimental validation.

Spatiotemporal organization of bacterial biofilm formation and functions — •Knut Drescher — Biozentrum, University of Basel, Basel, Switzerland

In nature, bacteria often live in three-dimensional communities termed biofilms, in which cells are attached to each other through an extracellular matrix. In this presentation, I will first introduce microscopy, image processing, and spatiotemporal transcriptome measurement techniques that enable us to monitor all individual cells in living biofilms. Based on these techniques, I will then show how we can identify the cell-cell interaction processes that determine the architecture development of biofilm microcolonies, across different species. I will then proceed to discuss how individual cells in biofilms coordinate their activities so that the biofilm community develops emergent functions, such as the predation of human immune cells, as well as the protection from viral predators. This talk will therefore shed light on the spatiotemporal development of bacterial communities, and the mechanisms underlying emergent functions of these communities.

BP 4.2 Mon 10:00 H46

Modelling the growth of biofilms on soft substrates — •Anthony Pietz[1], Uwe Thiele[1], and Karin John[2] — [1]Universität Münster, Münster, Germany — [2]Université Grenoble Alpes

Bacteria invade surfaces by forming dense colonies encased in a polymer matrix. Successful settlement of founder bacteria, early microcolony development and later macroscopic spreading of these biofilms on surfaces rely on complex physical mechanisms. Data show that on soft hydrogels, substrate rigidity is an important determinant for biofilm initiation and spreading. Using a thermodynamically consistent thin-film approach for suspensions on soft elastic substrates we investigate in silico the role of substrate rigidity in the osmotic spreading of biofilms. We show that on soft substrates spreading is considerably slowed down and may even be arrested depending on the biomass production rate. We find, that the slowing down of biofilm spreading on soft surfaces is caused by a reduced osmotic influx of solvent into the biofilm results from the coupling between substrate deformation and interfacial forces.

BP 4.3 Mon 10:15 H46

Dynamics of bacterial growth and colony development in heterogeneous mechanical landscapes — •Chenyu Jin[1] and Anupam Sengupta[1,2] — [1]Physics of Living Matter Group, Department of Physics and Materials Science, University of Luxembourg, 162 A, Avenue de la Faïencerie, L-1511, Luxembourg — [2]Institute for Advanced Studies, University of Luxembourg, Avenue de l'Université, L-4365, Esch-sur-Alzette, Luxembourg

Bacteria inhabit diverse confinements, experiencing different mechanical cues including surface stiffness and adhesion, friction and wettability [1]. Recent studies have revealed how local crowding and phenotypic noise impact bacterial growth and structural changes like the monolayer-to-multilayer transitions (MTMT)[2,3]. Yet how colonies proliferate in heterogeneous physical landscapes remain largely unknown [4]. Here we combine quantitative imaging and numerical modeling to compare the dynamics of colony growth within soft hydrogels with those in liquid media for different bacterial species. We find that the growth rate typically decreases across species, at both the colony and individual scales, while the critical area at the MTMT increases by an order of magnitude in the confined environment. An accompanying bioenergetic model offers mechanistic insights into the colony development in heterogeneous mechanical settings.

Capillary interactions organize bacterial colonies — •Ricard Alert[1,2,3], Matthew E. Black[4], Chenyi Fei[4,5], Ned S. Wingreen[4], and Joshua W. Shaevitz[4] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden — [2]Center for Systems Biology Dresden — [3]Cluster of Excellence Physics of Life, TU Dresden — [4]Princeton University — [5]Massachusetts Institute of Technology

Many bacteria inhabit hydrated environments like soil, textiles and agar hydrogels in the lab. In these environments, cells are surrounded by a water meniscus, and they experience capillary forces. I will show that capillary forces organize bacterial colonies, enabling cells to aggregate into densely packed nematic layers while still allowing them to slide past one another. Our collaborators developed an experimental apparatus that allows us to control bacterial collective behaviors by varying the strength and range of capillary forces. Our results suggest that capillary forces may be a ubiquitous physical ingredient in shaping microbial communities in partially hydrated environments.

BP 4.5 Mon 10:45 H46

CISS Effect in Bacterial Extracellular Electron Transfer — •Nir Sukenik[1], Mohamad El Naggar[1], Yossi Paltiel[2], Ron Naaman[3], and Lech Tomasz Baczewski[4] — [1]University of Southern California, Lis Angeles, CA, USA — [2]Hebrew University of Jerusalem, Jerusalem, Israel — [3]Weizmann Institute of Technology, Rehovot, Israel — [4]Polish Academy of Sciences, Warsaw, Poland

Electron transfer through chiral molecules is characterized by a coupling between the electron velocity and its spin through the Chirality Induced Spin Selectivity (CISS) effect. Since most biomolecules are homochiral, it was recently hypothesized that CISS underlies the highly efficient electron transfer observed in biological systems by reducing the probability of electron backscattering. A remarkable example of efficient long-distance electron transport in biology is the extracellular respiration of metal-reducing bacteria, where a pathway composed of multiheme cytochromes facilitates extracellular electron transfer (EET) from the cellular interior to external electrodes. Using conductive probe atomic force microscopy measurements of protein monolayers adsorbed onto ferromagnetic substrates, we show that electron transport is spin selective in two of the multiheme cytochromes, the membrane-associated decaheme MtrA and the tetraheme periplasmic STC. To assess the in vivo physiological impact of CISS, we also present evidence that the respiration of a different EET capable bacterium, depends on the magnetization direction of the underlying ferromagnetic electrode. Taken collectively, our results demonstrate the important role of spin in a biological mechanism essential to life.

BP 4.6 Mon 11:00 H46

Slower prior growth in E. coli confers a competitive advantage under carbon starvation — •Zara Gough[1], Hamid Seyed Allaei[1], Severin Schink[2], Elena Biselli[1], Sophie Brameyer[3], and Ulrich Gerland[1] — [1]Physics of Complex Biosystems, Physics Department, Technical University of Munich, 85748 Garching, Germany — [2]Department of Systems Biology, Harvard Medical School, 200 Longwood Ave, Boston, MA 02115, USA — [3]Microbiology, Faculty of Biology, Ludwig Maximilians University Munich, Martinsried, Germany

Bacteria spend much of their life cycle under nutrient limitation, competing for resources to survive. Recent research has quantitatively characterized the carbon starvation kinetics of E. coli in monoculture using two experimentally measurable parameters: the maintenance rate and the recycling yield. Building on this framework, we show that these same parameters can predict fitness changes when cultures with distinct prior growth rates are subjected to starvation in co-culture. We introduce an additional model that explores the interaction between intracellular energy reserves and extracellular medium energy during co-culture starvation, and accounts for different uptake rates resulting from prior growth rate. Using a bottom-up approach to modelling that is derived directly from bacterial physiology, our work extends the quantitative understanding of population dynamics in E. coli.

BP 5: Membranes and Vesicles I

BP 5.1 Mon 11:30 H46

In-Plane Correlations in Fluid Lipid Monolayers - Experiments and Molecular Dynamics Simulations — •Kay-Robert Dormann[1], Joshua Reed[1], Matej Kanduč[2], Benno Liebchen[1], and Emanuel Schneck[1] — [1]Institut für Physik kondensierter Materie, Technische Universität Darmstadt, Hochschulstr. 8, 64289 Darmstadt, Germany — [2]Department of Theoretical Physics, Jožef Stefan Institute, Jamova 39, SI-1000 Ljubljana, Slovenia

Biological membranes predominantly consist of fluid lipid phases featuring lateral mobility and a considerable disorder of their hydrocarbon chains. Langmuir monolayers of lipids at the air/water interface are versatile model systems for fundamental physicochemical and biophysical membrane investigations. Recent experimental studies utilizing grazing-incidence x-ray diffraction (GIXD) have probed the chain correlation peak in fluid phospholipid monolayers as a function of the lipids' lateral packing. However, interpretation of the peak characteristics with over-simplified models based, for example, on rod-like chains yields only limited insights.

Here, we perform molecular dynamics (MD) simulations of phospholipids in the same monolayer configuration and predict the diffraction patterns originating from the chain correlations for a rigorous comparison with the experimental ones. The MD simulations reproduce the peak characteristics and their dependence on lateral packing well. Moreover, the experimentally validated simulation trajectories contain comprehensive information on the underlying chain correlations.

BP 5.2 Mon 11:45 H46

Modelling Wave Propagation on Monolayers — •Philipp Zolthoff and Jan Kierfeld — TU Dortmund, Dortmund, Germany

Recent experimental advances have enabled precise studies of pressure wave propagation through monolayers at the air-water interface, triggered by embedded azobenzenes and light-induced trans-to-cis isomerization. This talk presents theoretical results, which show that fractional nonlinear wave equations of Lucassen type can describe wave propagation on monolayers quantitatively. The nonlinear differential wave equation includes fractional time derivatives, incorporates measured Langmuir isotherms and a dynamic second viscosity that depends on the local state of the monolayer.

BP 5.3 Mon 12:00 H46

Artificial Membranes Through Physical Vapor Deposition (PVD): Exploring the Lipid Rafts Model — •Nancy Gómez-Vierling[1], D.A. Saavedra[1], M.A. Cisternas[2], M. Soto-Arriaza[3], C. Shen[4], P. Huber[4], and U.G. Volkmann[1] — [1]Instituto de Física, Pontificia Univ. Católica de Chile, Santiago, Chile — [2]Escuela de Ingeniería Industrial, Univ. de Valparaíso, Santiago, Chile — [3]Facultad de Medicina y Ciencia, Univ. San Sebastian, Santiago, Chile — [4]DESY, Hamburg, Germany

Essential to life, cell membranes are currently modelled as functional microdomains known as lipid rafts. These cholesterol- and sphingolipid-enriched domains are fundamental for organizing and categorizing key cellular processes. This research explores the assembly of artificial membranes inspired by the lipid raft model using PVD. This solvent-free technique previously demonstrated in DPPC membranes, is now applied to mixtures of sphingomyelin, cholesterol, and DOPC to investigate the self-assembly of microdomains under controlled conditions. Optimizing parameters such as temperature, deposition time, and thickness enables the successful formation of thin films on silicon substrates. Preliminary FTIR and GISAXS analyses confirm molecular integrity after cholesterol and DOPC evaporation, while ongoing studies examine the desorption and thermal stability of these SLBs. This work advances our understanding of membrane physics and establishes a versatile platform for creating model membranes with potential applications in biotechnology and materials science. Acknowledgements: ANID Fellowships (DS, NGV); Puente UC 2024-25.

BP 5.4 Mon 12:15 H46

Structural and mechanical properties of lipid monolayers at the water-air interface — •Hyunyou Kim[1], Ivo Buttinoni[1], Laura Alvarez Frances[2], and Pantelis Mpourazanis[3] — [1]Institute of Experimental Physics of Condensed Matter, Heinrich-Heine University, Universitätsstr.1, 40225 Düsseldorf, Germany — [2]University of Bordeaux, CNRS, CRPP, UMR 5031, 33600 Pessac, France — [3]Fraunhofer IOSB, Gutleuthausstraße 1, 76275 Ettlingen, Germany

Lipid monolayers play a crucial role at air-water interfaces of body, such as in alveoli, where they regulate surface tension. When surface pressure increases, the interface transitions from liquid-expanded (LE) to liquid-condensed (LC) phases.

As experimental model, Dipalmitoylphosphatidylcholine (DPPC) and Cholesterol (Chol) are used. Langmuir-Blodgett trough monitors lipid monolayers during compression, while fluorescence microscopy visualizes the domains. Rheology is measured at various frequencies using an interfacial shear rheometer coupled with trough.

During compression, pure DPPC monolayers transition from LE to LC, with a plateau at surface pressure Π = 5-6 mN/m and collapse at Π = 60-65 mN/m. The domain shape changes from round to fractal. Adding Chol lowers the collapse pressure (Π = 45-50 mN/m) and eliminates the plateau when Chol exceeds 8.6 mol %. Rheology shows that Chol decreases surface viscosity and makes the monolayers more elastic at higher frequencies.

BP 5.5 Mon 12:30 H46

Study of Giant Unilamelar Vesicles' Fluidity in Microgravity Conditions — •Georgios Stogiannidis[1], Paulina Blair[1,3], Laura Alvarez[2], Thomas Voigtmann[1,3], and Ivo Buttinoni[1] — [1]Heinrich-Heine University, Düsseldorf, Germany — [2]Université de Bordeaux, Bordeaux, France — [3]Deutsche Zentrum für Luft- und Raumfahrt, Köln, Germany

In this study, we examine the effect of microgravity on the membrane fluidity of giant unilamellar vesicles (GUVs) made of DOPC and Cholesterol. GUVs are prepared using electroformation technique, during which a thin film of lipids is deposited on a conductive glass substrate while the application of AC electric field accelerates the swelling of the lipid film. We first study the fluidity of the vesicles over a range of DOPC/Cholesterol ratios using Fluorescence Recovery After Photobleaching (FRAP): a disk shaped area of the vesicle is bleached using a laser for a short amount of time and the fluidity is computed from the time of fluorescence-recovery time. The same fluidity also is investigated by means of fluorescence polarization anisotropy (FPA) technique, where the intensity of the sample's fluorescence emission is measured along two orthogonal polarization axes. The latter method can be implemented under microgravity conditions. We report a significant fluidity changes in microgravity conditions, where the vesicles display approximately 20% higher membrane fluidity compared to those measured on the ground. Our findings provide valuable insights on the cells' behavior in zero-gravity conditions and more specifically about the absorption of pharmaceuticals in the human body.

BP 5.6 Mon 12:45 H46

Translocation of vesicles through membrane-covered pores — •Nishant Baruah[1], Gerhard Gompper[1], Anil Kumar Dasanna[2], and Thorsten Auth[1] — [1]Theoretical Physics of Living Matter, Institute of Biological Information Processing and Institute for Advanced Simulation, Forschungszentrum Jülich, 52425 Jülich, Germany — [2]Department of Physical Sciences, Indian Institute of Science Education and Research (IISER) Mohali, Sector 81, Knowledge City, Mohali 140306, India

Apicomplexan parasites like Plasmodium, which transmits malaria, invade their host cells by translocating through a tight junction at the host plasma membrane. This process involves significant physical challenges, including the need for the parasite to deform its own membrane while squeezing through the tight junction and contending with the host membrane tension [1]. Here, we study as a model system the translocation of vesicles through membrane-covered pores driven by a contact interaction [2]. The calculations are performed using triangulated membranes and energy minimization. We predict stable translocation states for various vesicle- and host-membrane elastic properties and vesicle-to-pore size ratios. A finite-host membrane tension strongly suppresses pore translocation, which may explain protection against severe malaria in the Dantu blood group [3].

BP 6: Active Matter II (joint session BP/CPP/DY)

Time: Monday 15:00–17:00 Location: H37

BP 6.1 Mon 15:00 H37

Emerging cellular dynamics from turbulent flows steered by active filaments — Mehrana Nejad[1,4], Julia Yeomans[2], and •Sumesh Thampi[2,3] — [1]Department of Physics, Harvard University, Cambridge, MA 02138 — [2]The Rudolf Peierls Centre for Theoretical Physics, Parks Road, Oxford OX1 3PU, UK — [3]Department of Chemical Engineering, Indian Institute of Technology, Madras, Chennai, India 600036 — [4]School of Engineering and Applied Sciences, Harvard University, Cambridge, MA 02138, USA

Describing the mechanics of cell collectives and tissues within the framework of active matter, without resorting to the details of biology is an exciting area. We develop a continuum theory to describe the dynamics of cellular collectives, discerning the cellular force-generating active filaments from cells shape. The theory shows that active flows and straining part of the active turbulence can elongate isotropic cells, which form nematic domains. This is important as cell morphology is not only an indicator of diseases but it can affect the nucleus morphology, gene expression and other biochemical processes inside the cells. Our theory highlights the importance of distinguishing the roles of active filaments from cell shape and explains outstanding experimental observations such as the origin of cell-filament alignment patches. Further, we reconcile how the contractile forces generated by the cytoskeletal network makes the cells to exhibit flow behaviours similar to that of extensile active systems. Revealing the crucial role of activity and rheology to describe the dynamics of cellular layers, our study is in consonance with a number of experimental observations.

BP 6.2 Mon 15:15 H37

Defects in active solids: self-propulsion without flow — •Fridtjof Brauns[1], Myles O'Leary[2], Arthur Hernandez[3], Mark Bowick[1], and Cristina Marchetti[4] — [1]Kavli Institute for Theoretical Physics, Santa Barbara, USA — [2]Princeton University, Princeton, USA — [3]Leiden University, Leiden, the Netherlands — [4]University of California Santa Barbara, Santa Barbara, California 93106, USA

Topological defects are a key feature of orientational order and act as organizing centers of orientation fields. Self-propulsion of +1/2 defects has been extensively studied in active nematic fluids, where the defects are advected with the fluid through the flow field they generate. Here, we propose a minimal model for defect self-propulsion in a nematic active solid: a linear elastic medium with an embedded nematic texture that generates active stress and in turn is coupled to elastic strain. We show that such coupling gives rise to self-propelled +1/2 defects that move relative to the elastic medium by local remodeling of the nematic texture. This mechanism is fundamentally different from the fluid case. We show that this mechanism can lead to unbinding of defect pairs and stabilize +1 defects. Our findings might help explain how orientational order, e.g. of muscle fibers, is reconfigured during morphogenesis in solid-like tissues. For instance, motility and merging of +1/2 defects play a crucial role in setting up the body axis during Hydra regeneration.

BP 6.3 Mon 15:30 H37

Isovolumetric dividing active matter — Samantha R. Lish[1], Lukas Hupe[1], Ramin Golestanian[1,2], and •Philip Bittihn[1] — [1]Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — [2]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, Oxford OX1 3PU, United Kingdom

We introduce and theoretically investigate a minimal particle-based model for a new class of active matter where particles exhibit directional, volume-conserving division in confinement while interacting sterically, mimicking cells in early embryogenesis. We find that complex motion, synchronized within division cycles, displays strong collective effects and becomes self-similar in the long-time limit. Introducing the method of normalized retraced trajectories, we show that the transgenerational motion caused by cell division can be mapped to a time-inhomogenous random walk with an exponentially decreasing length scale. Analytical predictions for this stochastic process allow us to extract effective parameters, indicating unusual effects of crowding and absence of jamming. Robustness of our findings against desynchronized divisions, cell size dispersity, and variations in confinement hints at universal behavior. Our results establish an understanding of the complex dynamics exhibited by isovolumetric division over long timescales, paving the way for new bioengineering strategies and perspectives on living matter.

BP 6.4 Mon 15:45 H37

Tracking plankton-to-biofilm transition in phototrophic bacteria — •Anupam Sengupta — Physics of Living Matter Group, Department of Physics and Materials Science, University of Luxembourg, Luxembourg — Institute for Advanced Studies, University of Luxembourg, Luxembourg

Phototrophic bacteria commonly inhabit natural aquatic and marine ecosystems, exhibiting both motile and sessile lifestyles [1]. Yet, how and when they switch between the two states has remained unknown. Using quantitative imaging, AFM and mathematical modeling, we track the conditions and phenotypic changes across multiple generations in Chromatium okenii, a motile phototrophic purple sulfur bacterium [2]. Enhanced cell-surface adhesion together with changes in the cell shape and cellular mass distribution facilitate the motile-to-sessile shift. Our results, supported by cell mechanics model, establish a synergistic link between motility, mass distribution and surface attachment in promoting biofilm lifestyle. [1] T. Sommer et al., Geophys. Res. Lett. 44, 2017. [2] F. Di Nezio,.., & A. Sengupta, Plos one 19, e0310265, 2024.

BP 6.5 Mon 16:15 H37

How localized active noises influence the conformations and dynamics of semiflexible filaments — •Shashank Ravichandir[1], Jens-Uwe Sommer[1,2], and Abhinav Sharma[1,3] — [1]Leibniz-Institut für Polymerforschung, 01069 Dresden, Germany — [2]Technische Universität Dresden, 01069 Dresden, Germany — [3]Universität Augsburg, 86159 Augsburg, Germany

The structure and dynamics of active polymers have been recently studied in some detail. In these works all the monomers are considered to be active. However, in most biological systems non-equilibrium fluctuations manifest as activity only at isolated locations within the polymer. There have been only few studies of such polymers, in which the active monomers occur periodically along the polymer contour. We consider arbitrary active-passive copolymers and isolate the effects of the number and locations of active monomers on the conformational and dynamical properties of polymers. We use Langevin dynamics simulations to calculate the end-to-end distance, radius of gyration, and mean-squared displacement of such semiflexible filaments and classify the various states of these polymers based on their conformational properties. We also present preliminary results of polymers in which the location of active monomer moves dynamically along the chain contour. This is an idealized model of biopolymers such as DNA, during DNA transcription, and microtubules, which are driven by kinetic motors that traverse along its length.

BP 6.6 Mon 16:30 H37

Sequence-specific folding of partially active polymers — •Shibananda Das — Department of Physics, Indian Institute of Science, Bengaluru, India

Biological polymers like actin filaments and microtubules exhibit important physical properties due to their out-of-equilibrium behavior induced by ATP or GTP. In contrast, synthetic polymers rely on energy from their surrounding environment, often using local chemical, electrical, or thermal gradients to remain far from equilibrium. Theoretically, active polymers serve as minimal models for these systems, enabling systematic study of the competition between thermodynamic and active forces while they undergo conformational changes.

Using a combined analytical and numerical approach, we investigate an active polymeric chain composed of multiple self-avoiding units, representing good solvent condition in the absence of active forces. For partially active polymers without orientational constraints, we find that distribution of the active units in distinct sequences along the backbone can induce a significant collapse into folded, globular structures. Detailed analysis shows that this activity-dependent collapse is driven by a reduction in swim pressure of the monomers, linking the distribution of active forces along the polymer contour to its folded conformations.

BP 6.7 Mon 16:45 H37

Effect of interactions on the chemotactic response of active-passive chains — •Hossein Vahid[1], Jens-Uwe Sommer[1,2], and Abhinav Sharma[3] — [1]Leibniz-Institut für Polymerforschung, Dresden, Germany — [2]Technische Universität Dresden, Germany — [3]University of Augsburg, Augsburg, Germany

Living organisms, from single cells to populations, exhibit complex behaviors driven by the need to navigate toward favorable environments. These behaviors are often shaped by interactions within clusters or mixed populations, where collective dynamics play a crucial role in the characteristic properties of multicellular systems.

Chemotactic bacteria, found in diverse environments such as the gastrointestinal tract, plant surfaces, and aquatic ecosystems, demonstrate the significance of chemotaxis at the population level. While extensive research has focused on the properties of active polymers in spatially homogeneous activity fields, their behaviors in inhomogeneous fields remain less explored.

This study investigates the behavior of self-propelled polymers in activity gradients, emphasizing the effects of inter- and intra-chain interactions, such as steric and excluded volume effects, on chemotactic responses. These interactions give rise to distinct phases or collective behaviors that influence the stability and persistence of chemotaxis. Additionally, polymer density emerges as a critical factor impacting diffusion and the overall efficiency of chemotaxis. This work aims to study the dynamics of the active polymer populations in non-uniform environments systematically.

BP 7: Single Molecule Biophysics

Time: Monday 15:00–17:00 Location: H44

Invited Talk BP 7.1 Mon 15:00 H44

Single-molecule dynamic structural biology with Graphene Energy Transfer — •Philip Tinnefeld[1], Alan Szalai[1], Giovanni Ferrari[1], Lars Richter[1], Ingrid Tessmer[2], Andres Vera-Gomez[1], and Izabela Kaminska[1] — [1]Chemistry Department and Center for NanoScience, Ludwig-Maximilians-Universität München — [2]Rudolf Virchow Center, University of Würzburg, Würzburg

Obtaining structural information from single molecules is commonly associated with Fluorescence Resonance Energy Transfer that typically yields one distance between a fluorescent donor and an acceptor. Energy transfer to graphene with graphene-on-glass coverslips can extend the dynamic range to more than 30 nm. Based on the discovery that DNA can be placed vertically on graphene, we developed GETvNA (graphene energy transfer with vertical nucleic acids) that enables Angstrom precise visualization of DNA conformations and protein-DNA complexes. We envision that the alignment of DNA will additionally make it amenable to combined energy transfer and superresolution interrogation for dynamic structural biology.

BP 7.2 Mon 15:30 H44

Doubling the resolution of fluorescence-lifetime single-molecule localization microscopy with image scanning microscopy — •Niels Radmacher[1], Oleksii Nevskyi[1], José Ignacio Gallea[1], Jan Christoph Thiele[2], Ingo Gregor[1], Silvio O. Rizzoli[3,4], and Jörg Enderlein[1,4] — [1]Third Institute of Physics, Georg August University, Göttingen, Germany — [2]Department of Chemistry, University of Oxford, Oxford, UK — [3]Department of Neuro- and Sensory Physiology, University Medical Center Göttingen, Göttingen, Germany — [4]Cluster of Excellence - Multiscale Bioimaging: from Molecular Machines to Networks of Excitable Cells (MBExC),Göttingen, Germany

In this study, we integrate a single-photon detector array into a confocal laser scanning microscope, enabling the combination of fluorescence-lifetime single-molecule localization microscopy with image scanning microscopy. This unique combination delivers a twofold improvement in lateral localization accuracy for single-molecule localization microscopy (SMLM) and maintains its simplicity. Moreover, the addition of lifetime information from our confocal laser scanning microscope eliminates chromatic aberration, particularly crucial for achieving few-nanometre resolution in SMLM. Our approach is named fluorescence-lifetime image scanning microscopy iSMLM. And is demonstrated through dSTORM and DNA PAINT experiments on fluorescently labelled cells, showcasing both resolution enhancement and fluorescence-lifetime multiplexing capabilities.

BP 7.3 Mon 15:45 H44

Two-color single-molecule coincidence detection for the analysis of biological processes and high-affinity bi-molecular binding — •Benno Schedler[1], Olessya Yuknovets[1], Alida Meyer[1], Lennart Lindner[1], and Jörg Fitter[1,2] — [1]RWTH Aachen University, I. Physikalisches Institut (IA), Aachen, Germany — [2]FZ Jülich, ER-C-3, Jülich, Germany

Life on the molecular scale is based on a versatile interplay of biomolecules, a feature that is relevant for the formation of macromolecular complexes. Fluorescence based two-color coincidence detection is widely used to characterize molecular binding and was recently improved by a brightness-gated version which gives more accurate results [1]. We developed and established protocols which make use of coincidence detection to quantify binding fractions between interaction partners labeled with fluorescence dyes of different colors. Since the applied technique is intrinsically related to single molecule detection, the concentration of diffusing molecules for confocal detection is typically in the low pico-molar regime. This makes the approach a powerful tool for determining bi-molecular binding affinities, in terms of KD-values, in this regime. By measuring the affinity at different temperatures, we were able to determine thermodynamic parameters of the binding interaction. The results show that the ultra-tight binding is dominated by entropic contributions [2].

Maximizing Flavor: Leveraging Nano-biophysical Methods in Food Perception and Formulation Research — •Melanie Koehler — Leibniz-Institute for Food Systems Biology at the Technical University of Munich, Lise Meitner-Straße 34, 85354 Freising, Germany — TUM Junior Fellow at the Chair of Nutritional Systems Biology, Technical University of Munich, Lise-Meitner-Straße 34, 85354 Freising, Germany

The food industry faces the challenge of creating healthier products with less salt, sugar, fat, and calories while maintaining flavor and consumer satisfaction. Flavor perception, influenced by taste, smell, texture, and individual factors, requires a deeper understanding to drive innovation. This research highlights the use of nano-biophysical techniques, particularly bio atomic force microscopy (AFM), to explore taste and texture at the molecular level. AFM provides nanoscale insights into food components' interactions with sensory receptors (taste- and mechanoreceptors), and their role in flavor release. For instance, AFM revealed the binding of a bitter peptide (VAPFPEVF) to its receptor (TAS2R16) without triggering downstream signaling. It also sheds light on oral texture perception, which remains underexplored at the biomolecular level [1]. By combining AFM with biochemical assays, molecular simulations, and human sensory evaluations, this research bridges objective measurements and subjective flavor experiences. These findings offer new approaches to designing healthier, sensory-appealing foods, addressing critical health and nutrition challenges. [1] Koehler, M, et al. Nature Food (2024): 1-7.

BP 7.5 Mon 16:30 H44

Label-Free Photothermal Infrared Correlation Spectroscopy — •Arthur Markus Anton and Frank Cichos — Leipzig University, Peter Debye Institute for Soft Matter Physics, Linnéstr. 5, 04103 Leipzig

Correlation spectroscopy is an indispensable method in modern life science. It allows for retrieving analyte properties in solution like it's concentration or diffusion coefficient, and thus enables to calculate the hydrodynamic radius of proteins or the viscosity of membranes, for instance. Common techniques are based on fluorescence or scattering, such as fluorescence correlation spectroscopy or dynamic light scattering respectively, and therefore need fluorescent labeling of analytes or lack of molecular specificity.

In this contribution we present a novel spectroscopic correlation technique on the basis of pumping with IR light but probing by means of visible light. The absorption of IR light is highly specific and allows us for *label-free* addressing of specific vibrational modes within the analyte molecules via the particular pump wavelength. Upon absorption, energy is dissipated and transferred into heat which alters the refractive index of the medium surrounding the absorbing species. This *transient* refractive index change is then probed by means of visible light providing a similar probe focal volume as conventional correlation spectroscopy techniques. Consequently, on the basis of IR pumping and visible probing we calculate the analyte's concentration and diffusion coefficient.

BP 7.6 Mon 16:45 H44

Single-protein optical holography — •Jan Christoph Thiele[1,2], Emanuel Pfitzner[1,2], and Philipp Kukura[1,2] — [1]Kavli Institute for Nanoscience Discovery, University of Oxford, UK — [2]Department of Chemistry, University of Oxford, UK

Light scattering by nanoscale objects is a fundamental physical property defined by their scattering cross-section and thus polarizability. Over the past decade, a number of studies have demonstrated single-molecule sensitivity by imaging the interference between scattering from the object of interest and a reference field. This approach has enabled mass measurement of single biomolecules in solution owing to the linear scaling of image contrast with molecular polarizability. Nevertheless, all implementations so far are based on a common-path interferometer and cannot separate and independently tune the reference and scattered light fields, thereby prohibiting access to the rich toolbox available to holographic imaging. Here we demonstrate comparable sensitivity using a non-common-path geometry based on a dark-field scattering microscope, similar to a Mach-Zehnder interferometer. We separate the scattering and reference light into four parallel, inherently phase-stable detection channels, delivering a five orders of magnitude boost in sensitivity in terms of scattering cross-section over state-of-the-art holographic methods. We demonstrate the detection, resolution and mass measurement of single proteins with mass below 100 kDa. Separate amplitude and phase measurements also yield direct information on sample identity and experimental determination of the polarizability of single biomolecules.

Ferroelectric Microelectrodes for Hybrid Neuroelectronic Systems — •Maximilian T. Becker[1,2], Roland Thewes[3], and Günther Zeck[4] — [1]Department of Embedded Systems, Hahn-Schickard, Freiburg, Germany — [2]Faculty of Engineering, University of Freiburg, Freiburg, Germany — [3]Chair of Sensor and Actuator Systems, TU Berlin, Berlin, Germany — [4]Institute of Biomedical Electronics, TU Wien, Vienna, Austria

Direct electrical interfacing of semiconductor chips with individual neurons and neural networks forms the basis for a systematic assembly and investigation of hybrid neuroelectronic systems with future applications in information technology and biomedicine. The neuroelectronic interface is realized via microelectrodes to bidirectionally transmit electrical signals between neurons and the semiconductor chip. Here, we introduce the concept of ferroelectric microelectrodes and discuss the physics of ferroelectric interfaces in neuroelectronic applications. As an example, we present neural recordings from retinal ganglion cells (RGCs) interfaced with a ferroelectric complementary metal-oxide-semiconductor microelectrode array (CMOS-MEA) and discuss the results in detail.

BP 8.2 Mon 15:15 H46

Highly sensitive, specific and label-free detection of SARS-CoV-2, Influenza A and RSV proteins via surface plasmon resonance technique using the biofunctionalization with 1 nm thick carbon nanomembranes — •Ghazaleh Eshaghi[1], David Kaiser[1], Hamid Reza Rasouli[1], Rania Ennaciri[1], Martha Frey[1], Christof Neumann[1], Dominik Gary[2], Tobias Fischer[2], Katrin Frankenfeld[2], and Andrey Turchanin[1] — [1]Institute of Physical Chemistry, Friedrich Schiller University Jena, 07743 Jena, Germany — [2]Forschungszentrum für Medizintechnik und Biotechnologie (fzmb) GmbH, 99947 Bad Langensalza, Germany

Accurate and rapid detection of respiratory viruses like SARS-CoV-2, Influenza A and RSV is crucial for improving global health outcomes. We present a novel surface plasmon resonance (SPR) platform using a biofunctionalized 1 nm-thick carbon nanomembrane (CNM) for enhanced viral protein detection. The azide-modified CNM (N3-CNM) enables covalent antibody binding, ensuring selective immobilization of target proteins. Our platform achieves equilibrium dissociation constants (KD) of 570 * 30 pM and 22 * 3 pM for SARS-CoV-2 nucleocapsid and spike proteins, with detection limits (LODs) of ~190 pM and ~10 pM, respectively. For Influenza A and RSV, KD values are 86 * 4 pM and 3 * 0.2 pM, with LODs of ~90 pM and ~2 pM. Multiplexed detection with no cross-reactivity supports rapid, accurate point-of-care diagnostics. Validation with nasopharyngeal swabs confirms a LOD of ~40 pM for SARS-CoV-2 spike protein, highlighting CNMs' promise in infectious disease diagnostics.

BP 8.3 Mon 15:30 H46

Superselective multivalent client recruitment in biomolecular condensates — •Xiuyang Xia and Erwin Frey — Ludwig-Maximilians-Universität München

Biomolecular condensates (BMCs) are membraneless organelles formed via liquid-liquid phase separation, playing a crucial role in organizing cellular functions by selectively concentrating specific molecules. In this talk, I will present a new theoretical framework that models multivalent client recruitment in valence-limited, multicomponent systems like BMCs. We uncover how enthalpic and entropic factors interplay under valence constraints to enable switch-like recruitment and precise compositional regulation.

This work advances our understanding of the principles governing BMC composition and highlights the broader significance of multivalency in biological systems, offering insights into cellular organization and potential therapeutic applications.

BP 8.4 Mon 15:45 H46

What is the structure of a biomolecular condensate? — •Charlotta Lorenz[1,2], Teagan Bate[1], Takumi Matsuzawa[1], Kaarthik Varma[1], Sully Bailey-Darland[1], George Wang[1], Dana Matthias[1], Harsha Koganti[2], Nicola Galvanetto[2], Matti Valdimarsson[2], Aleksander Rebane[3], Etienne Jambon-Puillet[4], Ben Schuler[2], and Eric R. Dufresne[1] — [1]Cornell University, Ithaca, NY, USA — [2]University of Zurich, Zurich, Switzerland — [3]New York University Abu Dhabi, Abu Dhabi, United Arab Emirates — [4]École Polytechnique Paris, Paris, France

Biomolecular condensates are important for a variety of cellular functions, such as biochemical regulation, structural organization, and RNA metabolism. While the properties and physiology of these condensates depend on their structure, this important aspect has received little experimental consideration. On the other hand, recent simulations of disordered proteins with interactions based on the sticker-and-spacer suggest fascinating structures in the bulk and surface of condensates. We aim to reveal the structure of biomolecular condensates using X-ray scattering. Here, we will present results for a simple model system and apply our approach to the structure of condensates made of disordered proteins. We particularly consider the change in condensate structure due to small molecules.

BP 8.5 Mon 16:00 H46

Encoding how shear stress during gelation boosts the stiffness of collagen networks — •Pavlik Lettinga[1,2], Lens Dedroog[2], Olivier Deschaume[2], Yovan de Coene[2], Carmen Bartic[2], Erin Koos[2], and Mehdi Bouzid[3] — [1]Forschungszentrum Jülich — [2]KU Leuven — [3]Université Grenoble Alpes

Collagen is one of the main building blocks of the mammalian extracellular matrix, due to its ability to form tough structures with a wide variety of non-linear mechanical properties allowing it to support multiple tissue types. However, the mechanical properties of collagen gels have been extensively studied under static conditions, whereas in nature gelation will mostly take place in the presence of flow. Here we show how the elastic modulus of collagen hydrogels can be increased up to an order of magnitude by applying a stress ramp at a well-defined moment during gelation. Where the first stress block induces most of the final strain and alignment, sequential increases in stress cause a dramatic increase of the modulus. This high modulus is preserved by keeping the high stress until the gel is fully matured. Coarse-grained simulations of a model gel system show that that the microscopic mechanism of inducing high stiffness is due to formation of extra cross bridges and could be very generic. Thus, we not only show that the true non-linear capabilities of biomaterials are tenfold higher than previously assessed, but also provide insight into in vivo structure formation of collagen and potentially other (bio-)polymers.

Invited Talk BP 8.6 Mon 16:15 H46

In situ control of cells and multicellular structures at the microscale by two-photon lithography — •Christine Selhuber-Unkel — Heidelberg University, IMSEAM, Heidelberg, Germany

In vivo, cells and multicellular assemblies often experience strong confinement by their surrounding tissue environment, particularly in cancer. Thus, replicating these confined environments in situ is essential for investigating their impact on cellular systems. Using two-photon lithography, we printed structures directly within and around multicellular assemblies. For example, we fabricated dome-shaped confinements with micrometer-scale openings to encapsulate cancer spheroids. This enabled us to study how confinement influences cancer cell migration and spheroid behavior. Our findings revealed that confinement slows cell migration and alters actin dynamics. In addition, in situ printed structures can also directly interfere with migrating cellular assemblies. Additionally, elastic structures can be created to mechanically stimulate cells, offering further control over cellular behavior. Therefore, two-photon lithography proves to be a powerful tool for manipulating the growth, migration, and morphology of live cells, making it particularly useful for exploring how changing physical microenvironment in situ affect cell responses.

BP 9: Biomaterials, Biopolymers and Bioinspired Functional Materials II (joint session CPP/BP)

Time: Monday 17:00–18:00 Location: H46

BP 9.1 Mon 17:00 H46

Polymer Assisted Condensation and Heterochromatin — •Jens-Uwe Sommer — Leibniz-Institut für Polymerforschung Dresden (IPF), Hohe Straße 6, 01069 Dresden, Germany — TU Dresden, Insitut für Theoretische Physik, Zellescher Weg 17, D-01069 Dresden, Germany

Many biomolecular condensates are formed through the co-condensation of proteins and polynucleotides. In most cases, the proteins that constitute the majority of the condensate exhibit a miscibility gap in aqueous solution at elevated concentrations in vitro. Recently, we published the theory of Polymer-Assisted Condensation (PAC), which predicts the formation of the condensate within the

polymer's volume of gyration, where interactions with the three-dimensional conformation of the polymer trigger the phase transition of the protein component [1]. A key feature of these liquid condensates is their robustness against changes in parameters, as well as the dominant role played by the condensation free energy of the protein component. The formation and properties of heterochromatin, a genetically silenced region of eukaryotic chromosomes, can be explained by PAC, which resolves several issues present in previously published theories. Recently, we developed a field-theoretic approach to PAC to better understand the adsorption and desorption scenarios of heterochromatin at the nuclear lamina.

How specific binding induces sol-gel transitions and liquid-liquid phase separation in RNA/protein solutions: Coarse-grained simulations versus Semenov-Rubinstein Theory — •Xinxiang Chen, Jude Ann Vishnu, Pol Besenius, Julian König, and Friederike Schmid — Johannes Gutenberg-University, Mainz, Germany

Liquid-liquid phase separation plays a central role in cellular organization, including RNA splicing. RNA-protein interactions are crucial to these processes. A key factor in controlling the phase behavior of RNA-protein systems is the sequence of binding and neutral domains. Using molecular dynamics simulations, we investigate phase transitions in RNA-protein solutions that are driven solely by specific binding interactions. The model omits nonspecific interactions including electrostatic interactions. We show that specific binding interactions induce a percolation transition with double reentrant behavior without phase separation, if the neutral linker size is long. Comparing our results with the two-component Rubinstein-Semenov theory, we find that the theory qualitatively reproduces the phase diagram of the percolation transition and the impact of the neutral domains. Phase separation is observed when reducing the neutral linker size in an asymmetric system, resulting in a closed-loop phase diagram. We also study the effect of modulating the sequence and find that blockiness of sticker sites introduces microstructure in the dense liquid phase. These insights enhance our understanding of how specific binding and domain arrangement regulates condensate formation in RNA-protein systems.

BP 9.3 Mon 17:30 H46

Model particles to study interaction of microplastic particles — •Kai Gossen, Andreas Fery, and Günter Auernhammer — IPF Dresden, Dresden, Germany

Microplastic in the environment is typically coated by natural organic matter forming an ecocorona. We present an approach to model ecocorona on particles with well-defined polymers, synthetic and derived from natural polymers. Polystyrene particles were coated with fluorescent polyelectrolyte multilayer systems, PS(Chitosan/Hyaluronic acid) and PS(Poly(dimethyldiallylammonium chloride) /Polystyrene sulfonate) by the layer-by-layer method. Systems with 2, 4 and 6 bilayers were synthesized. The second layers were fluorescently labelled with SNARF conjugated dextran.

It was found that zeta potentials of the PS(Chi/HS)2/4/6 systems assume values (-20 mV to -35 mV) that are similar to those of PS-ecocorona particles (-40 mV to -5 mV). The pH-dependent fluorescence of particle suspensions and individual particles were measured at pH values between pH 3 and pH 8. A well measurable pH dependence between pH 4.5 and 8 for the PS(Chi/HS) systems and the PS(PDADMAC/PSS) system could be measured. The system could serve to selectively study effects of surface properties of ecocorona coated particles such as surface stiffness or zeta potential.

BP 9.4 Mon 17:45 H46

Microgels for Enhanced Adsorption of Endothelial Cells on Artificial Networks — •Souraj Mandal[1], Anna Fritschen[2], Alina Filatova[3], and Regine von Klitzing[1] — [1]Soft Matter at Interfaces, Department of Physics, Technical University of Darmstadt, Darmstadt 64289, Germany — [2]BioMedical Printing Technology, Department of Mechanical Engineering, Technical University of Darmstadt, 64289 Darmstadt, Germany — [3]Stem Cell and Developmental Biology, Technical University of Darmstadt, 64287 Darmstadt, Germany

Three-dimensional cellular models hold great promise for drug testing, but their success relies on maintaining a controlled supply of oxygen and nutrients. Artificial vascular networks aim to mimic blood vessel functions, yet ensuring robust endothelial cell (EC) attachment remains a significant challenge. In this study, we designed a mediator between artificial network surfaces and ECs using Poly(N-isopropylacrylamide) (PNIPAM) microgels (MGs) that remain mechanically stable in nutrient solutions. Charged MGs were synthesized and tested for adhesion on plasma-treated model surfaces. The microgel-coated substrates were exposed to cell static culture media and under defined flow. Atomic force microscopy (AFM) confirmed stable adhesion of MG particles before and after exposure. Initial experiments explored EC attachment on positively and negatively charged MG surfaces, followed by mechanical property characterization. The MG coatings were biofunctionalized with integrin-recognized ligands to enhance EC adhesion and proliferation further.

BP 10: Focus Session: Nonlinear Dynamics in Biological Systems I (joint session DY/BP)

Nonlinear dynamics play a central role for biological systems to achieve remarkable complexity and adaptability. They underlie processes where small changes cascade into large effects, critical thresholds drive transitions, and feedback mechanisms maintain intricate balances. Biological systems are often far from equilibrium, exhibiting behaviors shaped by competing forces, stochastic fluctuations and emergent behavior. From the amplification of sensory signals near bifurcation points to the development of turbulence, concepts from nonlinear dynamics provide a unifying framework for studying patterns, stability, and collective behavior in living systems. This focus session explores the richness of nonlinear dynamics across biological scales, from molecular circuits to population-level phenomena, spanning vastly different fields from cardiac dynamics, embryogenesis and cell motility to active fluids, condensates and origin of life. Through theoretical models, experimental insights, and computational approaches, the talks illustrate how nonlinear-dynamics principles unravel the mechanisms driving function and complexity in biology, offering new perspectives across disciplines.

Organized by Philip Bittihn (Göttingen), Stefan Klumpp (Göttingen), and Carsten Beta (Potsdam)

Time: Tuesday 9:30–12:30 Location: H43

Invited Talk BP 10.1 Tue 9:30 H43

Robust signal amplification and information integration via self-tuned proximity to bifurcation points — •Isabella Graf — Developmental Biology Unit & Theory Transversal Theme, EMBL Heidelberg, Germany

Many living systems demonstrate exquisite sensitivity to small input signals. A tempting hypothesis is that these systems operate close to bifurcation or critical points, where the system's response exhibits a diverging susceptibility to the control parameter and small signals are amplified into a large collective response. A common concern, however, is that proximity to such points requires fine-tuning of parameters, which seems impossible for noisy biological systems. Based on several distinct sensory systems, we have investigated a feedback motif that robustly maintains these systems close to their respective bifurcation point. The key ingredient is that the collective response feeds back onto the control parameter. To illustrate this idea, I will mention several examples ranging from snake thermosensing to mammalian hearing and discuss the functional benefits associated with being near-critical.

BP 10.2 Tue 10:00 H43

Exceptional Points and Stability in Nonlinear Models of Population Dynamics having PT symmetry — •Alexander Felski — Max Planck Institute for the Science of Light, Erlangen, Germany

Nonlinearity and non-Hermiticity, for example due to environmental gain-loss processes, are a common occurrence throughout numerous areas of science. For the latter, parity-time-reflection (PT) symmetry has played an eminent role in understanding exceptional-point structures and phase transitions in these systems. Yet their interplay has remained by-and-large unexplored. We analyze models governed by the replicator equation of evolutionary game theory and related Lotka-Volterra systems of population dynamics. These foundational nonlinear models offer a broad platform for non-Hermitian theory beyond physics. In this context we study the emergence of exceptional points in two cases: (a) when the governing symmetry properties are tied to global properties of the models, and, in contrast, (b) when these symmetries emerge locally around stationary states–in which case the connection between the linear non-Hermitian

model and an underlying nonlinear system becomes tenuous. We outline further that when the relevant symmetries are related to global properties, the location of exceptional points in the linearization around coexistence equilibria coincides with abrupt global changes in the stability of the nonlinear dynamics. Exceptional points may thus offer a new local characteristic for the understanding of these systems.

BP 10.3 Tue 10:15 H43

Pattern selection and the route to turbulence in polar active fluids — Henning Reinken[1], Sebastian Heidenreich[2], •Markus Bär[2,3], and Sabine Klapp[3] — [1]OVGU Magdeburg, Germany — [2]Physikalisch-Technische Bundesanstalt, Germany — [3]TU Berlin, Germany

Active fluids, such as suspensions of microswimmers, are well known to self-organize into complex spatio-temporal flow patterns. An intriguing example is mesoscale turbulence, a state of dynamic vortex structures exhibiting a characteristic length scale. Here, we employ a minimal model for the effective microswimmer velocity field to explore how the turbulent state develops from regular, stationary vortex patterns when activity is increased. First, we demonstrate analytically that the system develops a stationary square vortex lattice in the absence of nonlinear advection. Subsequently, we perform an extended stability analysis and uncover a linear instability, above which the square vortex lattice becomes unstable. In numerical simulations, we confirm that this instability is predictive for the unset of turbulence. In addition, an extended region of hysteresis where turbulence and a stable vortex lattice coexist, is found Reference: H. Reinken, S. Heidenreich, M. Bär, S. Klapp, New J. Phys. 26 063026 (2024).

BP 10.4 Tue 10:30 H43

Likelihood-based inference for heterogeneous motile particle ensembles — •Jan Albrecht[1], Cristina M. Torres[1], Carsten Beta[1], Manfred Opper[2,3,4], and Robert Grossmann[1] — [1]Institute of Physics and Astronomy, University of Potsdam, 14476 Potsdam, Germany — [2]Faculty of Electrical Engineering and Computer Science, Technische Universität Berlin, 10587 Berlin, Germany — [3]Centre for Systems Modelling and Quantitative Biomedicine, University of Birmingham, B15 2TT, United Kingdom — [4]Institute of Mathematics, University of Potsdam, 14476 Potsdam, Germany

The inherent complexity of biological agents often leads to motility behavior that appears to have random components. Robust stochastic inference methods are therefore required to understand and predict the motion patterns from time discrete trajectory data provided by experiments. In many cases second-order Langevin models are needed to adequately capture the motility. Additionally, population heterogeneity needs to be taken into account when analyzing data from multiple individual organisms. We present a maximum likelihood approach to infer stochastic models and, simultaneously, estimate the heterogeneity in a population of motile active particles from discretely sampled trajectories. To this end we propose a new method to approximate the likelihood for nonlinear second order Langevin models. We demonstrate that our approach outperforms alternative methods for heterogeneity estimation, especially for short trajectories, while also providing a measure of uncertainty for the estimates. We use the approach to investigate population heterogeneity in systems of ameboid cells.

BP 10.5 Tue 10:45 H43

Surviving the first "winter": Protocells with polymerization reactions protects against environmental fluctuations — •Xi Chen, Jens-Uwe Sommer, and Tyler Harmon — Leibniz Institute of Polymer Research, Dresden, Germany

The origin of life has been a long standing question with various hypotheses describing the emergence of the first protocells. Phase separated condensates are promising candidates for protocells because they are compartments that enrich specific polymers and host nonequilibrium reactions that leads to growth and division. However, the ability of protocells to survive in an environment that has large fluctuations, such as temperature and composition, is poorly understood. We show with a mean-field model that condensates formed by polymers which undergo nonequilibrium polymerization/depolymerization reactions exhibit significant robustness to large environmental fluctuations.

This robustness occurs when the nonequilibrium polymerization reactions are faster inside condensate phases than outside. The first condensate does not form until environmental factors lead to strong enough reactions that polymers long enough to phase separate form. The effects of nonequilibrium polymerization is then fully realized because a condensate exists. From here, the condensate does not dissolve until the nonequilibrium reactions are diminished to significantly below when the condensate formed. Altogether, this forms a hysteretic loop with respect to the environmental factors that drive nonequilibrium reactions. We show this hysteretic loop prevents protocells from dying from environmental fluctuations.

BP 10.6 Tue 11:00 H43

How inter-particle interaction affects two species transport in nano-channels — •Wolfgang Bauer — Dept. of Internal Medicine I, UKW, Würzburg, Germany

Channel transport mechanisms of multiple species is essential for cell physiology and nanotechnology. Here, we present a model maintaining spatial correlations of two species, moving away from mean field approaches. The spatial occupations of the channel give the state space, where local flux and entropy production determine channel transport and its thermodynamic efficiency. Optimal transport coupling between species occurs in an attractive empty channel and strong repulsive forces between particles of the same species. This confines state space to a circular topology with concentration gradients of the two species acting as thermodynamic driving forces in series. For opposing gradients, the species with the stronger gradient produces positive entropy, while the other negative entropy. Attenuating the repulsive force within one species and maintaining that of the other adds a bypass path on the circular topology in state space. This enables a leak flow of the less repulsive species parallel to its gradient, generating local positive entropy on the bypass. For a certain range of opposing gradients, both species can produce positive overall entropy simultaneously. However, the rectifying potential of the concentration gradient of the species with bypass option is diminished, i.e. it cannot rectify flow of the other species above a threshold of the latter's opposing gradient. Vice versa the flow of the species with bypass option may always be rectified parallel to the concentration gradient of the other.

Beyond the connectionist view: (De-)synchronizing neural networks via cell-intrinsic dynamics — •Susanne Schreiber — Humboldt-Universität zu Berlin, Institute for Theoretical Biology, Berlin, Germany

Neural computation is thought to arise from the connectivity among neurons. Accordingly, we are often more than happy to ignore seemingly unimportant and potentially overwhelming biological detail, for example, related to the properties of the neurons themselves. In this talk, however, I will highlight how cell-intrinsic dynamics, namely the biophysics of action-potential generation, can have a decisive impact on network behaviour. Recent work of my lab shows that, among regularly firing neurons, the somewhat unattended homoclinic type (characterized by a spike onset via a saddle homoclinic orbit bifurcation) particularly stands out: First, spikes of this type foster specific network states - synchronisation in inhibitory and splayed-out/frustrated states in excitatory networks. Second, homoclinic spikes can be easily induced in by changes in a variety of physiological parameters (like temperature, extracellular potassium, or dendritic morphology). As a consequence, small changes in these parameters can suffice to induce drastic switches in network states. I will discuss functional consequences of homoclinic spikes for the design of pattern-generating motor circuits in Drosophila as well as for mammalian pathologies like febrile seizures. Our work predicts an interesting role for homoclinic action potentials as an integral part of brain dynamics in both health and disease.

BP 10.8 Tue 12:00 H43

Transient spatiotemporal chaos in cardiac excitable media — •Melvin Dix[1,2], Thomas Lilienkamp[1,3], Stefan Luther[1,4,5], and Ulrich Parlitz[1,2,5] — [1]Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — [2]Institute for the Dynamics of Complex Systems, Georg-August-Universität Göttingen, Göttingen, Germany — [3]Faculty for Applied Mathematics, Physics, and General Science, Computational Physics for Life Science, Nuremberg Institute of Technology Georg Simon Ohm, Nürnberg, Germany — [4]Institute of Pharmacology and Toxicology, University Medical Center Göttingen, Göttingen, Germany — [5]German Center for Cardiovascular Research (DZHK), Partner Site Göttingen, Göttingen, Germany

Life-threatening cardiac arrythmia such as ventricular fibrillation have been linked to spatiotemporal chaotic dynamics governed by scroll or spiral waves. It has been observed in vivo and in vitro that these dynamics can be transient, e.g. abruptly stop. Using simulations with different numerical models we investigate the effects of factors such as heterogeneities, motivated by the complexity of the heart. We show that these perturbations can (significantly) prolong the duration of chaotic transients and may also lead to persistent chaos or stable periodic wave patterns [1].

[1] Melvin Dix et al. Physical Review E 110(4), 044207 (2024).

BP 10.9 Tue 12:15 H43

Nonlinear dynamics of heart and brain — •Irene Pellini[1,2], Simon Bauer[1], Johannes Zierenberg[1,3], Philip Bittihn[1,3], and Viola Priesemann[1,3] — [1]Max Planck Institute for Dynamics and Self Organisation, Göttingen, Germany — [2]Max Planck School Matter to Life, Heidelberg, Germany — [3]Institute for the Dynamics of Complex Systems, University of Göttingen, Germany

The core function of the heart and brain arises from the coordinated interaction of their cells. Both organs rely on excitable units – cardiomyocytes and neurons – that propagate electrical signals when a specific threshold is exceeded. Despite

this similarity, the two organs exhibit opposed collective behavior due to marked differences in intercellular dynamics and network topology. In the heart, localized electrical connectivity through reciprocal gap junctions generates local synchronization and traveling waves, ensuring efficient pumping function with low entropy. In the brain, long-range connectivity via delayed, non-reciprocal chemical synapses promotes asynchronous dynamics with high entropy, supporting information processing.

Using coupled FitzHugh-Nagumo oscillators, we showcase that characteristic non-linear dynamics for the heart and brain can be related to the network structure, which places both systems on opposite sides of a synchronization phase transition. Crossing this phase transition would lead to pathological conditions, e.g., heart arrhythmia or brain seizures, quantifiable via entropy measures. Our joint view on heart and brain dynamics may foster new perspectives on the function and pathology of both organs.

BP 11: Cytoskeleton

Time: Tuesday 9:30–11:30 Location: H44

Invited Talk BP 11.1 Tue 9:30 H44

Network connectivity determines the mechanisms responsible for cytoskeletal elasticity — •Martin Lenz — Université Paris-Saclay, CNRS, LPTMS, 91405, Orsay, France — PMMH, CNRS, ESPCI Paris, PSL University, Sorbonne Université, Université Paris-Cité, F-75005, Paris, France

Much of the cell's mechanics is dictated by the properties of its cytoskeleton, a dynamic collection of semiflexible filaments. Here we review both old and new results on the emergence of its large-scale elasticity from the filaments' individual mechanical properties. We emphasize the role of the network's connectivity in determining the underlying physical mechanism. At high connectivity or under high stress, the tensile strength of the filaments dominate. Moderately coordinated networks, on the other hand, are governed by the filaments' bending elasticity. Finally, we discuss the very low coordination of branched actin networks, and argue that it implies that interfilament contacts play a major role in its response. This makes the mechanics of these networks analogous to that of a ball of unspun sheep's wool under compression.

BP 11.2 Tue 10:00 H44

Buckling action of molecular motors damages microtubules beyond self-repair — •Shweta Nandakumar[1], Jonas Bosche[1], Morgan Gazzola[2], Mirko Wieczorek[1], Mona Grünewald[1], Manuel Thery[2], Reza Shaebani M[1], Ludger Santen[1], Stefan Diez[3], and Laura Schaedel[1] — [1]Center for Biophysics, Saarland University, Germany — [2]IPGG, Paris, France — [3]B-CUBE,TUD Dresden. Germany

Microtubules (MTs) are rigid, hollow biopolymers that constitute a key component of the cytoskeleton, essential for cellular processes such as mitosis, intracellular transport, and migration. Despite their large bending rigidity, MTs often adopt highly curved conformations, indicating that they are exposed to significant mechanical forces in cells. These forces typically arise from molecular motor proteins like kinesin.

In this study, we investigated microtubule damage and subsequent self-repair as a result of both bending as well as dynamic buckling using kinesin motor proteins in vitro. We reveal that motor-induced buckling imposes massive damage on MTs, occasionally leading to the renewal of majority of the MT lattice visualised by the incorporation of new tubulin subunits into the damaged regions. We find that at high motor densities, MT damage exceeds self-repair and leads to frequent MT breakage.

Our results highlight the impact of mechanical forces, which significantly speed up MT damage and self-repair, on MT integrity. Our findings provide a framework for understanding how cells maintain MT function under repeated mechanical stress.

BP 11.3 Tue 10:15 H44

Active self-organization of focal adhesions driving cell shape changes — •waleed ahmad mirza, matt govendir, alejandro torres-sánchez, and maria bernabeu — European Molecular Biology Laboratory, Barcelona

Focal adhesions (FAs) are dynamic protein complexes that mediate the interplay between the actin cytoskeleton and the extracellular matrix (ECM), enabling cells to sense and respond to mechanical and biochemical cues. These complexes drive essential processes such as cytoskeletal reorganization, cell shape modulation, and migration. To investigate these processes, we developed an active gel mathematical model that couples the dynamics of FAs, actin cytoskeleton, and cellular shape changes, capturing the three-way interplay between these components. Numerical solutions of the model successfully recapitulated experimental observations, demonstrating its ability to predict how cells adapt to mechanical and topographical cues. Specifically, the model reproduced key phenomena such as the influence of substrate stiffness on FA dynamics, with stiffer substrates promoting larger, more stable FAs, aligned stress fibers, and enhanced cell motility. It also captured how anisotropic ECM features, such as aligned collagen fibers or patterned topography, direct cytoskeletal organization and cell alignment. Additionally, the model demonstrated how curvature and shear flow provide critical mechanical cues that shape cellular morphology and behavior. This work provides a novel framework for understanding the mechanistic feedback loops underlying cell-ECM interactions and highlights the central role of FAs in regulating cellular behavior.

BP 11.4 Tue 10:30 H44

Interactions between single actin and vimentin filaments — •Pallavi Kumari and Sarah Köster — Institute for X-Ray Physics, University of Göttingen, Germany

The cytoskeleton plays a crucial role in maintaining cellular structure, mechanics, and function. Recent advances suggest that the diverse tasks of the eukaryotic cytoskeleton depend on the interactions between its filamentous components - microtubules, actin filaments, and intermediate filaments. Despite a growing number of studies to better understand these interactions, it remains unclear whether actin and intermediate filaments interact directly without an auxiliary protein. Previous in vitro studies on reconstituted mixed filament networks have reported contradictory results. To clearly resolve this contradiction, it is essential to further simplify the system down to the single filament level. Here, we present a study on the direct interactions between actin filaments and vimentin intermediate filaments at the single filament level, examining the effects of different ions at varying concentrations on the interaction force. We employ quadruple optical tweezers combined with confocal microscopy and microfluidics to precisely control the conditions for the interaction of the two reconstituted protein filaments, visualize the interactions, and measure the forces involved. Our research provides direct indications of interactions between actin and vimentin filaments. Our findings will provide important insight that will help to unravel the interplay of cytoskeletal filaments at the network level.

BP 11.5 Tue 10:45 H44

Active Gel Theory for Cell Migration With Two Myosin Species — •Nils Winkler, Oliver M Drozdowski, Falko Ziebert, and Ulrich S Schwarz — Institut für theoretische Physik und Bioquant, 69120 Heidelberg

Motility of animal cells is essential for a wide range of biological phenomena, from the development of embryos to the spread of cancer. It is mainly driven by flow of the actin cytoskeleton, which in turn is generated by both actin polymerization and actomyosin contractility. Non-muscle myosin II is present in three different isoforms, but it is unclear what their respective roles are. Starting from phenomenological binding kinetics that include the competition of the myosin motors for binding sites through excluded volume interactions, we derive an active gel model for cell migration that includes a fast and a slow variant, corresponding to the non-muscle myosin II isoforms A and B, respectively. We find non-linear diffusion laws and predict species gradients that agree with experimental observations. Through numerical continuation and simulations, we identify a pull-and-push mechanism that can produce different system states, including steady migration as well as cell oscillations in length and velocity.

BP 11.6 Tue 11:00 H44

Keratin networks in epithelial cells under strain — •Ruben Haag, Ruth Meyer, and Sarah Köster — Institute for X-Ray Physics, University of Göttingen, Germany

The cytoskeleton is mainly made up of microtubules, actin and intermediate filaments (IFs). The composition of the IF-network is cell-type specific and influences the viscoelastic properties of cells. In epithelial cells, the keratin IF network connects to desmomes in the cell membrane, while in the cell center keratin IFs can bind to the nuclear lamina via plectin proteins. The keratin IF network thus forms a mechanical link from the nucleus to the cell membrane. In in-vitro experiments, it was previously observed that IFs, unlike actin filaments, resist being stretched to high strains. We now ask whether this force-extension behavior of IFs is also relevant in whole cells and, more specifically, if mechanical signals from outside the cell are transmitted to the nucleus via the keratin IF network. To answer this question, we stretch cells both uniaxially to linear strains of 80 % and equibiaxially to area strains of 87 %. During stretching, we image the nuclei, deconvolve the images to recover their 3D shape, segment the nuclei and track each nucleus during stretching. This procedure allows us to investigate their deformation at increasing strain. We compare wild type epithelial cells to keratin knockout cells to study the influence of the keratin IF network on the nuclei. We find that the deformation orthogonal to the stretching direction of the nuclei matches the deformation of the cell better in the keratin wild type cells. Our results suggest, that the keratin network helps to adapt the nucleus to mechanical perturbation.

BP 11.7 Tue 11:15 H44

Investigating the interaction between two single heart cells through TNTs using ROCS and Fluorescence microscopy — •Arash Felekary and Alexander Rohrbach — Lab for Bio and Nano Photonics, IMTEK, Freiburg, Germany

Cell-cell communication is vital for biological processes, particularly in the heart. Tunneling nanotubes (TNTs), dynamic and thin protrusions, facilitate cellular interactions by transferring organelles, including mitochondria. To investigate TNT composition and their roles in cardiac fibroblast (FB) communication, we employed Rotating Coherent Scattering (ROCS) microscopy, a label-free super-resolution technique, in addition to Fluorescence microscopy. ROCS enables up to 100 Hz recordings of lamellipodia dynamics along TNTs, and 3D imaging across different z-planes up to 6μm in depth, which is critical for visualizing TNTs. We observed a linear correlation between TNT density and lamellipodia motion velocity. Lamellipodia, driven by actin polymerization and branching via Arp2/3 activation, play a key role in FB migration and interaction. Collagen staining demonstrated that TNTs and lamellipodia interact with collagen fibers, a major component of the extracellular matrix (ECM). This interaction not only influences ECM remodeling, but also activates actin branching signals that enhance FB migration and protrusion dynamics. In this presentation, we investigate the coordinated roles of TNTs, lamellipodia, and collagen in regulating FB interaction and migration, offering new insights into heart tissue repair.

BP 12: Biomaterials, Biopolymers and Bioinspired Functional Materials III (joint session CPP/BP)

Time: Tuesday 9:30–11:15 Location: H46

Invited Talk BP 12.1 Tue 9:30 H46

Hybrid materials from colloidally stable nanocellulose and nanoparticles - scattering techniques are needed for characterization — •Eva Malmström[1], Åsa Jerlhagen[1], Benedikt Sochor[2], Korneliya Gordeyeva[1], and Stephan Roth[1,2] — [1]KTH Royal Institute of Technology, Stockholm, Sweden — [2]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany

Cellulose nanofibrils (CNFs) have rendered increasing interest during the last decades as their high stiffness, strength, and aspect ratio are attractive features to further explore on the pathway to a more sustainable society.

Controlled radical polymerization procedures allow for the synthesis of well-defined, nearly monodisperse, block-copolymers. The development of the polymerization-induced phase self-assembled (PISA) technique enables the production of well-defined nanoparticles (nanolatexes), with controlled size (typically with a diameter smaller than 200 nm), charge density, chemical functionality, and glass transition temperature.

The combination of CNFs and well defined nanolatexes allows for the design of novel materials with unique properties. Scattering techniques have proven very useful to characterize the corresponding materials, for instance, a method to assess cross-section orientation.

In situ GISAXS investigation of different protein-templated titania nanostructures — •Linus Fidelis Huber and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany

Nanostructured titania thin films have been studied for a large variety of applications. An environmentally benign and scalable synthesis route for this material class could be of interest to many state-of-the-art devices, from solar cells to battery materials. Protein-assisted sol-gel synthesis is a low-temperature, low-cost, and highly scalable technique, that can be used to achieve a nanostructured titania thin film. It has been shown that the bovine whey protein β-Lg forms differently shaped aggregates at different solution pH values. With simple changes to the solution chemistry, different domain sizes, porosities, and morphologies are possible. Therefore, it is a promising candidate to create tunable and mesoporous titania structures. In this work, we investigate the film formation with in situ small-angle/wide-angle grazing incidence X-ray scattering (GISAXS/GIWAXS) techniques. It is found that films printed at acidic pH form significantly different final bulk morphologies than films printed at neutral pH. The crystallite phase is strongly reduced in average domain size and domain-domain distance. Agglomerate size is increased for the acidic template. The in situ data is complemented by SEM, PL, UV-Vis and static GISAXS/GIWAXS measurements.

BP 12.3 Tue 10:15 H46

With digital luminescence towards minimalistic, biodegradable information storage — •Sebastian Schellhammer, Heidi Thomas, Tim Achenbach, and Sebastian Reineke — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute for Applied Physics, Technische Universität Dresden, Dresden, Germany

Materials showing persistent luminescence, characterized by extended excited state decay times in the millisecond range and beyond, have gained much attention. Recently, we have reported a photonic device architecture based on organic functional materials called programmable luminescent tag (PLT) that is well suited for sensing, labelling, and information exchange applications. Information can be erased and rewritten repeatedly by using the design principle of digital luminescence, i.e. the control of the local oxygen concentration in a polymer:emitter blend and accordingly the emission by room temperature phosphorescence (RTP). We present the design of PLTs made from industrially compostable, ready-to-use materials (bioPLTs). As natural emitters, quinoline alkaloids show sufficient RTP when being embedded in a polymer matrix. Polylactic acid is used as matrix material and flexible substrate. RTP can be controlled adding oxygen blocking layers made from Exceval. Although organic semiconductors provide the potential of biodegradable technologies, prototypes do only rarely exist. With this work, a promising technology for compostable information storage and sensing systems is introduced.

BP 12.4 Tue 10:30 H46

Enhancing drug release at interfaces with photoresponsive surfactant-polyelectrolyte mixtures — •Ipsita Pani, Michael Hardt, and Björn Braunschweig — Institute of Physical Chemistry, Center for Soft Nanoscience (SoN), University of Münster, Corrensstraße 28-30, Münster 48149, Germany

Using micellar nanocarriers of a photoresponsive arylazopyrazole (AAP) surfactant, we have recently demonstrated the drug release at air-water interface.[1] In this work, we use a biopolymer poly-L-lysine (PLL) to form surfactant-polyelectrolyte mixtures to enhance the drug release of a chemotherapeutic drug doxorubicin. We observe a strong binding between the negatively charged AAP and the positively charged PLL at equimolar ratio. The information from UV-visible spectroscopy, light scattering studies, surface tensiometry and SFG spectroscopy has been utilized to identify the concentration of PLL at which the light-induced drug release is enhanced at the interface. We found that at higher PLL:AAP ratio, the complexes have low net charge and colloidal stability and the release of Dox from the bulk solution to the air-water interface is not observed. However, at lower PLL:AAP ratio, when the system is colloidally stable with a net negative charge, the drug release to the air-water interface is significantly enhanced. Further, the kinetics of drug release to the interface is faster in presence of PLL-AAP mixtures in comparison to pure AAP micelles. Reference : [1] Pani et al. Chem. Sci., 2024, 15, 18865-18871.

BP 12.5 Tue 10:45 H46

Proteins as foam stabilizers: From single foam lamellas to macroscopic foams — •Kevin Gräff, Sebastian Stock, Luca Mirau, Matthias Kühnhammer, Olaf Soltwedel, and Regine von Klitzing — Terchnische Universität Darmstadt, Darmstadt, Germany

Foams consist of foam lamellas, which separate single air bubbles from each other. Investigation of lamellas is crucial to understand foam properties. In order to untangle electrostatic, steric and network stabilization effects, we compare two globular proteins (β-lactoglobulin and Lupine Protein Isolate) and a disordered, flexible protein (whole casein) at different pH values. The Thin Film Pressure Balance (TFPB) device based on image intensity measurements generates spatially resolved disjoining pressure isotherms. We introduce feature tracking for the measurement of interfacial mobility and stiffness of lamellas as a novel method. Around the isoelectric point, Newton Black Films (NBFs) form, which are stable for the globular proteins while they are unstable for the disordered flexible one. This difference in film stability is explained by different characteristics of network structures in the lamellas from the respective protein solutions. Small-Angle Neutron Scattering (SANS) evaluation with a new model for foams proves the presence of NBFs within macroscopic foams. For a complete picture we compare the TFPB findings with X-ray reflectometry as well as with Brewster Angle Microscopy on single interfaces.

BP 12.6 Tue 11:00 H46

What makes a polysaccharide biomaterial a good candidate for tissue engineering applications? — •Emma Bobu Cimpoi[1], Codrut Costinas[1], Emilia Licarete[2], Tamás Gyulavári[3], Klara Magyari[4], and Monica Baia[4,5] — [1]Doctoral School of Physics, Babes-Bolyai University, Cluj-Napoca, Romania — [2]Centre for Systems Biology, Biodiversity and Bioresources "3B", Cluj-Napoca, Romania — [3]Department of Applied and Environmental Chemistry, University of Szeged, Hungary — [4]INSPIRE Research Platform, Babes Bolyai University, Cluj-Napoca, Romania — [5]Faculty of Physics, Babes-Bolyai University, Cluj-Napoca, Romania

Biomaterials are inovative systems used to solve medical issues. Daily, injuries produce major bleeding that affects people and, without proper care, leads to

other health problems. Traditional care methods are limited and outdated, so the focus is on natural materials with hemostatic properties, that are biocompatible and non-toxic. The aim of this work was to develop biomaterials based on pullulan, alginate and gelatin in various combinations, which could stop the bleeding and regenerate the wound. The developed sponge-like materials were characterized by FT-IR spectroscopy and X-ray diffraction. Then they were evaluated in vitro in terms of porosity, toxicity, swelling and charge on the surface, using SEM, cell viability assays, water up-take and mechanical tests. The investigations revealed good results as the synthesis was succesfull, the samples swell a lot, have good shape memory properties, are porous and non-toxic. These indicate their potential to stop bleeding, and therefore further in vivo tests will be carried out.

BP 13: Active Matter III (joint session DY/BP/CPP)

Time: Tuesday 9:30–13:00 Location: H47

BP 13.1 Tue 9:30 H47

From micro to macro: systematic coarse-graining of active particle models and implications on phase separation — •Sumeja Burekovic[1], Filippo De Luca[2], Cesare Nardini[1,3], Ananyo Maitra[4,5], and Michael E. Cates[2] — [1]CEA, Paris-Saclay, France — [2]DAMTP, University of Cambridge, UK — [3]LPTMC, Sorbonne Université, France — [4]LPTM, CY Cergy Paris Université, France — [5]LJP, Sorbonne Université, France

Significant insights into collective phenomena of active systems, such as phase separation, have been obtained through minimal field theories developed in a top-down manner. In contrast, the bottom-up approach seeks to link these continuum models to the microscopic dynamics of active particles, often formulated as Langevin equations for their position and orientation. This connection is typically achieved via explicit coarse-graining and allows active field theories to be expressed in terms of physically meaningful parameters. A major challenge in coarse-graining is the consistent elimination of irrelevant fast degrees of freedom to derive closed equations for the hydrodynamic variables or order parameters, such as the density field. We propose a systematic extension of standard homogenization/projection-operator techniques. As we show in minimal examples with few degrees of freedoms, our technique allows to go beyond the state of the art of homogenization in the mathematical literature. We then discuss the predictions of our coarse-graining methods for the large-scale phenomenology of non-aligning active particles, including cases in which microphase separation - rather than full phase separation - emerges due to activity.

BP 13.2 Tue 9:45 H47

Active Quadrupolar Dumbbells — •Margaret Rosenberg[1], Marco Musacchio[1], Lorenzo Caprini[2], and Hartmut Löwen[1] — [1]Heinrich-Heine University Düsseldorf, Universitätsstraße 1, 40225 Düsseldorf — [2]Università di Roma Sapienza, P.le Aldo Moro 2, 00185 Rome, Italy

The field of Active Matter has thrived in recent years, driven both by the insight that it underlies fundamental processes in nature, and by its vast potential for applications. Although the self-propulsion mechanisms of Active Matter allow us to consider and control a wide range of motions, there is - by default - no obvious control over the orientation and rotation of the particles. One approach to resolve this is the use of anisotropic particles and interactions. This contribution presents a computational study of a novel system composed of active, quadrupolar dumbbells, the phase behavior of which is determined by the competition between active motion and the orthogonal alignment favored by quadrupolar attraction. We explore the novel phase behavior unlocked by these anisotropic interactions, and discuss options for experimental realizations and applications.

BP 13.3 Tue 10:00 H47

Order by disorder in a swarm with obstacles — Pradeep Kumar[1], Sanjay Puri[1], and •Martin Weigel[2] — [1]School of Physical Sciences, Jawaharlal Nehru University, New Delhi – 110067, India — [2]Institut für Physik, Technische Universität Chemnitz, 09107 Chemnitz, Germany

Simple models of swarming and active matter such as the Vicsek model [1] have been studied in detail, and the phase diagram as a function of noise strength and particle density is by now well understood. Real active systems are usually affected by impurities and random disorder, however. The presence of a quenched distribution of disc-like obstacles in the domain of the Vicsek model is observed to have a dramatic effect on the ordering behavior [2]: in contrast to the model without obstacles, where the strongest alignment is observed for the lowest noise, as soon as obstacles are added only the presence of a certain amount of noise leads to a global alignment of particles. This order by disorder phenomenon for active systems is traced back to the interplay of multiple length scales in the system: the typical inter-obstacle distance, the typical cluster size, and the resulting mean-free-paths of cluster-obstacle and cluster-cluster collisions. We present scaling arguments explaining these connections and provide an outlook towards similar phenomena in related systems.

BP 13.4 Tue 10:15 H47

Autonomous navigation in synthetic microswimmers: solving mazes with chemical echolocation — •Aritra K. Mukhopadhyay[1], Linhui Fu[2], Kai Feng[2], Ran Niu[2], and Benno Liebchen[1] — [1]Technische Universität Darmstadt, Darmstadt, Germany. — [2]Huazhong University of Science and Technology, Wuhan, China.

Motile microorganisms like bacteria and algae combine self-propulsion, cooperation, and decision-making at the micron scale. Inspired by these biological systems, synthetic microswimmers are emerging as human-made counterparts capable of self-propulsion. Recent breakthroughs provide a platform to integrate additional functionalities, bridging the gap between biology and synthetic systems.

We propose and experimentally demonstrate a mechanism enabling synthetic microswimmers, such as autophoretic colloids, droplet swimmers, and ion-exchange-driven modular swimmers, to make autonomous navigational decisions. These swimmers generate chemo-hydrodynamic signals that interact with boundaries, creating echoes that carry structural information about the environment. Remarkably, these echoes invoke automatic responses, such as synthetic chemotaxis, enabling the swimmers to avoid dead ends and autonomously find paths through complex mazes.

Our findings illustrate how simple physical principles can endow synthetic systems with advanced navigation functionalities, which could be useful for developing self-navigating micromachines with potential applications in targeted drug delivery and environmental sensing.

BP 13.5 Tue 10:30 H47

Active Particles in Tunable Colloidal Environments — •Abhimanyu Nowbagh[1], Venkata M.S.G. Tanuku[2], Thomas Palberg[2], and Ivo Buttinoni[1] — [1]Institute of Experimental Colloidal Physics, Heinrich-Heine University, 40225 Düsseldorf — [2]Institute of Physics, Johannes-Gutenberg University, 55128 Mainz

Active colloids are microscopic particles which propel through aqueous media by converting the externally available energy into directed motion. Using non equilibrium thermodynamics to understand biological systems: interactions of active colloids with crowded systems, and emergent phenomena of ensembles of active particles, remain an important and open question.

In this work, we investigate the dynamics of active particles in crowded environments subjected to alternating-current (AC) electric fields. The AC electric field is used to control: i) the velocity of active particles and ii) the inter-particle interaction between passive colloids. As we increase electric field strength, the velocity of active particles increases and the inter-particle interaction between passive colloids becomes stronger. We study the behaviour of active particles as a function of: i) the frequency of the applied AC electric field, ii) the area fraction of the passive crowd, iii) the active to passive particle number ratio, and iv) the velocity of the active particles.

Our experimental findings show that the active particles reorient faster with an increasing electric field strength. With an increase in the active to passive particle ratio, we show that cluster formation is non-monotonically sensitive to the passive crowd density.

Invited Talk BP 13.6 Tue 10:45 H47

Beyond spheres - active matter in new shapes — •Juliane Simmchen — University of Strathclyde, Cathedral street 295, Glasgow UK

Surface minimisation for a given volume is energetically favourable on the small scale - this is why most colloidal particles are spherical. In active matter they have the added advantage of facilitating comparison between experiment and theory, one of the reasons why spherical Janus particles dominate the field.

However, broadening the range of materials has led to interesting discoveries - behaviour that would not have been observable in the spherical regime. This talk will give an overview of the intriguing behaviour of non-spherical active materials at the microscale - from plates to truncated bipyramids and rods.

BP 13.7 Tue 11:30 H47

Modeling Filamentous Cyanobacteria — •Elias Fischer and Holger Stark — Institute Of Theoretical Physics, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin, Germany

Filamentous cyanobacteria play an important role in many ecosystems and the carbon cycle of our planet, both in the present and the past. They triggered the great oxygenation event about 2.5 billion years ago, generating the atmospheric oxygen of our planet while contributing large parts of our fossil fuel record.

Filamentous cyanobacteria exhibit gliding motility when in contact with solid surfaces or each other. Despite their ecological relevance and increased use in biotech applications, the exact nature of the force-generating process remains not fully understood. Furthermore, the gliding of cyanobacteria is strongly affected by external cues, most importantly light. They aggregate in regions with the highest light intensity, which means best environmental conditions for photosynthesis.

Following recent advances in understanding the self-organization of cyanobacteria, we present a novel approach for modeling the mechanical and behavioral aspects of individual cyanobacteria filaments, including force synchronization and response to light. Each filament is modeled as a bead-spring chain in 3D with bending and torsional elasticity, as well as a hard-core repulsion between the filaments. Notably, the propulsion forces that drive the individual parts of the filament forward are only considered locally where the filament comes into contact with another surface. First results on the 3D bending and twisting motion of a filament and its reaction to light are presented.

BP 13.8 Tue 11:45 H47

Self-assembly and control of active and passive triblock Janus colloids — •Juri Franz Schubert, Salman Fariz Navas, and Sabine H. L. Klapp — Institut für Theoretische Physik, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin

Triblock Janus colloids belong to the family of patchy particles, interacting with hydrophobic attraction at opposite poles and electrostatic repulsion in the equatorial region. They are known to self-assemble into a colloidal kagome crystal from experiments [1] and theory [2,3,4]. However, investigating the self-assembly of such systems via Brownian Dynamics can result in timescales inaccessible to brute force simulations, often requiring complex sampling techniques [3]. Recently, it has been shown that introducing self-propulsion can significantly accelerate self-assembly and enhance the Kagome yield [4]. Here, we study the model introduced in [4] and further investigate the self-assembled structures in active and passive systems. Using simple time-dependent activity protocols, we are able to sample a temperature-density state diagram of the passive system. Our results closely match with earlier studies [2,3], where different triblock models and sampling techniques were used.

BP 13.9 Tue 12:00 H47

Enhanced Diffusion and Universal Rouse-like Scaling of an Active Polymer in Poor Solvent — Suman Majumder[1], Subhajit Paul[2], and •Wolfhard Janke[3] — [1]Amity Institute of Applied Sciences, Amity University Uttar Pradesh, Noida 201313, India — [2]Department of Physics and Astrophysics, University of Delhi, Delhi 110007, India — [3]Institut für Theoretische Physik, Universität Leipzig, IPF 231101, 04081 Leipzig, Germany

By means of Brownian dynamics simulations we study the steady-state dynamic properties of a flexible active polymer in a poor solvent condition. Our results show that the effective diffusion constant of the polymer D_{eff} gets significantly enhanced as activity increases, much like in active particles. The simulation data are in agreement with a theoretically constructed Rouse model of active polymer, demonstrating that irrespective of the strength of activity, the long-time dynamics of the polymer chain is characterized by a universal Rouse-like scaling $D_{\text{eff}} \sim N^{-1}$, where N is the chain length. We argue that the presence of hydrodynamic interactions will only have an insignificant effect on the observed scaling behavior.

BP 13.10 Tue 12:15 H47

A Pulsating Active Solid — •Umang A Dattani[1], Francesco Serafin[1], Jonas Ranft[2], and Etienne Fodor[1] — [1]Department of Physics and Materials Science, University of Luxembourg, L-1511 Luxembourg City, Luxembourg — [2]Institut de Biologie de l ENS, Ecole Normale Superieure, CNRS

Active matter has garnered significant attention in recent decades due to its numerous parallels with biological systems. Inspired by recent studies of biological tissues, such as cardiac cells, where constituent cell sizes periodically vary, a new form of activity termed "pulsating active matter" has been introduced recently. We propose a model of a pulsating active solid, consisting of size-changing particles linked by a triangular spring network. Despite the fixed connectivity, our model exhibits a variety of patterns and topological phase defects, akin to previous studies. Additionally, we explore the elastic continuum limit, which successfully predicts several essential features of the microscopic model. We conclude by highlighting intriguing properties of this system and its different potential parallels.

Invited Talk BP 13.11 Tue 12:30 H47

Emergent correlations and boundary fluctuations in epithelial cell sheets — •Silke Henkes — Lorentz Institute, Leiden University, Leiden, The Netherlands

In soft active materials, the driving motion of individual constituents competes with their mechanical interactions, giving rise to active liquids, solids or glasses. An especially important example of this are epithelial cell sheets, which form a barrier function in the body and where the active crawling motion of cells over the substrate acts against cell-cell adhesion and repulsion.

I will show that a minimal model of cell sheets with uncorrelated activity, based on active Brownian dynamics and a vertex model, is a good quantitative match to data from two experiments on corneal and MDCK cell sheets. Its core feature is an emergent correlation length, arising from the diffusive spread of active forces through an elastic solid. This is a very general result that emerges in many active solids.

The boundary of such cell sheets exhibits a 'fingering instability' where the initially straight boundary develops large, spatiotemporally correlated fluctuations. Despite previous interpretations within many frameworks as an instability, I will show that it can be fully explained as arising from the active correlations of the cell sheets driving the boundary.

BP 14: Poster Session I

Bacterial biophysics, computational biophysics, membranes and vesicles, synthetic life-like systems and origin of life, systems and networks biophysics

BP 14.1 Tue 10:00 P3

The Role of Localized Metabolic Activity in Streptomyces Hyphae: An Agent-Based Approach — •Ricardo Santander[1], Denis Iliasov[2], Thorsten Mascher[2], and Vasily Zaburdaev[1] — [1]Max-Planck Zentrum für Physik und Medizin, Kussmaulallee 2, Erlangen — [2]Institut für Mikrobiologie, Zellescher Weg 20b, Dresden

The filamentous bacterium Streptomyces undergoes complex multicellular development characterized by hyphal growth and branching. Recent discoveries of LpdA-containing fluorescent foci within the hyphae suggest localized sites of elevated metabolic activity and ATP production. To investigate their influence on hyphal morphogenesis, we developed an agent-based model simulating key cellular components and their interactions.

Simulations reveal that localized ATP production and high consumption rates near the tips create spatial heterogeneity in metabolic activity. By adjusting model parameters, the model replicates typical growth patterns and hyperbranching phenotypes observed experimentally.

Our findings suggest that the spatial distribution of metabolic foci and localized ATP production influence Streptomyces morphology and multicellular organization.

BP 14.2 Tue 10:00 P3

Optically driven thermofluidic assembly of bacteria — •Desmond Joseph Quinn[1], Selina Hanisch[2], Rohan Karande[3], and Frank Cichos[1] — [1]Peter Debye Institute for Soft Matter Physics, Faculty of Physics and Earth Sciences, Leipzig University, Leipzig, Germany — [2]Helmholtz Center for Environmental Research (UFZ), Leipzig, Germany — [3]Biophysical Chemistry, Leipzig University, Leipzig, Germany

Bacteria in their planktonic state are known to assemble into biofilms in the vicinity of a solid surface. The complex cascade that results in the adhesion of the

bacteria to the surface is usually triggered by the diffusion of bacteria to its vicinity. We propose a method that makes use of temperature induced flow fields and depletion interactions for the localized assembly and manipulation of bacteria. In addition to the physical interactions that contribute to the assembly process, the motility of the bacteria affects the assembly and can be altered by the induced temperature and altered distribution of molecules. We try to disentangle these effects by studying passive and active bacteria independently. We look at how motility parameters change in response to the fields induced by the laser, and how this in turn affects assembly. Such controlled assembly of bacteria could be useful for technological applications in bioreactors. In addition, our method provides a way of experimentally probing the effect of localized temperature, osmotic pressure, and flow fields on the motility of bacteria.

BP 14.3 Tue 10:00 P3

Growth and characterization of MoS2 nanowalls on Ti-based bone implants — •Rania Ennaciri, Axel Printschler, Christof Neumann, and Andrey Turchanin — Friedrich Schiller University Jena, Institute of Physical Chemistry, Lessingstraße 10, 07743 Jena, Germany

Antibiotic resistance presents an important issue in the medicine field particularly in the context of bone replacement surgeries, where infections from antibiotic-resistant bacteria can lead to severe health complications and even fatalities. While titanium (Ti) is the conventional choice for bone implants, there is a clear need for further improvements of this material to enhance its antimicrobial resistance. In this regard, hybrids based two-dimensional (2D) materials, such as molybdenum disulfide (MoS2), present a great promise due to their intrinsic antimicrobial activity and biocompatibility. These properties are generally manifested through biochemical reactions, by the generation of reactive oxygen species (ROS) that can lead to the damage of bacteria DNA, proteins and lipids. Also, mechanical actions, where the sharp edges of the nanowalls can cut the bacteria wall can lead to its death. To investigate these mechanisms, we use metal-organic chemical vapor deposition (MOCVD) technique to grow different morphologies and sizes of MoS2 nanowalls on Ti implants. We use scanning electron microscope (SEM), Raman spectroscopy and X-ray electron microscopy (XPS) to characterize the structural and chemical properties and to correlate them prospectively with the antimicrobial properties as well as with the growth bone cells.

BP 14.4 Tue 10:00 P3

Infrared Hyperspectral Mapping of Biofilms Growing in Confinement — •Felix Hermann Patzschke[1], Valentina Schmitz[2], Rohan Karande[2,3], and Frank Cichos[1] — [1]Leipzig University, Peter Debye Institute for Soft Matter Physics, Linnéstr. 5, 04103 Leipzig — [2]Leipzig University, Institute for Biochemistry, Johannisallee 21-23, 04103 Leipzig — [3]Helmholtz Centre for Environmental Research, Permoserstraße 15, 04318 Leipzig

Biofilms are microbial communities characterized by complex spatial organization and dynamic chemical composition. The formation and growth of biofilms in confined environments are of significant interest in fields such as medicine and bio-engineering. We seek to establish a clearer understanding of the interplay between physical confinement and microbial behavior by investigating whether specific quantifiable aspects of a cavity's geometry can influence the likelihood of biofilm initiation and the rate of its growth.

We utilize Photothermal Infrared (PTIR) hyperspectral microscopy to acquire infrared spectral data at sub-cellular spatial resolutions. Through spectral decomposition, we aim to map the chemical composition of biofilms and distribution of nutrients in space and time. Our results provide a detailed view of biofilm structure, metabolic activity, and growth dynamics in confined settings. This work underscores the potential of PTIR microscopy as an impactful tool for advancing the understanding of biological systems in scientifically and technologically significant domains.

BP 14.5 Tue 10:00 P3

Self-Organized Colonization Resistance without Physical Barriers — •Christian Westendorf[1], Valentin Slepukhin[1], Birgit Koch[1], Victor Peris[1], and Oskar Hallatschek[1,2] — [1]Peter Debye Institute for Soft Matter Physics, Leipzig University. — [2]Department of physics, University of California, Berkeley.

Small micrometer-scale cavities, such as gut crypts, soil pores, and plant apoplasts, represent key bacterial habitats, in which different strains compete for resources and space. Recent studies have shown that the physical structures of these microhabitats can influence the stability and resilience of bacterial colonizers by protecting local populations from invasion. Building on this, we experimentally and computationally investigate the dynamics of mixed bacterial populations within interconnected microfluidic cavities, examining the influence of geometric features and surface interactions on microbial organization and diversity. Our findings reveal that surface roughness and friction can drive self-organization into effectively isolated subpopulations, safeguarding slower-growing strains from competitive exclusion. By comparing velocity fields of growing populations with stochastic and analytical simulations, we demonstrate how local geometry and emergent microhabitats balance selective pressures, maintaining microbial diversity under competitive and evolutionary stress. Our work suggests that colonization-resistant microhabitats can form dynamically, even in the absence of physical barriers.

BP 14.6 Tue 10:00 P3

Comparing graphene and 2D MoS_2 nanopores for protein translocation and detection — •Peijia Wei, Mayukh Kansari, and Maria Fyta — Computational Biotechnology, RWTH Aachen University, Worringerweg 3, 52074 Aachen, Germany

Nanopores, nanometer-scale openings in materials, have shown their strong potential in realizing ultra-fast, cost-effective, and real-time next-generation sequencing technology. These nanopores can electrophoretically drive charged biomolecules and detect these. Using computer simulations, we compare two-dimensional nanopores, namely graphene and MoS_2, to evaluate their effectiveness in protein detection. We modulate protein translocation and dynamics by adjusting the type and concentration of the surrounding solvent, using a typical monovalent salt solution and a molecular solution. Utilizing atomistic simulations, we assess the efficiency of both nanopores in threading proteins, based on measurable ionic current signals. Our results show that graphene nanopores strongly interact with proteins, hindering translocation under physiological conditions. This issue is addressed by introducing a denaturant, which creates a hydrophilic-cationic layer on the pore surface, facilitating the linearized threading of proteins. In contrast, MoS_2 nanopores facilitate protein passage even in physiological solutions, offering an alternative approach to controlling translocation speed. We analyze the two nanopore materials based on molecular interactions among the material, protein, and solvent, emphasizing their impact on protein dynamics and ionic signal enhancement for efficient 2D nanopore protein detection.

BP 14.7 Tue 10:00 P3

Exploring coarse graining RNA force fields via Machine Learning — •Anton Dorn[1] and Alexander Schug[1,2] — [1]Forschungszentrum Jülich, Jülich, Germany — [2]KIT Scientific Computing Center, Karlsruhe, Germany

In Protein structure prediction there have been massive improvements recently with the help of machine learning. In RNA structure prediction however the situation is less ideal due too much sparser experimental data. Here we attempt to solve a modified version of the problem by determining a coarse-grained RNA force field for Molecular Dynamics simulations. The data sparsity can here be alleviated by atomistic RNA simulations using proven and established force fields. In a first step we show the viability of this approach with a limited scenario of only small RNA molecules. For this we adapt the invariant Graph Neural Network architecture, cgSchnett.

BP 14.8 Tue 10:00 P3

Parameterization of a dissipative particle dynamics thermostat (DPD) thermostat for coarse-grained molecular dynamics — •Karan Venkatesh, Viktor Klippenstein, and Nico F. A. van der Vegt — Technische Universität Darmstadt

Coarse-grained (CG) simulations represent a viable approach for modelling dynamics on long length and time scales inaccessible with atomistic simulations. In this work, we present a single-site coarse-graining method designed to match the dynamical and structural properties of a molecular liquid (cyclohexane).

We employ a DPD thermostat, in which the pairwise forces are decomposed into parallel and perpendicular components. An iterative optimization scheme is implemented to parameterize the parallel and perpendicular forces, aiming to match the diffusion coefficient and shear viscosity of the system, respectively. In our study, we find that matching the diffusion coefficient also leads to a match in the shear viscosity. However, this correspondence may not always hold, especially when dealing with structurally anisotropic molecules and soft potentials, as commonly encountered in soft matter systems. This approach can be further extended to simulate mixtures of CG molecular liquids, and study penetrant dynamics in CG polymer melts.

Leveraging Experimental Vasculature Data for High Resolution Brain Tumor Simulations — •Eric Behle[1], Julian Herold[2], and Alexander Schug[1] — [1]NIC Research Group Computational Structural Biology, Jülich Supercomputing Centre, Jülich Research Center, Jülich, Germany — [2]Steinbuch Centre for Computing, KIT, Karlsruhe

Cancer remains a leading cause of mortality. Multidisciplinary studies probe its pathology to increase treatment options. Computational modeling of tumors on HPC resources offers insight into its progress and an avenue for advancing our understanding. However, initialization and parameterization of the underlying models require high-resolution data from real tissue structures. Here, we leveraged HPC resources and a massive dataset of a mouse brain's entire vascu-

lar network. We processed these image stacks into detailed 3D representations, identified brain regions of interest, and conducted a series of large-scale simulations to investigate how tumor growth is influenced by local vascular network characteristics. By simulating tumor growth with sub-cellular resolution, we can probe to which extent vessel density and network length influence growth. We determined that vessel density is the primary determinant of growth rate. Finally, our results allowed us to extrapolate tumor cell growth predictions for the entire mouse brain, highlighting the critical role of vascular topology in tumor progression. Such increasingly realistic simulations of cancer cells may enable researchers to bridge the gap between basic biology and clinical practice, supporting development of cancer therapies.

BP 14.10 Tue 10:00 P3

Boundary integral method for elastic solids in Stokes flow and applications in real-time deformability cytometry — •Thomas Mayr and Stephan Gekle — Universität Bayreuth, Deutschland

A Newtonian fluid at small Reynolds numbers can be described using the Stokes equation. A common choice to solve the Stokes equation numerically is the boundary integral method. Previously, this method was mainly used to describe rigid particles or capsules with an elastic membrane such as red blood cells. Here a technique is presented how to extend the boundary integral method to elastic solids discretized by the finite element method. This can be used as simple model to describe the stiffness of cells with a nucleus and a cytoskeleton, e.g. in some deformation experiments. In our case we will compare the simulations with an experimental technique called real-time deformability cytometry (RT-DC).

BP 14.11 Tue 10:00 P3

Mathematical Modeling of Intercellular Calcium Waves in Fibroblast Networks — •Kara Nachtnebel — Isarstr, 6, 93057 Regensburg

Inflammatory responses are essential for defending against pathogens but can result in tissue damage when not properly regulated. Resident tissue macrophages (RTMs) play a crucial role in maintaining immune homeostasis by modulating inflammatory cascades. Disruptions in these regulatory mechanisms can lead to heightened immune responses and may contribute to the development of autoimmune diseases. This study explores the role of fibroblast networks and their calcium signaling dynamics in maintaining tissue homeostasis. We aim to understand the mechanisms underlying these dynamics and predict calcium signal propagation in both healthy and pathological tissues. A mathematical model is developed to describe intracellular calcium ion diffusion and Inositol-1,4,5-triphosphate (IP3) signaling in fibroblast cells interconnected by gap junctions (GJs). This model incorporates intracellular calcium stores and IP3-sensitive receptor (IPR) dynamics, which significantly influence calcium release into the cytoplasm. IP3 generation is modeled as a function of phospholipase-C (PLC) activation, triggered either by external stimuli or by calcium, leading to calcium-induced calcium release (CICR). Our approach provides insights into how calcium signaling networks contribute to tissue homeostasis and how their dysfunction occurs in pathological conditions.

BP 14.12 Tue 10:00 P3

coarse-grained simulations of Lge1(1-80) peptide. — •Agaya Johnson[1], Anton Polyansky[2], Pedro Sanchez[1], Bojan Zagrovic[2], and Sofia Kantorovich[1] — [1]Computational and soft matter physics, University of Vienna, Kolingasse 14-16, 1090, Vienna, Austria. — [2]Department. of structural and computational biology, Campus- Vienna-biocenter 5, 1030 Vienna, Austria.

Biomolecular condensates in cells such as p-bodies, nucleoli and stress granules play an important role in regulating biological processes like transcription and ribosome biogenesis. Studying of such biomolecular condensates will give insight into the molecular basis of disease, like neurodegenerative diseases, cancer and diabetes. The main purpose of this study is to understand the main phenomenon, which leads to the formation of these biomolecular condensates such that we get a conclusion, whether is it phase separation, self-assemble or an aggregation. We use Lge1(1-80) peptide as a model for study because Lge1(1-80) is mostly disordered prone to form many cation - pi and pi - pi interaction (R, G and Y rich sequence) and because of its alternating net charge which are the prerequisites for the phase separation. Due to the limitations of high-resolution experimental techniques, we are using molecular dynamics simulation with coarse-grained approaches with the help of software package ESPResSo. Our goal is to develop a coarse-grained model for proteins that exhibit structural transitions and to understand fundamental mechanisms under those transitions.

BP 14.13 Tue 10:00 P3

Optimizing a Biomimetic Cross-Flow Microplastics Filter Inspired by Manta Rays — •Ioannis Gkekas[1] and Tim Robertino Baumann[2] — [1]Universität Bielefeld — [2]Universität Bielefeld

Microplastic pollution poses a significant threat to aquatic ecosystems, necessitating innovative filtration solutions. This study continues previous research on a biomimetic cross-flow filter inspired by manta ray feeding mechanisms. The objective is to optimize the filter's geometry and material properties to enhance efficiency and durability. Using COMSOL simulations, various geometrical configurations are being tested to identify an optimal design for maximizing filtration efficiency and clean water output. To address material durability, we reenforced PDMS (polydimethylsiloxane) with glass fibers to mitigate bursting under operational stress. Initial results indicate that the composite material significantly enhances durability compared to the original PDMS design. Once the simulations are complete, the optimal design will be fabricated for in-lab performance evaluation. This research advances the development of sustainable, high-efficiency microplastic filtration systems inspired by natural processes.

Autonomous, intrinsic circadian oscillator at cell membranes — •Mauro Ariel Forlino[1], Oreste Piro[2], and Martín García[1] — [1]Universität Kassel, Kassel, Germany — [2]Universtat de les Illes Balears, Palma, España

Circadian rhythms originated in endogenous cellular clockworks are the evolutionary solution that allows organisms to anticipate and synchronize their internal processes with the predictable changes in their environment on a daily basis. According to the conventional paradigm, eukaryotic cells generate circadian rhythms as outputs from gene-based biochemical oscillators comprised of transcription/translation feedback loops, necessarily involving processes occurring within the nucleus. However, mounting evidence has recently emerged indicating that circadian rhythms also exist in cells devoid of such nuclear clocks, notably seen in the circadian variation of red blood cell metabolism. Here, we demonstrate the existence of a completely different mechanism for generating endogenous circadian oscillations that solely involves processes within the cell membrane and its immediate vicinity, entirely independent of the nuclear clock. Rather than relying on the transcription/translation/repression loop as in nuclear oscillators, this membrane-located clock operates through an analogous regulatory circuit that involves the homeostatic regulation of ion channels and their gating kinetics.

BP 14.15 Tue 10:00 P3

Influence of the sapogenin gypsogenin on vesicles from 1,2-dimyristoyl-sn-glycero-3-phosphocholine (DMPC) — •Melanie Gettinger and Thomas Hellweg — Physical & Biophysical Chemistry, University Bielefeld, Bielefeld, Germany

Small unilamellar vesicles (SUVs) composed of phospholipids, such as 1,2-dimyristoyl-sn-glycero-3-phosphocholine (DMPC), are commonly used as model membrane systems. DMPC bilayers undergo phase transitions from a gel to a fluid phase at around 24°C. While the effects of saponins on DMPC membranes are well-documented, the impact of their aglycones, sapogenins, remains less explored. Gypsogenin, a pentacyclic triterpenoid found in soapwort (Saponaria officinalis) and gypsum herb (Gypsophila oldhamiana), is of interest due to its anti-cancer potential. Gypsogenin shares structural features with cholesterol but has contrasting effects on membrane properties. While cholesterol increases membrane thickness and reduces fluidity, gypsogenin incorporation decreases the vesicle core radius and membrane thickness, as shown by small-angle X-ray scattering (SAXS) and cryo-TEM. UV-vis spectroscopy was used to monitor turbidity in solutions containing 0 to 25 mol% gypsogenin over a wide temperature range, showing a reversible increase upon cooling, indicating thermally reversible phase transitions. SAXS measurements revealed significant structural changes at 25 mol%. The core radius and membrane thickness decreased compared to pure DMPC vesicles. These findings suggest that gypsogenin alters DMPC membranes significantly at higher concentrations.

BP 14.16 Tue 10:00 P3

Properties of Long-Chain Lipid Enriched Regions in Biological Membranes: Insights from MD Simulations — •Annemarie Quas, Clara Rickhoff, and Andreas Heuer — Institut für Physikalische Chemie, Universität Münster, Corrensstraße 28/30, 48149 Münster

Experimental studies of yeast plasma membranes reveal gel domains enriched in long-chain lipids and depleted in ergosterol [1]. To explore these findings, we perform coarse-grained molecular dynamics simulations of membranes with varying concentration of long-chain lipids. To enhance our understanding, we simulate both asymmetric membranes with long-chain lipids in the outer leaflet, as observed experimentally, and symmetric membranes containing long-chain lipids in both leaflets. Our analysis focuses on characterizing key membrane properties and examining the influence of long-chain lipids. The role of ergosterol is also investigated. Additionally, we assess non-affine lipid movements to provide insights into the dynamics within these gel domains. This study aims to bridge experimental observations with molecular-level mechanisms, advancing our understanding of gel-phase organization and its implications for membrane functionality.

G-FETs for label-free biosensing of protein interactions — •Florian Steinbach, Mykola Fomin, Margarete Schwirblat, and Carola Meyer — Institute of Physics, University of Osnabrück, Germany

Graphene field-effect transistors (G-FETs) offer a promising approach for label-free biosensing due to their sensitivity and compatibility with liquid environ-

ments. In this work, we investigate liquid-gated G-FETs functionalized with lipid monolayers for detecting protein interactions at membrane interfaces.

The fabrication process was refined to improve device stability and reduce measurement variability. To enable reusability, we employed tris-NTA-functionalized lipids, allowing reversible binding and elution of hexahistidine (H6)-tagged proteins while preserving device functionality for subsequent detection cycles. Adjustments to the functionalization protocol included histidine-based elution, which better preserved the passivation layer compared to standard imidazole methods. Electrical measurements were used to monitor functionalization steps and protein interactions. Using monomeric enhanced green fluorescent protein (H6-mEGFP) as a model system, we present characteristic shifts and changes in transconductance during each step of the protocol.

These developments contribute to the optimization of G-FETs for biosensing applications, with particular attention to the stability of functionalized interfaces under physiological conditions. The findings will be discussed in the context of improving sensor design and extending the approach to more complex biomolecular systems.

BP 14.18 Tue 10:00 P3

Theory of spatial aggregation and shell formation — •Pranay Jaiswal, Ivar Haugerud, and Christoph Weber — Institute of Physics, University of Augsburg, Augsburg, Germany

Many biological systems use coexisting phases composed of proteins and RNA to regulate chemical processes and molecular transport. In particular, the interface can act as a nucleation site for aggregation of proteins, leading to the formation of a solid-like shell. This shell provides a physical barrier for molecular transport of further biomolecules, giving rise to molecule-specific interface permeabilities. Here we propose a theoretical model for spatio-temporal protein aggregation in phase-separated systems. To this end, we use a phase-field of proteins and RNA combined with a phase-field characterising the solid-like, aggregated state. Our key finding is that aggregation is thermodynamically favored at the interface, making aggregation shells a likely phenomenon in phase-separated systems of aggregation-prone proteins. We show how such aggregation shells control molecular transport and shell permeabilities. Our theory can be applied to experimental systems undergoing irreversible aggregation to unravel the molecular mechanism underlying ageing in protein mixtures.

BP 14.19 Tue 10:00 P3

Cell-free protein synthesis measured in flowing nanolitre-droplets — Benno Schedler[1], Alexandros Katranidis[2], and •Jörg Fitter[1,2] — [1]AG Biophysik, I. Physikalsiches Institut (IA), RWTH Aachen University, D-52074 Aachen, Germany — [2]Forschungszentrum Jülich, ER-C-3, D-52425 Jülich, Germany

Cell-size confinement of biological reactions by utilizing microfluidic water-in-oil droplets has been widely used to revolutionize the field of biomolecular research. This approach capitalizes on the precise control and manipulation of nanoliter-sized droplets within microfluidic channels. The confinement facilitates reduced reagent consumption and improved scalability. Analysing cell-free protein synthesis (CFPS) is an ideal application of this approach and represents a complex multistep process which can be monitored in individual droplets if fluorescent proteins are synthesized [1]. Understanding the physicochemical principles underlying CFPS reactions, including the role of macromolecular crowding, is crucial for optimizing protein synthesis yields and functionality [2]. Here we present the results of our ongoing research using the example of the synthesis of green fluorescent protein (GFP), which we have analysed employing confocal fluorescence microscopy. Focus is set on the high throughput capability of the approach and thus the possibility of analysing several hundred parallel reactions. The latter provide important information about the average synthesis productivity and the distribution widths for reactions under different environmental conditions. BP 14.20 Tue 10:00 P3

Enhancing polymerization of prebiotic building blocks by wet-dry cycling — •Almuth Schmid and Dieter Braun — AG Braun, LMU Systems Biophysics, Munich, Germany

Prebiotic chemistry is limited by several factors as concentration or availability of starting materials on the early Earth. On top of that, many artificial and natural activation agents are too complex to have been a part of prebiotic reaction networks. To overcome this problem, amino acids might help reaching ideal environmental conditions, enhancing prebiotic reactions like polymerization of nucleotides. Preliminary experiments demonstrated, that in a wet-dry cycling system rel. yields of GC polymers are boosted up to 70% in the presence of amino acids.

By using wet-dry cycles and including other prebiotic plausible activating agents like volcanic rocks, a better control of the polymerization can be accomplished. Tracking the polymerization on tholeiite basaltic rock with SEM reveals first hints on where and how the polymers interact with the mineral.

BP 14.21 Tue 10:00 P3

Phase-separation enhances sequence selection via templated ligation — •Manav Koul, Ivar Haugerud, and Christoph Weber — Universität Augsburg, Universitätsstraße 2, 86159 Augsburg

The emergence of highly selective catalytic sequences was a crucial step towards the origin of life. templated ligation of RNA has been proposed as a pre-biotic mechanism to achieve self-replicating sequences without complex machinery. A question remains as to how sufficiently long and abundant templates can emerge from short nucleotides in a non-conducive prebiotic pool. As phase separation has been shown to provide versatile hubs of correlated sequences, we investigate its role in facilitating and directing templated ligation. To this end, we develop a non-equilibrium thermodynamic model to describe the oligomerization of sequences and their ligation at non-dilute conditions in phase-separated systems. We find that phase-separation enhances the selection pressure of this mechanism, resulting in a sequence distribution dominated by highly structured sequence of low entropy. Our results highlight that out-of-equilibrium condensed phases could provide versatile hubs for Darwinian-like evolution toward functional sequences, both relevant for the molecular origin of life and de-novo life.

BP 14.22 Tue 10:00 P3

Phase Transitions in Non-Hydrated DPPC Lipid Bilayers Deposited on Silicon: Effects of Dry Nitrogen Atmosphere and Thermal Cycling — •Nicolás Moraga[1], Daniel Saavedra[1], Nancy Gomez-Vierling[1], Marcelo A. Cisternas[2], María José Retamal[3], and Ulrich G. Volkmann[1] — [1]Instituto de Física, Pontificia Universidad Católica de Chile, Santiago, Chile — [2]Escuela de Ingeniería Industrial, Universidad de Valparaíso, Chile — [3]Facultad de Ingeniería, Universidad Finis Terrae, Santiago, Chile

This study investigates the phase behavior of DPPC lipid bilayers in a non-hydrated state, deposited on silicon substrates, under conditions that are both experimentally innovative and highly relevant for applied science and fundamental research. By assembling these bilayers in vacuum and exposing them to dry nitrogen atmospheres, we present a novel platform that extends beyond classical hydrated systems, with significant implications for biosensing technologies. Through controlled thermal cycling using high-resolution ellipsometry, a technique offering exceptional sensitivity to subtle changes, we analyze phase transitions, uncovering the impact of hydration-free environments on lipid bilayer organization. These findings provide new insights into the thermal resilience of DPPC bilayers, highlighting potential phase stability domains. Additionally, this approach simulates extraterrestrial-like conditions where water is absent, underscoring the adaptability of lipid-based structures and advancing our understanding of molecular organization under vacuum and inert atmospheres. BP 14.23 Tue 10:00 P3

Cooperative Effects in Compartmentalized Irreversible Self-Assembly — •Severin Angerpointner, Richard Swiderski, and Erwin Frey — Arnold Sommerfeld Center for Theoretical Physics, Ludwig-Maximilians-Universität München, Germany

From biomolecular compartments, protein patterns to porous rocks: Many biological and chemical systems like living cells or prebiotic chambers exhibit some form of spatial organization which separates biochemical processes. This is known to play a key role in the assembly of virus capsids or the enrichment of prebiotic chemicals. We systematically explore the effects of such spatial separation on the self-assembly of irreversibly binding identical particles. We show that already in a simplified model of two coupled biochemical compartments cooperative effects emerge through limiting compartment exchange. Further, these findings generalize to spatially extended systems like intracellular chemical gradients or membrane-assisted assembly.

BP 14.24 Tue 10:00 P3

Mathematical modelling of immune response on the example of psoriasis — •Nadezhda Esenkova[1,2], Lukas Pöschl[1,2], Gerard C. L. Wong[3], and Vasily Zaburdaev[1,2] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — [2]Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany — [3]University of California, Los Angeles, USA

In recent years it was shown that antimicrobial peptides (AMPs) can contribute to the immune response by triggering Toll-Like Receptors (TLRs) on immune cells. Apart from natural AMPs it was suggested that proteolytic enzymes, secreted by neutrophils can digest other signaling molecules to AMP-like fragments, which can stimulate immune response and lead to disease progression. The goal of this work is to create a mathematical model of immune response by introducing this novel link of AMP-like fragments. To this aim we constructed a comprehensive signaling network of the immune response based on one of the best studied autoinflammatory diseases – psoriasis. Taking into account the key biological pathways we reduced it to the core network model, which we investigate using theoretical dynamical systems analysis and modern machine learning methods. We aim to understand how the hypothesized mechanism of autoinflammation due to AMP-like fragments augments the disease outcomes from full resolution, to chronification and rapid exacerbation.

BP 14.25 Tue 10:00 P3

Formation of thermally driven pH gradients from salts — •Riccardo Schiroli, Thomas Matreux, and Christof B. Mast — Systems Biophysics, LMU München, Munich, Germany

The impact of pH on biomolecule stability and chemical reactions suggests its crucial role in prebiotic chemistry. Thermophoresis, the movement of molecules along a thermal gradient, has been shown to accumulate and select a wide range of biomolecules, including RNAs and amino acids as well as different salt species leading in specific conditions to the emergence of pH gradients.

In this study, we investigated the formation of heat flow driven pH gradients in simulated rock fissures under various experimental conditions, including different salt solutions, initial pH values, and temperature gradients. Ion chromatography, combined with complexation techniques and fluorescent analysis, was used to analyze the distribution of ions and pH profiles within the fissures.

Our findings show that heat flows can efficiently induce pH gradients in solutions containing various salt species. We observed significant accumulation of common ions, leading to pH gradients in both alkaline and acidic solutions. Furthermore, we found that certain metal ions, such as lanthanides and iron, can significantly enhance the formation of pH gradients, even at micromolar concentrations. This study provides evidence for the role of heat flows in creating localized pH gradients under prebiotically plausible conditions. Our results highlight the ease with which pH gradients can form under a wide range of prebiotic plausible conditions, driven by simple heat flows.

BP 15: Cell Mechanics I

Does Oncology Need Physics of Cancer? — •Josef Käs — Peter Debye Institute for Soft Matter Physics, Leipzig University, Linnéstr 5, 04103 Leipzig

Cancer is a complex disease that accounts for nearly one in six deaths worldwide. More than 90 percent of deaths are due to metastasis * the process by which cancer cells spread from the primary tumor and seed a secondary tumor in a distant tissue. Despite advances in cancer treatment, metastatic recurrences remain a significant challenge. Understanding metastasis is crucial for a reliable predictive diagnosis needed for personalized oncology and to develop therapies that inhibit cancer spreading. The metastatic cascade routes in a mechanical problem for tumor cells on their way through the human body squeezing through dense tissues. Two clinical trials with more than 2000 breast cancer patients in each study prove that the onset of cancer cell motility can be explained as an unjamming transition and local cancer spreading of cancer cell clusters embedded in ECM must be described as active nematic droplets in a nematic phase. The gained physical parameters can be used a prognostic tumor marker for metastatic risk that improves breast cancer diagnosis by 26 percent. Beyond diagnostics the mechanical modulation of cancer cells by adipocytes points us towards migrastatic therapies to suppress metastasis.

BP 15.2 Tue 12:15 H44

Prostate cancer associated fibroblasts have distinct morpho-mechanical features that predict patient outcome — Antje Garside[1], Angela Jacobi[1], Shivakumar Keerthikumar[2,3], Michelle Richards[2], Birunthi Niranjan[2], Gail Risbridger[2,3], Mitchell Lawrence[2,3], and •Anna Taubenberger[1] — [1]BIOTEC, TUD, Dresden, Germany. — [2]Monash University, Victoria, Australia — [3]Peter MacCallum Cancer Centre, Melbourne, Australia.

Prostate cancer is among the most commonly diagnosed types of cancer. A key role in tumor progression has been attributed to the tumor stroma including its cellular components such as cancer associated fibroblasts (CAFs). Here we present a comprehensive study where we quantitatively assessed the morpho-mechanical properties of patient-derived prostatic CAFs and matched normal prostatic fibroblasts from a cohort of 35 patients, through combination of cell morphometric analysis and high-throughput mechanical probing of single cells by real-time deformability cytometry. CAFs comprised distinct morpho-mechanical features compared to their normal counterparts, including nuclear size and shape, cytoskeletal arrangement, cellular volumes and elastic properties. A combined score of these mechanical and morphological parameters distinguished patients with shorter and longer time to clinical relapse. Morpho-mechanical changes across patients were correlated with transcriptomic alterations in cellular components and pathways. In summary, our results suggest that high-throughput assessments of the biophysical properties of CAFs can serve as a complementary tool to predict patient outcome.

BP 15.3 Tue 12:30 H44

Viscoelasticity of Cancer Cells: New Insights from Magnetic Rotational Spectroscopy — •Jean-François Berret — Université Paris Cité, CNRS, Matière et systèmes complexes, 75013 Paris, France

Cell mechanical properties are linked to tumor progression and can serve as diagnostic biomarkers. Over the past two decades, numerous studies have shown that cancer cells are softer than healthy cells. While the viscoelastic nature of cells is well known, most studies focus on elasticity, with limited attention to viscosity. To address this, we developed Magnetic Rotational Spectroscopy (MRS), an active technique using non-toxic magnetic wires embedded in the cytoplasm and tracked via optical microscopy under a rotating magnetic field. This allows simultaneous measurement of viscosity η and elastic modulus G. MRS studies on 15 human and animal cell lines, both healthy and cancerous, uncovered a new finding: intracellular viscosity increases with wire size following a quadratic η(L)-relationship. Furthermore, in breast epithelial cells, only viscosity, not elasticity, could differentiate cells with low and high metastatic potential. A meta-analysis of literature on cell viscosity, covering whole-cell and intracellular data finally reveals that cancer cells have viscosities about 50% lower than healthy cells, suggesting that cancer cells are not only softer but also more fluid, offering potential for selective diagnostic tools in cell biomechanics. [1] A.M. Markl et al., Cancer Heterog. Plast., (2024). [2] J.-F. Berret, Nat. Commun. 7, 10134 (2016). [3] M. Dessard et al., Nanoscale Adv. 6, 1727 (2024).

BP 15.4 Tue 12:45 H44

Living Cells Feel the Surface Tension of Soft Solids — •Johannes Rheinlaender, Hendrik von Eysmondt, and Tilman E. Schäffer — Institute of Applied Physics, University Tübingen, Germany

For about 20 years it has been known that living cells actively respond to the stiffness of their microenvironment - most obviously - by a change in cell spreading area but also other properties such as stiffness, nucleus shape, and gene expression, denoted as mechanosensing. These effects are commonly investigated using hydrogels with a bulk Young's modulus in the kPa range, where cells respond to substrate stiffnesses typically between 1 and 100 kPa. On other soft materials such as elastomers, cell behavior has been shown to be different and weaker, plateauing below about 10 kPa, but the reason remained a matter of debate. On the microscale, surface properties such as surface tension are of increasing relevance, but probing interfaces with micro-indentation techniques such as atomic force microscopy is challenging due to adhesion effects. We therefore use scanning ion conductance microscopy (SICM), a unique scanning probe method benefiting from its non-contact measurement principle, to probe the surface tension of soft solids showing that elastomers exhibit surface tensions of about 10 mN/m, relatively independent of their bulk Young's modulus and surface treatment. Hence, cells mostly "feel" the bulk properties of elastomers for Young's moduli above about 10 kPa, but below mostly the surface tension, demonstrating that the substrate's surface tension is an important yet underestimated aspect in mechanobiology.

BP 16: Focus Session: Nonlinear Dynamics in Biological Systems II (joint session DY/BP)

Nonlinear dynamics play a central role for biological systems to achieve remarkable complexity and adaptability. They underlie processes where small changes cascade into large effects, critical thresholds drive transitions, and feedback mechanisms maintain intricate balances. Biological systems are often far from equilibrium, exhibiting behaviors shaped by competing forces, stochastic fluctuations and emergent behavior. From the amplification of sensory signals near bifurcation points to the development of turbulence, concepts from nonlinear dynamics provide a unifying framework for studying patterns, stability, and collective behavior in living systems. This focus session explores the richness of nonlinear dynamics across biological scales, from molecular circuits to population-level phenomena, spanning vastly different fields from cardiac dynamics, embryogenesis and cell motility to active fluids, condensates and origin of life. Through theoretical models, experimental insights, and computational approaches, the talks illustrate how nonlinear-dynamics principles unravel the mechanisms driving function and complexity in biology, offering new perspectives across disciplines.

Invited Talk BP 16.1 Tue 14:00 H43

Mechanistic origins of temperature scaling in the early embryonic cell cycle — •Lendert Gelens — Laboratory of Dynamics in Biological Systems, Department of Cellular and Molecular Medicine, KU Leuven, Herestraat, 49, Leuven, Belgium

Temperature profoundly impacts organismal physiology and ecological dynamics, particularly affecting ectothermic species and making them especially vulnerable to climate shifts. Even though complex physiological processes usually involve dozens of enzymes, empirically it is found that the rates of these processes often obey the Arrhenius equation, which was originally derived for single enzyme-catalyzed reactions. Here we have examined the temperature scaling of the early embryonic cell cycle, with the goal of understanding why the Arrhenius equation approximately holds, and why it breaks down at temperature extremes.

Using experimental data from different frog, fish, fly, and worm species, we find that the apparent activation energies for the early embryonic cell cycle for diverse ectotherms are all similar. Computational modeling and experiments with frog egg extracts show that the non-Arrhenius scaling can be accounted for by biphasic temperature scaling in critical individual components of the cell cycle oscillator circuit, in combination with imbalances in the activation energies for different partially rate-determining enzymes. These findings provide mechanistic insights into the dynamic interplay between temperature and complex biochemical processes, and into why biological systems fail at extreme temperatures.

BP 16.2 Tue 14:30 H43

Reshaping morphogen gradients through porous tissue architecture — •Diana Khoromskaia[1,2] and Zena Hadjivasiliou[1,2,3] — [1]Francis Crick Institute, London, United Kingdom — [2]University College London, London, United Kingdom — [3]London Centre for Nanotechnology, London, United Kingdom

The morphogenesis of tissues during embryonic development is controlled by concentration gradients of morphogens – signalling molecules whose readout determines cell fate decisions. How the spread of morphogens is affected in tissues with complex geometry and spatially heterogeneous architecture is not well understood. To address this question, we introduce a porous vertex model, by explicitly considering the network of extracellular spaces between the cells. Morphogens produced by source cells disperse through the tissue via three modes of transport: extracellular diffusion, membrane-bound diffusion, and cell-based transport through recycling. With this model we investigate numerically and analytically how cell-scale geometry, such as cell size, cell shape anisotropy, and cell distance, influences effective diffusion and degradation of morphogens at tissue-scale. We further show that a non-linear coupling between cell packing and morphogen concentration renders the morphogen gradient robust to perturbations, for instance by locally buffering fluctuations in the production. Our characterisation of tissues as active porous materials provides new insights into how morphogenesis and cell fate determination may interact during embryonic development.

BP 16.3 Tue 14:45 H43

Active viscoelastic condensates provide controllable mechanical anchor points — •Oliver Paulin[1], Luise Zieger[2,3], Júlia Garcia-Baucells[5], Alexander Dammermann[5], Sebastian Aland[2,3,4], and David Zwicker[1] — [1]Max Planck Institute for Dynamics and Self-Organization, Göttingen — [2]TU Bergakademie Freiberg — [3]HTW Dresden — [4]Center for Systems Biology, Dresden — [5]Max Perutz Labs, University of Vienna

Many biological materials must couple mechanical strength with the ability to rapidly self-assemble at a specific location. In particular, biomolecular condensates readily self-assemble via phase separation, but may also need to anchor external forces to fulfil their function. Spatial localisation of condensate formation can be controlled by active cores that preferentially drive the production of condensate material at a particular point, while resistance to external forces can be facilitated by viscoelastic material properties. Here, we develop a continuum model of viscoelastic growth around an active core, and investigate the results in a spherically symmetric geometry. We find that viscoelastic stresses restrict condensate growth, but also impart resistance to deformation. We investigate the effect of varying different mechanical properties on condensate growth and strength, and also study how strain-dependent material incorporation may limit the maximum rate of growth. Finally, we compare the predictions of our model to experimental data from centrosomes in C. elegans embryos, identifying a parameter regime in which rapid growth can be combined with appropriate mechanical strength.

BP 16.4 Tue 15:00 H43

Modelling cell crawling on different substrate stiffness — Sohei Nakamura and •Mitsusuke Tarama — Kyushu University, Fukuoka, Japan

Crawling cells sense the mechanical properties of the underlying substrate and change their dynamics accordingly. This ability called durotaxis is of great importance in various biological processes including development and homeostasis. In order to understand how intracellular chemical reactions and cellular mechanics give rise to durotaxis, we constructed a simple model from reaction diffusion equations for intracellular chemical compounds and force balance equations for the intracellular mechanics including the effect of the substrate stiffness. We found that within the model, the cell speed and diffusion coefficient change non-monotonically with the substrate stiffness, indicating the existence of an optimal substrate stiffness for migration. This non-monotonic behavior of the cell speed is consistent with experimental observations and can be understood to be caused by the competition between substrate adhesion and cell shape deformation. We further discuss cell migration on a patterned substrate.

Effect of cilia length on the motility of confined microbes — •Tom Sosniok, Alexandros Fragkopoulos, Rodrigo Catalan, and Oliver Bäumchen — University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany

Many microorganisms utilize their cilia or flagella to propel and navigate through their surrounding liquid environment. Often times though, the habitats of such microswimmers comprise confined spaces, and therefore, cell interactions with boundaries play an important role on their navigation. *Chlamydomonas rein-*

hardtii, a biciliated, green microalga that is commonly found in soil, typically swims in close proximity to curved boundaries [1]. We found that this near-wall swimming motility is controlled by gradients of wall curvature and steric interactions between the cilia and the surface [2]. Here we explore the effect of the cilia length on the motility and surface interactions of the cells using different *C. reinhardtii* mutant strains with different cilia lengths in quasi-2D circular confinement. We extract information about their motion from their mean squared displacements and visualize the wall-guided swimming via relative and radial probability densities. By comparing the results for the different strains we can directly analyse the influence of the cilia length on their swimming motility in confinement.

BP 17.2 Tue 18:00 P4

Stochastic modeling of a two-component polymer engine — •Yasmin Abdelghaffar[1] and Marcus Jahnel[1,2] — [1]Cluster of Excellence Physics of Life, Technical University Dresden, Dresden, Germany — [2]Biotec, Technical University Dresden, Dresden, Germany

Long coiled-coil tethering proteins and small GTPases have recently been shown to form a new class of biomolecular motors driven by entropic collapse. The working principle of this motor is a cyclic flexibility transition of its filamentous tether, triggered by the GTPase unit. While a basic working model was proposed (Singh, 2023), many fundamental aspects of these two-component molecular motors remain unexplored. Here, we developed a stochastic model as an over-damped to-state semi-flexible polymer to describe the mechanochemical cycle that drives this motor. Using this model, we can predict how efficiency and power of this motor are affected by changes in model parameters such as persistence lengths. Additionally, by introducing force-dependent rates in the mechanochemical coupling of our model, we can potentially explain previous discrepancies in the measured hydrolysis rate of GTP between in bulk experiments, which occur under no force, and tweezer experiments, where the system is under tension. Our simulation study thus makes an indication on the chemical nature of the coiled-coil protein within the motor, identifying it as a potential GTPase-activating protein.

BP 17.3 Tue 18:00 P4

Modeling dynamics and density distribution of magnetotactic bacteria in traps — •Theo Richter, Sascha Lambert, and Stefan Klumpp — Institut für Dynamik komplexer Systeme, Universität Göttingen, Göttingen, Germany

Magnetotactic bacteria are microorganisms that navigate using internal magnetosomes, aligning them along magnetic fields. They represent an intriguing model system for studying active Brownian particle dynamics under an external alignment field. Previous studies have analyzed their movement through crowded channels, where the orientation along the magnetic field and their interaction with obstacles prove to be important mechanisms for navigation. In such complex environments, bacteria often find themselves trapped in corners, where the dynamics of how they escape these traps are crucial and remain mostly unexplored.

In this work, we aim to understand the density profiles, escape rate and general dynamics of single active Brownian particles under an alignment field inside trapping geometries. We investigate these quantities via simulations in varying trap geometries, with a focus on triangular traps, characterizing the effects of system parameters such as magnetic field strength and particle-wall interactions. We relate the behavior of the bacteria in these geometries to the sedimentation of active Brownian particles.

BP 17.4 Tue 18:00 P4

Light-switchable adhesion and clustering of *C. noctigama* at liquid-air interfaces — •Gustav Nolte, Alexandros Fragkopoulos, and Oliver Bäumchen — University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany

Microalgae are unicellular photoactive organisms that are ubiquitous in liquid-infused natural environments. The biciliated microalga *Chlamydomonas reinhardtii* shows light-switchable adhesion and clustering at surfaces, a process so far exclusively observed for solid-liquid interfaces [1,2,3]. Here we report on the light-switchable formation of clusters by *Chlamydomonas noctigama*, a related species with increasing relevance in the field of optogenetics, at liquid-air interfaces. The morphology and dynamics of these clusters differ significantly from the clusters formed by *C. reinhardtii*. Apart from the average cluster size and polydispersity, the growth dynamics of individual clusters are studied for a wide range of cell densities. We find a critical cell density above which the number of clusters decreases over time. For the underlying principles of cluster formation and dynamics, we address potential mechanisms like preferential attachment and Ostwald ripening. Reversible clustering may provide an advantage for *C. noctigama* by allowing the cells to accumulate in locations optimal for photosynthesis while also increasing resilience to environmental stress within the cluster.

BP 17.5 Tue 18:00 P4

The Dynamics of Spatiotemporal Self-organization in Active Turbulence — •Henri Jörn Schmidt — Max-Planck institute for self-organisation and dynamics, Göttingen, Germany

Spontaneous pattern formation in nature has been subject to extensive research in recent decades, with more and more emphasis being put on the dynamics of their creation processes.

In this work we investigate coherent structures in fluid flows. Specifically, this work concentrates on eddy currents found in the turbulent regime of active nematics. We analyse their formation and evolution as well as how their dynamics is affected by the cross-talk between different length scales. In doing so, we introduce a new methodology to record the overlaps of eluded structures in an agent-based approach. This allows for size changes in individual structures without inflicting biases in the computed intersection ratios.

Our results seem to indicate no particular cascade of different length scales. However, we do observe an universal evolution of the eddy currents, marked by a pronounced growing and shrinking phase. Usually, these stages take place within an encapsulating parent structure. Likewise, as the eddies have attained their nominal size, they give rise to new eluded structures themselves. These dynamics seem to be independent from both, the size ratio of clusters and their elapsed life time.

BP 17.6 Tue 18:00 P4

Macroscopic transports in cellular aggregates driven by dipole forces — •Subhadip Chakraborti[1,2] and Vasily Zaburdaev[1,2] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — [2]Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany

The large-scale collective behavior of biological systems can be understood through macroscopic transport processes that emerge from the active interactions of individual components at the microscopic level. A striking example is the clustering and the associated transport slowdown observed in colonies of *Neisseria gonorrhoeae* bacteria, driven by active, contractile forces mediated by pili. In this study, we analytically derive the fluctuating hydrodynamics from the microscopic dynamics of a 2D model system representing an *N. gonorrhoeae* bacterial colony. The hydrodynamic current of cells involves two macroscopic transport coefficients: bulk diffusivity and conductivity, which generally depend on cell density and other microscopic parameters. Remarkably, our simulation results strongly support the analytical predictions of transport slowdown during the colony formation process. Beyond bacterial colonies, these findings offer insights into how contractile forces influence transport in other biological systems, such as tumor spheroids and neuronal organoids, and suggest experimental approaches for studying these phenomena.

BP 17.7 Tue 18:00 P4

Dynamics, stresses and cell fate in confluent cell monolayers — •Stefano Villa[1,2], Giorgio Scita[3], Roberto Cerbino[4], and Fabio Giavazzi[2] — [1]Max Planck Institute for Dynamics and Self-Organization, 37077 Göttingen — [2]Universitá degli Studi di Milano, 20090 Segrate — [3]IFOM-FIRC Institute of Molecular Oncology, 20139 Milan — [4]University of Vienna, 1090 Vienna

Confluent cell monolayers are 2D active systems exhibiting a variety of dynamical states, ranging from solid-like jammed systems to fluid-like flocking systems. Such a rich panorama results in different mechanical stresses the single cells within the monolayer are subjected to. Due to their impressive complexity, cells do not merely react to the mechanical stresses but actively interact with the environment, e.g. adapting their mechanical properties to the stimuli. The investigation of the close interplay between dynamical state and mechanical properties of tissues is therefore of paramount interest for unraveling how cells respond to mechano-physical stimuli. We present a detailed analysis based on cell segmentation performed on time-lapse microscopy videos showing the effect of motility-induced stresses on the single cell mechanics, comparing cell models mimicking healthy tissues and tumor-like tissues. We show how the increase in dynamics leads to larger cell deformations to which the cells respond by increasing the stiffness of the nucleus. Finally, we show how mechanical stresses within the monolayer can affect tissue morphogenesis in real systems, thus highlighting once again the relevance of mechano-physical stimuli for the cell and tissue development and fate.

BP 17.8 Tue 18:00 P4

Analysis of Wall-Torques for Rod-Shaped Active Particles — •Merle Duchêne, Sascha Lambert, and Stefan Klumpp — University of Göttingen, Institute for the Dynamics of Complex Systems, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

The motility of living things and synthetic self-propelled objects is often described using Active Brownian particle models. To account for interactions with complex environments, this model can be expanded with empirical forces or torques, such as those describing their alignment with an obstacle or wall after

a collision. Here, we evaluate the quality of these empirical models by comparing their output predictions with trajectories of rigid rod-shaped active particles that scatter sterically at a flat wall. Specifically, we analyze the torque reorienting the rod-shaped particle and compare it to predictions from a phenomenological model. We employ a classical least-squares method to evaluate the instantaneous torque and identify essential model parameters. In addition, a Bayesian inference procedure can be applied to construct the posterior distribution of plausible model parameters which provides a complementary perspective to the least-squares analysis.

BP 17.9 Tue 18:00 P4

Onset of bioconvection in a simple continuum model — •Marius M. Kaiser, Fabián Álvarez-Garrido, and Michael Wilczek — Universität Bayreuth

Dense suspensions of swimming micro-organisms show bioconvection, i.e.~the emergence of self-organized flow patterns much larger than the individual swimmers, under certain conditions. Here, we analyze the onset of bioconvection in a simple continuum model. The model is derived from the Fokker-Planck equation for the swimmer concentration field and the swimmer orientation field [Pedley, J. Fluid. Mech. 647, 335 (2010)] coupled to the Navier-Stokes equation, in which we only consider buoyancy effects (no cell stresses) and approximate higher-order moments in terms of the polar order parameter. A linear stability analysis in the idealized case of a prescribed polar orientation field shows that the system exhibits a type-II instability. The results of our linear stability analysis are in agreement with direct numerical simulations of our model. Simulations of the model, now with dynamically evolving polar orientation field, suggest that the type of spatial instability remains the same, albeit with shifted critical values. Our findings shed light on the mechanism driving pattern formation in this type of suspensions.

BP 17.10 Tue 18:00 P4

DNA origami laden with bespoke magnetic nanocubes: A route to programmable torques at the nanoscale — Florian Rothfischer[1], Yihao Wang[2], Lennart Weiss[1], Christopher Pauer[3], Kevin Lang[3], Susanne Kempter[3], Rabia Amin[2], Elena Eiwanger[3], Jan Lipfert[4], Tim Liedl[3], Friedrich C Simmel[1], Joe Tavacoli[3], and •Aidin Lak[2] — [1]Physics Department E14, Technical University Munich — [2]Institute for Electrical Measurement Science and Fundamental Electrical Engineering and Laboratory for Emerging Nanometrology (LENA), TU Braunschweig — [3]Faculty of Physics and Center for NanoScience, LMU Munich — [4]Institute for Physics, Augsburg University

Magnetic-field responsive actuators offer minimally-invasive and deep-tissue perturbation of cellular processes. Despite progress, the magnetic manipulation of cells at the single receptor level is still challenging; magnetic nanoparticles (MNPs) can only exert ~ fN forces. To achieve biologically relevant pN forces, it is necessary to assemble MNPs together in a controllable manner. This has not yet been achieved utilizing soft-synthetic templates, where control over the number, and orientation of MNPs remains a challenge. DNA origami (DNAO) can overcome this limit, specifically so for its capacity to arrange nanoparticles at high spatial resolution. Here, we demonstrate assembly of bespoke MNPs on 6 helix-bundle DNAO and show the controlled magnetic rotation of magnetic DNAOs under circulating magnetic fields of 8 mT. Our magnetic DNAOs are promising torque nanoprobes for activation of sub-cellular processes at high resolution.

BP 17.11 Tue 18:00 P4

Engineering Shear-Thinning Hydrogels: A Dynamic Scaffold for 3D Tissue Culture — •Bruno Schmelz[1], Fen Li[2], Kai Zhang[2], and Timo Betz[1] — [1]Third Institute of Physics, University of Göttingen, Germany — [2]Sustainable Materials and Chemistry, Department of Wood Technology and Wood-based Composites, University of Göttingen, Germany

Extracellular matrix (ECM) scaffolds are essential for advanced 3D cell culture systems, providing structures for cell movement as well as physical and chemical cues that promote migration, proliferation, and differentiation. Hence, the ECM is crucial for functional tissue formation. However, natural ECM materials used in vitro, such as collagen and elastin, are difficult to control regarding elastic properties, polymer mesh size, and homogeneity. Our objective is to design a dynamic hydrogel tailored to meet the specific requirements of 3D tissue culture, such as viscoelastic properties and cell-binding sites, that initially supports tissue formation but can be dissolved and replaced by cell-generated ECM. We propose a hydrogel with non-covalent cross-linking moieties that allow for reorganization by embedded cells, similar to the reorganization of collagen fibers in physiological tissues. We present the rheological properties of the hydrogels and the initial findings of cell invasion into them. When subjected to stress, the hydrogels exhibit a transition to a more liquid-like state, with the potential to solidify again upon stress relaxation. This behavior allows cells to remodel their surrounding matrix and shape their environment, as evidenced by experiments with cells cultured on the hydrogels.

BP 17.12 Tue 18:00 P4

Supramolecular ordering in lipopolymer monolayers at the air/water interface — •Issam Assi, Heiko Ahrens, and Christiane A. Helm — Institute of Physics, University of Greifswald

Lipopolymers with covalently bound poly(ethylene oxide) (EO_N) bound to the head groups have been introduced to stabilize bilayer membranes. Langmuir monolayers of the lipopolymer DSPE-EO_N at the air/water interface show in the isotherm a transition from the liquid expanded to the liquid condensed phase, which is confirmed by in-situ Grazing Incidence X-ray Diffraction (GID at DESY, Hamburg). A laterally inhomogeneous film of condensed ordered alkyl chains embedded in a matrix of solvated polymers is formed. Small Angle GID shows these lipid domains are ordered in a hexagonal lattice (repeat distance about 12 nm). The films stay homogeneous on the micrometer scale as observed with Brewster Angle Microscopy. On transferred monolayers, these supramolecular phases were observed with AFM. Fast compression of DSPE-EO_{44} monolayers is necessary to maintain the hexagonal superstructure at relatively high lateral pressures, whereas slow compression induces a lamellar structure. Also, the superstructure of lipopolymers with shorter polymers (DSPE-EO_{11} and DSPE-EO_{22}) was explored.

BP 17.13 Tue 18:00 P4

Nanoscale drug delivery system aggregates controlably on graphite — •Henrik Siboni[1,2], Leonhard Grill[2], and Andreas Zimmer[1] — [1]Pharmaceutical Technology & Biopharmacy, University of Graz, Austria — [2]Single Molecule Chemistry, University of Graz, Austria

Nanoscale drug delivery systems are nanoparticles used to enhance the efficacy of drugs and their effectiveness depends on physical properties such as size, shape and aggregation behaviour. These parameters can be measured on a substrate with atomic force microscopy, but conserving the individual nanoparticles has proven challenging. In this study, we show that the substrate highly-oriented pyrolytic graphite allows for controllable imaging of single as well as aggregated protamine-oligonucleotide drug delivery systems. This approach can potentially be used to screen drug delivery systems and avoid unnecessary in vivo test.

BP 17.14 Tue 18:00 P4

Printed biometamaterials for mechanical regulation of cells — •Clara Schaefer[1], Alexander Berkes[2], Martin Wegener[2], Natalie Munding[1], and Motomu Tanaka[1,3] — [1]Institute of Physical Chemistry, Heidelberg University, 69120 Heidelberg, Germany — [2]Institute of Applied Physics, KIT, 76131 Karlsruhe, Gemany — [3]Kyoto University, Kyoto 606-8501, Japan

Ample evidence has shown that cells detect and respond to the mechanical properties of their microenvironment. Materials with non-conventional mechanical properties (mechanical metamaterials) have shown significant effects on human mesenchymal stem cells (Munding, et al. Adv. Funct. Mater. 2024). The key requirements are to make the unit cell size smaller than the cells and to make the materials deformable by cell traction forces. The anisotropic elastic properties lead to different responses in the traction force field that are distinct from those to bulk materials. To deal with multicellular systems and to follow cell migration, one of the challenges is to increase the lateral size to several hundreds of μm. To achieve this goal, we increased the printing speed by using a new multi-focus device in two-photon laser printing. This enables to fabricate even asymmetric metamaterial structures that can potentially be used to induce cell polarization.

BP 17.15 Tue 18:00 P4

Subcellular distribution of green-emitting carbon nanodots — •Mariell Gassen, Mine Polat, Carla Sprengel, and Thomas Heinzel — Condensed Matter Physics Laboratory, Heinrich Heine University, Düsseldorf, Germany

Carbon nanodots are promising fluorescent nanoparticles for biomedical imaging applications and drug delivery. They frequently show fluorescence in the blue range, which causes interference with the autofluorescence of the cell [1]. To circumvent this, we produced green-emitting carbon nanodots and incubated them in cells. We report tests about their subcellular distribution and studies of their suitability as carriers for active substances.

BP 17.16 Tue 18:00 P4

Red Blood Cells under brightfield microscopy — •Aaron Kreis, Sarah Tabea Hermes, Thomas John, and Christian Wagner — Experimental Physics, University Saarland

The observation of red blood cells under a conventional light microscope is a common practice in research and medicine. In many cases, the particular cell shape is the object of interest, see [1]. Red blood cells are composed mostly of hemoglobin, which shows its maximum absorption at ~ 420 nm. Nevertheless, the cells are mostly observed under white or red light. Furthermore, the refractive index of the cytosol is greater than that of water and refraction occurs. The combination of refraction and absorption leads to very different microscopy images at different focal points. We have quantified this using calculations by ray

tracing and we can explain the observed microscopy images, including the white 'halos' due to refraction at various focal positions. Diffraction isn't a major contribution in observed cell shapes. We demonstrate that the use of blue light results in a significantly better image contrast of the cell shapes without artifacts, compared to the usual observation with white light.

BP 17.17 Tue 18:00 P4

High-resolution chemical characterization of retinal pigment epithelium (RPE) using mid-infrared photo-induced force microscopy — •Maryam Ali[1,2], Robin Schneider[1], Patrick Then[1], Mohammad Soltaninezhad[1,2], Sebastian Unger[1,2], Christoph Krafft[1,2], Christine A. Curcio[3], Rainer Heintzmann[1,2], Thomas Ach[4], and Daniela Täuber[1,2] — [1]Leibniz Institute of Photonic Technology, Jena, Germany — [2]Friedrich Schiller University, Jena, Germany — [3]University of Alabama at Birmingham, United States — [4]University Hospital Bonn, Germany

Nanoscale infrared (IR) spectroscopic imaging methods fill a gap in bioimaging. Mid-IR photo-induced force microscopy (PiF-IR) combines powerful IR illumination with non-contact atomic force microscopy, resulting in high spectral and unprecedented spatial resolution (< 5 nm)[1]. We applied PiF-IR to a cross-section of the retinal pigment epithelium (RPE) layer of a human donor eye. The strongly polar RPE cells play a major role in the vision cycle. Several types of autofluorescent granules in RPE cells[2] contribute to fundus autofluorescence, a clinical imaging technique used for the diagnosis of retinal diseases. In spite of their importance, the chemical composition of these organelles is not fully known. A combined chemometrics analysis of three PiF-IR hyperspectra from locations across the RPE layer reveals variations in the protein content of the surfaces of granular organelles. –[1] J. Joseph et al., Spectrochimica Acta Part A: Molecular and Biomolecular Spectroscopy 2024, 306, 123612. [2] K. Bermond et al., IOVS 2020, 61, 35.

BP 17.18 Tue 18:00 P4

Preparation of green fluorescent carbon nanoparticles — •Mine Polat, Carla Sprengel, and Thomas Heinzel — Condensed Matter Physics Laboratory, Heinrich Heine University, Düsseldorf, Germany

Carbon nanodots (CNDs) are promising materials for biomedical applications due to their unique fluorescent properties and biocompatible structure. However, many CNDs emit in the blue range, which is less favorable for specific applications. In this project, green-emitting CNDs were synthesized, their optical properties were analyzed, and the quantum yield was calculated. The results of absorption and emission spectra are presented.

BP 17.19 Tue 18:00 P4

Real-time monitoring of fluctuations in ATP levels and mechanobiological signatures in living cells — •Albina Nizamieva and Matthias Weiss — Experimental Physics I, University of Bayreuth, Bayreuth, Germany

Living cells are genuine non-equilibrium systems with a typical energy turnover of roughly 10^8 times thermal energy in every second. This translates to about 10^7 ATP hydrolysis events per second, with which cells may fuel, for example, signaling cascades and/or contractions of the actomyosin cytoskeleton to probe and migrate on the substrate underneath. Here we have used fluorescent reporter molecules to quantify in living cells (1) the temporally fluctuating ATP levels, and (2) fluctuations of a key mechanosensory protein that connects cellular mechanics and signaling cascades. Our data reveal marked fluctuations on the scale of minutes and beyond, whereas short-term fluctuations appear to only report on fundamental and ubiquitous physico-chemical fluctuations that are rooted, for example, in the dyes' photophysics and diffusional motion.

BP 17.20 Tue 18:00 P4

Microscopic observation of red blood cell band patterns formed by centrifugation — •Luca Hastenteufel, Thomas John, Felix Maurer, and Christian Wagner — Experimental Physics, Saarland University

Percoll is a common medium composed of coated silica particles. It is widely used as the standard medium for the density separation of cells or subcellular compounds. The centrifugation of red blood cells in Percoll exhibits a heterogeneous structure characterized by discrete bands, however the density gradient is continuous. These band patterns have primarily been analysed using macroscopic images, such as photographs. We developed a microscopic scanning setup to examine these patterns in detail, from single cell level in μm-range up to the full pattern structure at 6 cm. This provides higher-resolution insights compared to traditional imaging methods. Additionally, high dynamic range (HDR) methods using multiple exposure levels lead to a more detailed pattern observation. Understanding these band patterns offers valuable information about red blood cell aggregation energy and the severity of related diseases.

BP 17.21 Tue 18:00 P4

Accessing local aggregation in phalloidin-stained Actin filaments using 2D Polarization Fluorescence Imaging — •Shangjun Cheng[1,2,3], Yutong Wang[1,2], Yunhao Mei[1,2], Hossein Zarei Oshtolagh[1,2], Lukas Spantzel[1,3], Patrick Then[1,4], Hans-Dieter Arndt[1], Adrian T. Press[1,3], Rainer Heintzmann[1,2], and Daniela Täuber[1,2] — [1]Friedrich Schiller University Jena — [2]Leibniz Institute of Photonic Technology, Jena — [3]Jena University Hospital — [4]Microverse Imaging Center, Jena, Germany

2-dimensional polarization-resolved fluorescence imaging (2DPOLIM) can discriminate between aggregated and non-aggregated protein forms independent of the sample's alignment by providing access to the full in-plane polarization properties of the sample. In combination with a semi-quantitative analysis of Förster Resonance Energy Transfer between similar fluorophores (homo-FRET) it can map the local aggregation in cells and tissue [1]. Actin assembly and disassembly is essential for cellular dynamics. A previous study has shown the direct link between infection and aggregation of F-Actin in hepatocytes [2]. Here, we present our speeded-up home-built 2DPOLIM setup [3] along with its calibration and image registration protocols allowing for an acquisition time in the range of a second. First results from application to the investigation of phalloidin-stained Actin filaments are presented. – [1] R. Camacho, et al., Advanced Materials, 31, 1805671, 2019. [2] P. Martinac, et al., Infection, 47, S6-S7, 2019. [3] Y. Wang, et al., Klosters, Switzerland, January 2023. doi:10.13140/RG.2.2.35169.79204

BP 17.22 Tue 18:00 P4

Liquid-cell Scanning Transmission Electron Microscopy (STEM) of isolated mitochondria and respective Au labels — •Eric Lieberwirth[1], Kevin Oldenburg[2], Anja Schaeper[3], Marcus Frank[4], Ingo Barke[1], Simone Baltrusch[3], and Sylvia Speller[1] — [1]Institute of Physics & LLM, University of Rostock — [2]ELMI-MV, University of Rostock — [3]Institute of Medical Biochemistry and Molecular Biology, Rostock University Medical Center — [4]Electron Microscopy Center, Rostock University Medical Center

In situ liquid-cell Scanning Transmission Electron Microscopy (STEM) holds the promise to observe biological organisms in a native state such as organelles, bacteria and eukaryotic cells [1,2]. In addition to acquisition of individual images, movies can be recorded during manipulation of tissue [3]. The potential radiation damage due to the transit of the electron beam through the sample is still under debate [4]. We imaged isolated mitochondria in Krebs-Ringer medium, and extracted imaging performance, and external features of radiation damage. We also study Au labels in the physiologic medium and show that atomic resolution of the nanoparticles is attainable. Such labelling is expected to increase resolution [1] and validate the presence of mitochondria in the STEM. One of the next challenges is validating the metabolic activity of the mitochondria during or upon the (S)TEM measurement.

BP 17.23 Tue 18:00 P4

Three-Axis Structured Illumination Lightsheet Microscopy — •Meelad Lalenejad and Alexander Rohrbach — University of Freiburg, Freiburg, Germany

Light-sheet microscopy (LSM) is known for increased image contrast and reduced photo-bleaching and toxicity since only those parts of the object are illuminated from the side that is in the focus of the objective lens. In addition, larger volumes are scanned plane-wise or line-wise by optimized laser beams, so LSM is significantly faster than point-wise scanning methods. However, for imaging a small number of cells, the spatial resolution is limited by the numerical aperture of the objective lens. We tackle the problem of limited resolution by combining holographically shaped illumination beams with three-axis interferometric arrangements. We use structured illumination microscopy (SIM) to obtain 3D super-resolved images in scattering media by generating interference fringes between every two beams from different illumination objective lenses.

BP 17.24 Tue 18:00 P4

Investigating Neutrophil dynamics using 200 Hz Rotating Coherent Scattering Microscopy — •Vera Obloh and Alexander Rohrbach — Lab for Bio- and Nano-Photonics, Department of Microsystems Engineering (IMTEK), University of Freiburg, Georges-Koehler-Allee 102, 79110 Freiburg, Germany

Neutrophils, the largest population of leukocytes in the human bloodstream, are initial responders in the rapid innate immune defense against most bacterial and fungal pathogens. They are activated before the complex humoral and lymphocyte-mediated processes of acquired immunity can effectively respond to an infection. To ensure effective defense, Neutrophils rapidly and efficiently move to areas of infection, based on highly dynamic processes of cytoskeleton reorganisation. Due to their ability to migrate rapidly and their availability and ease of cultivation, HL-60 Neutrophils are well suited for observations with Rotating Coherent Scattering (ROCS) microscopy, a novel 200 Hz label-free imaging technique with resolutions well below 200 nm. ROCS represents a powerful,

high-speed alternative to fluorescence microscopy, especially for observations over thousands of frames. We represent first images and analyses of so far unseen details and dynamics of Neutrophil migration.

BP 17.25 Tue 18:00 P4

Characterisation of fluorescent dyes and their uptake by M2 cells using FLIM — •Jana Sütterlin[1], Francisco Páez-Larios[1,2], Lukas Harder[1], Lea Klepsch[3,4], Vivien Bachmann[5], Antje Vollrath[3,4], Paul Jordan[5], Ulrich Schubert[3,4], Oliver Werz[5], Christian Franke[1], and Christian Eggeling[1,2] — [1]Institute for Applied Optics and Biophoysics, Friedrich-Schiller-Universität Jena, Jena, Deutschland — [2]Department of Biophysical Imaging, Leibniz-Institut für photonische Technologien e.V., Jena, Deutschland — [3]Jena Center for Soft Matter, Friedrich-Schiller-Universität Jena, Jena, Deutschland — [4]Institute for Organic and Macromolecular Chemistry, Friedrich-Schiller-Universität Jena, Jena, Deutschland — [5]Department of Pharmaceutical and Medical Chemistry, Friedrich-Schiller-Universität Jena, Jena, Deutschland

Polymeric nanocarriers are used to incorporate active substances into cells, that otherwise would have limited bioavailability. To study the particle-cell-interaction, the nano-particles contain a fluorescent dye, which allows monitoring by fluorescence microscopy. Since a dye's fluorescence lifetime depends on its environment, the dye's release from the nanoparticle into the cellular cytosol can be evaluated temporally and spatially by fluorescence-lifetime-imaging (FLIM). To that end, lifetime behaviour of Nile Red, ATTO 665 and ATTO Rhodamine 3B is characterised under different solvent conditions mimicking different cellular compartments. By this, a comparison with FLIM data of live cell uptakes is possible, which can yield insights into the dynamic interaction of drug-loaded nanoparticles and their target cell.

BP 17.26 Tue 18:00 P4

MINFLUX-derived particle traces reveal Mean Back Relaxation to study active systems — •Deisel Tobias, Muenker Till, Vos Bart, and Betz Timo — Third Institute of Physics, Georg-August Universität Göttingen, Göttingen, Germany

Living systems like cells exhibit dynamics far from thermodynamic equilibrium. In order to study such non-equilibrium systems, we need to use analytical methods beyond the classical methods developed in statistical physics. In order to quantify the activity in a living, we have recently introduced the Mean Back Relaxation (MBR), which exploits a three-point probability function and is solely derived from passive measurements. A main hurdle in using the MBR in the requirement of particle trajectories with high temporal and spatial precision, that are sufficiently long to detect activity. In normal flourescence microscopy this is not possible to achieve because of probe bleaching. To overcome this, we measure the MBR using MINFLUX nanoscopy, which is able to track fluorescent particles at a spatio-temporal resolution in the order of nanometers at a frequency in the order of a few kHz. We explore the MBR of fluorescent particles in living cells and study its change under the influence of cytoskeletal inhibition.

BP 17.27 Tue 18:00 P4

Thermal and directional motion of trapped particles in periodic potentials — •Ellen Hermle and Alexander Rohrbach — Lab for Bio- and Nano-Photonics, Department of Microsystems Engineering (IMTEK), University of Freiburg, Georges-Koehler-Allee 102, 79110 Freiburg, Germany

Molecular fiction can be considered as continuous on-binding and off-binding of molecules between two sliding surfaces. This complex process of energy dissipation to the environment, is important on most length scales, time scales and across disciplines. Usually, the relation between dynamic friction and velocity is quantified by a coefficient, which depends on various on- and off-binding parameters. Here, optical tweezers based Photonic Force Microscopy (PFM) has proven to be a suitable technique is used to analyse friction processes on mesoscopic length scales, specially at soft (-bio) interfaces. By 3D interferometric position tracking at 1 MHz we determine mean particle displacements and forces, as well as fluctuations of displacements and forces. Besides Brownian dynamic simulations, we present first experimental results of fluctuating particles dragged through a periodic potential, which can be generated by an optical potential from two interfering beams or by a specifically coated glass surface.

BP 17.28 Tue 18:00 P4

Investigating Ultrasonic Effects on Oral Cancer Cells Using Fluorescence Microscopy — •Wafa Tounsi, Amar Avdakovic, Vivian Maria Gulczynski, and Mathias Getzlaff — Institute of Applied Physics, University of Duesseldorf

Head and neck squamous cell carcinoma (HNSCC) is a challenging and often resilient cancer that affects many people globally. As conventional treatments sometimes fall short of effectively targeting these cancer cells without causing damage to surrounding healthy tissue, our research focuses on finding innovative alternatives. Our contribution explores the potential of using ultrasonic frequencies to selectively affect cancer cells while sparing healthy ones, offering a possible new avenue for treatment. In this study, we investigate how HNSCC cells respond to ultrasonic waves at frequencies between 20 and 250 kHz. We compare their reactions to benign oral keratinocytes, aiming to pinpoint acoustic conditions that might selectively disrupt cancer cells. In combination with Fluorescence Microscopy, we track various cellular responses, including changes in cell shape, membrane stability, and mitochondrial activity, using specific fluorochromes such as CellMask Green for plasma membranes, Hoechst for nuclear staining, and MitoTracker for mitochondria. By observing these differences, especially in the cytoskeleton, we gain valuable insights into the unique vulnerabilities of HNSCC cells, potentially paving the way for ultrasound-based, non-invasive treatments. Exploiting the distinct mechanical properties of cancer cells could enhance patient outcomes by enabling safer, more targeted treatments.

BP 17.29 Tue 18:00 P4

A flavin-based photoreceptor controls the photoactivation of ciliary adhesion in *Chlamydomonas*. — •Rodrigo E. Catalan[1,2], Antoine Girot[1,2], Alexandros Fragkopoulos[1,2], Olga Baidukova[3], Peter Hegemann[3], and Oliver Bäumchen[1,2] — [1]University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany — [2]Max Planck Institute for Dynamics and Self-Organization (MPIDS), 37077 Göttingen, Germany — [3]Humboldt University of Berlin, Institute of Biology, 10115 Berlin, Germany.

Light-activated proteins or photoreceptors play a crucial role on the behavior and, ultimately, the survival of photoactive microorganisms. The unicellular biciliated microalga *Chlamydomonas reinhardtii* has become a model organism to study light-mediated phenotypes, such as photosynthesis and phototaxis, among many others. Recently, we discovered that *C. reinhardtii* can reversibly switch on and off the adhesiveness of their cilia in blue and red light, respectively [1,2]. We characterized the action spectrum of this phenotype in wild-type (WT) *C. reinhardtii* cells via single-cell micropipette force measurements, and showed that it resembles the spectral sensitivity of a flavin-based photoreceptor. Further comparison of the ciliary adhesion forces between WT and photoreceptor-targeted mutants reveals that the deletion of two flavin-containing photoreceptors, namely animal- and plant cryptochromes, completely disrupts light-switchable adhesion.

BP 17.30 Tue 18:00 P4

Ciliary Adhesion of *Chlamydomonas reinhardtii* on Charge-Functionalized Surfaces — •Lea Rupprecht[1], Rodrigo Catalan[1], Christina Heinritz[2], Thomas Scheibel[2], and Oliver Bäumchen[1] — [1]University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany — [2]University of Bayreuth, Biomaterials, 95447 Bayreuth, Germany

Elucidating the physical phenomena underlying the interactions between microorganisms and surfaces is crucial for developing technologies to control the formation of microbial biofilms. While most studies use bacteria as model organisms, the principles of microbial adhesion remain rather elusive for eukaryotic photosynthetic microorganisms. Recently it was discovered that the model unicellular microalga *Chlamydomonas reinhardtii* adheres to surfaces by means of its two cilia under blue light [Kreis *et al.*, Nature Physics, 2018]. With *in vivo* single-cell micropipette force spectroscopy, the ciliary adhesion forces of *C. reinhardtii* on functionalized substrates were characterized to dissect the influence of surface energy, van der Waals and electrostatic interactions [Kreis *et al.*, Soft Matter, 2019]. The results suggest that the predominant nature of the protein-mediated cilia-substrate adhesion of *C. reinhardtii* is due to electrostatic interactions. Here we present adhesion force measurements of *C. reinhardtii* on poly-L-lysine- and recombinant spider silk-coated silicon, revealing no charge preference for ciliary adhesion. In contrast to prokaryotic microorganisms, our results show *C. reinhardtii* uses highly versatile cilia to achieve microbial adhesion to surfaces of a broad range of physicochemical properties.

BP 17.31 Tue 18:00 P4

Intracellular mechanics in migrating cells — •Jannis Fischer, Mohammad Amin Eskandari, and Timo Betz — Third Institute of Physics, Göttingen, Germany

To fulfill their incredibly large number of different tasks, biological cells have developed mechanisms to adapt their physical properties and appearance. The proper control of these changes is crucial, as they are not only essential for healthy cells, but can also distinguish healthy from diseased cells. Important examples related to such changes in mechanical properties are cell shape variation or cell migration. It is still not clear whether the changes in these mechanical properties are due to passive or active processes. Investigating and understanding these processes is the core of this work. For this, I will analyze the behavior of migrating cells, which are induced to move alternately on patterns and within channels. To connect the observed dynamics with the underlying mechanical properties and activities I will use the new quantity of mean back relaxation (MBR). Findings in this area could provide information for the big question of whether the mechanical properties of cells can be predicted by their activity.

BP 17.32 Tue 18:00 P4

Same, but different: Shared viscoelastic signature in hydrogels and cells — •Dorian Marx, Till M. Münker, Bart E. Vos, and Timo Betz — Third Institute of Physics - Biophysics, Georg-August-Universität Göttingen, Germany

We report the discovery of a striking "mechanical fixed point" in the response of polyacrylamide-based hydrogels to shear strain. Characterized by a pronounced and invariant relationship of parameters of the mechanical model, this leads to a convergence of the complex shear moduli of all measurements at a frequency of approximately 5 kHz. Intriguingly, reviewing existing literature reveals that this phenomenon is not unique to our simple hydrogel. Rather, there are many qualitatively similar observations in the distinct realm of (intra-)cellular mechanics, as probed by diverse techniques including optical tweezers and atomic force microscopy using many different cell types. Despite the fundamentally different natures of these systems - one being passive and at equilibrium (hydrogel), the other active and out-of-equilibrium (cell) - they show this peculiar viscoelastic signature. The existence of the mechanical fixed point hints at an unresolved constraint governing the mechanics across vastly different biological and synthetic systems.

BP 17.33 Tue 18:00 P4

: Identifying the proteins controlling the intracellular active mechanics — •Noémie Veyret, Till Münker, and Timo Betz — Third institute of Physics, University of Göttingen, Germany

Over the past few years, the study of cell mechanical properties has allowed new insights on the understanding of biological processes and life complexity. According to previous work, intracellular mechanical properties can be narrowed down to a fingerprinting of only 6 parameters. Through the use of active and passive microrheology measurements via optical tweezers, frequency dependent viscoelastic properties and intracellular activity were found to vary for different cell types. The aim of this project is to find a correlation between changes in protein expressions and mechanical fingerprint of cells. To do so optical tweezers measurements will be performed during the differentiation process of induced Pluripotent Stem Cells (iPSCs) into cell types derived from the three germ layers, namely neurons (ectoderm), skeletal muscles (mesoderm) and hepatocytes (endoderm). This measurement allows the characterization of the mechanics during the iPSC differentiation process. In parallel, the cell proteome will be studied using mass spectroscopy. Combining both, we hope to find the connection between proteins and their mechanical role, the intracellular "mechanome".

BP 17.34 Tue 18:00 P4

Investigating the rheology of intracellular transport by magnetic tweezers — •Katharina Beitzinger, Simon Wieland, and Holger Kress — Biological Physics, University of Bayreuth, Germany

Intracellular transport is an important part of phagocytosis, the cellular internalization of extracellular objects such as bacteria or microplastic particles. After uptake, the phagosome is transported mainly by dyneins along microtubules to the perinuclear region as part of the phagosomal maturation process. However, the kinetics of the recruitment of the motors to the phagosome is largely unknown. In order to investigate the mechanics of the transport, we use magnetic tweezers in combination with paramagnetic particles, internalized by mouse macrophages. By switching the tweezers on and off periodically, we exert alternating forces on the particle during the transport. The changes in the local viscoelastic cell properties are determined by modeling the creep compliance with a power law. First experiments show that the viscosity of the cells around the phagosomes remains almost constant, while the stiffness increases over time. The change in stiffness can be an indicator for a progressive adaption of the cell towards external stress by a recruitment of molecular motors to the phagosome. We expect that a quantification of the local viscoelastic cell properties during phagosomal transport can lead to a better understanding of this fundamental cellular process.

BP 17.35 Tue 18:00 P4

Optimizing Microfluidic Synthesis of Polymer Beads for In-Vivo Force Cell Sensing — •Jordan Dieter Groh, Alejandro Jurado Jiménez, and Timo Betz — Drittes Physikalisches Institut, Göttingen, Deutschland

Since the first use of deformable beads inside living tissue as force sensors about ten years ago, the technique has been refined with the introduction of new materials and methods to measure deformation. In many experiments, polyacrylamide beads have been used to assess forces in all kinds of in-vivo and in-vitro systems such as developing embryos, cancer spheroids, or reconstituted muscle tissue. However, using shear-induced emulsions as a fabrication method still shows two main limitations: a broad size distribution and small variations in polymer stiffness. We were able to optimize the production of polyacrylamide beads in two ways. First, by adoption of flow-focusing in a microfluidic setup. This technique is commonly employed in diverse fields, including drug delivery and food industry, for creating emulsions with precise control over droplet sizes. Second, by the use of a UV light-sensitive polymerization initiator that was triggered after the emulsion was created. The UV initiation of polymerization is instrumental in avoiding clogging of the microfluidic chips as polymerization happens only after emulsification. These improvements resulted in large beads with diameters of 93 um, which are still too large for many applications. Current approaches aim to reduce the bead size to around 5 um or even below.

BP 17.36 Tue 18:00 P4

Characterizing diffusion properties at liquid-liquid interfaces in microfluidic channels — •Eric Schneider, Eric Sündermann, Bob Fregin, and Oliver Otto — Institute of Physics, University of Greifswald, Greifswald, Germany

Real-time deformability cytometry is a powerful and widely used method for investigating the mechanical properties of cells in suspension. Here, cells are deformed by hydrodynamic stress in a microfluidic system, that is comparable in size to the cells. Consequently, the range of cell sizes has to match the physical channel dimensions to ensure proper cell deformation. Virtual fluidic channels (VFCs) address this limitation, by allowing for the channel width to be adjusted within seconds. VFCs are formed by the liquid-liquid interface between two co-moving aqueous polymer solutions. The introduction of these two different polymer solutions generates a density gradient within the microfluidic channel, which can give rise to diffusive processes. We investigated the diffusive properties within VFCs and the influence of the liquid-liquid interface. For this, we examined the temporal behavior of a fluorescent dye distribution within the microfluidic chip. We modelled the diffusive behavior self-consistently by solving the kinetic diffusion equation, which accounts for the differential flow velocities within the microfluidic channel. Finally, by combining theoretical and experimental results, we determine the characteristic diffusion timescales in the VFC and across the liquid-liquid interface. With this we provide a general framework to investigate the diffusive properties along laminar flow boundaries.

BP 17.37 Tue 18:00 P4

A fast and quantitative method to study the membrane tension of suspended cells — •Eric Sündermann, Bob Fregin, Doreen Biedenweg, and Oliver Otto — Institute of Physics, University of Greifswald, Greifswald, Germany

The development of high-throughput methods for cell mechanical research is becoming increasingly important as the analysis of large samples improves the statistical robustness to identify rare cell populations and transfer results from basic science into clinical applications. Various techniques are available for bulk mechanics, but none can analyse membrane tension with the throughput of a flow cytometer.

Here, we present membrane tension cytometry (MTC), that uses Flipper-TR, a fluorescent dye with a fluorescence lifetime being proportional to the tension inside a lipid bilayer. First, we established a calibration procedure using osmotically-stressed red blood cells. Next, we move to HL60 cells, a myeloid precursor cell line, which we exposed to various chemical and mechanical stresses. We find an increased fluorescence lifetime for increasing hydrodynamic stresses, as expected. Finally, we used methyl-β-cyclodextrin and Cytochalasin D to disturb cholesterol and filamentous actin levels, respectively. Our results show, that MTC is sensitive to membrane changes while being insensitive to cytoskeletal alterations.

BP 17.38 Tue 18:00 P4

Thermomechanical properties of bat erythrocytes as a blueprint for human hibernation — •Bob Fregin[1,2], Doreen Biedenweg[1], Oliver Otto[1,2], and Gerald Kerth[3] — [1]Institute of Physics, University of Greifswald, Greifswald, Germany — [2]German Center for Cardiovascular Research, Partner Site Greifswald, Greifswald, Germany — [3]Applied Zoology and Nature Conservation, Zoological Institute and Museum, University of Greifswald, Greifswald, Germany

The ability to sustain efficient blood circulation at low body temperatures is a critical adaptation in hibernating mammals. Here, the mechanical properties of red blood cells (RBCs) could play a crucial role, which we studied for the hibernating common noctule bat, the non-hibernating Egyptian fruit bat, and humans. Using dynamic real-time deformability cytometry RBC elasticity and viscosity were measured at physiologically-relevant time scales (Milliseconds) and temperatures (37°C, 23°C, and 10°C).

Our findings reveal a temperature-driven increase in elasticity and viscosity, which is mainly influenced by membrane properties and not the cytosol. This effect is significantly enhanced in bats. Finally, our data demonstrate that RBC membranes of both bat species display a transition to a viscous-like state at lower temperatures, which is not explained by seasonal variations of environmental factors but seems to originate from physical properties of the cell membrane. Our results suggest RBC thermomechanical properties as a target for future research on human hibernation.

BP 17.39 Tue 18:00 P4

Passively Measuring Cell Activity via Mean Back Relaxation — •Sarah Louisa Lädke[1], Till Moritz Münker[1], Julian Schulz[1], Gabriel Knotz[2], Matthias Krüger[2], and Timo Betz[1] — [1]Third Institute of Physics, Georg-August-Universität Göttingen — [2]Institute of Theoretical Physics, Georg-August-Universität Göttingen

While many statistical methods are available for the characterization of passive motion in thermodynamic equilibrium, the investigation of active motion in liv-

ing systems remains a significant challenge. In particular, the study of intracellular mechanical properties requires techniques such as active microrheology to quantify the response of tracer particles to forces exerted via optical or magnetic tweezers. However, these methods often involve expensive and complex equipment, and their invasive nature can alter cellular behavior.

To address these limitations, we present an alternative approach to study intracellular mechanical properties and activity that relies only on passive measurements. To this end, we combine darkfield microscopy, highspeed imaging and image post-processing techniques to obtain trajectories of microparticles in Hela cells with nanometer and 300 microseconds spatial and temporal resolution. To filter noise that occurs in our particle tracking, we developed a new, Bayesian approach that can reliably differentiate between noise peaks and intrinsic fluctuations found in the frequency spectrum. Using the novel observable Mean Back Relaxation (MBR), we can link the particle tracks to intracellular activity and their mechanical properties.

BP 17.40 Tue 18:00 P4

Competition between deformation and free volume quantified by 3D image analysis of red blood cell — •Pavlik Lettinga[1,2], Mehrnaz Babaki[1,2], Dmitry Fedosov[1], Amirezza Gholivand[1], Remco Tuinier[3], and Joeri Opdam[3] — [1]Forschungszentrum Jülich — [2]KU Leuven — [3]TU Eindhoven

Cells in living organisms are subjected to mechanical strains caused by external forces like overcrowding, resulting in strong deformations that affect cell function. We study the interplay between deformation and crowding of red blood cells (RBCs) in dispersions of nonabsorbing rod-like viruses. We identify a sequence of configurational transitions of RBC doublets, including configurations that can only be induced by long-ranged attraction: highly fluctuating T-shaped and face-to-face configurations at low, and doublets approaching a complete spherical configuration at high, rod concentrations. Complementary simulations are used to explore different energy contributions to deformation as well as the stability of RBC doublet configurations. Our advanced analysis of 3D reconstructed confocal images of RBC doublets quantifies the depletion interaction and the resulting deformation energy. Thus, we introduce a noninvasive, high-throughput platform that is generally applicable to investigate the mechanical response of biological cells to external forces and characterize their mechanical properties.

BP 17.41 Tue 18:00 P4

Red blood cell membrane tension modulation by photo switchable molecules — •Tim Kutz[1], Bart Vos[1], Jan Bart Ravoo[3], Andreas Janshoff[2], and Timo Betz[1] — [1]Third Institute of Physics, Georg August Universität Göttingen, Göttingen, Germany — [2]Institute of Physical Chemistry, Georg August Universität Göttingen, Göttingen, Germany — [3]Organic Chemistry Institute and Center for Soft Nanoscience, University of Münster

Cellular stiffness and surface tension are fundamental determinants of cell behavior and function. However, the precise contributions of membrane and cortical components to overall cell mechanics remain unclear. Building upon our recently developed multi-modal approach, which combines atomic force microscopy, confocal spinning disk fluorescence microscopy, and micropipette aspiration, we investigated the mechanical properties of human red blood cells (hRBC) as a model system, with a focus on membrane manipulation. By incorporating photo switchable azobenzenes into the hRBC membrane, we created a dynamic system to modulate membrane properties through light-induced conformational changes.Comparisons were made between wild-type hRBCs and those containing azobenzenes in both the cis and trans states. This approach enabled us to directly correlate changes in membrane conformation with alterations in mechanical properties. Our results demonstrate the feasibility of using photo switchable molecules to modulate cellular mechanics in a controlled and reversible manner. This approach and novel platform advances our understanding of the contribution of the membrane to cellular tension.

BP 17.42 Tue 18:00 P4

Theoretical perspectives on controlling cells by ultrasound — •Niels Gieseler[1,2,3], Falko Ziebert[1,2], and Ulrich S. Schwarz[1,2] — [1]Institute for Theoretical Physics, Heidelberg University, Philosophenweg 19, Heidelberg 69120 Germany. — [2]BioQuant, Heidelberg University, im Neuenheimer Feld 267, Heidelberg 69120 Germany — [3]Max Planck Institute for Medical Research, Jahnstrasse 29, 69120 Heidelberg, Germany

Aside from the well-known use of ultrasound in medical imaging, there are many other biomedical applications of ultrasound, including enhanced bone healing, neurostimulation and sonogenetics. Different mechanisms have been implicated for these processes, including temperature changes, cavitation, radiation forces and acoustical streaming. In this work, we are interested in the interaction between ultrasound and tissue (including organoids) at the single-cell level. Combining concepts from hydrodynamics, elasticity theory and soft matter, we aim at theoretical predictions of the relative relevance of these different effects. In particular, we use the theory of viscoelasticity to predict whether intracellular streaming and organelle movement can be controlled by ultrasound.

BP 17.43 Tue 18:00 P4

Predicting mass density of eukaryotic nuclei and cells — •Omar Muñoz[1,2,3], Abin Biswas[1,3,4], Kyoohyun Kim[1,3], Jochen Guck[1,3], Vasily Zaburdaev[1,2], and Simone Reber[4,5] — [1]Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany. — [2]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — [3]Max Planck Institute for the Science of Light, Erlangen, Germany — [4]Max Planck Institute for Infection Biology, Berlin, Germany — [5]University of Applied Sciences Berlin, Berlin, Germany

Biophysical properties of the cell nucleus are important for various cellular processes from transcription to migration, but largely are still not well understood. The mass density is one such example, since we observed for a wide range of species that the cells maintain a certain nuclear to cytoplasmic mass density ratio with nuclear mass density being lower than its cytoplasmic counterpart. Moreover, in diseased states such as senescence we observed a breakdown of this density ratio where dilution of the cytoplasm made nuclei appear more dense, which suggests that the density ratio is a potential marker of proper cell functionality. Theoretical modeling can contribute to a better understanding of how this density ratio is established. There are two essential model components: a pump leak model to predict compartment volume and a model to determine the dry mass in the system, which is usually an active, dynamic process. Here we present the models for different systems such as human cells, nuclei in Xenopus egg extract and discuss their differences.

BP 17.44 Tue 18:00 P4

Modeling the endothelial cytoskeleton response to blood flow — •Berin Becic and Stephan Gekle — Biofluid Simulation and Modeling, University Bayreuth, Germany

As present in blood flow, it was observed that a shear flow leads to an alignment of endoethelial cells, which is connected to an alignment of its cytoskeleton. Understanding this behavior is important as its failure can lead to chronic inflammation which is one cause for the formation of artherosclerosis and other cardiovascular diseases. In order to do this we develop a three-dimensional model for the formation of the cytoskeleton based on the stress- and strain-dependency of the stress-fiber association and dissociation dynamics, as proposed by Deshpande et al (A bio-chemo-mechanical model for cell contractility , PNAS 2006). This model also offers the opportunity to study the spatially resolved formation of the cytoskeleton as observed in cells adhering to a substrate or the mechanic interactions between the cell and its nucleus.

BP 17.45 Tue 18:00 P4

Combining computational and experimental advances in microparticle traction force microscopy — •Bastian Kraus[1], Simon Brauburger[1], Tobias Walther[2], Kerstin Göpfrich[2], and Ulrich S. Schwarz[1] — [1]Institute for Theoretical Physics, Heidelberg University, 69120 Heidelberg, Germany — [2]Center for Molecular Biology of Heidelberg University (ZMBH), Heidelberg University, 69120 Heidelberg, Germany

Traction force microscopy (TFM) infers cellular forces from the motion of fiducial markers embedded in soft elastic substrates. Over the last years, this approach has been extended to elastic microparticles, typically made from polyacrylamide. In contrast to flat substrates, this approach allows to infer forces either from the motion of embedded fiducial markers or from the deformation of the surface. Here, we compare these two different approaches from the viewpoint of elasticity theory and with computer simulations that include the image processing steps. We then apply the method to experimental data from DNA microbeads, for which one can implement markers for both bulk and surface deformations.

BP 17.46 Tue 18:00 P4

An FEM based framework to reconstruct cellular traction forces in arbitrary geometries — •Cornelis Mense and Ulrich Schwarz — Heidelberg University

In the last two decades, the reconstruction of cellular traction forces has been a valuable tool in mechanobiology and biomedical experiments. Traction forces are traditionally computed for displacements of soft elastic substrates, imaged using fluorescent micro-beads. These substrates have largely been planar surfaces, owing to the availability of methods by which to analyse such experimental data. But, as of late, a curiosity and drive has arisen to extend these experiments to arbitrary three-dimensional geometries. Here, a framework is proposed to inversely reconstruct tractions using the Finite Element Method. This method attempts to reduce noise and non-physical tractions by iteratively projecting experimental displacement fields onto force-balanced configurations using the principle of virtual work. The efficacy of the method is demonstrated through toy problems, wherein tractions are first prescribed onto a geometry to generate mock data sets of displacement fields. These fields are then artificially made noisy, after which the FEM software is tasked with retrieving the initially prescribed tractions. The experimental design space, that would be opened up by this framework, could prove a valuable tool in further understanding cell motility.

BP 17.47 Tue 18:00 P4

Investigating Particle Binding above Epithelial Cells with Photonic Force Microscopy — Nils le Coutre and •Alexander Rohrbach — IMTEK, Department for Microsystems Engineering, Freiburg, Germany

A significant portion of today's airborne particulates originates from human activities such as industrial processes and the combustion of crude oil-based fuels. This has been linked to an increased risk of diseases including asthma, lung cancer, and cardiovascular pathologies, correlating significantly with the inhalation of particulate matter. Here, we investigate the fluctuation-based interaction of single optically trapped particles with epithelial cells. Using photonic force microscopy, we trap the particles through a layer of epithelial cells and interferometrically track the thermal motions of the particle with the goal to recover binding and friction parameters in contact with the cell surface. This approach is challenging since the cell perturbs the phase of the trapping and tracking beam, such that the characteristic trajectories - obtained by interference and encoding the interactions - require a novel analysis method.

BP 17.48 Tue 18:00 P4

Investigating cell membrane tension — •Tina Boric[1,2], Julia Butzke[1,2], Eva Kreysing[2,3], and Kristian Franze[1,2,3] — [1]Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany — [2]Institute of Medical Physics and Microtissue Engineering, Friedrich-Alexander-Universität, Erlangen-Nürnberg, Erlangen, Germany — [3]Department of Physiology, Development and Neuroscience, University of Cambridge, Cambridge, UK

Cellular membranes are known to change their mechanical properties in response to external and internal mechanical stimuli, such as shear forces and changes in tissue stiffness. Membrane tension contributes to the transduction of these mechanical signals into intracellular responses via mechanosensitive ion channels. However, how and if a change in tissue stiffness affects the surface mechanics of the cell, which in turn would contribute to the activation of mechanosensitive ion channels, is not yet known. We are investigating the dependence of the effective membrane tension of HEK 293T cells on the expression levels of the mechanosensor Piezo1 using optical tweezers. Furthermore, we are comparing tether forces of cells grown on compliant custom-made substrates of biologically relevant stiffness. We also expose the cells to different pharmacological treatments that primarily affect the actin cortex to investigate how membrane-to-cortex attachment affects tether forces. Ultimately, our aim is to understand how changes in membrane tension lead to the activation of Piezo1. Our work will contribute to the understanding of how mechanosensitive ion channels are gated, which may have important implications for drug design in the future.

BP 17.49 Tue 18:00 P4

Revealing minimal cell particle interactions by thermal noise frequency decomposition — •Max Wechlin, Felix Jünger, and Alexander Rohrbach — Lab for Bio- and Nano-Photonics, Department of Microsystems Engineering (IMTEK), University of Freiburg, Georges-Koehler-Allee 102, 79110 Freiburg, Germany

Nearly every interaction process in nano-scale soft materials, especially in living cells is governed by thermal noise. However, it is hardly known or often disregarded that many interaction processes take place only on specific timescales. This means that observing or measuring on the wrong timescale, can lead to wrong results or even no results. While interactions can be visible on one timescale, they can be completely invisible on another. Therefore, it is not only necessary to measure on a much broader frequency range than usually, but also to decompose the broadband fluctuation data with appropriate mathematical models. This way minimal or even hidden interactions can be revealed. We use optical tweezers based Photonic Force Microscopy with MHz-rate interferometric 3D particle tracking to approach 1*m-sized polystyrene beads to functional gels or to living cells. We demonstrate that interactions between particles and cells change in stiffness or friction over time and distance only on certain frequency bands, but not over the average fluctuations in energy and position.

BP 17.50 Tue 18:00 P4

Regulation of plasma membrane tension through the actin cytoskeleton and hydrostatic pressure — •Yogishree Arabinda Panda and Elisabeth Fischer-Friedrich — Excellence Cluster Physics of Life, TU Dresden, Dresden, Germany

The plasma membrane and its associated proteins serve as a critical signaling hub, transmitting information between the extracellular environment and the intracellular space. It plays essential roles in regulating the intracellular ion content, the membrane potential and processes such as endocytosis and exocytosis. Consequently, the plasma membrane is central to many physiological processes including cell differentiation, migration, and proliferation. Recent studies have shown that the activity of many transmembrane proteins is influenced by mechanical tension in the plasma membrane. Despite its importance in cellular signaling, the mechanisms by which cells regulate membrane tension remain poorly understood. In this study, we investigate the regulation of plasma membrane tension in mitotically arrested cells using FLIM in conjunction with the membrane dye FlipTR. Specifically, we explore how components of the actin cytoskeleton, intracellular hydrostatic pressure, and cell shape contribute to both actual and apparent membrane tension.

BP 17.51 Tue 18:00 P4

Single-cell physical phenotyping of blood and tissue biopsies — •Marketa Kubankova[1,2], Despina Soteriou[1,2], Martin Kräter[1,2], and Jochen Guck[1,2] — [1]Max Planck Institute for the Science of Light, Erlangen, Germany — [2]Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany

Deformability cytometry [1] is a microfluidic technique that allows the assessment of physical properties of single cells in a label-free and high-throughput manner, with up to 1000 cells analysed per second. Cell deformation and other physical phenotype parameters such as cell size and aspect ratio are obtained directly from brightfield cell images.

The diagnostic potential of deformability cytometry was previously demonstrated in various diseases [2, 3]. Here we show how deformability cytometry accurately discriminates between healthy and tumorous tissue in biopsies of mouse and human colons [4]. Cell deformation was a crucial parameter for the correct distinction of tumour tissue in colon cancer patients. Furthermore, we present new findings on how the physical properties of blood cells change during infectious diseases, and how they correlate with commonly used markers of infectious inflammation. Our findings pave the way for establishing deformability cytometry as a fast and marker-free diagnostic technique to sensitively detect pathological changes in solid and liquid biopsies.

Mechanobiology of immune cell confined migration — •Fatemeh Abbasi[1], Timo Betz[2], and Eva Kiermaier[1] — [1]LIMES Institute, University of Bonn, Bonn, Germany — [2]Third Institute of physics, University of Göttingen, Göttingen, Germany

In vivo, cells experience complex tissue environments and have to adjust their behavior and function based on their surrounding. Immune cells are the renowned examples. On their way from the bone marrow, where they are born, to the infection site, they have to cope with various physical challenges including geometrical confinement and different mechanical properties of the host tissues. To perform a successful confined migration, cells need to squeeze their nucleus, the most stiff and largest cell organelle, as well as reorganize their cytoskeleton. Despite the importance of this subject in immunology and pathology, it is still not well-understood how immune cells can adopt different nuclear morphologies and cytoskeleton organization while migrating through the small junctions and pores. Here, we use CFM (Confinement Force Microscopy), which was developed in the lab of Timo Betz, to confine immune cells in a 2.5D environment of various stiffness. We will study the role of centrosome, microtubule and nuclei morphology in innate immune cell confined migration. This study can help us to find out how nuclei and cytoskeletal organelles facilitate immune cell migration through confined microenvironments of different mechanical properties. Simultaneous measurement of the cell forces on the microenvironment will enable us to find out the mechanobiology of immune cell confined migration.

BP 17.53 Tue 18:00 P4

Processivity of myosin assemblies: ATP dependence and effect on network dynamics — •Jaskaran Singh and Stefan Klumpp — University of Göttingen, Institute for the Dynamics of Complex Systems, Göttingen,Germany

Motors proteins like myosin, kinesin are a major source of activity in cellular mechanisms like cell division and perform tasks such as maintaining cellular structure and transporting cargo within the cell. These motors form complexes of multiple motors and cooperate and give rise to complex behaviors not seen in single-motor dynamics. Myosin motors form medium sized (~100 motors) assemblies called myosin minifilaments that bind to and move along actin filaments. The mechano-chemical cycle of individual motors in the motor assembly is dependent on ATP. We are exploring the concentration of ATP as a control parameter for the processivity (walking distance) of myosin minifilaments through stochastic modelling. Here we propose processivity as a parameter to tune the activity in system. On the cellular scale, we explore the effect of processivity on cytoskeletal network structures at large. Preliminary results show that decrease in ATP concentration increases the processivity of myosin assemblies. However, the velocity of motor assembly decreases with decreasing ATP. Thus, an optimal trade-off between processivity and velocity must be maintained for efficient assembly performance. To study the effect of processivity on network level structures, we use the simulation package Cytosim. The simulation shows that higher processivity leads to a more pronounced contraction of the actin network.

BP 17.54 Tue 18:00 P4

Mechanosensing and shape adaption of cells on substrates of varying stiffness — •Pooja Yadav, Florian Rehfeldt, and Matthias Weiss — Experimentalphysik I,University of Bayreuth

Changes of characteristic cellular features with varying stiffness of the underlying substrate, e.g. shapes and sizes of cells and nuclei, are a hallmark of the complex interplay of mechano-biochemical feedback loops. To explore this in detail, we have quantified cellular features on polyacrylamide (PA) hydrogels of varying stiffness, from 2~kPa to 64~kPa, hence mimicking the diverse microenvironments found in vivo. In particular, we have quantified the areas of nuclei and cells, their aspect ratio, and the local order parameter of the cytoskeleton on different substrates, also in the absence and presence of cytoskeleton-severing drugs. As a result, we observed that cell and nucleus areas follow an isometric relation with both areas increasing with the stiffness of the substrate. In contrast, the aspect ratio of both show a non-trivial maximum at intermediate stiffnesses, which we attribute to the local nematic ordering of the cytoskeleton. Altogether, our data open up the way to investigate differential mechanical effects of nuclei and cells under perturbations.

Mechanical properties of microtubule in actin network — •Komal Bhattacharyya, Sarah Köster, and Stefan Klumpp — University of Göttingen, Göttingen, Germany

The cytoskeleton provides structural support and facilitates dynamic cellular processes such as growth and migration. Actin and microtubules are key components of the cytoskeleton. Actin, characterized by its semi-flexible nature, contrasts with the stiff, rod-like structure of microtubules. The synergy between these two elements plays a pivotal role in numerous biological phenomena. For instance, microtubules exhibit enhanced resistance to compressive forces when integrated into an actin network.

In our research, we use the simulation package Cytosim to study composite networks formed by actin and microtubules. Specifically, we analyze the buckling behavior of microtubules under compressive forces and thermal fluctuations and how it is affected by mechanical coupling to actin. We observe that long-range repulsive interactions between the filaments lead to very small elasticity and minimal suppression of microtubule buckling. As a consequence, the observed mechanical responses within composite networks can very likely not be explained without considering specific interactions between actin and microtubules.

BP 17.56 Tue 18:00 P4

Mechanical Properties of Intermediate Filament Networks — •Jonas Penning and Stefan Klumpp — Institute for Dynamics of complex systems, Georg-August-Universität Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen

The mechanical strength and dynamics of cells are essential for sustaining life. For instance, during simple activities such as breathing or walking, cells are subjected to significant tensile stresses as they are stretched, sheared, or compressed. The cytoskeleton - a cross-linked composite network of actin, microtubules, and intermediate filaments - plays a central role in determining the cells' mechanical properties. While actin and microtubule networks have been studied extensively, this work focuses on intermediate filaments, such as vimentin and keratin. Compared to actin, intermediate filaments exhibit much smaller persistence lengths, but are much more stretchable with highly nonlinear elasticity. Extedning the freely-jointed chain (FJC) model by nonlinear stretching elasticity, a simplified model has been developed to investigate the mechanical and physical properties of cross-linked intermediate filament networks. Analogous to experimental approaches, the mechanical properties of the model are tested by applying normal and shear strains or stresses and analyzing the resulting responses.

BP 17.57 Tue 18:00 P4

Infrared Spectroscopic Analysis of Structural and Thermal Dynamics in Cytochrome c-DNA Complex — •Berken Hamarat, Damla Melisa Balci, and Günnur Güler — Biophysics Laboratory, Department of Physics, Izmir Institute of Technology, Izmir, Türkiye

Cytochrome c (Cytc) plays a crucial role in cellular respiration and apoptosis, with potential for biosensor applications due to its electron transfer capabilities. The binding of Cytc to DNA enables its consideration as a target molecule in biosensors and facilitates the modulation of Cytc's electronic properties via protein-DNA interactions. Temperature-controlled FT-IR spectroscopy in the transmission mode was used to investigate the structural changes and thermal stability of Cytc upon DNA complex in oxidized and reduced forms. Deuterated samples of Cytc and DNA were used during the analysis. Structural changes were observed after DNA binding, with a reduction in α-helix content, particularly in the oxidized form. Thermal stability analyses showed that the Cytc-DNA complex lost structural integrity at lower temperatures compared to free Cytc. These results indicate that DNA binding not only alters Cytc's secondary structure but also reduces its thermal stability. While Cytc's high thermal stability makes it suitable for biosensor applications, the observed changes after DNA binding, particularly the decrease in thermal stability must be minimized and optimized to ensure effective biosensor functionality. (Supported by Scientific and Technological Research Council of Türkiye, TÜBITAK 2209-B Project, 1139B412200835).

BP 17.58 Tue 18:00 P4

Soft-landing Electrospray Ion Beam Deposition (ES-IBD) allows integration of native mass spectrometry and cryoEM to investigate membrane protein structure and function — •Carl von Hallerstein, Sophie Lawrence, Tarick El-Baba, Stephan Rauschenbach, and Carol Vivien Robinson — Kavli Institute for Nanoscience Discovery, University of Oxford, UK

Electrospray Ion Beam Deposition (ES-IBD) is an emerging sample preparation for the imaging of molecules (Esser et al. 2022, Faraday Discussions). Recently, using native mass spectrometry (nMS), the deposition and cryo-electron microscopy (cryoEM) imaging of soluble proteins was demonstrated (Esser et al. 2024, Sci. Adv.).

Here, we apply ES-IBD + cryoEM to membrane proteins, which only retain their native state while encased in lipid membranes or membrane-mimetics such as detergents or nanodiscs. ESIBD+cryoEM yields valuable information on lipid and surfactant interaction as well as hydration of the membrane protein.

BP 17.59 Tue 18:00 P4

Investigation into the dynamic structure of heat shock proteins using electrospray ion beam deposition and cryo-electron microscopy (ESIBD+cryoEM) — •Noor Naseeb, Lukas Eriksson, Jingjin Fan, Justin Benesch, and Stephan Rauschenbach — University of Oxford, Oxford, United Kingdom

The heat shock protein (HSP) family encompasses a wide variety of polydisperse proteins that act as chaperones in the cell as a means of preventing aggregation and misfolding of proteins under different forms of cellular stress. Standard methods, like X-ray crystallography (XRC), Nuclear magnetic resonance (NMR), and cryogenic electron microscopy (cryo-EM), lack the ability to properly study the structures of such dynamic and diverse proteins. To address this, we use electrospray ion beam deposition (ESIBD) that couples native mass spectrometry (MS), a chemically selective sample preparation technique, with cryo-EM. The combination allows for high-resolution visualization of a specific protein assembly by cryo-EM in their near-native state. Here we show that the chemically selective sample preparation technique via ESIBD enables structure determination of these dynamically assembled HSPs can be performed to better assess their structure, and therefore, function.

Hyperfine spectral diffusion in pulse EPR: theory and applications — •Sergei Kuzin[1,2], Gunnar Jeschke[1], and Maxim Yulkov[1] — [1]ETH Zurich, Zurich, Switzerland — [2]MPI for Multidisciplinary Sciences, G\"ottingen, Germany

Hyperfine interaction with nuclear spin bath and nuclear spin-spin interaction often dominate phase memory times of the electron spins in spin-diluted solids at cryogenic temperatures. Such an spin-ensemble effect also manifests is different EPR experiments as spectral diffusion.

Here, we present a new pulse EPR method called intermolecular hyperfine relaxation-induced dipolar modulation enhancement (ih-RIDME). This technique allows to investigate kinetics of spectral diffusion in amorphous solids. The sensitivity range of ih-RIDME lies within 1-3~nm around the spin centre. This makes it a powerful tool to probe nuclear spin arrangement at intermediate electron-nuclear distances. The quantification in ih-RIDME is based on a developed mathematical model of spectral diffusion resulting in a diffusion-like equation. With its help, ih-RIDME allows to quantify heterogeneous systems with a distribution of local proton densities.

We discuss the applications of ih-RIDME in dynamic nuclear polarization, structural biology, spin-labeled macromolecules and soft matter study.

BP 17.61 Tue 18:00 P4

Electron spin dynamics during MW pulses studied by 94 GHz chirp and phase-modulated EPR experiments — •Marvin Lenjer[1,2], Nino Will[3], Fabian Hecker[4], and Marina Bennati[1,2] — [1]MPI for Multidisciplinary Sciences — [2]Georg August University Göttingen — [3]Aarhus University — [4]Danish Technical University

Over the last decade, shaped microwave (MW) pulses have evolved into valuable tools for electron paramagnetic resonance (EPR) spectroscopy. They have been used to improve existing experiments by providing tunable broadband or band-selective frequency profiles as well as to design new experimental approaches. However, most applications were done at low fields (X- or Q-band) where high MW powers are available.

Here, we show the implementation of chirped and phase modulated pulses at a commercial Bruker E680 W-band (94 GHz) EPR spectrometer using a SpinJet arbitrary waveform generator. We apply these novel experimental tools to the analysis of spin dynamics during MW spin lock pulses. We measure inversion profiles in the intermediate regime between Rabi oscillations and saturation pulses via chirp echo EPR spectroscopy and analyze spin-spin relaxation during spin locking (i.e. $T_{2\rho}$) via phase modulation echoes during spin lock. Combination with density matrix simulations allows us to better understand electron spin evolution during long periods of MW irradiation. Altogether, these results promise future advances in design and applicability of hyperfine spectroscopy at high fields by use of spin locks and shaped pulses.

BP 17.62 Tue 18:00 P4

Human cardiac cadherin desmocollin 2 reveals ideal-, slip- and catch bonds in vitro — •Manuel Göz[1], Greta Pohl[2], Sylvia Steinecker[1], Volker Walhorn[1], Hendrik Milting[2], and Dario Anselmetti[1] — [1]Experimental Biophysics & Applied Nanoscience, Faculty of Physics, Bielefeld University, Bielefeld, Germany — [2]Heart & Diabetes Center NRW, University Hospital of the Ruhr-University Bochum, Bad Oeynhausen, Germany

Desmosomal cadherins like DSC2 are known to associate in a strand-swap binding motif in which an N-terminal tryptophan residue binds into the hydrophobic binding pocket of opposing cadherins. Although this binding pattern is highly specific, it is of low affinity and exhibits decreased bond lifetimes at a single-molecule level. Using AFM-based SMFS, we show that the strand-swap dimerized DSC2 has two further binding modes, which may play a role in the integrity of the cardiac muscle. At short interaction times, the DSC2 monomers associate only short-lived and force-independent. These ideal bonds are probably a precursor state that stabilizes the formation of the strand-swap dimer. Tryptophan added to the measurement buffer acts as a competitive inhibitor, preventing the N-terminal strand exchange. Here, DSC2 dimerizes as an X-dimer and shows a triphasic slip-catch-slip type of dissociation. Within a force-activated transition (catch) regime, DSC2 dimers switch between brittle low force and strengthened high force adhesion states. So we can assume that desmosomal adhesion is mediated not only by strand-swap dimers (slip bond) but also by their precursor states (ideal bond) and force-activated X-dimers (catch bond).

BP 17.63 Tue 18:00 P4

Trajectories of particles trapped in double well potentials show new behavior in the Mean Back Relaxation — •Christian Muñoz[1], Mohammad A. Eskandari[1], Bart E. Vos[1], Till M. Münker[1], Dorian Marx[1], Matthias Krüger[2], and Timo Betz[1] — [1]Third Institute of Physics - Biophysics, Georg August University Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany — [2]Institute for Theoretical Physics, Georg August University Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

Optical tweezers have been established as a powerful tool for studying microscopic particle dynamics in complex potentials. In this work, we investigate the behavior of a microparticle trapped in a double-well potential generated by optical tweezers. By systematically varying the laser power and the distance between the optical traps, we modeled the shape and depth of the potential. This approach allowed for a detailed analysis of the particle's stochastic transitions between the wells. Combining experimental measurements with Kramers' theory, we achieved accurate predictions of the transition rates between wells. Furthermore, we analyzed particle trajectories using the new quantity of Mean Back Relaxation (MBR), providing insights into the effects that a bistable system has on particle relaxation after defined fluctuations.

BP 17.64 Tue 18:00 P4

Cell-cell interactions of swimming ciliated microbes: from measured interaction dynamics to an effective potential — •Henrik Groh[1,2], Alexandros A. Fragkopoulos[1], Colin-Marius Koch[3], Michael Wilczek[3], and Oliver Bäumchen[1] — [1]University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany — [2]University of Bayreuth, Experimental Physics I, 95447 Bayreuth, Germany — [3]University of Bayreuth, Theoretical Physics I, 95447 Bayreuth, Germany

In suspensions of living microorganisms the interactions of individual agents may result in large-scale collective effects. Frequently such phenomena are studied more extensively with the goal of linking them to the microscopic single-cell motility and cell-cell interactions. *Chlamydomonas reinhardtii* represents a unicellular eukaryotic model organism that is used to study collective phenomena of puller-type microswimmers, e.g., induced by a self-generated oxygen gradient [1] or by light (phototaxis). In order to complement these studies with a systematic cell-cell interaction analysis, we investigated the mutual interactions of *C. reinhardtii* in a quasi-2D suspension with high temporal and spatial resolution. Our measurements allow for deriving a pair-correlation function and an effective potential, which may eventually enter simulation studies. With our study we provide more detailed insights into the cell-cell interactions of *C. reinhardtii* and thus enable a better understanding of collective phenomena in living suspensions.

Quantum Physics Meets Epigenetics: Does Nature Harness Charge and Energy Transfer in Methylated DNA? — •Dennis Herb[1,2], Mirko Rossini[1,2], and Joachim Ankerhold[1,2] — [1]Institute for Complex Quantum Systems, Ulm University, Germany — [2]Center for Integrated Quantum Science and Technology (IQST), Ulm-Stuttgart, Germany

Charge transfer processes through DNA play a crucial role in gene regulation, including processes such as DNA methylation, an epigenetic modification essential for gene expression. However, the effects of methylation on excitonic energy transfer (EET) and coherent charge transfer (CT) in DNA remain poorly understood. Here, we theoretically investigate the effects of DNA methylation, as well as conformational changes, on biologically relevant DNA sequences. Using a Linear Combination of Atomic Orbitals (LCAO) approach, we compute the molecular electronic structure of nucleic acid bases and derive parameters for a computationally efficient tight-binding (TB) model. Our model incorporates intrinsic relaxation mechanisms for excited states, mimicking internal conversion (IC), and electron-hole Coulomb interactions. This framework provides physical insights into excited state lifetimes, charge separation dynamics, and dipole moments across diverse DNA sequences. By integrating quantum physics and physical chemistry methodologies with genetic and epigenetic analyses, this study offers a powerful interdisciplinary approach to investigate the quantum mechanisms underlying DNA charge dynamics and their modulation by epigenetic modifications.

BP 17.66 Tue 18:00 P4

Modeling host-pathogen interactions: infection process as a population dynamics problem — •Soham Mukhopadhyay[1], Jonathan Pollock[2], David Voehringer[2], and Vasily Zaburdaev[1] — [1]Department of Biology, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — [2]Department of Infection Biology, Uniklinikum Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany

Helminth infections affect a large proportion of the world's population and cause significant morbidity. There are no vaccines against helminths, and the mechanisms by which the body fights off helminth infections are not well-understood. To better understand the immune system response we aim to develop a mathematical model describing the helminth load in different organs of the host as a function of time. As an experimental system, we use murine helminth infection by *Nippostrongylus brasiliensis*. We abstract infection progression as a state-transition process. The different host organs involved in the infection cycle act as the different states of the system, and the worms are treated as identical and independent particles transitioning from one state to another with fixed transition rates and delays. This allows simulation of the infection process via kinetic Monte Carlo and association of the infective dose of larvae to the number of eggs shed to the environment by adult worms from the intestine, which can then be compared against experimental data. Using simulations to generate training data, we employ Neural Network-based optimization to discover an optimal parameter set that can quantify the infection process.

BP 17.67 Tue 18:00 P4

Measuring activity from particle trajectories — •Lukas Abegg, Till M. Muenker, and Timo Betz — Third Institute of Physics, Georg August Universität Göttingen, Göttingen, Germany

Is it possible to distinguish activity from thermal fluctuations just from observed trajectories? The newly introduced statistical quantity Mean Back Relaxation aims to achieve exactly this by using three-point correlation functions. This non-dimensional function yields a measure for deviation from equilibrium within a confined system. It is calculated as the average displacement of a tracer article under the condition of having moved the distance d in advance. For an equilibrium process, this quantity results in a long time value of $\frac{1}{2}$. However, deviation from this value is a marker for broken detailed balance. To gain deeper insight into this new statistical measure, we investigate this quantity inside a controlled system, namely a viscoelastic polyacrylamide gel. This probe was tuned to imitate the mechanical properties of cells, containing polystyrene particles with a size of one micron. To drive this system out of equilibrium, we use a movable optical tweezer to simulate active motion of the particle. The Mean Back Relaxation is calculated for all trajectories and fitted with an analytical solution for a viscoelastic system. The results are used to quantify the diffusion coefficient of the trapping laser and thus, the activity of the system tuned by our experimental realisation. Additionally, we can calculate the shear modulus $G^\star$ from this result.

BP 17.68 Tue 18:00 P4

Active Soft Glassy Rheology as a model for cytoskeletal mechanics — •Raffaele Mendozza and Peter Sollich — University of Goettingen, Institute for Theoretical Physics

The cytoskeleton plays a vital role in cellular processes like growth, migration, and division, owing to its unique mechanical properties [1]. Advanced microrheology techniques have revealed a complex power-law viscoelastic spectrum in this and other biopolymer networks, reflecting the presence of a broad distribution of relaxation timescales [2]. Coarse-grained trap models capture this phenomenology, suggesting a connection between cytoskeletal and soft glassy rheology (SGR) [3,4,5]; however, the original SGR model lacks explicit consideration of active processes, ubiquitous in living cells. We therefore explore how activity influences the rheological response of a soft glassy material, based on different working hypotheses. By introducing an activity-dependent effective temperature, the characteristic SGR viscoelastic spectrum is recovered, while modelling activity as an effective strain rate introduces a competing timescale that modifies the response. The resulting active SGR model provides insights into the mechanical behavior of cells independent of biochemical intricacies, serving as a foundation for future models incorporating more detailed structural information.

Fluctuating liquid inclusions morphology in biomolecular condensates driven by fuel-dependent binding agents — •Leonardo Silva-Dias and Christoph A. Weber — Universität Augsburg, Augsburg, Germany

The presence of aggregation-prone proteins in non-dilute, multi-component solutions, such as the cellular environment, can lead to the formation of protein aggregates. In these environments, such proteins may also undergo phase separation, forming biomolecular condensates. Both processes are regulated by specialized molecules known as binding agents, examples of which include RNA, enzymes, and chaperones. These binding agents continuously consume biological fuels, driving the system out of equilibrium and enabling the emergence of complex behaviors, such as morphological changes in the condensates. Specifically, recent experimental evidence has shown that a system composed of aggregation-prone proteins and ATP-driven chaperones induces the formation of condensates with a fluctuating liquid inclusions morphology. Based on these observations, the present work provides a theoretical framework to describe the emergence of the fluctuating liquid inclusions state. The proposed description is developed through a mean-field model that accounts for chemical reactions and phase separation in the presence of stochastic fluctuations. In this system, we observed that local fluctuations trigger multiple nucleation events within the condensates, leading to the growth of many liquid inclusion structures, which ripen, dissolve, and renucleate.

BP 17.70 Tue 18:00 P4

Competitive resource sharing mechanism for synchronization and its energy cost — •Dongliang Zhang[1,2], Yuansheng Cao[1], Qi Ouyang[3], and Yuhai Tu[4] — [1]Department of Physics, Tsinghua University, Beijing, China — [2]Max Planck Institute for the Physics of Complex Systems — [3]School of Physics, Zhejiang University, Hangzhou, China — [4]IBM T. J. Watson Research Center, Yorktown Heights, New York, USA

Synchronization among a group of active agents is ubiquitous in nature. Although synchronization mechanism based on direct pairwise interactions between agents as exemplified by the Kuramoto model is well understood. The dynamics and energetics of another general mechanism based on indirect interactions among agents sharing a limited resource are less known. In this work, we proposed a simple thermodynamically consistent model for the resource-sharing (RS) mechanism.We find that synchronization relies on differential competence of agents for the limited resources.More advanced agents are less competent, which provides a negative feedback mechanism resulting in synchronization. We show that differential affinity breaks detailed balance and thus synchronization requires continuous energy dissipation in addition to the energy cost of the agents* processive motion. Our study reveals a tradeoff relation between the total energy dissipation rate and the performance of the system characterized by its average speed and synchronization accuracy. Different Pareto fronts with fixed dissipation or speed result naturally from the Energy-Speed-Accuracy (ESA) relationship.

BP 17.71 Tue 18:00 P4

Time irreversibility and effective temperature are independently regulated in the actin cortex of living cells — •N Narinder and Elisabeth Fischer-Friedrich — Cluster of Excellence Physics of Life, Technische Universität Dresden, Dresden, Germany

Living cells exhibit non-equilibrium dynamics driven by the intricate interplay between motor activity and their viscoelastic environment. The deviation from thermal equilibrium termed as irreversiblity is commonly characterized by an increased effective temperature and time-reversal symmetry breaking quantified through the Kullback-Leibler divergence (KLD). In this study, we determine entropy production as a measure of irreversibility both by the effective temperature and the KLD in the actin cortex of living cells using atomic force microscopy (AFM) with and without pharmacological treatments that modulate cellular activity and cortical mechanics. Surprisingly, we find that while the entropy production rate consistently increases with effective temperature, its time irreversibility estimated by the KLD can exhibit an opposite trend, depending on the mechanical properties of the cortex. Our findings underpin the role of mechanical properties on the irreversibility. Further, the findings are supported by a minimal model of the AFM tip as probe immersed in the viscoelastic environment of active cell cortex.

BP 17.72 Tue 18:00 P4

Triacylglycerols affect the water content and cohesive strength of collagen fibrils — •Martin Dehnert, Tiberius Klose, Yang Pan, Dietrich R. T. Zahn, Maximilian Voigtländer, Johannes F. Teichert, and Robert Magerle — Fakultät für Naturwissenschaften, Technische Universität Chemnitz, Germany

Collagens, lipids, and water are among the major molecular components of connective tissue, but surprisingly little is known about their interactions in vivo. Here, we provide direct evidence that type I collagen fibrils extracted from chicken calcaneal tendon contain triacylglycerols (TAG), which influence the water content of the fibrils and act as plasticizers that affect the mechanical properties of the fibrils. We use organic solvents to dissolve lipids from native collagen fibrils and identify them as TAG using Raman spectroscopy and NMR spectroscopy. Using atomic force microscopy-based 3D depth profiling, we quantify the changes in volume, water content, and indentation modulus of the fibrils caused by the removal of TAG at the single fibril level. Based on these findings, we propose a molecular model for the intercalation of TAG into collagen fibrils. The discovery of the biomechanical function of TAG is fundamental to understanding the role of lipids in collagen fibrils during development, aging, and disease.

Cellular Potts Model links tissue surface tension to cell proliferation — •Kai Lennard Fastabend[1], Cécile M. Bidan[2], John W. C. Dunlop[3], and Philip Kollmannsberger[1] — [1]Biomedical Physics, Heinrich Heine University Düsseldorf, 40225 Düsseldorf, Germany — [2]Max Planck Institute of Colloids and Interfaces, Dept. of Biomaterials, Golm, Germany — [3]Paris Lodron University, Salzburg, Austria

The shape and growth kinetics of tissue depend not only on biochemical factors but also on the geometry of the extracellular environment. Cellular Potts Model simulations of tissue growth on different substrate geometries are a promising approach to investigate the role of adhesion forces, cell elasticity and tissue surface tension in the formation and organisation of tissue. To investigate how tension-dependent cell proliferation in tissues can explain the observed link between scaffold geometry and tissue growth kinetics, we implemented a growth rule based on the stretching of cells in CompuCell3D. Systematic parameter scans reveal the role of cell-substrate adhesion as the driving factor for monolayer formation, while cortical contractility introduces a surface tension to the tissue. The minimization of the macroscopic tissue surface leads to bulk tissue growth beyond the monolayer depending on the underlying substrate geometry. Our results highlight how cellular contractility and adhesion, together with geometric boundary conditions can determine the macroscopic growth patterns of tissues, independent of soluble growth factors.

BP 17.74 Tue 18:00 P4

Nanomechanical ultrastructure of native tendon tissue — Mario Zerson, Martin Dehnert, Paul Zech, Tiberius Klose, and •Robert Magerle — Fakultät für Naturwissenschaften, TU Chemnitz

Tendon tissue is a natural, high performance material in which type I collagen fibrils act as the load-bearing elements. The collagen fibrils are embedded in the tendon ground substance, a hydrophilic gel. Using AFM-based nanoindentation measurements, we study the nanomechanical ultrastructure of collagen fibrils in native tendon tissue obtained from the calcaneus (Achilles) tendon of chicken. The sample is exposed to a flow of humid air with controlled relative humidity to maintain the water content close to physiological conditions. We reconstruct 3D depth profiles from measured force–distance data and analyze the tip–sample interaction with a recently developed hysteresis model with return point memory (Soft Matter 2024, *20*, 2831–2839). The latter describes the rate-independent nanoindentation response, which is dominated by an elasto-plastic deformation behavior. It allows us to quantify the elastic and dissipative contributions of the indentation response within individual collagen fibrils as well as in the contact regions between adjacent fibrils.

BP 17.75 Tue 18:00 P4

Adjustable tension in reconstituted heart muscle tissue to mimic physiological mechanical environment changes — •Anna Mukhina[1], Till Muenker[1], Mattias Luber[1], Arne Hofemeier[2], Bruno Schmelz[1], and Timo Betz[1] — [1]Third Institute of Physics - Biophysics, University of Goettingen — [2]Department of Pharmacology and Toxicology, University Medical Center Goettingen

The development of in vitro 3D muscle tissues is critical for studying muscle physiology, disease mechanisms, and drug responses. PMMA tissue chambers provide structural support for myogenic cells embedded in a 3D ECM scaffold, enabling organization into aligned myotubes resembling natural muscle tissue. Tissue self-organizes around posts of known stiffness, with muscle strength assessed via post-deflection during contraction. This project introduces a piezo-driven actuator into the PMMA chamber for external manipulation of tissue tension. Combining actuators with a direct readout of posts' positions enables feedback control to emulate diverse mechanical environments. This innovation investigates how varying mechanical loads influence muscle development, adaptation, and therapeutic responses.

The project involves: (1) design and integration of a piezo actuator system, using CAD and Labview for construction and feedback control; (2) validating the modified chamber with engineered human myocardium (EHM) derived from iPSCs, exposed to defined mechanical stresses to mimic physiological and pathological loads. Functional and morphological outcomes are assessed via post deflection analysis and fluorescence imaging, advancing insights into muscle biomechanics.

BP 17.76 Tue 18:00 P4

Illuminating forces in living tissues — •Lucia Baldauf[1], Anna Bajur[2], Katelyn Spillane[2], and Guillaume Charras[1] — [1]London Centre for Nanotechnology, University College London, UK — [2]Department of Life Sciences, Imperial College London, UK

How can epithelial tissues withstand large forces and support deformations that drastically increase their length? Adult epithelial tissues regularly experience forces that stretch them by up to 50 %, and deformations can reach several hundred percent during development. To fulfill their physiological barrier function, epithelia must accommodate such large deformations without fracturing. Consequently, cell-cell adhesions must be finely tuned, or pathologies like skin blistering or cancer metastasis can occur. However, the physical principles governing tissue integrity remain difficult to study, since tissue fracture is a multiscale process spanning up to 10 orders of magnitude in both size and force. Millimetre-sized tissues can withstand millinewton-forces, but tissue fracture results from the local failure of single nanometre-sized adhesion complexes that bear piconewton forces. New tools are needed to bridge these vastly different scales and understand what molecular processes lead to tissue failure. Here we develop a new experimental tool to study tissue integrity and force propagation across scales. We engineer living model tissues where DNA-based molecular force sensors in chimeric cell-cell junctions provide a local molecular-scale force readout, for the first time illuminating how forces propagate in living tissues under stretch.

BP 17.77 Tue 18:00 P4

Imaging cell mechanics of retina organoids using an oblique plane light-sheet microscope — •Achim Theo Brinkop[1,2], Florian Schorre[1], Stefan Stöberl[1], Elijah R. Shelton[1], Teresa Rogler[1,2], Michael Frischmann[1,2], Marie Lackmann[1], Kaustav Goswami[1], Alexander Zangl[1], Mythili Padavu[1], and Friedhelm Serwane[1,2,3] — [1]Faculty of Physics & Center for NanoScience, LMU Munich, Germany — [2]Institute of Biophysics, Ulm University, Germany — [3]Munich Cluster for Systems Neurology (SyNergy) & Graduate School of Systemic Neuroscience (GSN), Munich, Germany

Retina organoids have become a powerful testbed for studying retina formation and neuronal development. Our current measurements of the creep compliance in retina organoids with magnetic droplets point towards soft glassy rheology of developing retinal tissue at second to hour timescales. As a next step, we explore whether the motion of cells agrees with predictions for glassy materials. For this purpose, we built a custom oblique plane microscope for long-term volumetric imaging of the cell movements during organoid development. Using a processing pipeline based on open-source python packages (Cellpose3, Ultrack), we segment and track individual cells. The tracks allow us to quantify cell dynamics and compare these with existing models for glassy materials. In the future, we will integrate magnetic droplet compliance measurements with volumetric imaging in one set-up to simultaneously probe organoid mechanics *in situ*. Combining tissue mechanics measurements with cell dynamic recordings, we aim to shed light on the mechanical cues that guide retina formation.

BP 17.78 Tue 18:00 P4

Investigating the mechanosensitive expression of sema3A and slit1 in hydrogel-embedded neuroepithelial cells — •Niklas Gampl[1,2] and Kristian Franze[1,2,3] — [1]Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany — [2]Institute of Medical Physics and Microtissue Engineering, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — [3]Department of Physiology, Development and Neuroscience, University of Cambridge, Cambridge, UK

During brain development, neurons extend long axons that grow along well-defined pathways to their destination. This axon pathfinding is regulated by chemical guidance cues, which are produced by neuroepithelial cells, and by tissue stiffness. To investigate whether environmental stiffness regulates the expression of chemical guidance cues in the developing brain, we developed a framework to culture Xenopus tissue explants in collagen-based hydrogels with tunable stiffness. We found an increase in sema3A and slit1 mRNA levels in hypothalamic neuroepithelial tissue cultured in stiff hydrogels (G' = 450 Pa) compared to soft hydrogels (G' = 40 Pa). Additionally, 3D traction force microscopy revealed that strain energy, generated by the explants and stored in the matrix, increased with stiffness. These findings highlight a mechanochemical mechanism linking tissue stiffness to chemical guidance cue expression. Further investigation could improve our understanding of the complex interplay between guidance cues and their integration by cells.

BP 17.79 Tue 18:00 P4

AFM imaging of epithelial basement membrane with and without molecular perturbations — •Karla Yanin Guerra Santillan[1], Christian Dahmann[2], and Elisabeth Fischer-Friedrich[1] — [1]Cluster of Excellence Physics of Life, Technische Universit\"at Dresden, Dresden, Germany — [2]School of Science, Technische Universit\"at Dresden, Dresden, Germany

Understanding the precise regulation of growth and form is fundamental to the healthy development of all organisms. The basement membrane is a specialized sheet of extracellular matrix that forms at the basal face of epithelial tissues. This biopolymer network plays a major role in structural support, proliferation regulation and biochemical signalling. Here, we present data of high-resolution images of the basement membrane in developing wing discs of the fruit fly Drosophila melanogaster using atomic force microscopy. We find that depending on the developmental stage, micron-sized ripple patterns of different amplitude are present on the surface of the basement membrane that depend on the presence of individual ECM proteins.

BP 17.80 Tue 18:00 P4

Species-specific biomineral pattern formation in centric diatoms — •Francesco Leone[1], Nils Kröger[1,2], and Benjamin M. Friedrich[1] — [1]Physics of Life, TU Dresden, 01307 Dresden — [2]B CUBE, TU Dresden, 01307 Dresden

Diatoms are unicellular algae known for their intricately patterned cell walls, primarily composed of amorphous silica (SiO2). Their hierarchically patterns biomineral architectures display outstanding material properties but also represent an ideal model system to study species-specific pattern formation during biomineralization by living organisms. In centric "barrel-shaped" diatoms, the "lids" display three prominent pattern features: branched rib patterns with radial symmetry, nano-pores and transverse connections. How these different pattern features evolve and mutually influence each other is not known. We are extending a mathematical model of branching morphogenesis, previously developed in our group for a single model species [1], to account for the variety of patterns in related species and mutants. To facilitate a rigorous quantitative comparison to electron microscopy images, we are developing automated image analysis pipelines for the morphometric characterization of different phenotypes. Through this research, we aim to reverse-engineer putative chemical and physical mechanisms taking place during diatom silica cell wall formation.

Self-stimulated growth of epithelial model tissues — •Maja Milas[1], Damir Vurnek[2], Narmin Abasova[2], Kevin Höllring[2], and Ana-Sunčana Smith[1,2] — [1]Group for Computational Life Sciences, Division of Physical Chemistry, Ruđer Bošković, Institute, Zagreb, Croatia — [2]PULS Group, Center for Advanced Materials and Processes, FAU Erlangen-Nürnberg

The growth of epithelium is one of the fundamental biological processes required for sustaining the life of multicellular organisms. This process can be studied in appreciable detail using model systems such as radially growing 2D MDCK colonies. Typically, epithelium grows from low densities to the homeostatic state while expanding laterally. This process has, in the past, been captured using Fisher Kolmogorov-like growth laws, where shortly after the establishment of homeostasis, the moving front reaches a constant velocity and density profile. However, in experiments presented herein, we show that the moving front continues to accelerate and expand for days after the steady state density is achieved in the center of the colony. This radial expansion cannot be captured by currently established models, even after introducing a highly non-linear growth term and recently proposed delays. We can, nonetheless, rationalize this growth scenario by introducing self-stimulation by an activator secreted and absorbed in a density-dependent manner and coupling it with the equation for the evolution of the density. Further work is necessary to identify the biochemical pathway regulating the effect of the activator.

BP 17.82 Tue 18:00 P4

Epithelial Tissue Response Under Solid Shear Stress — •Narmin Abasova[1], Annemarie Wirth[1], Kevin Hoellring[1], Rudolf Merkel[2], and Ana-Sunčana Smith[1,3] — [1]PULS Group, Institute for Theoretical Physics, FAU Erlangen- Nurnberg (IZNF) — [2]Institute for Biological Information Processes (IBI), Forschungszentrum, 52428 Jülich, Germany — [3]Group of Computational Life Sciences, Division of Physical Chemistry, Ruder Bošković Institute, 10000 Zagreb, Croatia

Epithelial cells are subjected to a diverse range of mechanical stresses in the human body, from the dynamic forces generated during physical activity to the rhythmic pulsations of blood flow. To better understand the mechanobiological processes due to various stress types, it is essential to investigate how they influence cellular responses and tissue functionality. Among the different forms of mechanical stress, solid shear stress transmitted through the extracellular matrix (ECM) remains a relatively underexplored side of tissue mechanics. Our research addresses this gap by utilising a custom-designed device that applies controlled shear stress to the substrate supporting epithelial cell cultures. By subjecting targeted cell clusters to solid shear stress, we observe and document the tissue's behavior under a microscope. This study examines key aspects of cellular response, including stress relaxation, proliferation, morphological alterations and topological changes at cell membranes, where neighboring cells exchange positions. Using stress-generating devices in this context allows us to better understand how distinct stress types influence tissue behavior.

BP 18: Tissue Mechanics

Time: Wednesday 9:30–13:00 Location: H44

Invited Talk BP 18.1 Wed 9:30 H44

Mechanical Imprints of Cell Competition — •Benoit Ladoux — Institut Jacques Monod, Université Paris Cité & CNRS

Epithelial tissues are dynamic communities of cells characterized by close intercellular communication and highly coordinated motion. The mechanical properties of these tissues are crucial for understanding key biological processes, such as homeostasis, morphogenesis, and metastasis, and are tightly regulated through cell-cell interactions. In this presentation, I will explore the role of mechanical forces in cell competition - a process where the expansion of one cell population drives the elimination of another. I will demonstrate how intercellular force transmission governs this competitive interaction, shedding light on the interplay between mechanics and cellular mechanisms.

BP 18.2 Wed 10:00 H44

Regulation of Homeostatic Tissue Composition and Self- Organization via Pressure-mediated Cell Cycle Control in Stem Cell-Derived Epithelial Tissues — •Johannes Krämer[1], Edouard Hannezo[2], Gerhard Gompper[1], and Jens Elgeti[1] — [1]Forschungszentrum Jülich, Institute for Advanced Simulations — [2]Institute of Science and Technology Austria

Tissue homeostasis relies on a precise balance between cellular proliferation and differentiation, with spatial cell distribution playing a critical role in effective replenishment. The mechanisms governing self-renewing cell types, including their proliferation rates, mechanical interactions, and spatial organization, remain incompletely understood. Here, we present a study of epithelial tissue dynamics using a descendant lineage model derived from slow-cycling, self-renewing stem cells. Through mean-field analysis, we establish conditions for cell cycle parameters that maintain a well-defined tissue configuration and demonstrate the influence of mechanical regulation on division control. To further explore spatio-temporal properties, we implement the lineage model in an agent-based computational framework, incorporating cell-cell mechanical interactions. Our findings reveal a regime in which stem cells exhibit long-range order, forming small, localized niche-like clusters with slow diffusion. These insights offer a novel perspective on the interplay between proliferation, differentiation, and the role of mechanical interactions on the spatial organization of cells, advancing our understanding of tissue homeostasis.

BP 18.3 Wed 10:15 H44

Spatiotemporal Analysis of Active Deformation of Patient-derived Colon Cnacer — •Shogo Nagai[1], Ryo Suzuki[2], Go Yamakawa[3], Akihisa Fukuda[3], Hiroshi Seno[3], and Motomu Tanaka[1,4] — [1]Physical Chemistry of Biosystems, Heidelberg University, Heidelberg, Germany — [2]Department of Biosciences and Informatics, Keio University, Tokyo, Japan — [3]Department of Gastroenterology and Hepatology, Kyoto University Graduate School of Medicine, Kyoto, Japan — [4]Center for Integrative Medicine and Physics, Kyoto University, Kyoto, Japan

Biomedical cancer research has relied on the investigation of fixed cells and tissues, in which the non-equilibrium dynamics of cancer have been largely overlooked. Extending the recent studies shedding light on the dynamics of the isolated cells, spatiotemporal analysis of cancer on a multicellular level is expected to reveal the dynamic mechanisms of cancer progression.

In this study, the time evolution of active deformation of growing colorectal cancer organoids (miniaturized organ model) was quantitatively evaluated by the Fourier expansion. Thereby, the larger deformation of malignant genetic mutated organoids was extracted, which was attributed to the slow effective viscoelastic relaxation. The simulation of the double-cell stage indicated the characteristic dynamics of organoids could be related to cell-cell junctions. In addition, biomedical evaluations showed lower cell-cell junctions of malignant colorectal cancer on a protein and RNA level.

BP 18.4 Wed 10:30 H44

a novel 3D platform for investigating cancer cell migration and tissue organization under mechanical load — •Mattias Luber, Bruno Schmelz, Mahboubeh Farajian, and Timo Betz — Third Institute of Physics - University of Göttingen - Germany

Recent advances in tissue engineering and mechanobiology have highlighted the critical role of mechanical forces in guiding cellular organization and extracellular matrix (ECM) remodeling. Building on these findings, we introduce a novel platform for engineering connective tissues that facilitates high-resolution live imaging of self-organization and ECM remodeling under diverse experimental conditions. This platform employs controlled mechanical loading to induce fibroblast alignment, resulting in the formation of highly organized tissue structures. By enabling both global and localized measurements of tissue tension and providing precise control over mechanical load, it allows for the detailed investigation of ECM remodeling, cellular dynamics, and nuclear deformation. A key application of this platform is in uncovering how mechanical properties of the tissue environment influence cancer cell behavior. By integrating models of MDA-MB-231 breast cancer cells, we demonstrated how variations in tissue tension and ECM structure directly modulate cancer cell migration patterns. These findings highlight the critical interplay between mechanical forces and cellular invasiveness, providing insights into the biomechanical drivers of cancer progression.

BP 18.5 Wed 10:45 H44

Bridging the gap between single cell and tissue mechanics — •Mathilde G. Lettinga[1], Antje Garside[1], Vaibhav Mahajan[1], Franziska Baenke[2], Valeria Lozovanu[2], Daniel Stange[2], Ingolf Sack[3], and Anna V. Taubenberger[1] — [1]Center for Molecular and Cellular Bioengineering (CMCB), BIOTEC, Dresden University of Technology, Germany — [2]Department of Visceral, Thoracic and Vascular Surgery, University Hospital Dresden, Germany — [3]Department of Radiology, Charité - Universitätsmedizin Berlin, Germany

Tumours exhibit altered biophysical properties across spatial scales. Compared to healthy tissue, solid tumours are typically stiffer, while individual cancer cells are more compliant. The increased tissue stiffness can partly be attributed to the extracellular matrix. However, the contributions of single cell mechanics and collective cell behaviour to the emergent tissue properties remain unclear.

To bridge this gap between single cell and tissue mechanics, we have established a 3D in vitro tumour model, based on patient-derived colorectal liver metastasis organoids grown in hydrogels mimicking the extracellular matrix. Cells retrieved from dissociated organoids were mechanically characterised with real-time deformability cytometry and AFM. These data were benchmarked to the morphometric and mechanical properties of intact organoids, which were assessed in situ by confocal and Brillouin microscopy. The bulk mechanical properties of our model system were investigated using tabletop magnetic resonance elastography. Our data contribute to a better understanding of the mechanical coupling between single cells and tissues.

BP 18.6 Wed 11:00 H44

Exploring glassy dynamics in retina organoids through time-series imaging — •Alexander Johann Zangl[1], Achim Theo Brinkop[1,2], Elijah R. Shelton[1], Marie Lackmann[1,2], Teresa Rogler[1,2], and Friedhelm Serwane[1,2,3] — [1]Faculty of Physics & Center for NanoScience, LMU Munich, Germany — [2]Institute of Biophysics, Ulm University, Ulm, Germany — [3]Munich Cluster for Systems Neurology (SyNergy) & Graduate School of Systemic Neuroscience (GSN), Munich, Germany

Quantifying cell dynamics and the mechanical forces guiding such movements can provide crucial insights for understanding tissue development and disease progression. Stem cell derived neuronal organoids provide an accessible system for studying nervous tissue development in the laboratory. Recently, magnetic droplet based mechanical measurements in retina organoids revealed a weak power-law scaling in the mechanical properties, suggesting that the retinal tissue is a glassy material. While the mechanical observations are consistent with predictions of soft glassy rheology, whether the movements of the individual cells making up those tissues are also in agreement with a glassy material is still unknown. Using confocal fluorescent time-series imaging, we observe the movements of nuclei in the forming retina. By tracking cells, we can determine whether cellular movements also point to the retina as a solid-like material just above a glass transition. We characterize the cell dynamics of the tissue by analysing the scaling of the mean-square displacements of the nuclei. This will help us understand how mechanical cues guide retina formation.

BP 18.7 Wed 11:30 H44

Statistical Inference and Selection of a Mechanistic Model during Tissue Specification in Beetle Embryogenesis — •Zoë Lange[1,2], Franziska Krämer[3], Frederic Strobl[3], Ernst H.K. Stelzer[3], and Franziska Matthäus[1,4] — [1]Frankfurt Institute for Advanced Studies — [2]Fachbereich Physik, Universität Frankfurt am Main — [3]Buchmann Institute for Molecular Life Sciences — [4]Fachbereich Informatik und Mathematik, Universität Frankfurt am Main

During development of the beetle Tribolium castaneum, the blastoderm differentiates into embryo and extra-embryonic serosa tissues with distinct morphologies. Using statistical inference, we estimate effective cell tensions and pressures based on cell geometry and a force-balance assumption. Our analysis reveals an inverse relationship between tension and cell shape with characteristic slopes for serosa and embryo tissues. We identify and parametrize a mechanistic vertex model that captures the differing properties of serosa and embryo cells. This study demonstrates how statistical inference can guide the selection and refinement of mechanistic models to understand tissue dynamics during embryogenesis.

BP 18.8 Wed 11:45 H44

Dynamics and mechanics of germband extension in *Drosophila* — •Maryam Setoudeh[1,2,3], Giulia Serafini[3], Pavel Tomancak[3,4], and Pierre A. Haas[1,2,3] — [1]Max Planck Institute for the Physics of Complex Systems — [2]Center for Systems Biology Dresden — [3]Max Planck Institute of Molecular Cell Biology and Genetics — [4]Cluster of Excellence Physics of Life, TU Dresden

During *Drosophila* development, cell intercalations and cell divisions drive the extension of the germband on the dorsal side of the embryo towards its anterior. We and others [1] have recently observed that the shape of the germband is often curved, even in the wild-type, contrary to the textbook picture of a straight germband. Here, we develop a mechanical model in which the germband midline appears as an elastic line pushed by an effective force resulting from germband extension. Its motion is resisted by frictional forces from surrounding tissues and attachment at the tip mediated by the integrin scab. In this model, we discover an instability of the straight shape that explains the observed variability in the wild-type as well as the twisting phenotype observed in embryos in which scab is depleted. We also find that an alternative model of a growing rather than pushed elastic line cannot explain the observed instability. This highlights the mechanical role of these pushing forces in germband extension.

BP 18.9 Wed 12:00 H44

A mechanical model of the symmetry breaking of the shape of the primordial hindgut — Daniel S. Alber[1,2], Shiheng Zhao[3,4,5], Eric F. Wieschaus[2,6], Stanislav Y. Shvartsman[2,6,7], and •Pierre A. Haas[3,4,5] — [1]Department of Chemical and Biological Engineering, Princeton University — [2]Lewis-Sigler Institute for Integrative Genomics, Princeton University — [3]Max Planck Institute for the Physics of Complex Systems — [4]Max Planck Institute of Molecular Cell Biology and Genetics — [5]Center for Systems Biology Dresden — [6]Department of Molecular Biology, Princeton University — [7]Center for Computational Biology, Flatiron Institute

During early *Drosophila* morphogenesis, as the germband extends and the midgut invaginates, the initially circular primordial hindgut moves from the posterior pole of the embryo to its dorsal side and folds into a characteristic keyhole shape. Here, we develop a minimal model of this symmetry breaking in which the hindgut appears as an inextensible elastic ring in the plane. We discover that, as the area enclosed by the ring decreases (midgut invagination) while a diameter is held fixed (germband extension), the circular shape bifurcates robustly into the observed keyhole shape. Moreover, we show how embryonic curvature breaks symmetry further to select the observed orientation of the keyhole shape. This demonstrates that morphogenesis of the primordial hindgut can be a passive mechanical consequence of active deformations of the tissues that surround it.

BP 18.10 Wed 12:15 H44

What mouse embryos can teach us about tissue spreading — •María-José Franco-Oñate[1], Ricard Alert[1], and Kate Cavanaugh[2] — [1]MPI for the Physics of Complex Systems, Dresden, Germany — [2]University of San Francisco in California, United States

Processes such as embryogenesis, tissue repair and cancer metastasis are dependent upon the migration of large groups of cells through changes in group morphogenesis or collective migration. These processes entail both molecular and mechanical interactions between cells and their surrounding environment. Several attempts have been made to create models of these interactions [1].

In this study, we focus our attention on mouse embryos during implantation. In this process, the embryo adheres to the substrate and extends along it. The results of ongoing experiments indicate that embryos derived from older mice are unable to implant, resulting in a lack of spreading of the tissue that adheres to the substrate. The objective of this study is to gain insight into the mechanisms underlying the spreading process and its dependence on the age of the embryo. To this end, we employ a coarse-grained approach, in which the tissue is conceptualised as an active polar fluid, to investigate the dynamics of a spreading tissue [2]. To validate our theoretical model, we utilise traction force microscopy, which enables us to quantify the forces exerted by the tissue.

BP 18.11 Wed 12:30 H44

Growth control in development and regeneration in the zebrafish pectoral fin — •Maximilian Kotz[1,2], Lucas de Oliveira Petrocchi Ribas[1,3], Shivani G. Ramkumar[1,3], Rita Mateus[1,3], and Benjamin M. Friedrich[1,2] — [1]PoL, Dresden, Germany — [2]cfaed, Dresden, Germany — [3]MPI-CBG, Dresden, Germany

Although all multicellular organisms can develop from a single cell, only few organism can regenerate lost body parts in adulthood. If it as an open question whether the mechanisms controlling growth in regeneration are the same as those in development. We combine theory and experiment to address this question using the pectoral fin of zebrafish as a model system. As a novel paradigm, we compare unperturbed development and regeneration after partial amputation during development. To quantify growth, we developed machine learning-based image analysis pipelines and introduce a curvilinear coordinate system to describe the geometry of the tissue. Tissue samples from different individuals became comparable by defining diffeomorphisms that minimize an elastic pseudo-energy, which enables a rigorous statistical comparison of proliferation rates, shape changes and even morphogen gradients. This quantification revealed that volume growth is driven by distinct processes. In particular, growth along the different body axes is markedly different, with thickness growth apparently uncoupled from in-plane growth. To identify the underlying mechanisms of growth control, we probe predictions from different mathematical models by investigating different amputation scenarios, along with genetic or pharmacological perturbations.

BP 18.12 Wed 12:45 H44

Model of growth arrests and proportional growth inspired by axolotl limb regeneration — •Natalia Lyubaykina[1,2], Dunja Knapp[3], Pietro Tardivo[4], Tatiana Sandoval-Guzmán[3], Elly Tanaka[4], and Benjamin M Friedrich[1,2] — [1]Cluster of Excellence 'Physics of Life', Technical University Dresden, Dresden, Germany — [2]Center for Advancing Electronics, Technical University Dresden, Dresden, Germany — [3]CRTD/Center for Regenerative Therapies TU Dresden, Germany — [4]Research Institute of Molecular Pathology, Vienna Biocenter (VBC), Campus Vienna Biocenter, Vienna, Austria

Axolotl can regenerate lost limbs even as adults, posing the question of how the size of a regenerating limb is matched to a variable animal size. Two interacting morphogens, SHH and FGF8, regulate limb development and regeneration. Inspired by this biological example, we theoretically investigate general mechanisms of morphogen-controlled growth arrest and proportional growth. In the proposed model, tissue growth increases the spatial distance between both morphogen gradients, thus providing negative feedback that eventually arrests growth. We propose two distinct scaling scenarios of morphogen gradients: either dynamic scaling with regenerating blastema size, or static scaling with animal size. We show that only the latter ensures robust growth arrest and proportional growth. We compare theory predictions to experimental quantification of SHH and FGF8 dynamics at different time points of regeneration in different-sized animals, suggestive of scaling with animal size.

BP 19: Membranes and Vesicles II

Time: Wednesday 9:30–13:00 Location: H46

Atomistic Insights into pH-Dependent Structural Transitions in Lipid Mesophases: A Combined MD/SAXS Approach — •Akhil Sudarsan[1], Julian Philipp[2], Joachim Rädler[2], and Nadine Schwierz[1] — [1]University of Augsburg, Augsburg, Germany — [2]Ludwig Maximilians-University, Munich, Germany

Lipid nanoparticles (LNPs) are crucial delivery vehicles for mRNA-based therapeutics, enabling the encapsulation and release of negatively charged nucleic acids through ionizable lipids that exhibit pH-dependent fusogenic activity. This study investigates ionizable DLin-MC3-DMA (MC3) lipid/cholesterol mesophases that mimic the core structure of LNPs, focusing on the inverse hexagonal (H_{II}) and inverse micellar (L_{II}) phases, both featuring an internal water domain surrounded by ionizable lipids. By combining experimental SAXS data and molecular dynamics (MD) simulations, we show that the L_{II} phase, which is stable at higher pH, transitions to H_{II} at lower pH. We also calculate the water content of the simulated core phases through comparison with scattering data and elucidate the distribution of lipids in these mesophases. We further developed an approach to compute scattering profiles directly from MD simulations, which corrects for artifacts arising from periodic boundary conditions, enabling direct, model-free comparisons between experimental and simulated data enhancing the reliability of the structural interpretations. In summary, integrating SAXS experiments and MD simulations offer molecular insights into the dynamic behaviour and pH-dependent structural transitions of ionizable lipid mesophases.

BP 19.2 Wed 9:45 H46

The effect of long-chain sphingolipids on lipid bilayers — •Clara Rickhoff, Annemarie Quas, and Andreas Heuer — Institut für Physikalische Chemie, Universität Münster, Münster, Germany

Lipid bilayers are found to form microdomains, so called rafts, that support a

sorting of compounds in the bilayer, and that way are thought to be essential for cellular processes, such as vesicular traffic. One type of raft that is found in lipid bilayers of e.g. yeast cells in experiments are sphingolipid-enriched and sterol-depleted domains, that seem to form gel-like domains. In our work, we conduct MD simulations of lipid bilayers containing different concentrations of long-chain sphingolipids in order to investigate their effect on the membrane at the atomistic level. The remaining part of the lipid bilayer is chosen close to experimental results (Wedlich-Söldner group, University of Münster). From these simulations we gain insight into structural properties such as of e.g. the order parameter, the RDF or the interdigitation. This allows a deeper understanding of the order of the long-chain spingolipids, their effect on the overall membrane structure and the coupling between the leaflets.

BP 19.3 Wed 10:00 H46

Engineering asymmetric lipid vesicles for protein delivery — •Kevin Jahnke, Chenjing Yang, and David Weitz — Harvard University, Cambridge, USA

The delivery of therapeutics to cells is crucial for the treatment and prevention of diseases. To enhance targeting and protect therapeutics from degradation, they are often encapsulated into drug delivery vehicles like lipid nanoparticles, liposomes and viral vectors. However, there is no universal vehicle for all cargo types including small molecules, nucleic acids and proteins. Here, we present a method for engineering lipid vesicles with asymmetric leaflets and demonstrate their ability to deliver mRNA and proteins to cells (Yang,.., Weitz, Jahnke; biorxiv 2024). We show that leaflet asymmetry modulates the biophysical properties of lipid vesicles, leading to an enhanced vesicle uptake by cells, and an up to 5-fold increased transfection efficiency with mRNA. Additionally, we show that asymmetric vesicles can deliver a variety of proteins, including the gene-editing protein Cas9 and Cas9/sgRNA complexes. By modifying lipid vesicles with polysaccharides (Jahnke et al.; PNAS 2024) or the engineering of lipid-polymer hybrid vesicles, we further achieve the targeted delivery to specific cell types. Our method and findings expand the parameter space for engineering drug delivery vehicles and demonstrate the pivotal role of leaflet asymmetry in determining the biophysical properties of lipid vesicles. Consequently, our work leads to many applications, including the formation of more efficient, universal drug carriers that enable the delivery of proteins to cells.

BP 19.4 Wed 10:15 H46

Vesicle to bicelle decomposition can be correlated with the lipid's main phase transition: a direct evidence using chain-deuterated lipid — •Carina Dargel[1,2], Lara H. Moleiro[2], Aurel Radulescu[3], Tim J. Stank[2], and Thomas Hellweg[2] — [1]University of Münster, Institute of Physical Chemistry, Münster, Germany — [2]University of Bielefeld, Physical and Biophysical Chemistry, Bielefeld, Germany — [3]FZ Jülich, Jülich Centre for Neutron Science (JCNS) at Heinz Maier-Leibnitz Zentrum (MLZ), Garching, Germany

Mixtures of the phospholipid 1,2-dimyristoyl-sn-glycero-3-phosphocholine (DMPC) and the saponin β-aescin form bicelles above a critical saponin concentration. Modification of the membrane's phase state by temperature increase induces a structural growth of the bicelles resulting in membrane-like DMPC-aescin aggregates or mixed small unilamellar vesicles.

The temperature-induced transition is fully reversible, independent of the aescin content. Furthermore, the decomposition of the mixed vesicles back to bicelles shows a prominent hysteresis effect, which is correlated with the main phase transition temperature T_m of the lipid. This correlation was demonstrated for the first time by taking advantage of the shift of the membrane's T_m due to chain-deuteration and thus the use of d54-DMPC by both turbidimetry and small angle neutron scattering (SANS)[1].

BP 19.5 Wed 10:30 H46

Exploring DNA Linkers for Biomimetic Cell Adhesion of Red Blood Cells — •Sebastian W. Krauss[1], Roger Rubio-Sánchez[1], Bortolo M. Mognetti[2], Lorenzo Di Michele[1], and Pietro Cicuta[3] — [1]CEB, University of Cambridge, UK — [2]ULB, Brussels, Belgium — [3]Department of Physics, University of Cambridge, UK

Ligand-receptor interactions are fundamental to cellular membrane dynamics, influencing a range of processes like cell-cell signaling and viral infections. These interactions govern how adjacent membranes recognize, bind, and respond to one another. To better understand these mechanisms, we developed a biomimetic approach that grants precise control over the strength of interactions between opposing membranes. Our strategy employs short membrane-anchored amphiphilic DNA nanostructures featuring single-stranded 'sticky-ends', which are designed to bind through complementary sequences, providing an adaptive platform for membrane-membrane interactions [Chem. Comm. 57, 12725 (2021)]. We implemented our platform to functionalize red blood cells (RBCs), creating cellular aggregates with programmable morphologies, ranging from doublets to star-like geometries. Additionally, we used DNA-functionalized particles to selectively bind RBCs. By tuning the sequence, we precisely controlled interaction strength, enabling RBCs to progressively envelop beads. Furthermore, we employed optical tweezers to observe the rapid formation of strong bonds in situ [manuscripts in preparation]. This system offers insights into the forces and dynamics of RBC aggregation and their interactions with pathogens, such as Plasmodium species responsible for malaria.

BP 19.6 Wed 10:45 H46

Investigating Endosomal Escape Mechanisms of PEI-DNA Polyplexes with Computer Simulations — •Jonas Lehnen[1], Friederike Schmid[1], and Giovanni Settanni[2] — [1]Physik, Johannes Gutenberg Universität, Mainz — [2]Physik, Ruhr-Universität Bochum

Nucleic-acid-based therapeutics have recently demonstrated their potential thanks to the successful COVID-19 vaccination campaign. They have been already approved or in the latest stages of clinical trials as remedies for a broad range of pathologies, including cancer and genetic diseases. These approaches make use of complex delivery vehicles to take the nucleic acids to the target tissues. The presently used lipid-based nanoparticles still face a relatively low delivery rate and side effects. Polyplexes, formed by the aggregation of cationic polymers with the anionic nucleic acids, may provide a valid alternative. The transfection mechanism for these polyplexes is an ongoing topic of research. We use coarse grained molecular dynamics simulations to investigate contributing factors to the endosomal escape process which is a crucial limiting step in the transfection process. Our simulations model an endosome containing a polyplex, evaluating key factors such as the surface tension of the endosome caused by osmotic swelling and the interactions between the polyplex and the endosomal membrane, which are key factors in the predominant theories.

BP 19.7 Wed 11:00 H46

Modeling endosomal membrane budding patterns — •Felix Frey and Andela Saric — Institute of Science and Technology Austria, Klosterneuburg, Austria

Lipid membranes define cells and structure their interior. Endosomes, which are organelles that host molecular cargo sorting processes, are enclosed by flexible membranes from which small vesicles continuously pinch off. The reshaping of the endosomal membrane is mediated by filamentous proteins of the ESCRT-III family. Strikingly, in endosomes of flowering plant cells, arrays of concatenated membrane vesicles can form, which are connected either in parallel or in series with the membrane base. Here we combine coarse-grained molecular dynamics simulations and continuum theory with electron tomography to study the budding patterns at plant endosomal membranes [1]. We find that changes in ESCRT-III filament properties, such as curvature and membrane binding energy, determine the formation pathways and shapes of the emerging vesicle networks.

Invited Talk BP 19.8 Wed 11:30 H46

Rolling vesicles: From confined rotational flows to surface-enabled motion — •Laura R. Arriaga[1], Paula Magrinya[1], Pablo Palacios[1], Pablo Llombart[1], Rafael Delgado-Buscalioni[1], Alfredo Alexander-Katz[2], and Juan L. Aragones[1] — [1]Department of Theoretical Condensed Matter Physics, Condensed Matter Physics Center (IFIMAC) and Instituto Nicolás Cabrera, Universidad Autonoma de Madrid, 28049, Madrid, Spain — [2]Department of Materials Science and Engineering, Massachusetts Institute of Technology, Cambridge, MA, 02139, USA

Friction forces are essential for cell movement, yet they also trigger numerous active cellular responses, complicating their measurement in vivo. In this talk, we will introduce a synthetic model designed to measure friction forces between biomimetic membranes and substrates. The model consists of a vesicle with precisely controlled properties, fabricated via microfluidics, encapsulating a single ferromagnetic particle that is magnetically driven to rotate. The rotation of the particle generates a confined rotational flow, setting the vesicle membrane into motion. By adjusting the magnetic field frequency and vesicle size, the rotation frequency of the vesicle can be finely controlled, resulting in a rolling vesicle that functions as an effective tribological tool. At low frequencies, molecular contact between the membrane and substrate dominates frictional interactions, providing a measurement of the contact friction coefficient. Adjusting membrane fluidity within this model will enable the study of frictional processes in more complex biomimetic systems.

BP 19.9 Wed 12:00 H46

Dynamics of a microswimmer near a deformable boundary — •Sagnik Garai, Ursy Makanga, Akhil Varma, and Christina Kurzthaler — Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Straße 38, 01187 Dresden, Germany

We study the hydrodynamic interactions of swimming microorganisms with nearby deformable boundaries omnipresent in their natural habitats. The boundary, characterized by its surface tension and bending rigidity, is deformed by the disturbance flow produced by the microswimmer and thereby modifies its swimming velocities. Describing the far-field flow of the agent as a combination of a

force and torque dipole, we compute small deformations of the boundary. We further use the Lorentz reciprocal theorem to obtain leading-order corrections of its swimming velocities and compute a phase diagram based on the swimmer's initial orientation and the material properties of the deformable boundary. Our results reveal that pushers can both re-orient away from the boundary, leading to overall hydroelastic repulsion, or hover near the boundary, while pullers exhibit enhanced attraction. These findings demonstrate that the complex elastohydrodynamic interactions can generate behaviors that are fundamentally different to swimming near planar walls.

BP 19.10 Wed 12:15 H46

Uptake of microgels by membrane wrapping — •Tanwi Debnath[1], Jiarul Midya[1,2], Thorsten Auth[1], and Gerhard Gompper[1] — [1]Theoretical Physics of Living Matter, Institute for Advanced Simulation, Forschungszentrum Jülich, 52425 Jülich, Germany — [2]School of Basic Sciences, IIT Bhubaneswar, 752050, India

The interaction of nano- and microcarriers with lipid-bilayer membranes plays a key role for cellular engulfment and drug delivery [1]. The physico-chemical parameters of the particles that control engulfment are their size, shape, and deformability [2]. Microgels are particularly versatile because their elasticity can be tuned in a wide range by changing the density of crosslinkers. Using a mass-spring model for the microgel and a continuum model for the membrane, we study microgel wrapping at lipid-bilayers. We use the Hertz theory to characterize the microgel's Young's modulus and Poisson's ratio. With the help of triangulated membranes and energy minimization, we determine the interplay of microgel and membrane deformation. We predict wrapping diagrams for microgels with various Young's moduli at membranes with various tensions. A higher microgel deformability increases the stability of partial-wrapped states; there is a transition from oblate at low wrapping fractions to cup-like shape at high wrapping fractions. Our results on this tunable and responsive system will allow the design of the microgels with optimal elastic properties for biomedical applications. [1] S. Dasgupta et al., J. Phys. Condens. Matter **29**, 373003 (2017). [2] J. Midya et al., ACS Nano **17**, 1935 (2023).

BP 19.11 Wed 12:30 H46

Shaping Cellular Interfaces — •Susanne Liese[1], Xueping Zhao[2], Tiemei Lu[3], Marcel Mokbel[4], Sebastian Aland[4], Evan Spruijt[3], Frank Jülicher[5], and Christoph Weber[1] — [1]Universität Augsburg — [2]University of Nottingham Ningbo China — [3]Radboud University, Nijmegen — [4]TU Freiberg — [5]Max Planck Institute for the Physics of Complex Systems

The interaction between liquid droplet-like coacervates and biological membranes is central to cellular organization and drives essential processes including endocytosis, intracellular transport, and signaling. In our research, we uncover the complex dynamics underlying these interactions, demonstrating how non-equilibrium processes, chemical activity, and mechanical deformations dictate the behavior of droplet-membrane systems. We demonstrate that non-equilibrium binding of biomolecular condensates to membranes gives rise to rich physical phenomena, and we also reveal how membrane reshaping contributes to behaviors such as anomalous wetting and deformation-driven uptake. By integrating experiments, theoretical models, and computational simulations, our work provides new insights into the mesoscale physics of cellular systems and reveals the intricate interplay of chemical and mechanical forces at the droplet-membrane interface. This understanding advances both fundamental biology and potential applications in synthetic biology and intracellular delivery.

BP 19.12 Wed 12:45 H46

Biomolecular condensates wetting membranes - dynamical insights from numerical simulations — •Sebastian Aland — HTW Dresden — TU Freiberg

Biological cells use membranes and condensates (liquid-like droplets) to compartmentalize their interior. As every structure within a cell is either enclosed by a membrane or by a liquid interface it is fundamental to understand what happens if these two come into contact. Recent studies suggest that membrane-droplet interactions are involved in various key biological processes. As experimental image resolution is limited at the corresponding length and time scales, numerical methods are essential to shed light on the dynamics of the process. Using a combination of sharp and diffuse interface models, we derive a mathematical model to describe the interplay of a thin elastic membrane with a two-phase fluid. We demonstrate that the wetting interaction by capillary forces leads to a range of fascinating phenomena like droplet wrapping, endocytosis and an inverted cheerios effect.

Separating bio-condensates with surfactant-like proteins — Jannik Kindermann and •Tyler Harmon — Leibniz Institute for Polymer Research, Dresden, Germany

Biocondensates are prevalent in cells as individual compartments that separate material and reactions in space. Many condensates share similar components and/or chemical interactions that drive their formation. This would suggest that the condensate:condensate interface would have a very low surface tension compared to the condensate:solvent interfaces. Supported by in vitro results, this leads to condensate-inside-condensate or dumbbell-like architectures which minimize the condensate:solvent interfaces. However, in vitro, condensates are most often isolated in space from each other. This could play important roles such as limiting the direct flow of material from one condensate to another. The mechanism in cells that separates droplets in space is unknown.

We show using simulations and theory that proteins or other biopolymers that have surfactant like molecular architectures can separate condensates in space. We show how robust this mechanism can be with respect to condensate specificity and the expression levels of surfactant-like molecules in cells.

BP 20.2 Wed 15:15 H44

Phase separation in membranes and compartments with binding reactions — •Riccardo Rossetto, Gerrit Wellecke, and David Zwicker — Max Planck Institute for Dynamics and Self-Organization

Biological cells exhibit a hierarchical spatial organization, where various compartments and membranes harbor condensates that form by phase separation. Cells can control the emergence of these condensates by affecting the physical interactions of the involved biomolecules, thus also tuning the binding affinity to the compartments. We describe this situation with a thermodynamically-consistent kinetic model considering passive and active binding reactions to elucidate their role in controlling the occurrence and timescales of phase separation in compartments. On the one hand, binding reactions can lead to the emergence of new equilibrium phenomena, such as re-entrant phase transitions and multistability. On the other hand, they can also affect the kinetics of phase separation. As a particular example, we consider protein droplets in cellular membranes when proteins can also unbind to the cellular bulk. For fast bulk diffusion, this leads to effective nonlocal transport, which fundamentally affects droplet dynamics. For instance, the seminal Lifshitz-Slyozov coarsening can be abolished. Furthermore, active binding reactions can both accelerate or fully suppress coarsening, leading to protein patterns on the membrane. The general conclusions from our model unveil fundamental mechanisms of phase separation in membranes and compartments, and will help us explain more biological observations in the future.

BP 20.3 Wed 15:30 H44

Reconciling conflicting selection pressures in the plant collaborative non-self recognition self-incompatibility system — Amit Jangid[1], Keren Erez[1], Ohad-Noy Feldheim[2], and •Tamar Friedlander[1] — [1]Faculty of Agriculture, food and environment, The Hebrew University of Jerusalem, Rehovot, Israel — [2]Einstein Institute for Mathematics, The Hebrew University of Jerusalem, Jerusalem, Israel

Complex biological systems should often reconcile conflicting selection pressures. Specifically, in systems relying on molecular recognition, molecules should recognize particular partners, but avoid others. Here we study how such selection pressures shape the evolution of the self-incompatibility system in plants. This system inhibits self-fertilization using specific molecular recognition between proteins, expressed in the plant female and male reproductive organs. We study the impact of these opposing selection pressures on the amino acid frequencies in these proteins' recognition domain. We construct a theoretical framework enabling promiscuous recognition between proteins and multiple partners each, as found empirically, and employ stochastic simulations. We find asymmetric responses to selection affecting mostly the female, but not the male protein composition. Using large deviations theory, we well-approximate the simulated frequencies and find agreement with genomic data. Our work offers a general theoretical framework to study the impact of multiple selection pressures, applicable to additional biological systems.

BP 20.4 Wed 15:45 H44

Learning the Equilibrium Free Energy from Non-Equilibrium Steady States with Denoising Diffusion Models — •Daniel Nagel and Tristan Bereau — Institute for Theoretical Physics, Heidelberg University, 69120 Heidelberg, Germany

Estimating accurate free energy profiles is crucial for predicting the behavior of complex molecular systems. While biased molecular dynamics simulations enhance the sampling of rare events, extracting reliable free energy landscapes from these simulations remains challenging. On the other hand, stochastic thermodynamics, i.e. the concept of entropy production, provides valuable insights into the dynamics of complex systems in non-equilibrium states. However, its computational complexity, due to dependence on time-dependent probability distributions, limits its application to smaller systems.

This work presents a novel approach that combines stochastic thermodynamics with the established machine learning technique of denoising diffusion models to efficiently estimate free energy profiles from biased non-equilibrium steady states. By linking the diffusion and simulation times, we show that the training objective, known as the score, can be decomposed into a non-trivial conservative contribution from the equilibrium potential and a trivial non-conservative part determined by external driving forces. To showcase the effectiveness of our approach and its ability to learn equilibrium free energy profiles, we apply it to a driven toy model and a Martini force field molecular dynamics simulation of a small molecule biased through a lipid bilayer.

BP 20.5 Wed 16:00 H44

Multiple Pareto-optimal solutions of the dissipation-adaptation trade-off — •Jorge Tabanera-Bravo and Aljaz Godec — Max Planck Institute for Multidisciplinary Sciences, Göttingen

Adaptation refers to the ability to recover and maintain "normal" function upon perturbations of internal or external conditions and is essential for sustaining life. Biological adaptation mechanisms are dissipative, i.e. they require a supply of energy such as the coupling to the hydrolysis of ATP. Via evolution the underlying biochemical machinery of living organisms evolved into highly optimized states. However, in the case of adaptation processes two quantities are optimized simultaneously, the adaptation speed or accuracy and the thermodynamic cost. In such cases one typically faces a trade-off, where improving one quantity implies worsening the other. The solution is no longer unique but rather a Pareto set—the set of all physically attainable protocols along which no quantity can be improved without worsening another. We investigate Pareto fronts in adaptation-dissipation trade-offs for a cellular thermostat and a minimal ATP-driven receptor-ligand reaction network. We find convex sections of Pareto fronts to be interrupted by concave regions, implying the existence of distinct optimization mechanisms. We discuss the implications of such "compromise-optimal" solutions and argue that they may endow biological systems with a superior flexibility to evolve, resist, and adapt to different nvironments.

Centrosome positioning in cell migration and immune response — •Heiko Rieger — Department of Physics and Center for Biophysics, Saarland University, Saarbrücken, Germany

Leukocytes are the key players of the immune system in eliminating pathogen-infected or tumorigenic cells. During these processes centrosome positioning plays a crucial role for establishing cell polarization and directed migration, targeted secretion of vesicles for T cell activation and cellular cytotoxicity as well as the maintenance of cell integrity. Here, we give an overview over microtubule organization and dynamics during immune processes and present models for centrosome repositioning during the formation of the immunological synapse and during cell migration. We focus particularly on actin-myosin crosstalk, which is involved in regulating the polarity and morphology of migrating cells and encompasses mechanical interactions, mediated by crosslinkers and molecular motors, as well as cytoskeletal regulators. Based on recent experimental results we develop a computational whole-cell model involving dynamical microtubules that interact not only mechanically but also via signaling with an active cell boundary. A rich self-organized dynamical behavior emerges, comprising varying positions of the microtubule organizing center relative to the nucleus in the migration direction, varying migration characteristics and cell shapes, and complex migratory behavior in obstacle parks and microfluidic setups. Specific dependencies of these behaviors from parameters like the average microtubule length or the cell-boundary stiffness are predicted and compared with experimental observations.

BP 20.7 Wed 17:00 H44

Modelling neuron growth dynamics and role of extra-cellular matrix — •Pritha Dolai, Federica Furlanetto, Sven Falk, Marisa Karow, and Vasily Zaburdaev — Friedrich-Alexander-Universität (FAU) Erlangen-Nürnberg, Erlangen

Biological tissues are composed of cells embedded in extracellular matrix (ECM) and extracellular fluid. We study the role of cell-matrix interactions in the context of brain tissues and the mechanism of neuron growth through this matrix. We consider two modes for the neurite growth: linear growth by tip extension and growth by the traction force at the tip of the neurite with the ECM. In the second mechanism, growth happens solely due to the interaction of the growing appendages with the particles modeling the matrix. With an agent based model we recapitulate experimentally observed neuron growth patterns in healthy neurons and neurons with mutations corresponding to a disease state performed in organoid models. In experiments, neuron growth is quantified by the dynamics of the growing tips. Additionally we compare further growth characteristics such as track length and velocity of the tip, tortuosity, and angular correlation of growth direction. Our model provides mechanistic description of the neurite growth and can be useful in describing neuronal network formation during early development.

BP 20.8 Wed 17:15 H44

Cellular morphodynamics as quantifiers for functional states of resident tissue macrophages in vivo — •Miriam Schnitzerlein[1,2], Eric Greto[3,4], Anja Wegner[3,4], Anna Möller[3,4], Oliver Aust[3,4], Oumaima Ben Brahim[3,4], Stefan Uderhardt[3,4], and Vasily Zaburdaev[1,2] — [1]Department of Biology, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU) — [2]Max-Planck-Zentrum für Physik und Medizin, Erlangen — [3]Department of Medicine 3 - Rheumatology and Immunology, FAU und Universitätsklinikum Erlangen — [4]Deutsches Zentrum für Immuntherapie, FAU

Resident tissue macrophages (RTMs) perform essential tasks such as clearing cellular debris to ensure tissue homeostasis. Such actions are accompanied by morphological changes in cell shape which reflect their functional states. Until now, RTMs were mostly studied *in vitro*, even though their dynamic behaviour *in vivo* is fundamentally different.

We employed a high-resolution, intravital imaging protocol to generate dynamic data of *in vivo* peritoneal RTMs of mice. Next we built a custom image processing pipeline to assess RTM morphodynamics via a set of human-interpretable cell shape and size features. Those features could quantitatively and also qualitatively differentiate between cells in different activation states. Furthermore, we showed that unperturbed RTMs exhibit a wide range of morphodynamical phenotypes, constituting a naive morphospace of behavioural motifs. Analysing cells challenged by chemical stimulations or due to aging gave us insights into how RTMs respond and adapt to inflammatory stimuli.

Slimming down through frustration — •Martin Lenz — Université Paris-Saclay, CNRS, LPTMS, 91405, Orsay, France — PMMH, CNRS, ESPCI Paris, PSL University, Sorbonne Université, Université Paris-Cité, F-75005, Paris, France

In many disease, proteins aggregate into fibers. Why? One could think of molecular reasons, but here we try something more general. We propose that when particles with complex shapes aggregate, geometrical frustration builds up and fibers generically appear. Such a rule could be very useful in designing artificial self-assembling systems.

BP 20.10 Wed 17:45 H44

RNA fitness prediction with sparse physics based models - A way to explore the sequence space — •Christian Faber[1], Francesco Calvanese[2], Alexander Schug[1], and Martin Weigt[3] — [1]Forschungszentrum Jülich, Jülich, Germany — [2]Sorbonne-Université, Paris, France — [3]CNRS, Paris, France

The field of medicine uses macromolecules as a means of therapeutic intervention. Consequently, the functional attributes of these novel molecules are assuming greater significance. To complement the wet-lab experiments, we have devised a series of statistical physics based models that are capable of predicting the fitness of RNA molecules based on one- and two-point mutation scans. The experimental data were employed as training data to fit models of increasing complexity, commencing with an additive model and concluding with a model that accounts for global and local epistasis. The models were validated using fitness data from scans with higher order mutations of the wild-type. In contrast to conventional AI algorithms, the parameters of our models were designed for direct interpretation. In examining more distant sequences, we can distinguish the corresponding RNA family from random sequences with a high degree of accuracy. Moreover, the models facilitate interpretations of evolutionary processes and the significance of epistatic terms. Our model can be used to create a fitness landscape far beyond the experimental sequence space, thus identifying promising RNA molecules. Furthermore, the extension to the entire sequence space can be used as a blueprint for other molecules, providing a novel avenue for questions in biomolecular design.

BP 21: Networks, From Topology to Dynamics (joint session SOE/BP/DY)

Time: Wednesday 15:00–17:30 Location: H45

BP 21.1 Wed 15:00 H45

Self-organized transport in noisy dynamic networks — •Frederic Folz[1], Joshua Rainer Ganz[1], Kurt Mehlhorn[2], and Giovanna Morigi[1] — [1]Theoretische Physik, Universität des Saarlandes, 66123 Saarbrücken, Germany — [2]Algorithms and Complexity Group, Max-Planck-Institut für Informatik, Saarland Informatics Campus, 66123 Saarbrücken, Germany

We present a numerical study of multicommodity transport in a noisy, nonlinear network. The nonlinearity determines the dynamics of the edge capacities, which can be amplified or suppressed depending on the local current flowing across an edge. We consider network self-organization for three different nonlinear functions: For all three we identify parameter regimes where noise leads to self-organization into more robust topologies, that are not found by the sole noiseless dynamics. Moreover, the interplay between noise and specific functional behavior of the nonlinearity gives rise to different features, such as (i) continuous or discontinuous responses to the demand strength and (ii) either single or multistable solutions. Our study shows the crucial role of the activation function on noise-assisted phenomena.

BP 21.2 Wed 15:15 H45

Critical properties of Heider balance on multiplex networks — •Krishnadas Mohandas, Krzysztof Suchecki, and Janusz Hołyst — Faculty of Physics, Warsaw University of Technology, Koszykowa 75, PL-00-662 Warsaw, Poland

Heider's structural balance theory has proven invaluable in comprehending the dynamics of social groups characterized by both friendly and hostile relationships. Extending this understanding to multiplex networks, we investigate Heider balance dynamics in systems where agents exhibit correlated relations across multiple layers. In our model, intralayer interactions adhere to Heider dynamics, while interlayer correlations are governed by Ising interactions, using heat bath dynamics for link signs. This framework reveals a multifaceted equilibrium landscape, with distinct phases coexisting across layers. Starting from a paradise state with positive links in all layers, increasing temperature induces a discontinuous transition to disorder, similar to single-layer scenarios but with a higher critical temperature, as verified through extended mean-field analysis and agent-based simulations.

We extend this analysis to Erdös-Rényi random graphs in noisy environments. We predict a first-order transition with a critical temperature scaling as p^2 for monolayers and follow a more complex behavior for bilayers. To replicate dynamics observed in complete graphs, intralayer Heider interaction strengths must scale as p^{-2}, while interlayer interaction strengths scale as p^{-1} in random graphs. Numerical simulations confirm these analytical predictions for dense graphs.

BP 21.3 Wed 15:30 H45

Functional Motifs in Food Webs and Networks — •Melanie Habermann[1,2,3], Ashkaan Fahimipour[4], Justin Yeakel[5,6], and Thilo Gross[1,2,3] — [1]Helmholtz Institute for Functional Marine Biodiversity (HIFMB), Oldenburg, GER — [2]Alfred-Wegener Institute (AWI), Helmholtz Center for Polar and Marine Research, Bremerhaven, GER — [3]Carl-von-Ossietzky University, Institute for Chemistry and Biology of the Marine Environment (ICBM), Oldenburg, GER — [4]Florida Atlantic University, Boca Raton, FL, USA — [5]University of California Merced, Merced, CA, USA — [6]The Santa Fe Institute, Santa Fe, NM, USA

It is interesting to ask when the presence of a small subgraph in a complex network is sufficient to impose constraints on system dynamics that are independent of the broader network structure. We refer to these subgraphs as functional motifs. A classic example can be found in ecology with the competitive exclusion motif in food webs, where two species compete for the same resource without regulation. The presence of this motif precludes any stable equilibrium for the entire system. However, examples of other motifs with similarly definitive implications for system stability are rare. But our usual notion of asymptotic stability is just one among many different concepts of stability. Another one, reactivity, captures a system's immediate response to small perturbations. In this talk, we explain why functional stability motifs are rare and show that every subgraph is a functional reactivity motif. This highlights reactivity as a promising concept for exploring a vast range of networked phenomena.

BP 21.4 Wed 15:45 H45

Infecting Apex Predators Could Lead to Their Extinction — •Fakhteh Ghanbarnejad[1] and Hooman Saveh[2] — [1]SRH University of Applied Sciences, Leipzig, Germany — [2]Sharif University of Technology, Tehran, Iran

Food webs have been extensively studied from both ecological and mathematical aspects. However, most of the models studied in this area do not capture the effects of infectious diseases simultaneously. Recently, the idea of including an infectious disease in a food web model has been investigated. We study and simulate a small food chain consisting of only prey, predators, and apex predators governed by the generalized Lotka-Volterra equations and we implement the Susceptible-Infected-Recovered (SIR) model on only one of the species at a time in the food chain. To study the effects of an infectious disease on the food chain, we introduce a new parameter that increases predation rate by a factor of w and decreases hunting rate by a factor of $1/w$ for infected species. When the infectious disease is in our predators we observe that predators do not extinct under any set of parameters, however, an oscillation in its population size occurs under some circumstances which we do not observe in ordinary SIR or the generalized Lotka-Volterra equations alone. When an infectious disease is present in apex predators, oscillations in the population size do not happen; but if the set of parameters is in a specific range the apex predators may extinct. Furthermore, the chance of survival of the community, known as community persistence, increases for the predators and decreases for the apex predators.

BP 21.5 Wed 16:15 H45

Behavioral Heterogeneity in Disease Spread: Contrasting Effects of Prevention Strategies and Social Mixing — •Fabio Sartori[1,2] and Michael Maes[1] — [1]Chair of Sociology and Computational Social Science, Karlsruhe Institute of Technology, Karlsruhe — [2]Max Planck Institute for Dynamics and Self Organisation, Göttingen, Germany

Despite mounting evidence of behavioral heterogeneity in response to disease threats, the majority of epidemiological models assume uniform behavior across populations for mathematical tractability. We analyze three distinct mechanisms of behavioral response to disease threat: susceptibility reduction (e.g., mask-wearing), active testing, and vaccination propensity. Through extensive numerical analysis, we demonstrate that the impact of behavioral heterogeneity strongly depends on the specific mechanism involved. While heterogeneous susceptibility-reducing behaviors generally decrease disease spread, heterogeneity in testing rates and vaccination propensity typically amplifies epidemic severity. Furthermore, we show that non-homogeneous mixing patterns, particularly when correlated with behavioral traits, exacerbate disease spread across all three mechanisms. These findings reveal fundamental principles about the interplay between behavioral heterogeneity and epidemic dynamics, challenging the conventional homogeneous assumption and providing important implications for public health interventions and policy design.

BP 21.6 Wed 16:30 H45

Modelling retweet cascades using multivariate Hawkes processes on sparse networks — Alexander Kreiss[1] and •Eckehard Olbrich[2] — [1]Leipzig University, Germany — [2]Max Planck Institute for Mathematics in the Sciences, Leipzig, Germany

We apply a model that considers vertices in a network who are able to cast events, e.g. users of the online social media platform Twitter. Furthermore, there is a directed edge from vertex A to vertex B if A takes note of the events cast by B and changes its own behavior accordingly. More precisely, the model assumes that the activity of B increases the activity of A and likewise its other neighbors. This is called peer effects. However, there might also be other information, which also influences the activity of the vertices, e.g. the time of the day for social media posts. This is called global effects. We use a Hawkes model that incorporates, both, peer and global effects. This allows for the estimation of the network, that is, the influence structure while controlling for network effects or the estimation of the global effects while controlling for peer effects. The estimation is based on a LASSO strategy, which respects sparsity in the network. We apply this model to retweets on Twitter in order to reconstruct potential retweet cascades and identify accounts that are influential in sharing information.

BP 21.7 Wed 16:45 H45

Influence, Incidence, Imitators and Individualists: Comparing social influence models of protective behavior in an epidemic — •Andreas Reitenbach — Karlsruhe Institute of Technology, Karlsruhe, Germany

To manage a pandemic, it is critical that citizens voluntarily engage in protective behavior (e.g. masking or vaccinating). Voluntary behavior is subject to complex dynamics of social influence, however. While various models couple social influence dynamics with disease spreading, assumptions about how individuals influence each other differ markedly. Models assuming herding implement that agents imitate their peers. On the contrary, rational agents (individualists) engage in protective behavior when their peers are not and vice versa, potentially free-riding on others' contributions to herd immunity.

Here, I study whether and why these competing behavior models translate into different disease dynamics. Following a recent call to abstract from psychological mechanisms underlying social influence, I translate the behavior theories into influence-response functions.

I find that individualists self-coordinate on a moderate level of protection and

experience long-lasting but flat incidence curves. Herding, in contrast can result in rapid cycling through waves of high incidence and strong collective efforts to mitigate. Whether herders or individualists navigate an epidemic better can depend on the population's hospital capacity and disease parameters.

BP 21.8 Wed 17:00 H45

Formalism and Physical Principles of Human Mobility and Routine — •Marlli Zambrano[1], Ashish Thampi[2], Alejandra Rincon[2], Andrzej Jarynowski[1], Steven Schulz[2], and Vitaly Belik[1] — [1]Freie Universität Berlin, Germany — [2]Machine Learning Unit, NET CHECK GmbH, Berlin, Germany

The physical principles underlying human mobility have been extensively studied in recent years, enabled by the availability of large-scale mobile phone data. While significant progress has been made in understanding general mobility patterns, capturing the dynamics of individual trajectories, specifically how mobility varies from person to person and day to day, remains challenging due to the need for highly detailed and persistent data. This study addresses this challenge by examining sequences of individual daily mobility motifs, as defined by Schneider et al., from a stochastic process perspective. The analysis uses a persistent mobile phone user panel in Berlin, with high-frequency GPS data collected over four years. Twenty motifs were identified, covering 96% of all observations. The extent of inter- and intra individual variability is explored, focusing on how motifs change within individuals over time and differ between individuals in various contexts (e.g., weekends, seasons). Additionally, sequences of motifs are modeled as a stochastic process, and properties such as transition probabilities are analyzed. These findings provide deeper insights into the variability and structure of human mobility, contributing to a better understanding of individual mobility dynamics.

BP 21.9 Wed 17:15 H45

The world air transportation network: import risk of diseases, pandemic potentials and passenger routes — •Pascal Klamser[1,2], Adrian Zachariae[1,2], Benjamin Maier[3], Olga Baranov[4], and Dirk Brockmann[1,2] — [1]Technische Universität Dresden, Dresden, Germany — [2]Robert Koch-Institute, Berlin, Germany — [3]University of Copenhagen, Copenhagen, Denmark — [4]LMU München, München, Germany

Disease propagation between countries strongly depends on their effective distance, a measure derived from the world air transportation network. It reduces the complex spreading patterns of a pandemic to a wave-like propagation from the outbreak country, establishing a linear relationship to the arrival time of the unmitigated spread of a disease. However, in the early stages of an outbreak, what concerns decision-makers in countries is understanding the relative risk of active cases arriving in their country*essentially, the likelihood that an active case boarding an airplane at the outbreak location will reach them. While there are data-fitted models available to estimate these risks, accurate mechanistic, parameter-free models are still lacking.

We (i) introduce the "import risk" model, which defines import probabilities using the effective-distance framework, (ii) show its application to estimate the pandemic potential of emerging variants of COVID-19 and (iii) show that the effective distance shortest path tree, on which the "import risk" model is based on, is an extremely accurate representation of true passenger routes.

Invited Talk BP 22.1 Wed 15:00 H46

From DNA Nanotechnology to biomedical insight: Towards single-molecule spatial omics — •Ralf Jungmann — LMU and MPI of Biochemistry, Munich, Germany

Super-resolution fluorescence microscopy is a powerful tool for biophysical and biological research. The transient binding of short fluorescently labeled oligonucleotides (DNA-PAINT) can be leveraged for easy-to-implement multiplexed super-resolution imaging that achieves molecular-scale resolution across large fields of view. This seminar will introduce recent technical advancements in DNA-PAINT including approaches that achieve sub-10-nm spatial resolution and spectrally unlimited multiplexing in whole cells followed by recent developments in novel protein labeling probes that have the potential to facilitate DNA-barcoded labeling of much of the proteome within intact cellular environments. Applications of these new approaches will be discussed in cell surface receptor imaging and neuroscience. Visualization and quantification of cell surface receptors at thus far elusive spatial resolutions and levels of multiplexing yield fundamental insights into the molecular architecture of surface receptor interactions thus enabling the future development of more refined *pattern*-based therapeutics. A key approach in implementing these methods has been to leverage standard off-the-shelf fluorescence microscopy hardware as a tool for spatial omics, thus democratizing the ability to visualize most biomolecules and probe their network-wide interactions in single cells, tissues, and beyond with single-molecule-based "Localizomics".

BP 22.2 Wed 15:30 H46

3D Single-Nanoparticle Tracking with Fluorescence Lifetime Imaging for Investigating Lipid Nanoparticles Endosomal Pathways — •Thomas Kellerer[1,2], Judith A. Müller[2], Tanja Grawert[1], Lukas Moser[1], Joachim O. Rädler[2], and Thomas Hellerer[1] — [1]Multiphoton Imaging Lab, Munich University of Applied Sciences, 80335 Munich, Germany — [2]Faculty of Physics and Center for NanoScience, Ludwig Maximilians-University, 80539 Munich, Germany

Lipid nanoparticles (LNPs) are vital for delivering mRNA in drug delivery systems, but the kinetics and intracellular pathways of their cargo release remain often unclear. To address this, we developed a microscopy technique to track single nanoparticles in 3D over extended periods. This approach integrates a lock-in amplifier for simultaneous image based 3D tracking and fluorescence lifetime measurement, enabling analysis of the microenvironment, such as pH changes. Achieving a frame rate of 7.6 fps at 1024x1024 resolution and lifetimes measured within 102 ns, our method provides novel insights into LNP dynamics and endosomal acidification in live cells. This technique was applied to study the acidification kinetics of endosomes during transfection. By measuring pH changes in real time, we provided insights into the intracellular behavior of LNPs and their role in mRNA delivery. This approach establishes a new standard for tracking nanoparticles and analyzing their microenvironments with high spatial and temporal resolution.

BP 22.3 Wed 15:45 H46

The dynamics of binding and uptake of SARS-CoV-2 viruslike particles investigated by ROCS and fluorescence microscopy — •Alexander Rohrbach and Dominik Huber — Lab for Bio- and Nano-Photonics, University of Freiburg, Germany

Viruses such as coronavirus SARS-CoV-2 are challenging to observe during interactions with sales in life-cell imaging to their small size and remarkable speed. Techniques like fluorescence microscopy often struggle to visualize these interactions, especially due to their susceptibility to bleaching and the difficulty to label different structures without altering their function.

In our research we use 200 Hz Rotating Coherent Scattering (ROCS) microscopy in order to visualize the diffusion of 100 nm sized virus-mimicking particles (VLPs) and their interactions with macro*phages or epithelial cells. ROCS is a label-free imaging technique at 160 nm resolution, using coherent backscattering of a rotating laser. By tracking VLPs with ROCS and with fluorescence, we are able to analyze their fluctuations and thereby the dynamics of diffusing VLPs close to A549 lung epithelial cells. Using spatiotemporal and spectral analysis methods, we can investigate for the first time diffusion, binding and uptake events of single VLPs at the cell periphery.

BP 22.4 Wed 16:00 H46

Visualising immune cell interactions in lymph nodes — •Anna Schepers[1], Joannah Fergusson[1], Helena Coker[1], Robert Kochl[2], and Marco Fritzsche[1] — [1]Kennedy Institute of Rheumatology, Oxford, UK — [2]King's College London, UK

The inherently multiscale immune response is regulated by diverse cell interactions, relying on cues from tissues down to single cells and subcellular structures. The intricate dynamics of the immune system present challenges for the observation of the immune response. A technological advance has been achieved with the introduction of lattice light sheet microscopy (LLSM), allowing fast and gentle imaging of live samples while achieving subcellular resolution. By complementing LLSM-based volumetric imaging with advanced sample handling of *ex vivo* tissue samples and perfusion imaging chambers, we provide a system that preserves critical physiological complexity. The perfusion system ensures oxygen and nutrient supply to maintain and sample viability while, at the same time, enabling imaging of the perfused samples. We show that in our setup, we can follow single cells and their interactions in volumes several cell layers deep in living samples within their environment, providing nuanced insights into the immune response.

Platelet biomechanics in biochemical confinement — •Vincent Gidlund, Aylin Balmes, and Tilman Schäffer — Institute of Applied Physics, University of Tübingen, Tübingen, Germany

Platelets, as part of the human blood, play a critical role in wound healing, hemostasis, and thrombotic diseases. When platelets accumulate and form plugs during wound healing, they can experience confining microenvironments. For a deeper understanding of platelet biomechanics, it is important to investigate the effects of a confining microenvironment on platelets. It is known that platelets can adapt to line-shaped microenvironments, but the mechanical properties of platelets subjected to two-dimensional confining microenvironments remain unexplored. We use microcontact printing of fibrinogen patterns of different shapes (circles, triangles) and areas to create a biochemically confining microenvironment for platelets. We then apply epifluorescence microscopy and scanning ion conductance microscopy (SICM) to measure F-actin distribution, topography, and stiffness of platelets confined to these shapes. We found that platelets adapt their morphology to match the shape of the underlying fibrinogen pattern. They show a redistribution of F-actin towards the periphery, as has been observed in other cell types. Additionally, a reduced shape area leads to decreased platelet stiffness.

Near infrared fluorescent silicate nanosheets for Bioimaging — •Bjoern F. Hill and Sebastian Kruss — Physical Chemistry II, Ruhr-University Bochum, Bochu, Germany

Fluorophores emitting in the near-infrared (NIR) are highly advantageous in photonics and biosensing due to reduced light scattering, low phototoxicity, and minimal autofluorescence in this spectral region.

Egyptian Blue (CaCuSi4O10) combines properties that make it a promising material for bioimaging and -photonics: It exhibits bright and stable NIR fluorescence (λ_em=935 nm), its layered structure enables exfoliation into 2D nanosheets (EB-NS), additionally it features a high quantum yield, proven biocompatibility and low production costs.

We present a surfactant-assisted exfoliation route to produce monodisperse EB-NS, tailored to nm-scale diameters, with thicknesses as low as single monolayers, while retaining their NIR fluorescence [1].

Addidionally, we demonstrate the integration of EB-NS with single-walled carbon nanotubes (SWCNTs) to create a ratiometric fluorescence sensor for dopamine. This sensor achieves robust, non-invasive imaging of neurotransmitter release from live cells, while the remarkable stability of the EB-NS fluorescence compensates for environmental fluctuations and enhances measurement reliability [2].

In summary, EB-NS represent a novel, accessible, and highly stable NIR fluorescent nanomaterial with broad applications in bioimaging and -photonics.

BP 22.7 Wed 17:00 H46

Lysosomal activity in response to incubation of pristine and functionalized carbon nanodots — •Carla Sprengel[1], Céline David[2], Lena Berning[2], Cathrin Nollmann[1], Björn Stork[2], and Thomas Heinzel[1] — [1]Condensed Matter Physics Laboratory, Heinrich Heine University, Düsseldorf, Germany — [2]Institute of Molecular Medicine I, Medical Faculty and University Hospital Düsseldorf, Heinrich Heine University, Düsseldorf, Germany

Fluorescent carbon nanodots (CNDs) have emerged as promising carriers for drug delivery systems due to their high biocompatibility and functionalizability. We could not find an influence of CNDs on cellular lysosomal functions, as characterized via the cathepsin B and L activity and autophagic markers p62 and LC3B-II, even under high CND concentrations. Functionalization of CNDs with branched polyethylenimin (bPEI) as a model drug conjugate leads to a greater accumulation of bPEI-CND compounds within lysosomes compared to native CNDs. Here, changes in the lysosomal size and function can be explained exclusively by bPEI. This leads us to conclude that CNDs are highly efficient and inert carriers for delivering functional molecules into lysosomes as target while minimizing lysosomal escape and therefore preventing unintended side effects on other cell organelles.

BP 22.8 Wed 17:15 H46

Grating Based X-ray Phase Contrast CT with Laboratory Setups — •Luka Gaetani[1,2], Josef Scholz[1,2], Lorenz Birnbacher[2,3], and Julia Herzen[1,2] — [1]Research Group Biomedical Imaging Physics, Department of Physics, TUM School of Natural Sciences, Technical University of Munich, 85748 Garching, Germany — [2]Chair of Biomedical Physics — [3]Institute for Diagnostic and Interventional Radiology, TUM Klinikum rechts der Isar, 81675 München, Germany

Grating-based X-ray Phase Contrast Computed Tomography (CT) represents a significant advancement in imaging, offering enhanced sensitivity to soft tissues and low-density materials by capturing phase information complementary to absorption contrast. This technique utilizes a series of optical gratings to measure phase shifts introduced by the sample, enabling the reconstruction of high-resolution phase contrast images. Laboratory-based implementations of this method, facilitated by compact X-ray sources and precise grating alignment, have extended its accessibility and applicability to diverse fields. However, optimizing these setups necessitates addressing challenges such as coherence management, efficient data acquisition, and advanced reconstruction algorithms to maximize their performance in non-synchrotron environments. This presentation will demonstrate how a grating-based interferometer enables the quantitative determination of electron density, a physical property of the sample, by accurately correlating the sample's influence on the gray values in the recorded X-ray images.

BP 22.9 Wed 17:30 H46

Nanomaterials: A Versatile Sensitizer for Enhanced Singlet Molecular Oxygen Generation — •Zahid Ullah Khan[1], Latif Ullah Khan[1,2], Hermi Felinto Brito[1], and Paolo Di Mascio[1] — [1]Institute of Chemistry, University of São Paulo (USP), 05508-000, São Paulo-SP, Brazil — [2]Synchrotron-light for Experimental Science and Applications in the Middle East (SESAME) P.O. Box 7, Allan 19252, Jordan

Singlet molecular oxygen (1O2) plays a crucial role in various fields, including optoelectronics, photooxygenation reactions, and biomedical therapies, particularly as a major contributor to the success of photodynamic therapy (PDT). Since direct excitation of oxygen from the triplet ground state (3O2) to the singlet-excited state is spin-forbidden, thus, making the design of heterogeneous sensitizers crucial for efficient 1O2 production. For this purpose, nanomaterials, such as quantum dots (QDs) and rare earth fluoride nanoparticles (NPs), have emerged as versatile sensitizers for 1O2 generation, either individually or in combination with other inorganic or organic materials. Hence, conjoining the photophysical properties of QDs and rare earth NPs with other materials, e.g., coupling/combining with other inorganic materials, doping with the transition metal ions or lanthanide ions, and conjugation with a molecular sensitizer provide the opportunity to achieve high-efficiency quantum yields of 1O2 which is not possible with either component separately. Hence, the current work focuses the development of semiconductor QDs and rare earth-based nanosensitizer for efficient production of 1O2.

BP 23: Poster Focus Session Chemical Imaging for the Elucidation of Molecular Structure (joint session O/BP)

Time: Wednesday 18:00–20:00 Location: P2

Oncogenic signaling and stiffness sensing — •Johanna Ivaska — University of Turku

Tissue homeostasis is dependent on the spatially controlled localization of specific cell types and the correct composition of the extracellular stroma. Integrin-mediated adhesions, in conjunction with the actin cytoskeleton and signaling by receptor tyrosine kinases, regulate cell fate and identity and allow cells to migrate and invade the surrounding extra-cellular matrix (ECM). We have previously uncovered key differences between normal and cancer-associated stroma, whereby the mechanical and architectural features of normal stroma inhibit tumour growth and may epigenetically reprogram aggressive breast cancer cells towards a more benign phenotype. Recently, we turned our attention to other putative crosstalk mechanisms between cancer cells and the tumor microenvironment as well as tumor cell interactions with distinct tissue borders during systemic dissemination in the body. I will describe different control mechanisms guiding cancer cell invasion across physiological borders and their relevance to cancer progression and metastasis.

BP 25.2 Thu 10:00 H44

Perfect stabilization of biomolecular adhesions under load — •Anton Francis Burnet[1,2] and Benedikt Sabass[1,2] — [1]Department of Veterinary Sciences, Ludwig-Maximilians-Universität München, 80752 Munich, Germany — [2]Faculty of Physics and Center for NanoScience, Ludwig-Maximilians-Universität München, 80752 Munich, Germany

Cell focal adhesions are complex molecular assemblies that demonstrate the remarkable capability to adapt to mechanical load by changing their size. Drawing from the molecular mechanisms believed to drive this behavior, we present a minimal adhesion model for mechanically induced aggregation of adhesion molecules. If the internal states of adhesion molecules are coupled to their aggregation dynamics sufficiently strongly, the system becomes instable and unbounded growth ensues. Unexpectedly, the very same type of instability can lead to perfect stability under mechanical load, where adhesions adapt their size to withstand arbitrarily large load without rupturing-a phenomenon we term perfect stabilization. We derive state diagrams characterizing adhesion stability under stationary load and show that perfect stabilization also occurs for dynamic loads on physiologically relevant timescales. Finally, we show that perfect stabilization is a generic phenomenon that can be realized in many different ways by coupling aggregation rates with internal molecular states and argue that the phenomenon has broad implications for understanding cellular mechanics.

BP 25.3 Thu 10:15 H44

Environmental stiffness regulates neuronal maturation via Piezo1-mediated TTR activity — •Eva Kreysing[1,2,3], Hélène Gautier[1], Leila Muresan[1], Sudipta Mukherjee[1,2,3], Alexander Winkel[1], Xiaohui Zhao[1], Ragnhildur Thóra Káradóttir[1], and Kristian Franze[1,2,3] — [1]University of Cambridge, UK — [2]FAU Erlangen — [3]MPZ Erlangen

During the development of the nervous system, neurons grow axons and dendrites to connect with other cells. As neurons become integrated into the neural network, they mature and develop electrical activity. While mechanical interactions between neurons and their environment are critical for axon growth and pathfinding, the role of mechanical cues in the electrical maturation of neurons, and thus the formation of circuits in the developing brain, remain unexplored. Here, we cultured rat hippocampal neurons on substrates with different mechanical properties and found that electrical activity developed earlier on soft hydrogels compared to stiff hydrogels. This stiffness-dependent neuronal maturation was mediated by the mechanosensitive ion channel Piezo1. Using RNA sequencing, pathway analysis and Western blots, we identified a downstream signalling cascade responsible for the differential expression of neurotransmitter receptors. Finally, we found that stiffening of the developing Xenopus brain leads to impaired synapse formation in vivo. Our findings highlight the critical role of mechanical signals in neuronal maturation and suggest that local brain tissue stiffness is a critical parameter for circuit formation in the developing brain.

BP 25.4 Thu 10:30 H44

The positioning of stress fibers in contractile cells minimizes internal mechanical stress — •Valentin Wössner[1,2], Lukas Riedel[3,4], Dominic Kempf[3], Falko Ziebert[1,2], Peter Bastian[3], and Ulrich S. Schwarz[1,2,3] — [1]Institute for Theoretical Physics, Heidelberg University, Heidelberg, Germany — [2]BioQuant, Heidelberg University, Heidelberg, Germany — [3]Interdisciplinary Center for Scientific Computing, Heidelberg University, Heidelberg, Germany — [4]Institute for Environmental Decisions, ETH Zürich, Zürich, Switzerland

Stress fibers are contractile bundles of actin filaments found in the cytoskeleton of animal cells. They play crucial roles in force generation, mechanical adaptation, shape control and mechanosensing. While the physical description of single stress fibers is well-developed, much less is known about their spatial distribution on the level of whole cells. Here, we combine a finite element method for one-dimensional fibers embedded in a two-dimensional elastic bulk medium with dynamical rules for stress fiber formation based on genetic algorithms [1]. We postulate that their main goal is to achieve minimal mechanical stress in the bulk material with as few fibers as possible. We find that stress fibers typically run through the cell in a diagonal fashion and that they cross each other under biaxial stretch. In the future, our approach can be extended to three dimensions and to stress fibers with viscoelasticity.

BP 25.5 Thu 10:45 H44

Towards a better understanding of the cytokinetic contractile ring — •Francine Kolley-Köchel[1] and Sebastian Aland[1,2] — [1]Faculty of Mathematics and Informatics, TU Freiberg, 09599 Freiberg, Germany — [2]Faculty of Informatics/Mathematics, HTW Dresden, 01069 Dresden, Germany

The dynamics of viscoelastic surfaces plays an important role in biological systems. One prominent example is the actin cortex, with elastic properties on short time scales and viscous on long time scale. Numerical simulations of such a system can provide a better understanding of the real biological system. Here we present a novel monolithic model of viscoelastic surfaces within a dominant surface rheology, capturing both, shear and dilational dynamics. We demonstrate that these full three dimensional simulations are numerically stable for low and high surface viscosities and show spontaneous pattern formation, induced by active stress regulation. We discuss how this model can guide future work towards a betters understanding of complex viscoelastic surface dynamics and the formation of the cytokinetic contractile ring.

BP 25.6 Thu 11:00 H44

Using microfluidics for measuring microplastic particle-cell interactions — •Matteo A. Kumar[1], Simon Wieland[1,2], Anja F.R.M. Ramsperger[1,2], Christian Laforsch[1,2], and Holger Kress[1] — [1]Biological Physics, University of Bayreuth, Germany — [2]Animal Ecology I and BayCEER, University of Bayreuth, Germany

The growing presence of microplastic particles (MPs) in the environment increases human exposure to these contaminants, which can accumulate in tissues and spread throughout the body. Various MP properties, such as shape, size, charge and surface morphology, influence their interactions with cells. We have recently shown that the zeta-potential of MPs significantly affects their adhesion to and internalization into cells*. However, the question, whether the zeta-potential directly or another underlying parameter influencing it (e.g. the number of functional surface groups) plays the decisive role, remains unsolved.

To address this, we use a microfluidic platform and combine it with a convolutional neural network to allow the measurement of hundreds of interactions in parallel. By allowing MPs with different surface functionalizations to sediment onto the cells, we determine their binding kinetics. We subsequently exert a well-defined flow force on the MPs to quantify their adhesion to the cells. Our work contributes to understanding which properties of MPs are determining particle-cell interaction and therefore identifying potential drivers for their biological impact.

BP 25.7 Thu 11:30 H44

Direct mechanical communication of cellular to nuclear shape in oocytes — •Bart Vos[1], Yamini Vadapalli[2], Till Muenker[1], Peter Lenart[2], and Timo Betz[1] — [1]Third Institute of Physics, University of Göttingen, Göttingen, Germany — [2]Max Planck Institute for Biophysical Chemistry, Göttingen, Germany

Mechanics play a crucial role in a wide range of cellular processes, from differentiation to division and metastatic invasion. Additionally, mechanical signaling can regulate protein expression. Although the mechanical properties of the cytoskeleton, providing shape, motility and mechanical stability to the cell, have been extensively studied, remarkably little is known about the mechanical environment within the nucleus of a cell and the exact mechanisms of force transduction between the cytoplasm to the nucleus.

To address these questions, we apply external deformations to oocytes of different species to observe how cellular deformations can be transmitted to the nucleus, leading to nuclear deformations. We combine this with optical tweezers-based microrheology in the cellular nucleus, allowing a direct comparison between intracellular and intranuclear mechanics. The observed viscoelastic behavior of the nucleoplasm on various time scales is profoundly different from the cytoskeleton. In addition, we probe the role of activity in the mechanics of the nucleus. Depending on the mechanical properties of the cytoplasm and nucleoplasm, nuclei can be highly susceptible to external strain or be largely

shielded, suggesting a mechanical communication that might be relevant for proper oocyte function.

BP 25.8 Thu 11:45 H44

Robust mitotic events in C. elegans embryos with and without mechanical perturbations — Vincent Borne and •Matthias Weiss — Experimental Physics I, University of Bayreuth, Germany

Early embryogenesis of the nematode Caenorhabditis elegans proceeds in an autonomous fashion within a protective chitin eggshell. Cell-division timing and the subsequent mechanically guided positioning of cells is virtually invariant between individuals, especially before gastrulation. By mechanically perturbing the embryo without breaking its eggshell, we have probed the limits of this stereotypical and robust developmental program. Compressing embryos to half of their native diameter frequently resulted in a loss of cytokinesis, yielding a non-natural syncytium that still allowed for multiple divisions of nuclei. The orientation of mitotic axes was strongly altered in the syncytium, but key features of division timing and spatial arrangement of nuclei remained surprisingly similar to those of unperturbed embryos in the first few division cycles. Our data suggest that few very robust mechanisms govern the progress of early embryogenesis of C. elegans.

BP 25.9 Thu 12:00 H44

Density and viscosity Measurements of the cytosol of human red blood cells — •Thomas John and Christian Wagner — Experimental Physics, Saarland University

We present a method to determine the viscosity of the intracellular liquid - the cytosol - of human red blood cells (RBCs). Our method combines the measurement of the mass density distribution of RBCs and the viscosity of the cytosol as a function of the water content. The density distribution is measured through buoyant density centrifugation combined with cell counting. By correlating this Gaussian distribution of cell population densities with the viscosity-density relation of the cytosol, we obtain a log-normal distribution of the cytosol viscosity of healthy RBCs. The viscosity contrast λ, defined as the ratio of viscosities between the RBC cytosol and the blood plasma under physiological conditions, is determined to have a mean value of $\bar{\lambda} = 10$. This value is significantly larger than those used in the literature for numerical simulations.

BP 25.10 Thu 12:15 H44

Aggregation and disaggregation of red blood cells — •Kirill Korneev[1], Nicolas Moreno[2], Thomas John[1], Christian Wagner[1], and Dmitry Fedosov[3] — [1]Experimental Physics, Saarland University — [2]Basque Center for Applied Mathematics, Bilbao Spain — [3]Theoretical Physics of Living Matter, Forschungszentrum Jülich

Laser tweezers (LT) are devices for manipulating, trapping and force measurement on particles into optical traps. Red blood cells (RBCs) are the majority of blood cells. Those cells are very deformable and show spontaneously forming complex structures at rest state, due to aggregation. The mechanisms of RBCs aggregation are not fully understood, however there are currently two main hypotheses that can explain it: the bridging model based on mobile and immobile bonds, and the depletion layer model. In this work, experimental values of the RBCs disaggregation force were obtained by stretching RBC aggregates. We will show, that the mechanism of RBCs disaggregation involves these two hypotheses. We will also show that the bridging model with mobile bonds reproduces well the corresponding experimental data, offering insights into the interplay between bridging and depletion interactions and providing a framework for studying similar interactions between other biological cells.

N. Moreno, et al., Aggregation and disaggregation of red blood cells: depletion versus bridging, bioRxiv 2024.11.20.624311 (2024)

BP 25.11 Thu 12:30 H44

Dynamic states of P. falciparum infected erythrocytes adhering in shear flow - a qualitative study of rolling and flipping motions — •Katharina Scholz[1], Leon Lettermann[2], Jessica Kehrer[3], Michael Lanzer[3], Ulrich Schwarz[2], and Motomu Tanaka[1] — [1]Institute for Physical Chemistry, University of Heidelberg, Germany — [2]Institute for Theoretical Physics, University of Heidelberg, Germany — [3]Center of Infectious Diseases, Heidelberg University Medical School, Germany

As surviving strategy, the malaria parasite remodels the red blood cell by causing the expression of adhesive proteins on its surface. The modification allows the infected cell to adhere to the endothelial cells in the blood stream, thereby avoiding clearance by the spleen.

This transformation also alters cell shape and movement behaviour during development. We used Reflection Interference Contrast Microscopy (RICM) in quantitative flow chamber experiments and employed a high-speed camera to gain more information about the contact footprint of cells. With this setup, we tracked parasitised erythrocytes individually, label-free and non-invasively. Early-stage trophozoites exhibited flipping behaviour, while late-stage schizonts showed a steady rolling motion. Our results provide a quantitative understanding of how parasite development affects dynamic cytoadhesion behaviour and shed light on understanding endothelial cell activation.

BP 25.12 Thu 12:45 H44

Deformability cytometry for large-scale mechano-genomic screening in interphase and mitosis — •Laura Strampe[1], Katarzyna Plak[2,3], Christine Schweitzer[1], Cornelia Liebers[1,2], Buzz Baum[3], Jona Kayser[1], and Jochen Guck[1,2] — [1]Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany — [2]Biotechnology Center of TU Dresden, Dresden, Germany — [3]MRC Laboratory of Molecular Biology, Cambridge, United Kingdom

We demonstrate the scalability of real-time fluorescence and deformability cytometry (RT-FDC) for large-scale cell cycle-resolved mechano-genomic screening. Using RNA interference, we screened 215 kinase and phosphatase genes on their effects on cell mechanics in interphase and mitosis. RT-FDC combines high throughput (up to 100 cells per second) with fluorescence-based cell cycle classification, enabling single-cell mechanical phenotyping of entire populations. We show that cell cycle resolution is essential for identifying genetic regulators of cell mechanics, as stiffness differences between interphase and mitotic cells can obscure genuine knockdown effects or generate false-positive hits. Genes regulating mitotic mechanics or softening cells upon knockdown are particularly likely to be masked. Of the 81 genes identified as affecting cell stiffness, 22 were detected only through cell cycle resolution. These include *PRL-1*, a cancer metastasis marker with opposing effects across the cell cycle: stiffening interphase cells and softening mitotic cells. This suggests that *PRL-1* overexpression in metastatic cells expands the range of mechanical phenotypes during cell cycle progression, facilitating tumor adaptability.

BP 26: Synthetic life-like systems and Origins of Life

Time: Thursday 9:30–12:15 Location: H46

BP 26.1 Thu 9:30 H46

Heat flows through rock cracks purify life's building blocks and protect RNA from hydrolysis — •Paula Aikkila[1], Thomas Matreux[2], Dieter Braun[1], and Christof Mast[1] — [1]Ludwig-Maximilians-Universität München — [2]ESPCI Paris

The emergence of biopolymer building blocks is a crucial step during the origins of life. However, their synthesis pathways usually require feedstocks of pure reactants and defined purification and mixing steps to suppress unwanted side reactions, which is required for high product yields. We show that heat flows through thin crack-like compartments purify complex mixtures of prebiotically relevant building blocks and drive prebiotically relevant reactions such as the dimerization of glycine. In these same compartments, we furthermore study how heat-flows can locally switch on and off pH gradients, thereby enabling or disabling RNA hydrolysis depending on their hybridization state. We seek to explore how this enables spontaneous symmetry breaking in the sequence and folding space, possibly facilitating the emergence of functional ribozyme.

BP 26.2 Thu 9:45 H46

Membraneless protocell confined by a heat flow — •Alexander Floroni[1], Noël Yeh Martín[2], Thomas Matreux[1], Laura Weise[3], Sheref Mansy[4], Hannes Mutschler[5], Christof Mast[1], and Dieter Braun[1] — [1]Systems Biophysics, LMU Munich; München, Germany — [2]Institute of Biotechnology HiLIFE, University of Helsinki, Helsinki, Finland — [3]MPI of Biochemistry; Martinsried, Germany — [4]Department of Chemistry, University of Alberta; Edmonton, Canada — [5]Department of Chemistry and Chemical Biology, TU Dortmund; Dortmund, Germany

In living cells, a complex mixture of biomolecules is assembled within and across membranes. This state is maintained by a sophisticated protein machinery. It imports nutrients, removes waste, and orchestrates cell division. Here we show how the molecular contents of a cell can be coupled in a coordinated way to the non-equilibrium of a heat flow. A temperature difference across a water-filled pore accumulated the core components of a modern cell to make a functional reaction. The mechanism arose from the interplay of convection and thermophoresis. Protein synthesis was triggered as a direct result of the up-concentration. The same non-equilibrium setting continued to attract nutrients from an adjacent fluid stream, while keeping the cellular molecules confined. Our results show how a simple and archaic non-equilibrium physical process can assemble the many different molecules of a cell and trigger its basic functions. The framework provides a membrane-free environment to bridge the long evolutionary times from an RNA world to a protein-based cell-like proto-metabolism.

BP 26.3 Thu 10:00 H46

A game of life with dormancy — •Daniel Henrik Nevermann[1], Claudius Gros[1], and Jay Lennon[2] — [1]Institute for Theoretical Physics, Goethe-University Frankfurt, Germany — [2]Department of Biology, Indiana University, Bloomington, IN 47405, USA

The factors contributing to the persistence of life are fundamental for understanding complex living systems. Many species contend with harsh environments by entering a reversible state of reduced metabolic activity, a phenomenon known as dormancy. Here, we develop Spore Life, a model to investigate the effects of dormancy on population dynamics. It is based on Conway's Game of Life, a deterministic cellular automaton where simple rules govern the metabolic state of an individual based on its neighborhood. For individuals that would otherwise die, Spore Life provides a refuge in the form of an inactive state. These dormant individuals (spores) can resuscitate when local conditions improve. The model includes a parameter $\alpha \in [0, 1]$ that controls the survival probability of spores, which yields stochastic dynamics between the limits $\alpha = 0$ (Game of Life) and $\alpha = 1$ (Spore Life). In addition to identifying the emergence of unique periodic configurations, we find that spore survival increases the average number of active individuals and buffers populations from extinction. Contrary to expectations, the population stabilization does not require large and long-lived seed bank. Instead, the demographic patterns in Spore Life only require a small number of resuscitation events. Spore Life can be interactively explored at `https://itp.uni-frankfurt.de/spore-life/`.

BP 26.4 Thu 10:15 H46

Continuous Evolving Game of Life with Diversity — •Alexandre Guillet and Frank Jülicher — MPI-PKS, Dresden, Germany

The complex phenomenology of J. Conway's "Game of Life" cellular automaton, in particular its gliders, has been translated into continuous fields in space and time in a 2011 preprint by S. Rafler. The striking organic feel associated with these artificial life simulations in isotropic space has attracted the attention of a growing online community at the intersection of citizen science and computer art, which has recently culminated in the exploration and classification of the diverse morphologies of the "Lenia" gliders by BWC. Chan and others.

Our research focuses on a minimal variant of these continuous nonlinear dynamical systems that is capable of generating gliding, self-replicating and vanishing patterns, with striking resemblance to cell division, motility and death. Elaborating upon the governing partial integro-differential equation, we allow each cell to carry individual variations of the parameters, thus introducing a spatial diversity of rules. A conservation law is enforced on the resources of the cells as a selection pressure, together with a mutation process as a random source of diversity. The spontaneous evolution of the system from a single cell leads to a rich phenomenology, ranging from mycelial growth to epithelia and amoeboid motion.

This continuous and evolving model with diversity raises the Game of Life into a toy model for the morphogenesis and evolution of primordial lifeforms.

BP 26.5 Thu 10:30 H46

Cooperative effects in compartmentalized irreversible self-assembly — •Richard Swiderski, Severin Angerpointner, and Erwin Frey — Arnold Sommerfeld Center for Theoretical Physics, Ludwig-Maximilians-Universität München, Germany

From biomolecular compartments, protein patterns to porous rocks: Many biological and chemical systems like living cells or prebiotic chambers exhibit some form of spatial organization which separates biochemical processes. This is known to play a key role in the assembly of virus capsids or the enrichment of prebiotic chemicals. We systematically explore the effects of such spatial separation on the self-assembly of irreversibly binding identical particles. We show that already in a simplified model of two coupled biochemical compartments cooperative effects emerge through limiting compartment exchange. Further, these findings generalize to spatially extended systems like intracellular chemical gradients or membrane-assisted assembly.

Theory for sequence selection via phase separation and oligomerization — •Christoph Weber — University of Augsburg, Universitätsstr. 1, 86159 Augsburg

Non-equilibrium selection pressures were proposed for the formation of oligonucleotides with rich functionalities encoded in their sequences, such as catalysis. Since phase separation was shown to direct various chemical processes, we ask whether condensed phases can provide mechanisms for sequence selection. To answer this question, we use non-equilibrium thermodynamics and describe the reversible oligomerization of different monomers to sequences at non-dilute conditions prone to phase separation. We find that when sequences oligomerize, their interactions give rise to phase separation, boosting specific sequences' enrichment and depletion. Our key result is that phase separation gives rise to a selection pressure for the oligomerization of specific sequence patterns when fragmentation maintains the system away from equilibrium. Specifically, slow fragmentation favors alternating sequences that interact well with their environment (more cooperative), while fast fragmentation selects sequences with extended motifs capable of specific sequence interactions (less cooperative). Our results highlight that out-of-equilibrium condensed phases could provide versatile hubs for Darwinian-like evolution toward functional sequences, both relevant for the molecular origin of life and de novo life.

BP 26.7 Thu 11:30 H46

Prebiotic RNA Replication through Templated Ligation by Humidity and pH Cycles — •Felix T. Dänekamp and Dieter Braun — Systems Biophysics LMU, Munich, Germany

To replicate long RNA strands, templated ligation from 2',3'-cyclic phosphate RNA is a promising pathway. Preliminary screenings suggest that through tuning of monovalent salt content and through adding Lysine or other amino acids to the solution, no additional catalysts are required to attain yields of 50% ligation product in one day. Cycling physical conditions such as pH and salt/RNA concentration likely solves the strand inhibition problem. This opens up the possibility of prebiotic ligation chain reactions and thus open-ended evolution from short RNA strands.

BP 26.8 Thu 11:45 H46

Gravitationally induced oscillations of active droplets — •Advait Thatte[1], Judit Sastre[2], Alexander Bergmann[2], Michele Stasi[2], Marta Tena-Solsona[2], Job Boekhoven[2], and Christoph Weber[1] — [1]Faculty of Mathematics, Natural Sciences, and Materials Engineering, and Institute of Physics, University of Augsburg, Universitätsstrasse 1, 86159 Augsburg, Germany — [2]Department of Bioscience, School of Natural Sciences, Technical University of Munich, Lichtenbergstrasse 4, 85748 Garching, Germany

Oscillations in the formation and dissolution of compartments inside living cells are pivotal in orchestrating various cellular functions and processes. Recent experiments on synthetic cells showed the spontaneous emergence of spatio-temporal oscillations in the number of droplets, their size, and position. Oscillations occur because droplets grow via gravitationally induced fusion above their stationary size. As a result droplets shrink, feeding the nucleation of new sedimenting droplets, restarting the cycle. The stationary droplet size is a consequence of deactivating droplet material inside and activating outside. Here we present a theoretical model for phase separation with non equilibrium chemical fuelling including a sharp interface model for many active droplets. The model quantitatively describes the stationary droplet size and the oscillation frequency observed experimentally.

BP 26.9 Thu 12:00 H46

Linking fitness landscape topography to the characteristics of the underlying genotype-phenotype map — Malvika Srivastava[1,2], Ard A. Louis[3], and •Nora S. Martin[4] — [1]Institute of Integrative Biology, ETH Zurich, Zurich, Switzerland — [2]Swiss Institute of Bioinformatics, Lausanne, Switzerland — [3]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, Oxford, UK — [4]CRG (Barcelona Collaboratorium for Modelling and Predictive Biology), Dr. Aiguader 88, Barcelona 08003, Spain

The topographies of fitness landscapes are central in models of evolutionary processes. Key topographical features include the prevalence of fitness peaks, as well as the existence of accessible (i.e. fitness-increasing) paths to the global fitness optimum. Recent numerical work found that such accessible paths commonly exist in fitness landscapes based on biophysical models of genotype-phenotype (GP) maps, even when fitness values are randomly assigned to phenotypes [1]. Here, we examine such landscapes with random phenotype-fitness assignment more thoroughly to investigate, how their topography depends on the characteristics of the underlying GP map. By simplifying the GP map to a "neutral component" (NC) graph, we can compute the expected prevalence of fitness peaks based only on two GP map characteristics: the evolvabilities and sizes of NCs. Evolvabilities are also important for peak heights and for the existence of accessible paths to global optima. [1] S. F. Greenbury, A. A. Louis, S. E. Ahnert, Nat Ecol Evol. 6, 1742-1752 (2022).

BP 27: Focus Session Chemical Imaging for the Elucidation of Molecular Structure I (joint session O/BP)

Unravelling the multiscale molecular heterogeneity at interfaces is one of the main challenges in modern biophysics and surface science due to the major role specific structural properties play in determining their macroscopic function and behavior. In the last few decades, several specialized chemical imaging techniques have been developed that can reveal many of these crucial structural details, representing an enormous advance in our elucidative capabilities. Clear examples of this range from super-resolution and 3D tomography to tag-free characterization down to the single-molecule level. This focus session will explore the vast range of methods and possibilities for characterizing the different structural aspects in heterogeneous molecular systems and specifically highlight the potential complementarity of the different techniques through multi-modal approaches. Overall, by bringing together different communities, this session aims to foster scientific exchanges that could spark the next major developments in chemical imaging.

Organized by
Martin Thämer (FHI Berlin), Alexander Fellows (FHI Berlin), and Kerstin Blank (University Linz)

Time: Thursday 15:00–17:30 Location: H24

Invited Talk BP 27.1 Thu 15:00 H24

Infrared Nanoscopy and Tomography of Intracellular Structures — Joachim Heberle[1], Katerina Kanevche[1], •Emmanuel Pfitzner[1], David Burr[2], Janina Drauschke[2], Andreas Elsaesser[2], and Jacek Kozuch[1] — [1]Freie Universität Berlin, Department of Physics, Experimental Molecular Biophysics, — [2]Experimental Biophysics and Space Sciences, Arnimallee 14, 14195, Berlin, Germany

Although techniques such as fluorescence-based super-resolution imaging or confocal microscopy simultaneously gather morphological and chemical data, these techniques often rely on localized and chemically specific markers. To eliminate this flaw, we have developed a method of examining cellular cross-sections using the imaging power of scattering-type scanning near-field optical microscopy (sSNOM) and Fourier-transform infrared spectroscopy at a spatial resolution far beyond the diffraction limit (nanoFTIR). Herewith, nanoscale surface and volumetric chemical imaging are performed using the intrinsic contrast generated by the characteristic absorption of mid-infrared radiation by the covalent bonds. We employ infrared nanoscopy to study the subcellular structures of eukaryotic (C. reinhardtii) and prokaryotic (E. coli) species, revealing chemically distinct regions within each cell. Serial 100 nm-thick cellular cross-sections were compiled into a tomogram, yielding a three-dimensional infrared image of subcellular structure distribution at 20 nm spatial resolution. The presented methodology can image biological samples with less interference due to the low energy of infrared radiation and the absence of labeling.

Invited Talk BP 27.2 Thu 15:30 H24

Coherent Raman Imaging — •Michael Schmitt[1] and Juergen Popp[1,2] — [1]Institute of Physical Chemistry and Abbe Center of Photonics, Friedrich-Schiller-University Jena, Helmholtzweg 4, 07743 Jena, Germany — [2]Leibniz Institute of Photonic Technology, Member of Leibniz Health Technologies, Albert-Einstein-Straße 9, 07745 Jena, Germany

Raman-based technologies have profoundly impacted life sciences and biomedical research. Despite their unmatched molecular specificity, traditional Raman spectroscopy suffers from limited sensitivity, making it less suitable for rapid imaging. This limitation is addressed by coherent Raman scattering (CRS) microscopy, primarily through coherent anti-Stokes Raman scattering (CARS) and stimulated Raman scattering (SRS). This talk examines the potential of CARS and SRS imaging for biological and biomedical analysis, offering detailed insights into the molecular composition of biomedical specimens, such as cells or tissue. The presentation will focus on the applications of these techniques in molecular and functional diagnostics in the fields of medicine and life sciences. Furthermore, recent developments in translating CRS into compact, clinically viable systems, such as handheld probes, will be presented, focusing on intraoperative tumour diagnostics for early detection and improved improved therapeutic outcomes.

Invited Talk BP 27.3 Thu 16:00 H24

Sum Frequency Generation Microscopy of Electrochemical Interfaces — •Steven Baldelli — University of Houston, Houston, Texas

Sum frequency generation spectroscopy (SFG) is a valuable technique to study the molecular properties of surfaces. As a second-order technique, it is uniquely sensitive to the average organization of molecules at the surface. However, as most surfaces are spatially heterogeneous, it isn't easy to interpret the spectrum as a single domain. The development of SFG into microscopy has allowed a more detailed and accurate analysis of the spatio-spectro-temporal evolution of surface chemistry. The SFG microscope development will be presented, and compressive sensing and the application toward electrocatalysis will be used.

BP 27.4 Thu 16:30 H24

Elucidating the Composition, Order, and 3D Molecular Orientation of Thin Films with Phase-Resolved Sum-Frequency Generation Microscopy — •Alexander Fellows, Ben John, Martin Wolf, and Martin Thämer — Fritz-Haber-Institute, Berlin, Germany

The vast majority of molecular interfaces have highly heterogeneous structures, ranging across all length-scales. These manifest as variations in density, composition, and molecular packing structure, all of which are critical in controlling the macroscopic properties and functional behaviour of the films. While various chemical imaging techniques can access many of these important structural details, characterising their relative order and specific packing arrangements represents a formidable challenge.

Here, we present a chemical imaging approach based on phase-resolved sum-frequency generation (SFG) microscopy. By probing molecular vibrations, this technique achieves molecular recognition and thus is sensitive to the local composition and density. Furthermore, through its symmetry selection rules, output SFG signals are dependent on absolute molecular orientations. This hence allows it to distinguish different molecular conformations and characterise the amount of orientational order in the system. Finally, with an azimuthal-scanning approach, the in-plane and out-of-plane signal contributions can be separated, allowing the 3D molecular orientations to be elucidated. By applying SFG imaging to model lipid monolayers, we gain an unprecedented overview of their hierarchical packing structures.

BP 27.5 Thu 16:45 H24

Low temperature multimode atomic force microscopy using an active MEMS cantilever — Michael G. Ruppert[1], Miguel Wiche[2], André Schirmeisen[2], and •Daniel Ebeling[2] — [1]University of Technology Sydney, Australia — [2]Justus Liebig University Giessen, Germany

Low-temperature atomic force microscopy (AFM) is one of the most powerful tools in surface science. With the chemical bond imaging technique, i.e., by using CO functionalized AFM tips, it became possible to visualize the chemical structure of individual organic molecules, which is essential for studying on-surface reactions and molecular manipulation processes. Routinely, such measurements are performed with qPlus sensors. Here, we present a proof of concept for an active microelectromechanical systems (MEMS) microcantilever with integrated piezoelectric sensing and demonstrate its capability to obtain scanning tunneling microscopy as well as high-resolution non-contact atomic force microscopy images on an atomically flat Au(111) surface. Equipped with a focused ion beam deposited tungsten tip, the active MEMS cantilever is able to obtain high contrast scanning tunneling and frequency shift images at the fundamental and a higher eigenmode of the cantilever. This is interesting for the application of multifrequency AFM operation modes that could enhance the capabilities of the bond imaging technique.

BP 27.6 Thu 17:00 H24

Instrumentation for high-resolution biomolecule imaging enabled by electrospray ion beam deposition (ES-IBD) — •Lukas Eriksson[1], Tim Esser[1,2], and Stephan Rauschenbach[1] — [1]University of Oxford, Oxford, UK — [2]Thermo Fisher Scientific, Eindhoven, Netherlands

Direct imaging of (bio-)molecules with cryogenic electron microscopy (cryo-EM) or scanning probe microscopy (SPM) is a powerful approach for elucidating molecular structure. However, sample preparation can be a major challenge: either very time- and resource-intensive or incompatible with the vacuum environment required by the imaging method.

Here, we explore preparative mass spectrometry as an alternative workflow towards structural elucidation of biomolecules. A novel, custom-built deposition stage extending a commercial mass spectrometer (Thermo Fisher Scientific Orbitrap UHMR) allows for the mass-filtered, soft-landed deposition of a wide mass range of target molecules (m = 100 to 10^6 Da) onto various surfaces, including cryo-EM grids and metal crystals for SPM. Successful deposition and subsequent imaging requires extensive control over conditions such as pressure, temperature, ion trajectories, sample surfaces, and sample transfer to obtain clean, chemically pure samples of the desired species in the right (i.e. native) configuration. The sample holder also enables controlled growth of ice layers for embedding deposited molecules, allowing high-resolution reconstructions of proteins from cryo-EM.

BP 27.7 Thu 17:15 H24

LFM study of copper oxide — •Sophia Schweiss, Alfred J. Weymouth, and Franz J. Giessibl — Universität Regensburg, Regensburg, Deutschland

Small-amplitude FM-AFM is a method to study surfaces and adsorbates with atomic resolution. At low temperature, the tip apex can be prepared so that it ends in a single O-atom, making the tip inert and enhancing imaging [1, 2]. With a laterally oscillating tip, i.e. lateral force microscopy (LFM), the conservative (frequency shift, Δf) and non-conservative (dissipated energy, E_{diss}) components of the tip-sample interaction can also be independently measured. Here too, inert tip apices are commonly used. One measurement of E_{diss} relies on the cocking and snapping of the tip over a single chemical bond, for which the current state of the art utilizes CO-terminated tips. In this work, a CO-terminated tip [1] is used to investigate the (2×1)O reconstruction of Cu(110) with LFM. Simulations are performed to guide interpretation. In this larger ongoing study, these LFM measurements will be repeated for a CuOx tip [2] to evaluate it as a tool for measuring E_{diss}.

BP 28: Microswimmers and Microfluidics (joint session DY/BP/CPP)

Time: Thursday 15:00–17:45 Location: H37

Invited Talk BP 28.1 Thu 15:00 H37

Light-Driven Manipulation of Passive and Active Microparticles — •Svetlana Santer — Institute of Physics and Astronomy, University of Potsdam, Germany

Chemical gradient near a solid/liquid can result in lateral long-range fluid transport termed diffusioosmotic (DO) flow. For instance, when photosensitive surfactant is irradiated with light converting the majority of the molecules in one of the possible isomers, emerging concentration gradient of isomers generates an osmotic pressure gradient tangent to the wall actuating the surrounding liquid to flow. [1-3] In my talk I will show how one can manipulate microparticles and even induce their self-propulsion by light urtilizing light driven diffusioosmotic (LDDO) phenomenon. Depending on the applied wave length one can either disperse/remove or gather particles. We will discuss how to establish light-driven hydrodynamics as a useful and versatile tool for investigating collective motion of self-propelled particles and aggregation

BP 28.2 Thu 15:30 H37

Regulated polarization of active particles in local osmotic flow fields — •Lisa Rohde, Desmond Quinn, Diptabrata Paul, and Frank Cichos — Molecular Nanophotonics Group, Peter Debye Institute for Soft Matter Physics, University Leipzig, Leipzig, Germany

Regulation in living systems is a fundamental principle for achieving robust functionality and maintaining specific non-equilibrium states. The control of certain properties and functionalities of systems on the microscale presents particular challenge since thermal fluctuations and environmental perturbations dominate. While synthetic active matter has demonstrated remarkable self-organization capabilities, examples of autonomous regulation processes at the single-particle level remain scarce. Here, we show experimentally that the interplay of two non-equilibrium processes leads to a regulated polarization state of active particles in local osmotic flow fields. Based on thermophoretic repulsive and attractive forces that are generated by a single heat source at the boundary, the active particles encircle the heat source at a stable distance depending on the heat source temperature. The balance of these temperature-induced processes causes a polarization of the active particles that is independent of the heat source temperature. The individual control of heat source and active particles in the experiment allows detailed investigation of the self-regulated polarization effect in which we find hydrodynamic interactions to dominate. As the effects rely on osmotic flows and phoretic interactions, we expect that the observed phenomena can be generalized to other active systems and flow fields.

BP 28.3 Thu 15:45 H37

Active particle steering in three dimensions — •Gordei Anchutkin and Frank Cichos — Molecular Nanophotonics Group, Peter Debye Institute for Soft Matter Physics, Leipzig University, Leipzig, Germany

Synthetic active particles serve as a model system that mimic the self-propulsion of living matter to explore fundamental aspects of non-equilibrium physics. Various collective phenomena of active agents have been studied, but mostly in the presence of hydrodynamic and physicochemical boundary effects. While theoretical works predict different collective dynamics in 3D, experimental investigations remain limited due the lack of experimental control over active swimmers in three dimensions.

Here we introduce three-dimensional control to the study of synthetic active matter. We demonstrate simultaneous control of thermophoretic microswimmers in 3D using single-particle tracking through digital holography and dark-field pattern tracking, with real-time wavefront shaping for steering. With the help of these experiments, we explore the interplay of thermophoretic propulsion, gravity, and optical forces for the active particles. By creating a three-dimensional active ensemble, we reveal how bulk interactions and boundary effects shape the collective behavior of active particles.

BP 28.4 Thu 16:00 H37

***Trypanosoma brucei* in microchannels: the role of constrictions** — •Zihan Tan, Julian I. U. Peters, and Holger Stark — Institute of Theoretical Physics, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin, Germany

Trypanosoma brucei (*T. brucei*), a single-celled parasite and natural microswimmer, is responsible for the fatal sleeping sickness in infected mammals, including humans. Understanding how *T. brucei* interacts with fluid environments and navigates through confinements is crucial for elucidating its movement through blood vessels and tissues, and across the blood-brain barrier.

Using a hybrid multiparticle collision dynamics (MPCD)–molecular dynamics (MD) approach, we investigate the locomotion of an in-silico *T. brucei* in three types of fluid environments: bulk fluid, straight cylindrical microchannels, and microchannels with constrictions. We observe that the helical swimming trajectory of the in-silico *T. brucei* becomes rectified in straight cylindrical channels compared to bulk fluid. The swimming speed for different channel widths is governed by the diameter of the helical trajectory. The speed first slightly increases as the channel narrows and then decreases when the helix diameter is compressed. An optimal swimming speed is achieved when the channel width is approximately twice the bulk helix diameter. Furthermore, *T. brucei* notably slows down when entering the narrow constriction in a microchannel and strongly speeds up upon exiting due to a release of deformation energy of the straightened cell body.

BP 28.5 Thu 16:15 H37

Helical motion of microorganisms can be more persistent than straight motion — •Leon Lettermann[1], Falko Ziebert[1], Mirko Singer[2], Freddy Frischknecht[2], and Ulrich S. Schwarz[1] — [1]BioQuant & Institute for Theoretical Physics, Heidelberg University — [2]Center for Integrative Infectious Disease Research, Heidelberg University

The movement of microorganisms has been extensively modeled by stochastic active particle models. In three dimensions, both swimming microorganisms, like sperm cells and some bacteria, and gliding microorganisms, like malaria sporozoites in the skin, often exhibit helical trajectories. If the internal driving force is the primary source of noise in the system, it induces random, yet time-correlated variations in the torque. To investigate this effect, we introduce a three-dimensional active rotational Ornstein-Uhlenbeck particle model. We find that the presence of a rotational component and the resulting helical path can mitigate the effect of intrinsic noise in the drive, allowing for larger long-time mean square displacements than straight movement at the same speed. The model not only provides qualitative insights into the constraints faced by microbes that may have led to the evolutionary selection of certain motility patterns, but also presents an analytical, quantitative tool for extracting information from these movements. We present and analyze corresponding data for malaria parasites gliding through hydrogels.

BP 28.6 Thu 16:45 H37

Corrugated channels can filter ciliated microorganisms based on the metachronal wavelength — •Gonçalo Antunes and Holger Stark — Technische Universität Berlin, Institute of Theoretical Physics, Hardenbergstr. 36, 10623 Berlin, Germany

Many microorganisms (e.g. Paramecium) move by a carpet of cyclically beating cilia that cover their surface. These cilia often beat in an organized fashion, such that the beating phases form a traveling wave, referred to as a metachronal wave. In this study, we investigate the swimming of such microorganisms in corrugated microchannels. We model the motion of the cilia via a time-varying effective slip velocity applied on the microorganism's surface, which we approximate as an infinite slab. By employing the lubrication approximation, we show analytically that the swimming speed of ciliated microorganisms placed inside a corrugated channel is sensitive to the corrugation height, provided that the wavelength of the corrugation matches that of the metachronal wave. Indeed, the direction of motion itself may invert with respect to swimming in bulk fluid, with the channel acting as a virtual barrier which blocks microorganisms under specific conditions for corrugation and slip-velocity modulations, but allow others to pass through. We also show that the interplay between the corrugation and the slip velocity profile allows for the swimming of microorganisms with zero time-averaged slip velocity, which thus cannot swim in bulk fluid. Finally, we complement our theory with preliminary results from hydrodynamic simulations for radially-symmetric microorganisms of finite length in radially-symmetric corrugated channels.

BP 28.7 Thu 17:00 H37

Motion of a single particle partially exposed in a simple shear flow — •Dominik Geyer[1,2], Aouane Othmane[1], and Jens Harting[1,2] — [1]Helmholtz-Institut Erlangen-Nürnberg for Renewable Energy (IET-2), FZ Jülich — [2]Department of Physcis, FAU Erlangen-Nürnberg

Sand immersed in the water can be imagined as a wet granular matter. Besides sedimentation, friction, and surface roughness are two relevant physical phonemes within this system. Many body systems in a turbulent regime have been studied using discrete elements methods for a long time, but a single particle in the Stokes flow regime is particularly interesting for biological systems and microfluidic devices.

A layer of quadratic-arranged spheres models the rough surface. The question arises of how to describe the motion of a single traveling particle over this substrate.

We choose a combined numerical and analytical approach. The Stokes equation is solved analytically for the sphere near a rough wall. Lattice Boltzmann simulations with momentum-exchange particle coupling are performed for different wall roughness and friction coefficients.

Although, the Stokes equation assumes that the particle Reynolds number is zero. Surprisingly, the numerical results match our theoretical description until a particle Reynolds number of two. In this regime, friction between the moving particle and the substrate significantly influences the angular velocity but has a minor influence on the traveling velocity in the flow direction.

BP 28.8 Thu 17:15 H37

Rational Design of Smart Microfluidics in Responsive Channels — •Arwin Marbini — Albert-Ludwigs Universität Freiburg

Responsive microfluidics offers exciting potential for self-regulating biomimetic systems. This study explores bifurcating microchannel networks with pressure-sensitive resistances, combining experiments with simulations based on the Hagen-Poiseuille equation and a linear model. These methods extract critical, experimentally inaccessible parameters under steady-state and dynamic conditions. Our findings enable the design of adaptable microfluidic networks, unlocking precise flow control for future applications in biology, soft robotics, and advanced material systems.

BP 28.9 Thu 17:30 H37

Blue Water: A passive, reusable microfiltration device for water purification — •Tim R. Baumann, Ioannis Gkekas, Martina Viefhues, and Dario Anselmetti — Experimental Biophysics, Bielefeld University

Water is the most vital resource for life on Earth. Due to pollution of freshwater and oceans, this valuable resource has become globally endangered. The effects of microplastic pollution are widely discussed in scientific, political, and socioeconomic contexts. Despite regulations on single-use plastics and microplastic output, efforts should also focus on reintegrating microplastics to achieve a sustainable circular economy. Furthermore, microplastic-sized particles can migrate through organic tissue and can therefore be classified as contaminants of emerging concern. However, filtering plastics of this size is a challenging task.

Thus, this work examines and extends the findings of Divi et al. regarding the suspension feeding mechanisms of various ray species. We studied the filtration performance and efficiency for different geometric ratios of channel widths in simulations and laboratory environments. First, we have the main inner channel connected to the pressure inlet. From this, two rows of tilted lamellae structures branch off laterally to the outer secondary channels.

By applying sufficiently high pressure ($> 6 \cdot 10^5\ Pa$) to the inlet and achieving flow and particle velocities of $> 35\ \frac{m}{s}$, we can purify 82 % of half of the initial fluid. To prevent rupturing of our microfluidic chip under this pressure, we further investigated using glass fiber reinforced PDMS and lowering the operating pressure.

BP 29: Focus Session: Innovations in Research Software Engineering (joint session BP/DY)

Research software engineering (RSE) is an emerging field in science, with practitioners spanning a continuous spectrum from "researchers who code" to "software engineers developing for science". In Germany, a growing movement supported by deRSE e.V. is gaining recognition, and more institutions are acknowledging the increasing demand across various disciplines. This focus session will provide a platform to highlight recent advances in applications, tooling, and software in the fields of biophysics, dynamics, and statistical physics, as well as developments in the recognition and proliferation of RSE as a profession within our field and academia in general.

Organized by Simon Christ and Sophia Rudorf (Hannover).

Time: Thursday 15:00–18:00 Location: H44

Invited Talk BP 29.1 Thu 15:00 H44

Community-driven software and data training for computational biology — •Toby Hodges — The Carpentries, Oakland, CA, USA

The Carpentries is a global community teaching essential software and data skills for research. Certified Instructors teach hundreds of workshops to thousands of learners all over the world every year, introducing them to essential skills for computational research such as programming, version control, and data organisation. In recent years, the community has also begun to develop and deliver lessons that build on these foundations, teaching more intermediate and advanced Research Software Engineering skills such as HPC, parallel programming, and containerised computing. This talk will explore how open source, collaborative training efforts can build capacity for computational research, discuss what makes this model work and some lessons learned along the way, and finish with a look at what the community plans to do next.

BP 29.2 Thu 15:30 H44

Python-based interface to micromagnetic simulation software: Ubermag — •Hans Fangohr[1,2,3], Martin Lang[1,2], Samuel J.R. Holt[1,2], Swapneel Amit Pathak[1,2], Kauser Zulfiqar[1,2,4], and Marijan Beg[5] — [1]MPSD, Hamburg, Germany — [2]CFEL, Hamburg, Germany — [3]Univ. Southampton, UK — [4]Univ. Hamburg, Germany — [5]Imperial College London, UK

We describe the Python-based user environment "Ubermag" to help scientists use well-established (micromagnetic) simulation packages.

Within Ubermag [1], researchers can express the physics problem they want to simulate in a scientist-friendly but machine readable problem definition based on Python syntax [2]. Ubermag translates this problem into the configuration files needed for micromagnetic simulation packages such as OOMMF or mumax3. On completion of the simulation, the computed data is presented back to the user at the Python level. Ubermag is often used in Jupyter Notebooks, and supports rich media to provide figures and equations within the notebook.

We report on the motivation for Ubermag, the design and implementation process, and our experiences made both from the perspective of science users and from the research software engineers. We touch on a range of topics, including interface design, domain specific languages, testing, packaging, Jupyter, and reproducibility.

This work was supported by EPSRC UK Skyrmion Grant EP/N032128/1, and the European research projects OpenDreamKit (676541) and MaMMoS (101135546).

BP 29.3 Thu 15:45 H44

OCTOPOS.jl: A Julia-based tool for synonymous codon optimization — Simon Christ[1], Jan-Hendrik Trösemeier[2], and •Sophia Rudorf[1] — [1]Institute of Cell Biology and Biophysics, Leibniz University Hannover, Germany — [2]independent researcher

OCTOPOS.jl is a research software designed to optimize synonymous mRNA sequences for improved heterologous gene expression in various host organisms. Combining a detailed mechanistic model of in-vivo protein synthesis with machine learning, OCTOPOS.jl predicts protein expression based on codon choice. Originally developed as a Java desktop application, the software has been reimplemented in the Julia programming language to enhance performance, modularity, and scalability. The new implementation serves as the foundation for a graphical user interface and a web application, accessible at https://octopos.cell.uni-hannover.de/. These updates improve accessibility and usability, broadening its appeal to both computational and experimental biologists. OCTOPOS.jl supports organism-specific genetic sequence engineering and detailed analysis of translation dynamics, thus providing a valuable resource for the synthetic biology and biotechnology communities.

BP 29.4 Thu 16:00 H44

Invert pattern forming systems with BayesFlow to bridge the gap from simulation to experimental observation — •Hans Olischläger — Interdisciplinary Center for Scientific Computing (IWR) — Heidelberg University

The description of experimental systems by complex spatial models, be it with (stochastic) partial differential equations, agent-based simulation or otherwise, is often the condensation of all the central scientific hypotheses regarding a particular object of study.

I argue, that making progress in this kind of modelling is currently hindered by the lack of a tool that enables solving the following inverse problem: Given an observation, determine all the model configurations that are able to produce it. In other words, what is the posterior probability of all model configurations given some (set of) experimental data.

Instead of just preaching that in theory a Bayesian treatment would be nice, I will then continue to present such a tool: amortized Bayesian inference (as implemented in the software package BayesFlow). I will give examples on the classical Gierer-Meinhardt pattern forming PDE and a biophysical model, the Min system, which is used by E. coli to control cell division.

I will also take a step back to give a broader picture of the newly available statistical methods that support complex spatial modelling and their limitations. The aim is to provide some guidance on what you can and cannot infer from your state-of-the-art scientific simulator given observations, and how to do it.

BP 29.5 Thu 16:15 H44

FAIR Data Management for Soft Matter Simulations using NOMAD — •Bernadette Mohr[1], Esma Boydas[1], Nathan Daelman[1], José M. Pizarro[1], Tristan Bereau[3], Claudia Draxl[1], Luca M. Ghiringhelli[4], Martin Girard[2], Denis Usvyat[6], Roser Valentí[7], Silvana Botti[5], and Joseph F. Rudzinski[1,2] — [1]CSMB, HU Berlin — [2]MPIP Mainz — [3]ITP, Heidelberg Uni. — [4]Dept. of Mater. Sci. and Eng., FAU Erlangen — [5]RC-FEMS and Faculty of Physics, RUB Bochum — [6]Inst. für Chem., HU Berlin — [7]ITP, GU FfM

NOMAD [nomad-lab.eu][1, 2] is an open-source, community-driven data infrastructure designed to facilitate FAIR data management in materials science. Currently, it supports over 60 computational codes and encompasses DFT, classical MD, and many-body methods. This contribution will focus on recent developments, following modern software practices, to enhance NOMAD's applicability to soft matter and biological systems, including support for coarse-grained representations and advanced workflows such as free energy calculations. Combined with a schema for representing force fields, molecular topologies, and hierarchical system structures, NOMAD tracks data provenance and streamlines data analysis and the creation of AI-ready datasets. The NOMAD framework meets the classical simulation community's needs for improved data management standards and provides a foundation for building a cohesive, interconnected scientific data ecosystem. [1] Scheidgen, M. et al., JOSS 8, 5388 (2023).

[2] Scheffler, M. et al., Nature 604, 635-642 (2022).

BP 29.6 Thu 16:30 H44

Estimation of kinetic rates by constrained optimization — •Federico Marotta[1], Maria Zimmermann-Kogadeeva[1], Peer Bork[1], Julia Mahamid[1], and Sophia Rudorf[2] — [1]European Molecular Biology Laboratory — [2]Leibniz Universität Hannover

Biological systems often rely on molecular motors to perform useful work. The kinetics of the reactions in a motor's cycle can be easily investigated *in vitro* or in model organisms, but it is difficult to generalize them to a different system. We present a method to estimate the transition kinetics in an uncharacterized system, where minimal data are available, by leveraging a reference system where the kinetics have been elucidated. The motor's activity is represented as a continuous-time Markov chain, characterized by an infinitesimal generator matrix Q whose entries are functions of the transition rates of the cycle (the vector ω) and possibly of the concentrations of external molecules. In the uncharacterized system, the available data induce a constraint on the admissible rates. By employing an extremum principle, we estimate the rates ω_{unc} that minimize the kinetic distance with respect to the reference rates ω_{ref} while respecting such constraint. As an application of this strategy, we describe a model of the translation elongation cycle, where reference data are available for *E. coli in vitro*, and estimate the rates either *in vivo* or in a different organism, under constraints on the total elongation time or the steady-state occupancies, respectively.

BP 29.7 Thu 16:45 H44

Software provisioning for HPC and RSE — •Martin Lang[1,2], Henning Glawe[1,2], Jehferson Mello[1,2], and Hans Fangohr[1,2,3] — [1]Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — [2]Center for Free-Electron Laser Science, Hamburg, Germany — [3]University of Southampton, Southampton, UK

All research software relies on existing libraries for various functionalities such as low-level math operations, FFTs, IO, or other domain-specific operations. Installing these dependencies, potentially based on different compilers or in multiple versions, with all inter-dependencies fulfilled is notoriously difficult.

In the first part of this talk we introduce the open-source package manager Spack, which has a strong focus on HPC and research software. Spack can install software in multiple versions and variants, and supports optimised compilation for the underlying hardware, including compiling on exotic hardware. It comes with a large, community-provided collection of commonly used packages. Spack's packaging files make it easy to specify required dependencies, provide optional features of a software, and ensure compatibility with other libraries.

In the second part we present the concrete setup at our institute. We use Spack to provide the software stack on the local HPC, including pre-compiled packages and toolchains (sets of compilers and libraries) for users to compile their own software. We report on requirements and challenges, and how we address these with Spack. We also touch on scripting the Spack-based installation process including the option to recreate the HPC software environment on a scientist's laptop.

BP 29.8 Thu 17:00 H44

Small scale Research Software Engineering — •Simon Christ — Leibniz Universität Hannover, Institut für Zellbiologie und Biophysik, Computational Biology

While we are in dire need of research software organizations on a faculty level or larger, small scale software engineering, that is one research software engineer in a group or institute, is something that can be achieved in a short time frame and is probably the most common form today. A field report from Computational Biology where research software engineers are involved in modeling, developing solutions, teaching and maintenance.

BP 29.9 Thu 17:15 H44

Estimation of pKa values in membrane bound proteins — •Jesse Jones[1], Nereu Montserrat i Busquets[1,2], Ana Gamiz Hernandez[3], Ville Kaila[3], and Maria Andrea Mroginski[1] — [1]Technische Universität Berlin, Berlin — [2]Freie Universität Berlin, Berlin — [3]Stockholm Universität, Stockholm

Many key bioenergetic processes involving electron and proton reactions take place in membrane bound protein complexes, generating a proton motive force. Yet the ionizable groups which facilitate these reactions are often buried in hydrophobic pockets in the membrane. These processes are mainly described through pK_a values, which continue to be poorly understood and difficult to obtain despite structural, biochemical and computational advances. Hence, estimating pK_a values of these residues without the need for weeks of work in a laboratory, is important to describe the dynamics of the system, providing information on possible proton pathways. In this work we preview Karlsberg3, a software which uses a Poisson Boltzmann Equation solver (APBS) for proteins and calculates pKa values. Karlsberg3 is, in contrast to its predecessor Karlsberg2+, parallelized, running in modern software environments, and able to take membranes into consideration.

The teachingRSE project - Towards a professionalization of RSE education. — •Florian Goth[1] and Simon Christ[2] — [1]Universität Würzburg, Institut für theoretische Physik und Astrophysik, Am Hubland, 97074 Würzburg — [2]Leibniz Universität Hannover, Institut für Zellbiologie und Biophysik, Herrenhäuser Str. 2 30419 Hannover

At the deRSE23, the second conference for research software engineering(RSE) in Germany, a group of people came together for a small workshop to discuss how to deal with questions revolving around RSE education. Overwhelmed by the immense resonance to that workshop we took home a tremendous amount of feedback that made obvious that a short blog post will not suffice to adequately represent it. Now it is two years later, and the project produced its first output, the second position paper https://arxiv.org/abs/2311.11457 of de-RSE e.V. and it has sprawled out into a multitude of follow-up projects. In this talk, I will give an overview over the original ideas that we tried to convey in the position paper, and go into more detail on how domain sciences like physics need to change in light of this new specialization.

BP 29.11 Thu 17:45 H44

Python-Based Analysis Pipeline for the Quantification of Mechanics in Neural Organoids — •Michael Frischmann[1,2], Elijah R. Shelton[1], Achim T. Brinkop[1,2], and Friedhelm Serwane[1,2,3] — [1]Faculty of Physics & Center for NanoScience, LMU Munich, Germany — [2]Institute of Biophysics, Ulm University, Ulm, Germany — [3]SyNergy & GSN, Munich, Germany

Neuronal tissues form under the influence of mechanical forces guiding cellular movements. In the mammalian retina, neuronal translocations occur over hours. However, mechanical probing at those timescales in situ have posed experimental challenges. We employed magnetic ferrofluid droplets in mouse stem cell-derived retinal organoids to probe tissue mechanics from seconds to hours. To quantify tissue strain we have developed a Python-based analysis pipeline featuring an accessible graphical user interface (GUI). This pipeline automates strain quantification, image segmentation, and fitting procedures, enabling high-fidelity creep compliance measurements over extended durations. Our measurements reveal power-law scaling of dynamic compliance as well as tensile loss and storage modulus, consistent with soft glassy rheology just above the glass transition. These results demonstrate that neuronal tissues remodel in a scale-free manner while maintaining solid-like properties. This discovery provides a framework for understanding how mechanical signals may govern connectivity in the central nervous system. Integrating neural organoid models, mechanical probing, and computational methods, prepares us to investigate the interplay between biomechanics and neurodevelopment.

A protein sensor for plasma membrane lipid composition – insights from coarse-grained simulations — Saara Lautala and •Sebastian Thallmair — Frankfurt Institute for Advanced Studies, Frankfurt a.M., Germany

Extended synaptotagmins (E-Syts) are tethering proteins, which keep the plasma membrane (PM) and the endoplasmic reticulum (ER) membrane in close proximity at ER-PM contact sites. C2 domains are responsible for the binding of E-Syts to the PM. After depletion of phosphatidylinositol 4,5-bisphosphate $PI(4,5)P_2$, resynthesis of $PI(4,5)P_2$ takes place at ER-PM contact sites and thus, requires their integrity. The terminal C2C domain of E-Syt3 is known to bind $PI(4,5)P_2$. This results in an apparent paradox as the membrane binding and thus the tethered ER-PM contact site potentially become instable upon $PI(4,5)P_2$ depletion.

Here, we applied coarse-grained molecular dynamics simulations with the Martini 3 force field to investigate the membrane binding of the E-Syt3 C2C domain. Our simulations show that the C2C domain not only exhibits a binding hotspot for $PI(4,5)P_2$, but an additional binding hotspot for phosphatidylserine (PS) as well as a region binding to the membrane core. We will discuss that binding to PS results in a reorientation of the protein on the membrane surface and compare the different binding strengths. Overall, the PS binding site not only contributes to the ER-PM contact site integrity upon $PI(4,5)P_2$ depletion, but might also play a role in sensing low $PI(4,5)P_2$ levels.

Cross correlations in the Fluctuation-Dissipation Relation Reveal Solvent Friction in Hydrophobic Folding Transition — •Niklas Wolf, Viktor Klippenstein, Madhusmita Tripathy, and Nico F. A. van der Vegt — TU Darmstadt, Darmstadt, Germany

The Generalized Langevin Equation is a powerful tool for modeling and understanding the conformational dynamics of molecules in solution. However, recent works[1] have demonstrated that for these kinds of applications, the usual fluctuation-dissipation relation connecting the statistics of the random force to the memory kernel could contain a cross-correlation term. This raises the question of how the memory kernel should be extracted from simulation data and if a naive approach via the Volterra equations even gives a kernel related to a Markovian friction coefficient. We propose an approximation[2] to account for the cross-correlation term and show in a systematic study[3] that this approximation leads to an improved description of long-time dynamics and transition rates. Finally, we show that cross-correlations play an important role in the coil-to-globule transition of a hydrophobic polymer under various solvent conditions, where a naive approach would predict a significant violation of the Stokes-Einstein relation and give a poor description of barrier crossing times with rate theories.

Multiscale simulation of protein phase separation — •Supriyo Naskar, Kurt Kremer, and Oleksandra Kukharenko — Max Planck Institute for Polymer Research, Mainz, Germany

The post-translational modifiers such as mono and poly ubiquitins and SUMOs are known for their ability to modulate protein-protein interactions by becoming covalently attached to other target proteins. Despite the high similarity in the tertiary structure and sequence, they differentially influence the target protein properties. In this work, we employed a multiscale simulation approach that encompasses atomistic to different level coarse-grained modelling techniques with data-driven machine-learning methods to explore the structural differences and multidimensional energy landscape of ubiquitin and SUMO and their conjugates. We finally study the influence of distinct features of the targets and modifiers on protein phase separation and aggregation, providing molecular-level insight into the corresponding in vitro measurements and instructing further experiments through adjustment of relevant parameters.

BP 30.4 Thu 15:45 H46

Sequence specificity and polymer physics — •Martin Girard — Max-Planck Institute for Polymer Research, Mainz, Germany

Sequence properties of disordered proteins in the context of phase separation has led to development of molecular grammar. So far, this has led to the development of empirical parameters tied to protein sequences.

Using surrogate models for low-complexity sequences, I will show that sequence-property relations are tied to the polymer collapse transition. I will further discuss implications for biological systems.

Invited Talk BP 30.5 Thu 16:00 H46

Topology in biological matter - are there double knots in proteins or maybe even more complicated knots? Prediction and in vitro verification. — •Joanna I Sulkowska — University of Warsaw, Banacha 2C, 02-097, Poland

We have been aware of the existence of knotted proteins for over 30 years-but it is challenging to predict what is the most complicated not that can be formed in proteins. Recently, based on AlphaFold (AF) method we predicted new and the most complex knotted topologies recorded to date - double trefoil knots (see AlphaKnot database). We found five domain arrangements that result in a doubly knotted structure in almost a thousand proteins. The double knot topology is found in knotted membrane proteins from the CaCA family, that functions as ion transporters, in the group of carbonic anhydrases that catalyze the hydration of carbon dioxide, and in the proteins from the SPOUT superfamily that gathers 31 knotted methyltransferases with the active site-forming knot.

Herein, I will present the first crystal structure of a double knotted protein TrmD-Tm1570 from Calditerrivibrio nitroreducens from SPOUT superfamily. The protein consists of two domains TrmD and Tm1570, each embedding a single trefoil knot, which can function on their own. We show that it folds in vitro and is biologically active.

I will also explain how AF and AI methods can be used to design artificially knotted proteins that can be obtained in vitro. This shows that AF, while predicting structure, also takes into account folding and overcoming a non-trivial looping pathway.

BP 30.6 Thu 16:45 H46

Single molecule FRET studies on folding properties of multidomain protein fragments — •Alida Meyer[1], Alexandros Katranidis[2], Nuno Bustorff[2], and Jörg Fitter[1,2] — [1]RWTH Aachen University, I. Physikalisches Institut (IA), AG Biophysik, Aachen, Germany — [2]Forschungszentrum Jülich, ER-C-3 Structural Biology, Jülich, Germany

Protein folding and unfolding are crucial for cellular function and stability. This study emloys single-molecule Förster resonance energy transfer (smFRET) to investigate structural transitions in yeast phosphoglycerate kinase (yPGK). We focus on its two-domain structure and the relationship between the Rossmann-fold topology and folding intermediates. Earlier studies with full-length yPGK labelled with fluorescent dyes at multiple different positions allowed to map several different intra-molecular distances during unfolding transitions [1,2]. To mimic co-translational folding properties, we performed smFRET measurements with truncated yPGK fragments. The results are compared with those of full-length proteins, including whether the same type of unfolding transition occurs as in the full-length protein (e.g., two state transitions or compact intermediates). In addition, the results from truncated fragments are also compared with nascent-chain folding in ribosome-nascent chain complexes (RNCs), analyzed via cryo-electron microscopy. These methods provide insights into how domain topol-

ogy and neighboring structural elements influence multidomain protein folding.

Probing the dynamics of small unilamellar vesicles inside Synapsin pools using X-ray photon correlation spectroscopy — •Titus Czajka[1], András Major[1], Hendrik Bruns[1], Christian Hoffmann[2], Dragomir Milovanovic[2], and Tim Salditt[1] — [1]Georg-August-Universität Göttingen — [2]Deutsches Zentrum für Neurodegenerative Erkrankungen, Berlin

The dynamics of many subcellular biological processes are difficult to access directly with microscopic techniques due to the resolution limit. Length and time scales beyond those accessible by conventional light microscopy can be probed via X-ray photon correlation spectroscopy (XPCS), even in dense media, by analysing the intensity autocorrelation function at different scattering vectors. However, the low scattering cross section of dilute biological samples and the sensitivity to radiation damage complicate the application of XPCS to biological systems. We have coated silica nanoparticles with a lipid bilayer to improve the scattering strength and overcome these challenges. Using such colloid-supported lipid bilayers (CSLBs), we have studied the dynamics of small unilamellar vesicles within synapsin protein pools, a system that exhibits evidence of both liquid-like and network-like phases. Our results show distinct diffusion constants at varying protein concentrations and provide evidence for non-diffusive behaviour within the pools.

BP 30.8 Thu 17:15 H46

Novel sample delivery for small nanoparticles and biomolecules for cryo-em — •Kevin Janson[1], Armando D. Estillore[1], Jiri Wald[4,5,6], Madeline Memovich[1], Thomas Marlovits[4,5,6], Amit K. Samanta[1,3], and Jochen Küpper[1,2,3] — [1]Center for Free-Electron Laser Science, Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [2]Department of Physics, Universität Hamburg, Hamburg, Germany — [3]Center for Ultrafast Imaging, Universität Hamburg, Hamburg, Germany — [4]Centre for Structural Systems Biology, Hamburg, Germany — [5]Institute of Structural and Systems Biology, University Medical Centre Hamburg-Eppendorf, Hamburg, Germany — [6]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany

Cryo-electron microscopy (Cryo-EM) is one of the key techniques in the field of structural biology. Recent years brought considerable improvements both on the software and hardware of the microscopes, and resolving high-resolution structures of proteins has become a standard procedure. However, most cryo-EM grids are still prepared by plunge freezing, a technique developed about ~40 years ago. During this process, proteins can be exposed to the air-water interface, possibly causing a preferential orientation or damaging their structure. We present the novel freeze-and-deposit sample delivery approach to deposit particles for cryo-EM using cryogenic shockfreezing technology. The cooling process produces cold high-density beams of nanoparticles. In this process, nanoparticles and macromolecules are aerosolized and rapidly cooled in the gas phase using a cryogenic buffer-gas cell.

BP 30.9 Thu 17:30 H46

Laser flash melting restores native protein conformation after cryoEM preparation by soft-landing, native electrospray ion beam deposition. — Sarah V. Barrass[1], Tim K. Esser[2], Nathan J. Mowry[1], Lukas Eriksson[2], Jakub Hruby[1], Laurence Seeley[3], Marcel Drabbels[1], Lindsay Baker[3], •Stephan Rauschenbach[2], and Ulrich J. Lorenz[1] — [1]EPFL Lausanne — [2]Univ. of Oxford, Dept. of Chem.. — [3]Univ. of Oxford, Dept. of Biochem.

Electron cryo microscopy (cryoEM) is today the dominating method for protein structure determination. Samples for cryoEM consist of thin, freestanding layers of amorphous ice in which proteins are embedded. Conventionally, these samples are prepared by shock-freezing of thin water films held in grid holes.

Alternative sample preparation methods are being developed, as the plunge-freezing method is not compatible with all types of protein sample. One of these methods is electrospray ion beam deposition (ESIBD) where mass-selected proteins from the gas-phase are landed on a thin amorphous carbon film in vacuum and embedded in ice grown from the gas phase for imaging. Recently it was shown that this method yields atomically resolved protein structures characterised by small changes in ternary structure due to dehydration.

Here we show that the dehydration can be reversed by irradiating the sample with short laser pulses, effectively melting the ice for a short time, allowing the protein to recover the native conformation, before the ice rapidly re-vitrifies.

BP 30.10 Thu 17:45 H46

Native Electrospray Ion Beam Deposition for Atomic-level Structure Analysis of Membrane Protein — •Jingjin Fan, Tim Esser, Clare De'Ath, Lukas Eriksson, Abdul Aziz Qureshi, Abraham Abraham, Laurence Seeley, Lindsay Baker, Carol Robinson, and Stephan Rauschenbach — The Kavli Institute for Nanoscience Discovery, University of Oxford, Oxford OX1 3QU, United Kingdom

Membrane proteins play vital roles in cellular physiology, but their structural analysis remains challenging due to heterogeneity, flexible conformations, and demanding native conditions. To address these challenges, we established electrospray ion beam deposition (ESIBD) to directly couple native mass spectrometry (MS) with cryogenic electron microscopy (cryo-EM) for studying membrane protein structures.

Standard membrane proteins, including aquaporin Z (AqpZ) and ammonium transporter B (AmtB), were selected as testing models. By optimizing surfactant, the ion transfer in vacuum and the embedding of the proteins after landing we successfully manipulated membrane protein particles and achieved soft-landing on grids, evidenced by high-resolution imaging in cryoEM.

Our results demonstrate that the membrane structures can be preserved even in the absence of visible micelle.This molecular-level structural analysis captured by ESIBD in vacuum provides new insights into the correct folding of membrane proteins and understanding fundamental questions in structural biology.

Invited Talk BP 31.1 Fri 9:30 H44

Wave propagation in systems of active filaments — •Kirsty Y. Wan — Living Systems Institute, University of Exeter, UK

Active hair-like protrusions called cilia are found in many eukaryotes where they produce physiological flows for a variety of functions. Cilia assume a myriad of configurations both external to an organism for the purposes of feeding or swimming motility, but also internally where they mediate mucociliary clearance in vertebrate tissues. Single cilia can propagate large-amplitude non-decaying bending waves, even in the absence of a cell body. These waves assume a variety of stereotyped forms and frequencies, depending on the species. Multiple cilia also interact to produce different types of local and global coordination patterns, including robust metachronal waves. Do these dynamic states of coordination arise spontaneously, or do they require some form of internal control by the cell or animal? We propose new and emerging organisms to address these questions.

BP 31.2 Fri 10:00 H44

Metabolic activity controls the emergence of coherent flows in microbial suspensions — •Florian Böhme[1], Alexandros Fragkopoulos[1,2], Nicole Drewes[2], and Oliver Bäumchen[1,2] — [1]University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany — [2]Max Planck Institute for Dynamics and Self-Organization (MPIDS), 37077 Göttingen, Germany

Photosynthetic microbes have evolved and successfully adapted to the spatio-temporal variations of environmental parameters within their habitat. In the absence of light, they can still sustain their biological functionality and metabolic activity through aerobic respiration. However, for the soil-dwelling microalga *Chlamydomonas reinhardtii*, their environment may be deprived of both oxygen and light, resulting in a significant reduction of their swimming velocity [1]. Here, we study the effect of motility and cell density of *C. reinhardtii* in a confined system, on the emergence of bioconvection [2]. This collective phenomenon can be reversibly switched by light and arises due to the natural tendency of the bottom-heavy cells to move against gravity. We show that the rate at which the system evolves, as well as the dominant wavelength of the instability can both be directly controlled by the number density of cells. Further, we provide insights on the internal flow fields and density profiles of single bioconvection plumes for different parameters.

Tumbling *E.coli* in bulk and close to surfaces — •Pierre Martin[1], Tapan Chandra Adhyapak[2], and Holger Stark[1] — [1]Institute of Theoretical Physics, Hardenbergstr. 36, 10623 Berlin, Germany — [2]Indian institute of science education and research (IISER), Tirupati, India

Escherichia coli (*E. coli*) swims by rotating multiple flagella which are connected to the cell body forming a thick bundle. To change direction, *E. coli* performs tumble events by reversing the rotation of one or more flagella. The involved filaments undergo a series of polymorphic transformations, altering both their helicity and handedness. This complex phenomenon involves the interplay of semiflexible filaments and hydrodynamic flow fields.

Here, we have developed a detailed numerical framework to simulate *E. coli*, capturing the full dynamics of flexible flagella, including their polymorphism and their hydrodynamic interactions. The filaments and the cell body are embedded in a viscous fluid, which we model using multi-particle collision dynamics. We analyzed a large number of tumble events, with fixed tumble time or taken from a gamma distribution, exploring the roles of hook and flagellar flexibility as well as flagellar polymorphism. We find that they strongly influence the distribution of tumble angles. Finally, we also show that close to a flat surface the mean tumble angle is strongly shifted to smaller values. This indicates that tumble events may not be recognized, which could give the impression of suppressed tumbling near surfaces.

BP 31.4 Fri 10:30 H44

***Trypanosoma brucei* (un)chained - effects of confinement on a parasitic microswimmer** — •Hannes Wunderlich[1], Marinus Thein[2], Lucas Brehm[2], Klaus Ersfeld[2], and Matthias Weiss[1] — [1]Experimental Physics I, University of Bayreuth — [2]Laboratory of Molecular Parasitology, University of Bayreuth

Trypanosoma brucei is a parasitic unicellular microswimmer that causes the African sleeping sickness. An active spiral movement of the parasite, mediated by a microtubule-driven flagellum that wraps around the cell body, is mandatory to evade the host's immune system while exploring tissues and blood vessels. In addition, the nematic subpellicular micotubule array plays a pivotal role in the elasticity, propulsion, and navigation of the parasite. To study the features and mechanisms behind the cell's motion in such complex environments, we have mimicked spatial confinement in microfluidic devices with different geometries. Our data show that spatial constraints in narrow channels and channel networks can improve cell locomotion of wild-type trypanosomes, supposedly due to the interaction of the elastic cell body and nearby walls. The addition of microtubule-disrupting drugs or the use of mutant strains with altered post-translational modifications of microtubules resulted in significantly altered swimming velocities and marked changes in the intermittent switching between run and tumble phases. Shape analyses of individual cells suggest that microtubules in the sub-pellicular array, the corset that keeps trypanosomes in their native spindle-like shape, are most affected in these cases.

BP 31.5 Fri 10:45 H44

Micro-swimmer motility in presence of signaling factors — Agniva Datta, Robert Grossmann, and •Carsten Beta — Institute of Physics and Astronomy, University of Potsdam, Germany

The navigation of bacteria through aqueous environments, driven by the rotation of helical flagella, has been a significant region of interest in the biophysics community for the last few decades. In this study, we focus on the motility of our model organism, Pseudomonas putida, which exhibits persistent mobile episodes (Active Brownian motion) interrupted by stochastic reorientation events (turns), driven by flagellar self-propulsion, thereby leading to a run-and-turn motility.

Key motility parameters including tumbling rates, run lengths, trajectory persistence (rotational diffusion coefficient), and the characteristics of the self-propulsion force*are hypothesized to depend on the density of quorum-sensing autoinducer molecules, produced by the bacteria themselves as signaling factors. To test this hypothesis, we expose swimming bacteria to aqueous environments with controlled autoinducer concentrations and analyze the resulting changes in motility patterns. Through a combination of experimental data and theoretical modeling, we aim to elucidate the principles of micro-swimmer motility in presence of signaling molecules.

BP 31.6 Fri 11:00 H44

Collective dynamics of active dumbbells near a circular obstacle — •Chandranshu Tiwari[1] and Sunil Singh[2] — [1]Department of Physics, Indian Institute of Science Education and Research, Bhopal 462066, India. — [2]Department of Physics, Indian Institute of Science Education and Research, Bhopal 462066, India.

We present the collective dynamics of active dumbbells in the presence of a static circular obstacle using Brownian dynamics simulation. The active dumbbells aggregate on the surface of a circular obstacle beyond a critical radius, and the aggregate size increases with the activity and the curvature radius. The dense aggregate of active dumbbells displays persistent rotational motion with a certain angular speed, which linearly increases with activity. Furthermore, we show a strong polar ordering of the active dumbbells within the aggregate. The polar ordering exhibits long-range correlation, with the correlation length corresponding to the aggregate size. Additionally, we show that the residence time of an active dumbbell on the obstacle surface increases rapidly with area fraction due to many-body interactions that lead to a slowdown of the rotational diffusion. This article further considers the dynamical behavior of a tracer particle in the solution of active dumbbells. Interestingly, the speed of the passive tracer particle displays a crossover from monotonically decreasing to increasing with the size of the tracer particle upon increasing the dumbbells' speed. Furthermore, the effective diffusion of the tracer particle displays non-monotonic behavior with the area fraction; the initial increase in diffusivity is followed by a decrease for a larger area fraction.

BP 31.7 Fri 11:15 H44

Free growth under tension — •Chenyun Yao and Jens Elgeti — Forschungszentrum Jülich GmbH, Jülich, Germany

Ever since the ground breaking work of Trepat et al. in 2009, we know that cell colonies growing on a substrate can be under tensile mechanical stress. The origin of tension has so far been attributed to cellular motility forces being oriented outward of the colony. Works in the field mainly revolve around how this orientation of the forces can be explained, ranging from velocity alignment, self-sorting due to self-propulsion, to kenotaxis.

In this work, we demonstrate that tension in growing colonies can also be explained without cellular motility forces! Using a combination of well established tissue growth simulation technique and analytical modelling, we show how tension can arise as a consequence of simple mechanics of growing tissues. Combining these models with a minimalistic motility model shows how colonies can expand while under even larger tension. Furthermore, our results and analytical models provide novel analysis procedures to identify the underlying mechanics.

BP 31.8 Fri 11:45 H44

A route to active turbulence in circular activity spots — •Arghavan Partovifard and Holger Stark — Institute of Theoretical Physics, Institut für Theoretische Physik, Technische Universität Berlin, Hardenbergstr. 36, 10623Berlin, Germany.

Active nematics exhibit distinctive behavior such as active turbulence and regular flow patterns under spatially varying activity [1]. Utilizing the Doi-Edwards theory supplemented by an active stress tensor [1], we investigate active nematics confined to a circular spot by switching off activity outside the spot. The open boundary allows topological defects to enter and leave the spot.

We calculate the total topological defect charge inside the spot using three approaches: counting all defects, measuring the rotation of the director field along the rim of the spot, and integrating the diffusive charge density. All methods agree that for spot radii just larger than the nematic coherence length, the system has a total topological charge of +1, where two +1/2 defects perform a regular swirling motion. As the radius increases, more defects enter and their motion becomes more and more chaotic. Ultimately, the charge per unit area saturates at the value characteristic of bulk active turbulence. For the range of radii where the total charge in the spot is +1, the nematic director exhibits shear-induced anchoring at an angle of 45° with respect to the tangent at the spot rim. With increasing radius, when more defects enter, the anchoring angle deviates from 45° but its distribution still peaks around this value.

Cognitive flocks: order-disorder transitions and threat evasion — •Priyanka Iyer[1], Cecilia Soroco[2], and Gerhard Gompper[1] — [1]Forschungszentrum Jülich — [2]University of British Columbia, Canada

Directed self-propulsion is ubiquitous in living organisms. From E.Coli dispersing in biofilms to migrating bird flocks, living organisms are constantly out-of equilibrium. By sensing their environment and adjusting their movement, organisms can exhibit emergent patterns and collective behaviors, such as self-organization in human crowds [1], bird flocks, and fish schools. The Inertial Spin Model (ISM) was introduced to explain the fast and robust propagation of information in bird flocks [2], when only alignment interactions are considered. However, more generally, agents exhibit a variety of interactions like local avoidance, cohesion and threat evasion. We show how such behaviors can be incorporated within the framework of the ISM. It is found that local avoidance introduces emergent noise in the system, triggering an order-disorder transition. Exploring the flock dynamics near this transition reveals a complex interplay between cohesion, alignment, and local avoidance, resulting in diverse behaviors such as pronounced shape and density fluctuations, and diffusive motion of the flock. Lastly, by applying the model to a stationary threat scenario, we analyze flock properties that govern threat information propagation in the flock.

Myosin-independent amoeboid cell motility — •Winfried Schmidt, Alexander Farutin, and Chaouqi Misbah — Univ. Grenoble Alpes, CNRS, LIPhy, F-38000 Grenoble, France

Mammalian cell motility is essential for many physiological and pathological processes, such as the immune system, embryonic development, wound healing, and cancer metastasis. Cells have developed the amoeboid migration mode which allows them to move rapidly in a variety of different environments, including two-dimensional confinement, three-dimensional matrix, and bulk fluids. We introduce a model for an amoeboid cell where the cortex is described as a thin shell along the cell surface. The cell shape evolves due to polymerization of actin filaments and the forces acting on the cortex. We find analytically and numerically that the state of a resting, non-polarized cell can become unstable for

sufficiently large actin polymerization velocities, resulting in the spontaneous onset of cell polarity, migration, and dynamical shape changes. Notably, this transition only relies on actin polymerization and does not necessitate molecular motors, such as myosin. These findings yield a deeper understanding of the fundamental mechanisms of cell movement and simultaneously provide a simple mechanism for cell motility in diverse configurations.

BP 31.11 Fri 12:30 H44

Active membrane deformations of a synthetic cell-mimicking system — Alfredo Sciortino[1], •Dmitry Fedosov[2], Gerhard Gompper[2], and Andreas Bausch[1] — [1]Physik Department, Technische Universität München, Garching bei München, Germany — [2]Institute for Advanced Simulation, Forschungszentrum Jülich, Jülich, Germany

Biological cells are fascinating micromachines capable of adapting their shape due to the complex interaction between a deformable membrane and the dynamic activity of the cytoskeleton. We investigate the behavior of an active synthetic cell-mimicking system using simulations and experiments. In simulations, the model consists of a fluid vesicle with a few encapsulated growing filaments. In experiments, giant vesicles contain an active cytoskeletal network composed of microtubules, crosslinkers, and molecular motors. These active vesicles show strong shape fluctuations reminiscent of shape changes of biological cells. We analyze membrane fluctuations and show how the intricate coupling between soft confinement and internal active forces results in fluctuation spectra with distinct spatial and temporal scales, differing significantly from those of passive vesicles. Simulations demonstrate the universality of this behavior, quantifying the impact of correlated activity on the dynamics of membrane deformations. This model makes a step toward quantitative description of shape-morphing artificial and living systems.

Force Generation by Enhanced Diffusion in Enzyme-Loaded Vesicles — Eike Eberhard, •Ludwig Burger, Cesar Pastrana, Giovanni Giunta, and Ulrich Gerland — Physik komplexer Biosysteme, Technische Universität München, Deutschland

Recent experiments show that the diffusion coefficient of some metabolic enzymes increases with the concentration of their cognate substrate, a phenomenon known as enhanced diffusion. In the presence of substrate gradients, enhanced diffusion induces enzymatic drift, resulting in a non-homogeneous enzyme distribution. In this work, we study the behavior of enzyme-loaded vesicles exposed to external substrate gradients using a combination of computer simulations and analytical modeling. We observe that the spatially inhomogeneous enzyme profiles generated by enhanced diffusion result in a pressure gradient across the vesicle, which leads to macroscopically observable effects, such as deformation and self-propulsion of the vesicle. Our analytical model allows us to characterize dependence of the velocity of propulsion on experimentally tunable parameters. The effects predicted by our work provide an avenue for further validation of enhanced diffusion, and might be leveraged for the design of novel synthetic cargo transporters, such as targeted drug delivery systems.

From slabs to cubes: finite size effects in biomolecular simulations — •Rodrigo F. Dillenburg and Martin Girard — Max Planck Institute for Polymer Research, Mainz, Germany

Coarse-grained simulations of intrinsically disordered proteins have become essential to the study of biomolecular condensates. Multiple choices of force fields, simulations techniques and box geometries have been employed in such studies, assuming that results will converge due to the law of large numbers. This assumption is, however, not automatically valid for all systems and needs to be carefully examined to assure the validity of the results. In our work we focused on the choice of box geometry (cubic or slab) and statistical ensemble (canonical or grand-canonical) and its effect on the phase behavior of systems undergoing liquid-liquid phase separation. Our results allow us to estimate if a system can be approximated by the thermodynamic limit or if finite size effects have to be taken into consideration. We are able to derive expressions for these corrections depending on the choice of system and are also able to relate it to condensate properties such as surface tension. Our results provide a rational approach to selecting the most appropriate simulation methods for a given system.

Interactions of Imidazolium with Elastin-Like Polypeptides: A Molecular Dynamics Study — •Julia Keil and Nico F. A. van der Vegt — Technische Universität Darmstadt, Germany

Biological buffers are commonly used to adjust the pH value of protein solutions and are typically assumed not to affect other properties of the system.[1] However, a series of experimental observations suggest buffer-specific effects on protein stability.[2] Despite these findings, studies on these effects remain limited, and the underlying mechanisms are still poorly understood.[2-4]

We performed molecular dynamics simulations at constant pH[4] to investigate the interactions between the buffer imidazolium (IMI) and elastin-like polypeptides (ELPs) that contain chemically different amino acids at their variable positions. Our analyses revealed a local accumulation of imidazole (IMI^{o}) around the ELPs and its hydrogen bonding to the ELP backbone, regardless of the ELP composition. In contrast, interactions with imidazolium (IMI^{+}) were found to depend on the ELP composition. A strong local accumulation of IMI^{+} was observed around ELPs containing negatively charged groups, accompanied by hydrogen bonding to their side chains. Conversely, local depletion of IMI^{+} occurred around ELPs with positively charged groups. As a result, the interactions of ELPs with IMI are determined by the specific composition of the ELPs.

BP 32.3 Fri 10:00 H46

Graphite-based Bio-mimetic Nanopores for Protein Sequencing and Beyond — •Chandan K. Das and Maria Fyta — Computational Biotechnology, RWTH Aachen University, Aachen, Germany

Protein sequencing via nanopores offers a transformative approach to bioanalytics, but challenges remain, particularly in linearizing unfolded proteins and controlling translocation speed through solid-state nanopores. This study introduces a novel solution: biomimetic graphite-based nanopores designed with nanometer-sized pores featuring a constriction zone inspired by the alpha-hemolysin protein pore. All-atom molecular dynamics simulations demonstrate the nanopores' ability to achieve ion selectivity and generate electro-osmotic flow (EOF) within the pore lumen due to tailored surface charges. This innovation enables the detection of peptides at the single amino acid level by analyzing ionic current fluctuations during peptide translocation. A critical feature of this design is its capacity to balance hydrodynamic drag, induced by EOF, with electrophoretic force (EPF), facilitating peptide linearization and extending amino acid residence time within the constriction zone. These advancements significantly enhance sequencing resolution and accuracy. Beyond protein sequencing, this technology holds potential for diverse applications, including seawater desalination via electrodialysis and renewable energy generation through salinity gradient-driven ion separation. By providing a robust computational foundation, this study advances the development of graphite-based biomimetic nanopores, offering versatile solutions for bio/nanotechnological challenges and sustainable energy innovations.

BP 32.4 Fri 10:15 H46

Helical transition of protein chain: An in silico study — •tika ram bhandari and martin girard — Max Planck Institute for Polymer Research, Mainz, Germany

Structural transformations in biomolecular systems are critical for physiological functions, with folding and unfolding transitions governing numerous cellular activities. Misfolding of proteins, however, is a key factor in the onset of severe diseases, emphasizing the need for comprehensive studies to understand and control these processes. Computational simulations provide valuable insights into such mechanisms. Here, we employed coarse-grained molecular simulations coupled with Hamiltonian Replica Exchange method to investigate the disordered-to-helical transition of IM30, the bacterial counterpart of the ESCRT-III. By systematically varying the strength of hydrogen bonds, we simulated an in-silico denaturation process, enabling a detailed analysis of the structural properties underlying this transition. Furthermore, we explore the impact of point mutations on the protein's helical propensity using free energy calculations. These approaches provide a deeper understanding of the molecular mechanisms influencing folding behavior and highlights the role of specific mutations in modulating protein structure.

BP 32.5 Fri 10:30 H46

Towards modeling cellular environments from cryo-electron tomography by high-confidence 3D template matching — •Sergio Cruz-León, Jan Philipp Kreysing, Maziar Heidari, Beata Turoňová, Martin Beck, and Gerhard Hummer — Max Planck Institute of Biophysics, Max-von-Laue-Str. 3, 60438, Frankfurt am Main, Germany

The simulation of biologically realistic systems requires precise knowledge of the composition and spatial arrangement of biomolecules in situ. This informa-

tion can be obtained from cryo-electron tomography (cryoET), which images the interior of intact cells in 3D. However, feature identification is limited by the low signal-to-noise ratio and anisotropic resolution of the tomographic data. In this talk, I will present our recent advances in high-confidence 3D template matching (hcTM) for cryoET [1] and how we use hcTM to generate simulation-ready molecular models directly from cells [1,2]. hcTM enables the automated and comprehensive detection of a wide variety of macromolecular complexes within crowded eukaryotic cells. The high-confidence molecular assignments have driven both technical advances [3] and biological discoveries [1,2], fostering robust connections between molecular functionality, spatial localization, and cellular context. Thus, hcTM paves the way for modeling and simulating the dynamics of biomolecules in their native environment.

BP 32.6 Fri 10:45 H46

Membrane insertion and channel formation of alpha-latrotoxins — •Andreas Heuer[1], Azadeh Alavizargar[1], Björn U. Klink[2,3], and Cristos Gatsogiannis[2,3] — [1]Institute for Physical Chemistry, University of Münster, Germany — [2]Center for Soft Nanoscience (SoN), University of Münster — [3]Institute for Medical Physics and Biophysics

Latrotoxins are the main toxic component of the venom of black widow spiders. It is known that the they provide ion channels in the plasma membrane, allowing, e.g., for a strong influx of Ca2+ ions which may induce a burst of neurotransmitters. Despite its importance, microscopic information about the microscopic structure of latroxin pore formation remained elusive.

In this presentation it is shown how detailed information can be gained by a combination of cryoEM, AlphaFold and Molecular Dynamics (MD) simulations [1]. From this analysis we can identify a unique mechanism of membrane insertion and channel formation for the example of Na+ and Ca2+ transport. From the MD simulations it is possible, e.g., to elucidate the efficiency and the time-scales of the transport processes and to show why the channel is efficient in transporting mono- and divalent ions but not trivalent ions.

BP 32.7 Fri 11:00 H46

Understanding the impact of functionalized gold nanoparticles (AuNPs) on the lipid bilayer and interfacial water through atomistic molecular dynamics simulations — •Haifa Al Mamari, Srinivasa Varanasi, and Issam Ali — Sultan Qaboos University, Department of Physics

Functionalized gold nanoparticles (AuNPs) show promise as drug delivery systems due to their customizable size, shape, biocompatibility, and surface modifications. However, crossing cell membrane barriers is a challenge, requiring efficient penetration for effective drug delivery. Interfacial water and ions play a crucial role in the interaction between AuNPs and bilayers, making it essential to understand the structural and orientational effects on lipid bilayers. This study explores how nanoparticle surface charge and lipid chemistry impact AuNP-lipid bilayer interactions, focusing on anionic (carboxylate) and cationic (quaternary ammonium) AuNPs with zwitterionic (DPPC), anionic (DPPG), and cationic (DPTAP) bilayers using molecular dynamics simulations.Our analysis shows that AuNPs significantly alter bilayer properties, impacting the area per lipid, membrane thickness, acyl chain order, electrostatic potential, dipole alignment, and head and tail tilt angles. These changes enhance water dipole alignment and modify electrostatic potentials, depending on the nanoparticles surface charge. These insights emphasize AuNPs' potential to reshape membrane properties, providing valuable guidance for nanoparticle-based therapeutic development.

BP 32.8 Fri 11:30 H46

Swimming by spinning: spinning-top type rotations regularize sperm swimming into persistently progressive paths in 3D — •Xiaomeng Ren and Hermes Bloomfield-Gadêlha — School of Engineering Mathematics & Bristol Robotics Laboratory, University of Bristol, BS8 1UB Bristol, UK

Sperm swimming is essential for reproduction, with movement strategies adapted to specific environments. Sperm navigate by modulating the symmetry of their flagellar beating, but how they swim forward with asymmetrical beats remains unclear. Current methods lack the ability to robustly detect the flagellar symmetry state in free-swimming spermatozoa, despite its importance in understanding sperm motility. This study uses numerical simulations to investigate the fluid mechanics of sperm swimming with asymmetrical flagellar beats. Results show that sperm rotation regularizes the swimming motion, allowing persistently progressive swimming even with asymmetrical flagellar beats. Crucially, 3D sperm head orientation, rather than the swimming path, provides critical insight into the flagellar symmetry state. Sperm rotations during swimming closely resemble spinning-top dynamics, with sperm head precession driven by the helical beating of the flagellum. These results may prove essential in future studies on the role of symmetry in microorganisms and artificial swimmers, as body orientation detection has been largely overlooked in favor of swimming path analysis. Altogether, this rotational mechanism provides a reliable solution for forward propulsion and navigation in nature, which would otherwise be challenging for flagella with broken symmetry.

BP 32.9 Fri 11:45 H46

Simulating Trypanosome Motility — •Florian Overberg, Gerhard Gompper, and Dmitry Fedosov — Theoretical Physics of Living Matter, Institute for Advanced Simulation, Forschungszentrum Jülich, 52428 Jülich, Germany

We investigate motility of the protozoan Trypanosoma brucei via numerical simulations, in which a trypanosome model is informed by experimental observations. The cell body is represented by a set of vertices distributed homogeneously on a pre-defined elongated surface, forming a triangulated elastic network of springs. This network model incorporates bending rigidity, area conservation, and volume conservation constraints. For the generation of propulsion, a flagellum is attached to the cell body. The flagellum consists of four parallel filaments, two of which are embedded in the body and used for generating a propagating bending wave. We examine the parasite behavior for various conditions, including different flagellum and body stiffnesses, beating frequencies, actuation wavelengths, and amplitudes. Our simulations yield swimming velocities and rotation frequencies around the swimming axis that are in a good agreement with experimental measurements. Additionally, we investigate the importance of various actuation characteristics, such as orientation of the beating plane and the stress-free conformation of the flagellum. We have also started to study parasite motility in a stationary blood suspension, which serves as a first step to understand trypanosome behavior in one of its natural environments such as blood vasculature.

BP 32.10 Fri 12:00 H46

Leveraging quantum data to advance machine-learning in (bio)molecular simulations — •Leonardo Medrano Sandonas[1], Mirela Puleva[2], Gianaurelio Cuniberti[1], and Alexandre Tkatchenko[2] — [1]TUD Dresden University of Technology, Germany. — [2]University of Luxembourg, Luxembourg.

The rapid advancement of machine learning (ML) applications in chemistry and physics has been driven by the increasing availability of comprehensive quantum-mechanical (QM) datasets. Recently, we introduced high-fidelity property data at the PBE0+MBD level of theory for both small [Sci. Data 8, 43, (2021)] and large [Sci. Data 11, 742, (2024)] drug-like molecules in equilibrium and non-equilibrium states. These datasets have been instrumental in advancing QM-based ML interatomic potentials [10.26434/chemrxiv-2024-bdfr0, (2024)] and enhancing semi-empirical (SE) methods [J. Phys. Chem. Lett., 11, 6835 (2020)], enabling accurate (bio)molecular simulations. In this presentation, we will discuss our recent efforts to improve the transferability and generalizability of the ML-corrected density functional tight-binding method. We demonstrate that equivariant neural networks significantly enhance the accuracy and scalability of ML-based many-body repulsive potentials trained on energies and forces of small organic systems. This approach facilitates the investigation of the energetic and structural properties of large drug-like molecules and molecular dimers. Hence, our findings indicate that combining ML with SE methods achieves both high accuracy and computational efficiency, paving the way for diverse applications in (bio)molecular simulations.

BP 32.11 Fri 12:15 H46

Calibrating 1D-0D Coupled Blood Flow Models: the potential of Neural Network based Surrogates — •Benedikt Hoock[1,2] and Tobias Köppl[3] — [1]Technische Universität München, School of Computation, Information and Technology — [2]Support by Computing Facilities of Leibniz-Rechenzentrum München — [3]Fraunhofer-Institut FOKUS, Berlin

Hydrodynamic models of the human arterial network can simulate the blood flow in parts or the whole body. The calculations can be simplified by solving the incompressible one-dimensional Navier-Stokes equations only for a set of larger vessels and coupling those at their outlets to a Windkessel model (*1D-0D approach*). Here, the right parametrization of the Windkessel parameters, i.e., the resistances and capacities, is crucial to obtaining realistic simulations. This can be done by calibrating the model parameters to match the model predictions with in-vivo blood pressure measurements. Since this requires many computationally expensive model evaluations, we test the potential of surrogates based on neural networks (NN). Once set up in an appropriate architecture, already ordinary fully connected NNs of moderate depth and width two can reproduce the simulations with high accuracy, advancing over e. g. the PINN approach due to their better trainability. We use these in an optimization algorithm to identify the target resistance and capacity with high precision in several test cases. Our efficient calibration scheme is an essential building block for an instantaneous visualization of the organ perfusion in a digital twin of a patient under different motion conditions on a digital treadmill.

BP 32.12 Fri 12:30 H46

MolecuTas: an ML platform for refining quantum properties and bioactivity of complex molecules — •Vicente Domínguez Arca[1,2], Jannis Krüger[2], Álvaro Vallejo Bay[3], Thomas Hellweg[2], and Luis Taboada Antelo[1] — [1]Biosystem and Bioprocesses Engineering, IIM-CSIC, Spain — [2]Physical and Biophysical Chemistry, Bielefeld University, Germany — [3]Applied Physics, University of Santiago de Compostela, Spain

The integration of machine learning (ML) and computational chemistry enables efficient prediction of quantum properties for complex molecules, crucial for advancing drug discovery and materials science. Our ML platform leverages Graph Convolutional Neural Networks (GCNNs) and the "sliding window" methodology to predict quantum mechanical parameters like partial atomic charges, overcoming traditional ab initio constraints. This approach scales to larger, biologically relevant molecules, enhancing molecular dynamics simulations and rational drug design.

Focusing on marine saponins -complex thalassochemicals with unique sulfated glycoside structures- our platform improves charge distribution predictions, enabling precise simulations of bioactive interactions. These advances highlight the therapeutic potential of marine saponins in oncology, lipid metabolism, and immune modulation. By applying our platform to marine saponins, this research bridges computational and experimental workflows, fostering the discovery of novel thalassochemicals for applications in functional foods, pharmaceuticals, and sustainability.

BP 32.13 Fri 12:45 H46

Ab-initio optimization and AI-powered inference for parametrizing complex biological models under low data availability — •Thomas R. Sokolowski — Frankfurt Institute for Advanced Studies (FIAS), Ruth-Moufang-Str. 1, 60438 Frankfurt am Main, Germany

Early development unfolds under diverse circumstances and time scales, but always facing the impacts of inevitable biological noise. To cope with this, various developmental mechanisms evolved, with their differences shaped by physical and environmental constraints. In spite of decades of research, we still lack theories that explain these processes truly mechanistically. Increasing computational power allows for constructing developmental models with increasing complexity, but since corresponding experimental data is scarce, the parametrization of such models becomes a key problem itself. I will contrast two strategies for parametrizing biophysical models in development and beyond: optimization of normative theories, and Bayesian inference. I will present a framework that unifies both strategies in a mathematically rigorous fashion and enables quantitative transition between them. I will then present our results combining both strategies for understanding embryogenesis in two organisms: (1.) optimization of a spatial-stochastic model of the gap gene system in Drosophila, and (2.) elucidation of robust cell-fate assignment in early mouse embryogenesis via AI-powered simulation-based inference (SBI). Our results highlight distinct developmental strategies that emerged under the different circumstances faced by the two organisms.

BP 33: Focus Session Chemical Imaging for the Elucidation of Molecular Structure II (joint session O/BP)

Unravelling the multiscale molecular heterogeneity at interfaces is one of the main challenges in modern biophysics and surface science due to the major role specific structural properties play in determining their macroscopic function and behavior. In the last few decades, several specialized chemical imaging techniques have been developed that can reveal many of these crucial structural details, representing an enormous advance in our elucidative capabilities. Clear examples of this range from super-resolution and 3D tomography to tag-free characterization down to the single-molecule level. This focus session will explore the vast range of methods and possibilities for characterizing the different structural aspects in heterogeneous molecular systems and specifically highlight the potential complementarity of the different techniques through multi-modal approaches. Overall, by bringing together different communities, this session aims to foster scientific exchanges that could spark the next major developments in chemical imaging.

Organized by
Martin Thämer (FHI Berlin), Alexander Fellows (FHI Berlin), and Kerstin Blank (University Linz)

Time: Friday 10:30–12:45 Location: H24

Invited Talk BP 33.1 Fri 10:30 H24

Multidimensional Super-resolution Imaging: Wasting Light to Learn New Things — •Steven Lee — University of Cambridge

The talk will outline two single-molecule fluorescence approaches that can be used to determine orthogonal metrics about a single emitter.

The first half introduces "POLCAM," a simplified single-molecule orientation localization microscopy (SMOLM) method based on polarised detection using a polarisation camera. POLCAM's fast algorithm operates over 1000 times faster than the current state-of-the-art, allowing near-instant determination of molecular anisotropy. To aid adoption, open-source image analysis software and visualization tools were developed. POLCAM's potential was demonstrated in studying alpha-synuclein fibrils and the actin cytoskeleton of mammalian cells. (Nature Methods 2024). The second approach focuses on "Single-Molecule Light Field Microscopy" (SMLFM), encoding 3D positions into 2D images for volumetric super-resolution microscopy. SMLFM shows an order-of-magnitude speed improvement over other 3D PSFs, resolving overlapping emitters through parallax. Experimental results reveal high accuracy and sensitivity in point detection, enabling whole-cell imaging of single membrane proteins in live primary B cells and high-density volumetric imaging in dense cytosolic tubulin datasets. (Nature Comms 2024)

Invited Talk BP 33.2 Fri 11:00 H24

MALDI mass spectrometry imaging: application examples ranging from food analysis to pharmaceutical research — •Andreas Römpp — Bioanalytical Sciences and Food Analysis, University of Bayreuth, Bayreuth, Germany

Mass spectrometry imaging is an analytical technique that provides spatially-resolved molecular information for a wide range of compound classes. In contrast to many histological methods, it does not require labeling. The capabilities and limitations of MS imaging will be discussed on the basis of several application areas with a focus on food analysis and pharmaceutical research. In our study 'MALDI mass spectrometry imaging: from constituents in fresh food to ingredients, contaminants and additives in processed food' (https://doi.org/10.1016/j.foodchem.2022.132529) we analyzed a range of plant-based and meat-based food. The analysis of natamycin in cheese and acrylamide in gingerbread constitute the first mass spectrometry imaging measurements of a food additive and a food contaminant, respectively. MS imaging is the only method that can analyze the distribution of drug compounds in animal models or human tissue (without labeling). This is exemplified on the detection of antituberculosis drugs in mouse model tissue including our most recent study on the clinical stage antibiotic BTZ-043 which has just been accepted for publication in Nature Communications (https://doi.org/10.1038/s41467-025-56146-9).

BP 33.3 Fri 11:30 H24

On-Surface Synthesis and Characterization of a Nitrogen-Containing Heterocycle — •Marco Thaler[1], Ricardo Ruvalcaba Briones[2], Matthias Zeilerbauer[1], Shadi Fatayer[2], and Laerte Patera[1] — [1]University of Innsbruck, Austria — [2]King Abdullah University of Science and Technology, Thuwal, Saudi Arabia

Nitrogen-containing heterocycles are fundamental building blocks in nature, forming the core of essential biomolecules and pharmaceuticals. This study demonstrates the on-surface formation of an N-heterocyclic organic compound via thermal activation of a tailored precursor. High-resolution non-contact atomic force microscopy (nc-AFM) provides bond-level resolution of the synthesized structures. Complementary scanning tunneling spectroscopy visualizes changes in the electronic structure resulting from the formation of the heterocycle. Density functional theory calculations (DFT) reveal the most probable reaction mechanism, highlighting the critical role of hydrogen release as the driving force of the reaction. These findings emphasize the versatility of on-surface synthesis as a powerful tool for creating complex organic compounds.

BP 33.4 Fri 11:45 H24

Elasticity Mapping of Nonahelicene with Submolecular Resolution by NC-AFM — •Max Halbauer[1], Takashi Kumagai[2], Martin Wolf[1], and Akitoshi Shiotari[1] — [1]Fritz-Haber-Institute, Faradayweg 4-6, 14195 Berlin, Germany — [2]Institute for Molecular Science, 38 NishigoNaka, Myo-daiji, Okazaki 444-8585, Japan

Controlled modification of atomic configurations of molecules and materials is an exciting goal for non-contact atomic force microscopy (NC-AFM). Certain changes like shifts of the electronic energy gaps may be expected, but are not well explored and not established on the molecular scale. Here we report quantitative measurement of atomic-scale deformation in single molecules with NC-AFM. Individual molecules of nonahelicene ([9]H) and coronene (Cor) were studied on a Ag(110) surface under ultrahigh vacuum and cryogenic conditions by the measurement of frequency-shift distance curves for this. The molecular responses can be replicated with an empirical Lennard-Jones model, but for [9]H an elastic contribution is required to account for its elastic nature. Furthermore, a 3D-force mapping technique, termed molecular deformation mapping (MDM), allows to study the lateral position dependence of the elastic response. The MDM of [9]H reveals a spatially strongly anisotropic behaviour for the elasticity, interaction forces, elongation and binding energy of the tip to the molecule. The result is rationalized in terms of an aromaticity model.

BP 33.5 Fri 12:00 H24

Detection and control of quantum proton ordering in hydrogen bonds at the atomic scale — •Yiqi Zhang — Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China

Directly probing the spatial arrangements and quantum nature of protons in hydrogen-bonded (H-bonded) materials and biosystems is the key to understand their macroscopic properties and functions. Here, exploiting bond-resolved atomic force spectroscopy (BR-AFS) combined with path-integral molecular dynamics method, we demonstrate for the first time that BR-AFS measurements along the apparent H-bond between proton donor and acceptor atoms allows the identification of both classical H-bonds with inherent directionality and non-classical H-bonds with quantum proton delocalization in self-assembled imidazole derivatives on surfaces. Unlike the conventional unidirectional H-bonding in linear chains, chiral cyclic hexamers exhibit unique quantum proton ordering in their ground states, which contain a mix of classical and non-classical H-bonds, breaking rotational symmetry. Furthermore, we show the capability to switch the quantum-proton-ordering state on and off by altering the adsorption registry coupled with a collective transfer of six protons within the cyclic H-bonds. These findings open new pathways for detecting and controlling complex proton orders and for engineering proton-based quantum states with atomic-level precision.

BP 33.6 Fri 12:15 H24

Imaging of the conformations of individual β-cyclodextrins with non-contact AFM — Marko Grabarics[1], •Benjamin Mallada[1,2,3], Shayan Edalatmanesh[2,3], Stephan Rauschenbach[1], Pavel Jelinek[2,3], and Bruno de la Torre[2] — [1]Kavli Institute for Nanoscience Discovery, University of Oxford, UK — [2]CATRIN, Palacký University Olomouc, CZ — [3]Institute of Physics, Czech Academy of Sciences, CZ

Glycans, biopolymers essential to biology and materials science, are highly complex due to their structural diversity, conformational flexibility, and numerous possible isomers. Conventional methods often struggle to resolve these structures with atomic precision, especially under solvent-free conditions. We employ nc-AFM under UHV to determine the atomic structure of β-cyclodextrin (β-CD), a cyclic glucose molecule.

Our results reveal the adsorption geometries, hydroxy group positions, and stabilizing hydrogen bonds on a Au(111) surface. The primary face forms a closed hydrogen-bond network, while the secondary face exhibits pairwise interactions between OH groups of the same glucose monomer. DFT calculations validate these findings, enabling precise structural assignment and capturing subtle conformational differences.

This work highlights nc-AFM's capability to overcome the limitations of conventional sequencing techniques and represents the first application of nc-AFM to glycans. Future integration with ion deposition techniques could extend its utility to more complex glycans.

BP 33.7 Fri 12:30 H24

Domain size effects in the spectra of micro-heterogeneous samples — •Thomas Mayerhöfer[1,2] and Jürgen Popp[1,2] — [1]Leibniz Institute of Photonic Technology (IPHT), Albert-Einstein-Str. 9, 07745 Jena, Germany — [2]Institute of Physical Chemistry and Abbe Center of Photonics, Friedrich Schiller University, Helmholtzweg 4, 07743 Jena, Germany

Samples are often not composed of a single pure compound but are instead mixtures of different substances. Under the Bouguer-Beer-Lambert approximation, the absorbance spectra of such mixtures can be simply derived by summing the spectra of the individual components, with each spectrum weighted by the molar fraction of the corresponding compound.

In the context of wave optics, the resolving power of light at a given wavelength becomes crucial. If a microscope using light at this wavelength can distinguish structural details within the sample, the sample is classified as micro-heterogeneous. In this case, spatial averaging occurs at the intensity level, involving reflectance and transmittance rather than absorbance.

The shift from micro-heterogeneity to macro-heterogeneity is gradual and cannot be described by an analytical formula due to the wave nature of light. This has significant implications for spectrum interpretation, as it can lead to substantial variations in peak shapes, positions, and intensities, e.g., during mitosis.

BP 34: Statistical Physics in Biological Systems II (joint session DY/BP)

Time: Friday 11:30–13:00 Location: H43

Invited Talk BP 34.1 Fri 11:30 H43

Equilibrium and non-equilibrium dynamics of biological systems with memory — •Roland Netz — Freie Universität Berlin, Fachbereich Physik, Berlin

Biological systems are many-body systems. Thus, their dynamics, when described in terms of a low-dimensional reaction coordinate, is governed by the generalized Langevin equation (GLE), an integro-differential equation of motion which contains friction memory [1]. Two examples will be discussed:

Protein-folding kinetics is standardly described as Markovian (i.e., memoryless) diffusion in a one-dimensional free-energy landscape. By analysis of molecular-dynamics simulation trajectories of fast-folding proteins the friction is demonstrated to exhibit significant memory with a decay time of the same order as the folding and unfolding times [2,3,4]. Memory friction leads to anomalous and drastically modified protein kinetics: the folding and unfolding times are not dominated by free-energy barriers but rather by non-Markovian friction.

Active motion of organisms obviously is far from equilibrium. The parameters of an appropriate non-equilibrium GLE are extracted from trajectories. It is demonstrated that the motion of single-cellular algae is characterized by pronounced memory friction, which allows to classify and sort individual cells.

[1] Memory and Friction: From the Nanoscale to the Macroscale, BA Dalton, A Klimek, H Kiefer, F N Brünig, H Colinet, L Tepper, A Abbasi, RR Netz, https://arxiv.org/pdf/2410.22588

BP 34.2 Fri 12:00 H43

Mean transient drift of synaptic weights in feed-forward spiking neural networks with spike-timing-dependent plasticity — •Jakob Stubenrauch and Benjamin Lindner — BCCN Berlin and Physics Department HU Berlin, Germany

Spike-timing dependent plasticity (STDP) [1] is a phenomenological model for the dynamics of single synaptic weights. This concise microscopic (single-synapse) description allows for the derivation of macroscopic network theories, capturing for instance learning, forgetting, and representational drift.

For the development of such theories it is important to characterize the stochastic process of synaptic weights. Early attempts capture this process for Poissonian presynaptic spikes and conditionally Poissonian postsynaptic spikes [2]. However, since STDP depends on fine spike-timing differences below 20 ms [1], it is important to characterize the synaptic dynamics for neuron models that describe the fast response mechanistically.

Leveraging a recent theory [3] as well as established results for the leaky integrate-and-fire neuron [4,5], we analytically compute the drift and diffusion of feed-forward synapses in a setup where a layer of presynaptic Poisson processes feeds into a recurrent network of leaky integrate-and-fire neurons.

[1] Bi and Poo, J. Neurisci. (1998) [2] Kempter et al., Phys. Rev. E (1999) [3] Stubenrauch and Lindner, Phys. Rev. X (2024) [4] Brunel et al., Phys. Rev. Lett. (2001) [5] Lindner and Schimansky-Geier, Phys. Rev. Lett. (2001)

BP 34.3 Fri 12:15 H43

A Biophysical Model for Temperature-Sensitivity of Neurons — •Julian Voits[1], Wojciech Ambroziak[2,3], Jan Siemens[2,4], and Ulrich S. Schwarz[1,5] — [1]Institute for Theoretical Physics, University of Heidelberg, Germany — [2]Department of Pharmacology, University of Heidelberg, Germany — [3]Department of Translational Disease Understanding, Grünenthal GmbH, Aachen, Germany — [4]Molecular Medicine Partnership Unit (MMPU), European Molecular Biology Laboratory (EMBL), Heidelberg, Germany — [5]BioQuant-Center for Quantitative Biology, University of Heidelberg, Germany

Control of body temperature is essential for our well-being and especially important during periods of fever or heat acclimation, e.g. due to traveling or climate change. An essential element of body temperature control are temperature-sensitive neurons, particularly warm-sensitive ones in the preoptic area of the hypothalamus. Since the discovery of temperature-sensitive ion channels, it has become clear that the underlying molecular mechanisms are rather diverse. In this work, we introduce a mathematical model based on a reduced version of the Hodgkin-Huxley model that can predict the frequently observed linear dependence of spiking rates on temperature in warm-sensitive neurons. Additionally, we present data showing how neurons adapt to varying temperatures over time, along with evidence of hysteresis in many temperature-sensitive neurons.

BP 34.4 Fri 12:30 H43

Position-Dependent Non-Markovian Effects Improve Protein Folding Simulations — •Lucas Tepper, Cihan Ayaz, Benjamin Dalton, and Roland Nezt — Freie Universität Berlin

It's common to project a protein's full atomic resolution onto a one-dimensional reaction coordinate to capture key aspects of its folding process. As a direct consequence of this dimensionality reduction, non-Markovian memory effects emerge. Accounting for memory effects in the framework of the generalized Langevin equation (GLE) with linear friction has proven efficient, accurate and insightful. However, recent advances in deriving GLEs with non-linear, position-dependent friction kernels raise questions about their applicability to protein folding simulations. We derive a novel method to extract position-dependent friction kernels from time series data via conditional Volterra equations. When applied to two protein test systems, the position- and time-dependent friction is strongest for long memory times in the folded states, where atoms are tightly packed. Additionally, we propose a novel and numerically efficient GLE simulation setup, confirming the accuracy of the extracted kernels. Compared to linear friction GLE simulations, our results show that position-dependent non-Markovian effects are critical for accurately reproducing protein folding kinetics when using low-dimensional reaction coordinates.

BP 34.5 Fri 12:45 H43

Multicomponent mixtures exhibit a vast nucleation-and-growth regime — •Yicheng Qiang, Chengjie Luo, and David Zwicker — Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, 37077 Göttingen, Germany

Phase coexistence is crucial for understanding how cells regulate biomolecular condensates. Despite of the multicomponent and multiphase nature of such condensates, the direct study of coexisting phases is limited to only few components since the parameter space is high-dimensional. So far, no theory provides a direct and concrete estimation of the phase coexistence behavior of multicomponent mixtures. As a first-level description of multicomponent phase behavior, we derive scaling relations for the number of coexisting phases in typical multicomponent mixtures in equilibrium. The scaling relations reveal that the interactions required to have many coexisting phases only scales very weakly with the number of components, whereas the stability analysis of the homogeneous state suggests a much stronger scaling. This discrepancy implies that large parts of the phase diagram of multicomponent mixture are in the nucleation-and-growth regime, where the homogeneous state is locally stable while multiple coexisting phases are preferred energetically. This suggests that multicomponent mixtures can achieve versatility and controllability in phase behavior with moderate interactions, which might be utilized by cells to create or destroy biomolecular condensates.

BP 35: Closing Talk (joint session BP/CPP/DY)

Time: Friday 13:15–14:00 Location: H2

Invited Talk BP 35.1 Fri 13:15 H2

Active control of forces, movement and shape: from biological to non-living systems — •Ulrich S. Schwarz — Heidelberg University, Heidelberg, Germany

Animal cells are highly dynamic and continuously generate force, for example for division, migration and mechanosensing. Their main force generators are myosin II molecular motors, whose activity is precisely controlled by biochemical circuitry. We first discuss how this system can be hijacked by optogenetics, thus that cellular force generation can be controlled in time and space using light. Next, we use active gel theory combined with van der Waals theory for myosin II molecules to demonstrate that cell contractility is sufficient to explain cell migration and that optogenetics can be used to initiate and revert migration. For two myosin II species, we predict the possibility of oscillations. We then move up in scale and analyze force generation in intestinal organoids, which are epithelia with the topology of a sphere. Combining experimental data, image processing and the bubbly vertex model, we show how apico-basal asymmetries can lead to cell extrusion and budding. We finally discuss how force generation and shape changes can be achieved in non-living systems, in particular for nematic elastomers, in which the direction of contraction is imprinted during polymerization and actuation is achieved by temperature control.

Overview of Invited Talks and Sessions

(Lecture halls H34, H38, and H46; Poster P3 and P4)

Invited Talks

CPP 1.1	Mon	9:30–10:00	H34	**Impact of smallest loops and composition fluctuations on the structure of end-linked polymer model networks** — •Michael Lang, Reinhard Scholz, Toni Müller
CPP 5.1	Mon	11:30–12:00	H38	**Theoretical characterization of sulfur/carbon copolymer cathodes for next-generation batteries via *ab initio* spectroscopy simulations** — •Daniel Sebastiani, Pouya Partovi-Azar
CPP 8.1	Mon	15:00–15:30	H38	**The Nanoscale Photovoltaics Laboratory on a Tip** — •Stefan Weber
CPP 16.1	Tue	9:30–10:00	H34	**Multifunctional structural batteries** — •Göran Lindbergh
CPP 17.1	Tue	9:30–10:00	H38	**Continuum models for water's peculiar behavior on the nanoscale** — •Alexander Schlaich
CPP 18.1	Tue	9:30–10:00	H46	**Hybrid materials from colloidally stable nanocellulose and nanoparticles - scattering techniques are needed for characterization** — •Eva Malmström, Åsa Jerlhagen, Benedikt Sochor, Korneliya Gordeyeva, Stephan Roth
CPP 20.1	Tue	11:30–12:00	H38	**Tailored polymer thin films enabled by initiated chemical vapor deposition (iCVD): From fundamentals to functional applications** — •Stefan Schröder
CPP 23.1	Wed	9:30–10:00	H34	**Advanced combined rheometer setups to in-situ correlate molecular dynamics and molecular structure formation with mechanical properties** — •Manfred Wilhelm
CPP 26.1	Wed	11:30–12:00	H34	**Polyelectrolytes in the confined space of mesopores for transport regulation** — •Annette Andrieu-Brunsen
CPP 30.1	Wed	16:15–16:45	H34	**Challenges and Opportunities in Bringing Machine Learning to a Synchrotron** — •Alexander Hexemer, Tanny Chavez, Wiebke Köpp, Dylan McReynolds, Stephan Roth, Tim Snow, Sharif Ahmed
CPP 31.1	Wed	16:15–16:45	H38	**Moving with minimum effort – Optimal work protocols for systems with memory** — •Sarah Loos, Samuel Monter, Felix Ginot, Clemens Bechinger
CPP 34.1	Thu	15:00–15:30	H34	**Understanding Nanocellulose-Water Interactions to Engineer Advanced Functional Materials** — •Valentina Guccini
CPP 37.1	Thu	16:15–16:45	H34	**Modelling Hygroexpansion of Compression and Opposite Wood of Conifer Branches: Bridging the Gap between Molecular and Cell Wall Level** — Marie Hartwig-Nair, Sara Florisson, Kristofer Gamstedt, •Malin Wohlert
CPP 38.1	Thu	16:15–16:45	H38	**Adsorption and Interaction of Amino Acids on Titanium Oxide Photocatalyst** — Miguel Blanco-Garcia, Mona Kohantorabi, Benedikt Socher, Ulrike Protzer, Stephan V. Roth, Cristiana Di Valentin, Andreas Stierle, •Heshmat Noei
CPP 41.1	Fri	9:30–10:00	H38	**Simulations of reaction equilibria in macromolecular systems** — •Peter Košovan

Invited Talks of the joint Symposium Physics of Embryonic Development Across Scales: From DNA to Organisms (SYED)

See SYED for the full program of the symposium.

SYED 1.1	Mon	9:30–10:00	H1	**Emergent crystalline order in a developing epithelium** — Kartik Chhajed, Natalie Dye, Marko Popović, •Frank Jülicher
SYED 1.2	Mon	10:00–10:30	H1	**A tissue rigidity phase transition shapes morphogen gradients** — Camilla Autorino, Diana Khoromskaia, Bernat Corominas-Murtra, Zena Hadjivasiliou, •Nicoletta Petridou

SYED 1.3	Mon	10:30–11:00	H1	**Building quantitative dynamical landscapes of developmental cell fate decisions** — •David Rand
SYED 1.4	Mon	11:15–11:45	H1	**Control of lumen geometry and topology by the interplay between pressure and cell proliferation rate** — •Anne Grapin-Botton, Byung Ho Lee, Masaki Sano, Daniel Riveline, Kana Fuji, Tetsuya Hiraiwa
SYED 1.5	Mon	11:45–12:15	H1	**Chromosomes as active communication and memory machines** — •Leonid A. Mirny

Invited Talks of the joint SKM Dissertationspreis 2025 (SYSD)

See SYSD for the full program of the symposium.

SYSD 1.1	Mon	9:30–10:00	H2	**Nanoscale Chemical Analysis of Ferroic Materials and Phenomena** — •Kasper Aas Hunnestad
SYSD 1.2	Mon	10:00–10:30	H2	**Advanced Excitation Schemes for Semiconductor Quantum Dots** — •Yusuf Karli
SYSD 1.3	Mon	10:30–11:00	H2	**Aspects and Probes of Strongly Correlated Electrons in Two-Dimensional Semiconductors** — •Clemens Kuhlenkamp
SYSD 1.4	Mon	11:00–11:30	H2	**Mean back relaxation and mechanical fingerprints: simplifying the study of active intracellular mechanics** — •Till Münker
SYSD 1.5	Mon	11:30–12:00	H2	**Coherent Dynamics of Atomic Spins on a Surface** — •Lukas Veldman

Invited Talks of the joint Symposium Pushing the Boundaries of Fair Data Practices for Condensed Matter Insights: From Workflows to Machine Learning (SYFD)

See SYFD for the full program of the symposium.

SYFD 1.1	Wed	9:30–10:00	H1	**Pushing the Boundaries of Fair Data Practices for Condensed Matter Insight** — •Astrid Schneidwind
SYFD 1.2	Wed	10:00–10:30	H1	**Establishing Workflows of Experimental Solar Cell Data into NOMAD** — Edgar Nandayapa, Paolo Graniero, Jose Marquez, Michael Götte, •Eva Unger
SYFD 1.3	Wed	10:30–11:00	H1	**Building up the EOSC Federation** — •Ute Gunsenheimer
SYFD 1.4	Wed	11:15–11:45	H1	**Data-Driven Materials Science for Energy-Sustainable Applications** — •Jacqueline Cole
SYFD 1.5	Wed	11:45–12:15	H1	**Machine Learning and FAIR Data in X-ray Surface Science** — •Stefan Kowarik

Invited Talks of the joint Symposium AI in (Bio-)Physics (SYAI)

See SYAI for the full program of the symposium.

SYAI 1.1	Thu	9:30–10:00	H1	**Predicting interaction partners and generating new protein sequences using protein language models** — •Anne-Florence Bitbol
SYAI 1.2	Thu	10:00–10:30	H1	**Realizing Schrödinger's dream with AI-enabled molecular dynamics** — •Alexandre Tkatchenko
SYAI 1.3	Thu	10:30–11:00	H1	**Emergent behavior of artificial intelligence** — •Steffen Rulands
SYAI 1.4	Thu	11:15–11:45	H1	**AI in medical research - navigating complexity with AI** — •Daniel Truhn
SYAI 1.5	Thu	11:45–12:15	H1	**Computational Modelling of Morphogenesis** — •Dagmar Iber

Sessions

CPP 1.1–1.6	Mon	9:30–11:15	H34	**Gels, Polymers Networks and Elastomers I**
CPP 2.1–2.11	Mon	9:30–12:45	H37	**Active Matter I (joint session DY/BP/CPP)**
CPP 3.1–3.7	Mon	9:30–11:15	H38	**Organic Electronics and Photovoltaics I**
CPP 4.1–4.6	Mon	11:30–13:00	H34	**Crystallization, Nucleation and Self-Assembly I**
CPP 5.1–5.5	Mon	11:30–13:00	H38	**Composites and Functional Polymer Hybrids**
CPP 6.1–6.4	Mon	15:00–16:00	H34	**Gels, Polymers Networks and Elastomers II**
CPP 7.1–7.7	Mon	15:00–17:00	H37	**Active Matter II (joint session BP/CPP/DY)**

Members' Assembly of the Chemical and Polymer Physics Division

Thursday 18:00–19:00 H38

Sessions

– Invited Talks, Contributed Talks, and Posters –

CPP 1: Gels, Polymers Networks and Elastomers I

Time: Monday 9:30–11:15 Location: H34

Invited Talk CPP 1.1 Mon 9:30 H34

Impact of smallest loops and composition fluctuations on the structure of end-linked polymer model networks — •Michael Lang, Reinhard Scholz, and Toni Müller — Leibniz-Institut für Polymerforschung, Dresden, Germany

A self-consistent scheme of differential equations is developed for predicting the frequency of the two smallest loop defects within polymer model networks. Without any adjustable parameter, we obtain excellent agreement with Monte Carlo simulations that sample loop formation only up to the given maximum loop size. The formation of loops of second generation leads to correlations between connected junctions that cannot be treated exactly by considering statistical arguments alone, which is in contrast to reversible networks where equilibrium statistics are sufficient. These correlations and the statistics of the junctions are provided by our model. Comparison with more realistic simulation data in three dimensions indicates that composition fluctuations of cross-links and chains clearly impact network formation. The differences between the statistics of the network junctions and our mean field predictions provide insight into the size of the domains with a predominance of chains or junctions and thus, regarding the quality of the mixture. Our results are highly relevant for an accurate modeling of network structure, improved estimates of the elastic properties of polymer networks, and for advanced analysis techniques of the network structure like network disassembly spectrometry or multiple quantum nuclear magnetic resonance.

CPP 1.2 Mon 10:00 H34

Hybrid PNIPAM Films for Green Hydrogen Production — •Morgan P. Le Dû[1], David P. Kosbahn[1], Thomas Baier[1], Qi Zhong[2], Apostolos Vagias[3], Robert Cubitt[3], Narendra Chaulagain[4], Karthik Shankar[4], Hagen Übele[5], Katharina Krischer[5], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]Zhejiang Sci-Tech University, Hangzhou, China — [3]Institut Laue-Langevin (ILL), Grenoble, France — [4]University of Alberta, Department of Electrical and Computer Engineering, Edmonton, Canada — [5]TUM School of Natural Sciences, Nonequilibrium Chemical Physics, 85748 Garching, Germany

Platinum (Pt) doped carbon nitride (CN) is a promising photocatalyst under visible light for green hydrogen (H2) production. We develop this system in a thin polymer film to make it industrially scalable. The poly(N-isopropylacrylamide) (PNIPAM) hydrogel is used as a host matrix and water storage medium to facilitate homogeneous dispersion of the catalytic centers. The hybrid film's vertical distribution and inner microstructure are studied under in situ conditions with time-of-flight neutron reflectometry (ToF NR) and grazing incidence small angle neutron scattering (GISANS). The resulting H2 produced is measured by gas chromatography.

CPP 1.3 Mon 10:15 H34

Effect of different network topologies on swelling and mechanical properties of polyelectrolyte hydrogels — •Somesh Kurahatti, Mariano Brito, David Beyer, and Christian Holm — Institute for Computational Physics, Stuttgart, Germany

We investigate the properties of polyelectrolyte hydrogels with various network heterogeneities, particularly their swelling capacity, elastic modulus and salt partitioning. We benchmark the scaling predictions for elastic modulus and equilibrium swelling ratio of the hydrogels under various salinity conditions, verifying the theoretically predicted behavior. Decoupling the elastic modulus from the swelling behavior is beneficial for applications such as super absorbers. Here, for example, now wants to increase the swelling ratio while maintaining a reasonable mechanical strength. We therefore explore mechanical and structural properties of the hydrogels with varying topologies, namely gels with dangling ends, gels with floating chains, and bottle-brush gels in counterpart to a reference regular gel. We observe that incorporating dangling ends changed swelling ratio and bulk modulus inline with the scaling predictions, whereas bottle-brush and floating-chain gels deviate from the predictions. Specifically, floating chains resulted in higher moduli and higher swelling ratio, while bottle-brush gels resulted in lower moduli and lower swelling ratios than the regular counterpart, each maintaining the same swelling ratio and modulus. The new swelling-mechanical relations allow us to treat them in a decoupled manner via the topology variation, which turns out to be of paramount relevance in the optimization and on-demand design of hydrogels.

CPP 1.4 Mon 10:30 H34

Aqueous foams stabilized by PNIPAM microgels: A multi-scale investigation — •Joanne Zimmer, Luca Mirau, Gaëtan Barth, and Regine von Klitzing — Soft Matter at Interfaces, Institute for Condensed Matter Physics, TU Darmstadt, Hochschulstraße 8, D-64289 Darmstadt

Foams possess several structural motifs on different length scales with the smallest building blocks being the foam films or even the liquid/air interface. In this work, PNIPAM microgels (MG) are used as foam stabilizers as they are highly interfacial active and temperature responsive. In addition, the MG stiffness and by this their interfacial activity can be tuned by variation of the crosslinker content. We present a multi-scale approach towards understanding how the MG properties are related to the macroscopic foam and foam film stability. Spatially resolved disjoining pressure isotherms are measured with a Thin Film Pressure Balance (TFPB). The isotherms provide information about the film thickness, surface mobility and film stability. These properties are correlated with macroscopic foam characteristics such as foamability, stability and drainage dynamics. Indeed, the results are in good agreement on all length scales: A lower crosslinker content supports foam formation due to a faster surface coverage and results in an increased foam stability, as a more rigid surface layer is formed. Increasing the amount of crosslinker in the MG induces a transition from Poiseuille flow to plug flow in the foam during drainage which coincides with an increasing mobility of the surface of a single foam film measured in a TFPB.

CPP 1.5 Mon 10:45 H34

Phase separation in elastic polymer networks — •Takahiro Yokoyama[1,2], Yicheng Qiang[3], Chengjie Luo[3], Oliver Paulin[3], David Zwicker[3], and Arash Nikoubashman[1,2] — [1]Leibniz-Institut für Polymerforschung Dresden e.V., Dresden, Germany — [2]Technische Universität Dresden, Germany — [3]Max-Planck-Institut für Dynamik und Selbstorganisation, Göttingen, Germany

Phase separation in polymer networks, from synthetic gels to biopolymer networks, significantly influences their structural and mechanical properties. While previous studies suggest that network mechanics regulate phase separation of the network itself and the embedded (complex) liquid, the fundamental principles governing this interaction remain poorly understood. To address this knowledge gap, we used molecular dynamics (MD) simulations to explore the phase behavior of elastic polymer networks. We systematically changed the quality of the (implicit) solvent, polymer chain length, and polymer flexibility. Our simulations identified two distinct phase separation behaviors depending on the polymer flexibility: macrophase separation into a polymer-rich and polymer-poor region for flexible polymer chains, and microphase separation with finite-sized pores for networks formed by semi-flexible chains. For the latter systems, we found that the pore size decreased with increasing chain stiffness. Furthermore, the network elasticity increased with decreasing pore size, following a power law as recently proposed by field theory. This study highlights the importance of polymer stiffness in shaping the size and distribution of (biomolecular) droplets within elastic networks.

CPP 1.6 Mon 11:00 H34

Nanoscopic measurements of the water content in microgels using fluorescence lifetime imaging — •Dominik Wöll[1], Alexandre Fürstenberg[2], Jörg Enderlein[3], Oleksii Nevskyi[3], Sankar Jana[1], Hannah Höche[1], and Leon Trottenberg[1] — [1]RWTH Aachen University, Institute of Physical Chemistry, Germany — [2]University of Geneva, Department of Physical Chemistry and Department of Inorganic and Analytical Chemistry, Genf, Switzerland — [3]Georg August UniversityGöttingen, 3rd Institute of Physics - Biophysics, Germany

The role of water molecules in the structure, function, and dynamics of (bio-)materials is significant, and thus, an estimation of the number of water molecules within different compartments is crucial. It has been demonstrated that the fluorescence of red emissive dyes is quenched in the presence of H_2O, with the excited energy transferred to surrounding H_2O molecules. Fluorescence lifetime imaging (FLIM) can thus be used to quantify the number of water molecules in proximity to the probing dye Atto 655, which was covalently embedded into microgels in the present study. Microgels represent an intriguing class of nanoparticles with considerable potential for applications in drug delivery and medicinal chemistry. We recorded FLIM images at varying H_2O:D_2O ratios, in both the swollen and collapsed states of the microgels at 22 °C and 40 °C, respectively. Stern-Volmer analysis enabled the calculation of the number of water molecules in the immediate vicinity of the dye molecule within the microgels at varying temperatures.

CPP 2: Active Matter I (joint session DY/BP/CPP)

Time: Monday 9:30–12:45 Location: H37

CPP 2.1 Mon 9:30 H37

Odd dynamics and pattern formation in mixtures of magnetic spinners and passive colloids — •Dennis Schorn[1], Stijn van der Ham[2], Hanumantha Rao Vutukuri[2], and Benno Liebchen[1] — [1]Technische Universität Darmstadt, 64289 Darmstadt, Germany — [2]MESA+ Institute, University of Twente, 7500 AE Enschede, The Netherlands

Starfish embryos aggregate into chiral crystals exhibiting odd elasticity (Tan *et al.* Nature **607**, 287 (2022)). Similar structures have been recently observed in externally driven magnetic colloids. In this talk, I present experiments and simulations of binary mixtures of magnetic spinners and passive colloids. We develop a model to predict the phase diagram of the system, which comprises four distinct phases that can be systematically reproduced in experiments. In particular, our simulations and experiments show a phase where the passive particles form a gel-like network featuring significant holes filled with self-organized rotating chiral clusters made of spinners. This phase can be reversed by changing the system's composition and magnetic field strength, featuring a system spanning spinner phase with embedded counter-rotating chiral clusters made of passive colloids. Our system may open the route towards a new type of viscoelastic active chiral matter involving nonreciprocal interactions between both species.

CPP 2.2 Mon 9:45 H37

Symmetry breaking in active non-reciprocal systems — •Kim L. Kreienkamp and Sabine H. L. Klapp — TU Berlin, Germany

Non-reciprocity significantly impacts the dynamical behavior in mixtures. One of its particularly striking consequences is the spontaneous emergence of time-dependent phases that break parity-time symmetry [1-3]. Here, we study a paradigmatic model of a non-reciprocal polar active mixture with completely symmetric repulsion [4,5]. Using a combination of field theory and particle-based simulations, we identify two qualitatively distinct regimes of non-reciprocity-induced dynamics. In the regime of weak intra-species alignment, non-reciprocity leads to asymmetric clustering in which only one of the two species forms clusters. Notably, the asymmetric density dynamics is driven alone by non-reciprocal orientational couplings [4,5]. In contrast, in the strongly coupled regime, the corresponding field theory exhibits exceptional points that have been associated with the emergence of chiral phases where the polarization direction rotates over time [2]. Our simulations confirm that spontaneous chirality arises at the particle level. In particular, we observe chimera-like states with coexisting locally synchronized and disordered regions. At the coupling strengths associated with exceptional points, the spontaneous chirality peaks.

CPP 2.3 Mon 10:00 H37

Emergent phases in a discrete flocking model with non-reciprocal interaction — •Swarnajit Chatterjee, Matthieu Mangeat, and Heiko Rieger — Center for Biophysics & Department for Theoretical Physics, Saarland University, 66123 Saarbrücken, Germany

Non-reciprocal interactions arise in systems that seemingly violate Newton's third law "actio=reactio". They are ubiquitous in active and living systems that break detailed balance at the microscale, from social forces to antagonistic inter-species interactions in bacteria. Non-reciprocity affects non-equilibrium phase transitions and pattern formation in active matter and represents a rapidly growing research focus in the field. In this work, we have undertaken a comprehensive study of the non-reciprocal two-species active Ising model (NRTSAIM), a non-reciprocal discrete-symmetry flocking model. Our study uncovers a distinctive *run-and-chase* dynamical state that emerges under significant non-reciprocal frustration. In this state, A-particles chase B-particles to align with them, while B-particles avoid A-particles, resulting in B-particle accumulation at the opposite end of the advancing A-band. This run-and-chase state represents a non-reciprocal discrete-symmetry analog of the chiral phase seen in the non-reciprocal Vicsek model. Additionally, we find that self-propulsion destroys the oscillatory state obtained for the non-motile case, and all the NRTSAIM steady-states are metastable due to spontaneous droplet excitation and exhibit motility-induced interface pinning. A hydrodynamic theory supports our simulations and confirms the reported phase diagrams.

CPP 2.4 Mon 10:15 H37

Emergent phases in a discrete flocking model with reciprocal interaction — •Matthieu Mangeat[1], Swarnajit Chatterjee[1], Jae Dong Noh[2], and Heiko Rieger[1] — [1]Saarland University, Saarbrücken, Germany — [2]University of Seoul, Seoul, Korea

We have undertaken a comprehensive study of the two-species active Ising model (TSAIM), a discrete-symmetry counterpart of the continuous-symmetry two-species Vicsek model, motivated by recent interest in the impact of complex and heterogeneous interactions on active matter systems. In the TSAIM, two species of self-propelled particles undergo biased diffusion in two dimensions, interacting via local intraspecies alignment and reciprocal interspecies anti-alignment, along with the possibility of species interconversion. We observe a liquid-gas phase transition, exhibiting macrophase-separated bands, and the emergence of a high-density parallel flocking state, a feature not seen in previous flocking models. With species interconversion (species-flip dynamics), the TSAIM corresponds to an active extension of the Ashkin-Teller model and exhibits a broader range of steady-state phases, including microphase-separated bands that further enrich the coexistence region. We also find that the system is metastable due to droplet excitation and exhibits spontaneous motility-induced interface pinning, preventing the system from reaching long-range order at sufficiently low noise. A hydrodynamic theory complements our computer simulations of the microscopic model and confirms the reported phase diagrams.

CPP 2.5 Mon 10:30 H37

Emergent collective behavior from cohesion and alignment — •Jeanine Shea and Holger Stark — Technische Universität Berlin, Institut für Theoretische Physik, Hardenbergstr. 36, 10623 Berlin, Germany.

Collective behavior is all around us, from flocks of birds to schools of fish. These systems are immensely complex. To explore their basic characteristics, we introduce a minimal model for cohesive and aligning self-propelled particles in which group cohesion is established through additive, non-reciprocal torques [1]. These torques cause constituents to effectively turn towards one another, while an additional alignment torque competes in the same spatial range. By changing the strength and range of these torque interactions, we uncover six states which we distinguish via their static and dynamic properties. These states range from disperse particles to closely packed worm-like formations. A number of the states generated by this model exhibit collective dynamics which are reminiscent of those seen in nature.

[1] Knežević, M., Welker, T. and Stark, H. Collective motion of active particles exhibiting non-reciprocal orientational interactions. Sci Rep 12, 19437 (2022).

Invited Talk CPP 2.6 Mon 10:45 H37

Collective behavior of photoactive macroscopic particles — •Iker Zuriguel — University of Navarra, Pamplona, Spain

Active matter refers to systems of interacting, self-propelled agents that convert energy into mechanical motion, representing a nice example of out-of-equilibrium systems. In this work, a novel type of active particles is introduced. These are active granular (i.e. they interact solely through physical contacts) and photoactive, meaning that they self-propel using energy from light. Therefore, by means of a programmable LED panel, we are able to change the illumination pattern and, consequently, the particle activity in space and time, allowing a precise exploration of a variety of scenarios related to collective behavior. This possibility has been exploited in microscopic systems but is genuinely new in macroscopic ones.

First, we will present the clustering behavior of these agents under homogeneous illumination. By varying the illumination intensities and changing the population size, we observed a power-law-like distribution for both the cluster sizes and durations. We identified a transition from unstable to stable clusters, as indicated by the divergence of average cluster durations. Higher particle activities and smaller populations led to the creation of small unstable clusters, while lower particle activities and larger populations result in big, stable clusters that persist over time. This transition is explained with the help of a simple model capturing the most important processes involved in cluster dynamics. In the last part of the talk, the collective behavior under inhomogeneous illumination patterns will be introduced.

CPP 2.7 Mon 11:30 H37

Swarming model with minority interaction exhibits temporal and spatial scale-free correlations — •Simon Syga[1], Chandraniva Guha Ray[2,3,4], Josué Manik Nava Sedeño[5], Fernando Peruani[6,7], and Andreas Deutsch[1] — [1]Technische Universität Dresden — [2]Max Planck Institute for the Physics of Complex Systems — [3]Max Planck Institute of Molecular Cell Biology and Genetics — [4]Center for Systems Biology Dresden — [5]Universidad Nacional Autónoma de México — [6]Université Côte d'Azur, Nice — [7]CY Cergy Paris Université

Collective motion is a widespread phenomenon in social organisms, from bird flocks and fish schools to human crowds and cell groups. Swarms of birds and fish are particularly fascinating for their coordinated behavior and rapid escape

maneuvers during predator attacks. Critical motion is hypothesized as an optimal trade-off between cohesive group behavior and responsiveness to well-informed individuals. However, traditional models only show criticality at the phase transition between ordered and unordered motion. Here, we extend the Vicsek model with a minority interaction, where individuals primarily follow neighbors but can switch to follow a defector moving against a well-aligned group. This triggers cascades of defections, leading to rich dynamics, including large-scale fluctuations, scale-free velocity distributions, and a scale-free return time distribution of the order parameter. Our model underscores the biological importance of minority interactions in swarming and their role in critical behavior.

CPP 2.8 Mon 11:45 H37

'Predator-prey' driven swarmalator systems — •Ginger E. Lau, Mario U. Gaimann, and Miriam Klopotek — Stuttgart Center for Simulation Science (SimTech), Cluster of Excellence EXC 2075, University of Stuttgart, Germany

Swarmalators are an active matter system of oscillators which exhibit swarming and collective motion in physical space, as well as synchronization behavior in an additional phase variable space, originally introduced by O'Keeffe *et al.* (*Nat. Commun.* 8(1), 1504, 2017). Such systems with bidirectional couplings in space and phase can be observed in nature, such as in the chorusing behavior of Japanese tree frogs characterized by Aihara *et al.* (*Sci. Rep.* 4(1), 3891, 2014). The interplay between attraction, repulsion, and phase synchronization provides several distinct regimes of self-organizational behavior. Akin to biological swarm systems responding to predator interactions, swarmalators can respond collectively to external perturbations by a repulsive driver. In previous work, driving was realized with a mobile 'pacemaker' by Xu *et al.* (*Chaos* 34(11), 113103, 2024). The present study introduces a new 'predator-prey' driven swarmalator model showing rich adaptive behavior. This could have a wide variety of potential future applications, from biological physics to swarm robotics to nature-inspired learning algorithms and methods of inference.

CPP 2.9 Mon 12:00 H37

Inertial active matter governed by Coulomb friction — •Alexander Antonov[1], Lorenzo Caprini[2], and Hartmut Löwen[1] — [1]Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany — [2]University of Rome La Sapenzia, Rome, Italy

Coulomb, or dry friction, is a common phenomenon that can be encountered in various systems, such as granular matter or Brownian motors. The Coulomb friction force resists the motion and, unlike the friction in wet systems, is almost independent of the relative velocity. We show that this characteristic feature of Coulomb friction leads to emergence of dynamical states when subjected to active, or self-propelled motion [1]. At low activity levels, the dynamics resembles Brownian motion, while at greater activity, a dynamic Stop & Go regime emerges, marked by continuous switching between diffusion and accelerated motion. At even higher activity levels, a super-mobile regime arises, characterized by fully accelerated motion and an anomalous scaling of the diffusion coefficient with activity. Near the transition between the Stop & Go and super-mobile regimes, we reveal a novel activity-induced phase separation in collective behavior [2]. Our theoretical findings have been also demonstrated in experiments, where vibrobots on a horizontal surface are activated by vertical oscillations generated using an electromagnetic shaker.

CPP 2.10 Mon 12:15 H37

Active nematic turbulence with substrate friction — •Peter A. E. Hampshire[1,2] and Ricard Alert[1,2,3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Center for Systems Biology Dresden, Dresden, Germany — [3]Cluster of Excellence Physics of Life, Dresden, Germany

Active nematics with high activity exhibit turbulent-like flows, characterized by vortices, spatio-temporal chaos and power laws in the energy spectra [1-3]. Continuum models have been successfully used to predict the scaling of the energy spectra with the wavevector. Most theoretical work has focused on free-standing, active nematic films. However, in several experimental realisations, such as bacterial colonies and epithelial monolayers, the active nematic is in contact with a solid substrate. We generalised a 2D, incompressible active nematic model to include substrate friction, and studied its impact on the transition to turbulence and the energy spectra of the turbulent-like flows. We find a variety of dynamic states including flow in lanes, stable vortices and both isotropic and anisotropic turbulence. At high activity and moderate friction, we found a power-law scaling in the kinetic energy spectrum $E(q) \sim q^3$, where q is the wavevector, at low wavevectors. The exponent of 3 can be justified with a power-counting argument. Overall, we have developed a model for active nematic turbulence on a substrate that can be compared to biological systems. [1] L. Giomi, *Phys. Rev. X* **5**, 031003 (2015). [2] R. Alert, J.-F. Joanny, J. Casademunt, *Nat. Phys.* **16**, 682-688 (2020). [3] B. Martínez-Prat*, R. Alert*, et al., *Phys. Rev. X* **11**, 031065 (2021).

CPP 2.11 Mon 12:30 H37

Self-sustained patchy turbulence in shear-thinning active fluids — •Henning Reinken and Andreas M. Menzel — Otto-von-Guericke-Universität Magdeburg

Bacterial suspensions and other active fluids are known to develop highly dynamical vortex states, denoted as active or mesoscale turbulence. We reveal the pronounced effect of non-Newtonian rheology of the carrier fluid on these turbulent states, concentrating on shear thinning. As a consequence, a self-sustained heterogeneous state of coexisting turbulent and quiescent areas develops, which results in anomalous velocity statistics. The heterogeneous state emerges in a hysteretic transition under varying activity. We provide an extensive numerical analysis and find indirect evidence for a directed percolation transition. Our results are important, for instance, when addressing active objects in biological media with complex rheological properties.

CPP 3: Organic Electronics and Photovoltaics I

Time: Monday 9:30–11:15 Location: H38

CPP 3.1 Mon 9:30 H38

Demonstration of flexible organic solar cells in space — •Lukas V. Spanier[1], Lennart K. Reb[2], Michael Böhmer[3], Zerui Li[1], Christoph Dreissigacker[4], Thomas Voigtmann[4], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]TUM School of Natural Sciences, Zentrales Technologielabor, Garching, Germany — [3]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany — [4]DLR Institut für Materialphysik im Weltraum, Köln, Germany

The deployment of flexible organic solar cells (OSCs) in space presents a transformative opportunity for exceptionally lightweight power generation on satellites and deep space research probes, promising record-breaking gravimetric power densities. In this study, we report the successfull launch, operation and recovery of flexible PEN-based OSCs on a suborbital rocket launch, assessing their performance in the harsh conditions of space. Flexible OSC modules were integrated into the payload and exposed to vacuum, microgravity, and cosmic radiation during the flight. Post-flight analysis of the recovered cells further confirmed the cells' operational viability. The experiment demonstrates the potential of OSCs for reducing launch mass and enabling novel satellite architectures, paving the way for their adoption in future space missions.

CPP 3.2 Mon 9:45 H38

Evaluate the energy losses in non-fullerene based organic photovoltaic — •Maryam Alqurashi[1], Shahidul Alam[2], Jose Jurado[1], Julien Gorenflot[1], and Frederic Laquai[1,2] — [1]Division of Physical Sciences and Engineering, King Abdullah University of Science and Technology, Thuwal 23955-6900, Saudi Arabia — [2]Physical Chemistry and Spectroscopy of Energy Materials, Department of Chemistry, Ludwig Maximilian University of Munich, D-81377 Munich, Germany

Organic photovoltaics that use non-fullerene acceptors are gaining popularity because they can potentially increase power conversion efficiency. However, they suffer from significantly higher total energy losses than inorganic photovoltaics, primarily due to non-radiative recombination, a process in which electron-hole pairs recombine without generating current. Electroluminescence spectroscopy helps evaluate charge transfer state energy, which is crucial in charge recombination. This study focused on three systems: PM6:Y6, PM6:IT-4F, and PM6:ITIC. The PM6:Y6-based device showed higher radiative recombination, while the PM6:IT-4F system exhibited the highest order of non-radiative recombination. The total open circuit voltage losses were 0.64 eV, 0.67 eV, and 0.56 eV for PM6:Y6, PM6:IT-4F, and PM6:ITIC, respectively. Despite PM6:Y6 achieving a higher power conversion efficiency, its open circuit voltage losses were comparable to that of the other two systems.

CPP 3.3 Mon 10:00 H38

Towards printing of organic solar cells out of green solvents — •Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany

Despite big achievements in terms of power conversion efficiencies in the last years, with champion efficiencies above the 20% limit, it remains an unresolved challenge to fabricate large-area organic solar cells without sacrificing efficiencies. Large-area deposition of the conjugated polymer donor and small molecule acceptor blends via printing is key in the device upscaling. Another issue calling the attention is the fabrication of environmentally friendly organic solar cells. To become environmental-friendly, the used solvents are a key factor. Today, still the most used solvents are harmful and can cause environmental pollution during the device fabrication process and waste solvent treatment. Accordingly, we investigate the printing of donor-acceptor blend films out of different solvents for use as active layers in organic solar cells with advanced in-situ scattering methods. We use grazing incidence small and wide-angle X-ray scattering (GISAXS and GIWAXS) in-situ during printing to gain a fundamental understanding of the underlying film formation processes. Different examples of polymer donors and small molecule acceptors are presented, and the resulting morphologies are correlated with solar cell device performance. A special emphasis is put on the shift towards more environmentally friendly solvents, which will also be a prerequisite to promote the large-scale production of organic solar cells.

CPP 3.4 Mon 10:15 H38

The Role of Oxygen Insertion on Performance of A-D-A-type Non-Fullerene Acceptors (NFA) in Organic Solar Cells — •Wejdan Althobaiti[1], Yakun He[1], Julien Gorenflot[1], Wisnu Hadmojo[1], Sandeep Sharma[1], Filip Aniés[1], Weimin Zhang[1], Shahidul Alam[1], George Harrison[1], Anirudh Sharma[1], Shadi Fatayer[1], Derya Baran[1], Iain McCulloch[2], Thomas Anthopoulos[1], Martin Heeney[1], and Frédéric Laquai[1] — [1]King Abdullah University of Science and Technology (KAUST), Saudi Arabia — [2]University of Oxford, UK

Charge transfer in OSCs can occur through two pathways: photo-induced electron transfer from the donor to the acceptor, controlled by the electron affinity (EA) offset, and photo-induced hole transfer from the acceptor to the donor, governed by the ionization energy (IE) offset. Here, we report the synthesis of a novel NFA coded TPTI-BT, whose properties were first predicted by computational chemistry before the material was synthesized. Despite the favorable properties for high device performance, TPTI-BT exhibited moderate device performance, in particular when compared with the structurally-related and efficient acceptor O-IDTBCN. In fact, the chemical structure of TPTI-BT is very similar to that of O-IDTBCN, it contains only two additional oxygen atoms in the donor core of the A-D-A-type acceptor backbone structure. Interestingly, this causes TPTI-BT to exhibit overall lower device performance. We present a comparative study of these two NFAs and elucidate the origin of the lower performance of the TPTI-BT caused by two additional oxygen atoms.

CPP 3.5 Mon 10:30 H38

Revealing the effect of solvent additive selectivity on morphology and formation kinetics in printed non-fullerene organic solar cells at ambient conditions — •Jinsheng Zhang and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany

Solvent additives have received tremendous attention in organic solar cells as an effective way to optimize morphology and phase separation. However, most research primarily focuses on solvent additives with superior solvation for non-fullerene acceptors (NFA) over polymer donors, such as the 1-chloronaphthalen (1-CN) and 1, 8-diiodooctane (1,8-DIO). Few researches are related to solvent additives characterized by better solubility for polymer donors than NFA. Furthermore, the impact of solvent additives is mainly investigated through spin coating rather than slot-die coating, which exhibits distinct kinetics in film formation. Hence, the influence of solvent additive selectivity on the kinetics of active layer formation in the printed active layer remains unknown. In this study, we use PBDB-T-2F as the donor and BTP-C3-4F as the acceptor and introduce two distinct solvent additives one with superior solubility for PBDB-T-2F compared to BTP-C3-4F, and the other with inferior solubility for PBDB-T-2F. The drying process of the slot die coated active layers with different solvent additives is studied by in situ UV-vis absorption spectra and in situ grazing incidence wide angle X-Ray scattering (GIWAXS).

CPP 3.6 Mon 10:45 H38

Locally Resolved Thermally Induced Degradation on PM6:Y6-based Organic Solar Cells — •Shahidul Alam[1,2], José P. Jurado[2], Biwajit Pal[2], Zhuo Xu[3,4], Aurelien D. Sokeng[3,4], Harald Hoppe[3,4], and Frédéric Laquai[1,2] — [1]Physical Chemistry and Spectroscopy of Energy Materials, Department of Chemistry, LMU Munich, Germany — [2]King Abdullah University of Science and Technology (KAUST), KAUST Solar Center (KSC), Kingdom of Saudi Arabia — [3]Laboratory of Organic and Macromolecular Chemistry (IOMC), FSU Jena, Germany — [4]Center for Energy and Environmental Chemistry Jena (CEEC Jena), FSU Jena, Germany

The commercialization of new photovoltaic technology is impeded by the degradation of organic photovoltaic devices caused by thermal factors. Therefore, it is crucial to have an in-depth awareness of the underlying causes of thermal device instability and to develop effective approaches to reduce its negative impacts. This study examines the thermal degradation of PM6:Y6 bulk heterojunction solar cells, which are currently considered at the forefront of organic solar cell technology. The investigation focuses on the effects of varying temperatures on the performance and locally resolved thermally induced impact of these solar cells. We report a comprehensive study probing the influence of thermal annealing of solar cells by the use of several advanced optoelectrical and imaging characterization techniques.

CPP 3.7 Mon 11:00 H38

Thermal degradation behavior of BTP-4F-12 based green-solvent organic solar cells — •Zerui Li[1], Jinsheng Zhang[1], Simon Wegener[1], Yingying Yan[1], Xiongzhuo Jiang[1], Kun Sun[1], Matthias Schwartzkopf[2], Sarathlal Koyiloth Vayalil[2,3], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]Deutsches Elektronen-Synchrotron DESY, 22607, Hamburg, Germany — [3]Applied Sciences Cluster, University of Petroleum and Energy Studies UPES, Dehradun, Uttarakhand, 248007, India

Thermal degradation is inevitable for organic solar cells in real application conditions. The common research of thermal stability could only observe ex-situ conditions before and after heating and the device behavior during heating is missing, which is insufficient to the understanding of degradation mechanisms. Herein, a new observation aspect is realized to analyze the thermal degradation of BTP-4F-12 based green-solvent organic solar cells with the application of operando GIWAXS/GISAXS, which provides a deep learning of thermal degradation. The OSC devices show a harsh Voc loss with temperature increase, which would recover mostly after getting cooled down to low temperature, while the loss of FF and Jsc during aging is irreversible. Thus, polymer donors play a crucial role in the device performance as well as thermal behavior. In addition, such thermal degradation is driven by the evolution of the molecular stacking and aggregation and thermal expansion/contraction during aging.

CPP 4: Crystallization, Nucleation and Self-Assembly I

Time: Monday 11:30–13:00 Location: H34

CPP 4.1 Mon 11:30 H34

Confined crystallization for studying kinetics and crystal orientation of interface-induced polymer crystallization — •Marthinus van Niekerk, Thomas Thurn-Albrecht, and Oleksandr Dolynchuk — Experimental Polymer Physics, Martin Luther University Halle-Wittenberg, Germany

Understanding interfacial interactions is essential to understanding the mechanisms and kinetics of interface-induced crystallization (IIC), namely heterogeneous nucleation or prefreezing, and resultant material properties. While heterogeneous nucleation is an activated process occurring below T_m, prefreezing is an equilibrium process producing a stable crystalline layer above T_m that thickens upon cooling. Quantifying the influence of interfacial interactions on the kinetics of IIC and crystal morphology has long been elusive and is addressed in this work. We present a systematic study of confined crystallization in micrometer-sized dewetted droplets of poly(ϵ-caprolactone) (PCL) on a range of substrates, allowing numerical analysis of isolated nucleation events and kinetics. Our results show that prefreezing significantly enhances crystallization kinetics compared to nucleation, resulting in simultaneous crystallization of PCL droplets close to T_m. X-ray scattering reveals the preferred crystal orientation in PCL droplets crystallized by IIC, which is strongest for prefreezing and is supported by striking differences in lamellar morphologies observed in AFM. Thus, we present both quantified nucleation kinetics and crystal orientation for different cases of IIC and show that prefreezing enhances crystallization kinetics and anisotropic crystal orientation most effectively.

CPP 4.2 Mon 11:45 H34

Liquid crystalline ordering of conjugated polymers at the vacuum interface — Anton Sinner, Alexander Johannes Much, and •Oleksandr Dolynchuk — Experimental Polymer Physics, Martin Luther University Halle-Wittenberg, Germany

Structure formation in films of conjugated polymers (CPs) strongly affects their optoelectronic properties and is of fundamental interest in the context of sanidic liquid crystalline (SLC) phases discovered in board-like polymers. Recent experimental results on films of the model CP poly(3-hexylthiophene) (P3HT) revealed the edge-on crystal orientation in the top film layer and suggested that the vacuum interface induces it. Here, we use grazing-incidence wide-angle X-ray scattering to study in situ the crystallization and melting in films of P3HT and polydiketopyrrolopyrrole (PDPP), another board-like CP, at the vacuum interface. Upon cooling from the melt, the ordering of both P3HT and PDPP indeed starts at the vacuum interface as an edge-on oriented disordered SLC phase and undergoes multiple SLC transitions with decreasing temperature. The same thermal hierarchy of SLC phases is observed for both CPs during melting, demonstrating that the vacuum interface stabilizes the edge-on disordered SLC phase above its bulk transition temperature, similar to the surface freezing of short alkanes. Notably, the observed effects are much stronger for PDPP, also resulting in a thicker edge-on oriented layer of more than 100 nm. Thus, we show that surface-induced SLC ordering is a general phenomenon of CPs, presumably due to their board-like architecture, and it significantly influences the molecular orientation in CP films.

CPP 4.3 Mon 12:00 H34

How Aqueous Solutions of Low-end Mono-alcohols Crystallize? — •Vasileios Moschos[1] and George Floudas[1,2] — [1]Department of Physics, University of Ioannina, 45110 Ioannina, Greece — [2]Max Planck Institute for Polymer Research, 55128 Mainz, Germany

Aqueous solutions of low-end aliphatic mono-alcohols, such as ethanol and 1-propanol, display several peculiar features originating from hydrogen bonding, and in particular, antagonistic hydrophilic/hydrophobic interactions of the head/tail that give rise to local nano-heterogeneity. By combining structural (XRD), thermodynamic (Differential Scanning Calorimetry, DSC) and dynamical (Dielectric Spectroscopy, DS) probes, the pertinent phase diagrams of the two binary mixtures are established, comprising of liquid 1-propanol/ethanol, liquid water, hexagonal ice and different hydrates. The two phase diagrams are discussed in terms of up to five different Regimes (Regime I-V), all sharing a droplet arrangement of the minority component, with the exception of Regime I in ethanol/water binary system, where molecular mixing of the two components occurs. By probing the dynamics of the mixtures over an extended frequency and temperature range, different relaxation processes are identified, either associated with with the dynamics of pure alcohol (Debye-like and α-process) or alcohol/water mixtures.

CPP 4.4 Mon 12:15 H34

Intra-crystalline chain diffusion, semicrystalline morphology and mechanical modulus of selected aliphatic polyesters — •Qiang Yu, Albrecht Pezold, and Thomas Thurn-Albrecht — Martin-Luther-University Halle-Wittenberg

Aliphatic polyesters are good candidates to replace commodity plastics in many applications due to their similar mechanical and thermal properties, and superior degradability. However, their intra-crystalline chain diffusion (ICD, the mobility of polymer chains in the crystalline phase) and semicrystalline morphology have not been widely studied. From our recent studies, based on model polymers, semicrystalline polymers exhibit different morphological features depending on the timescale of ICD ($\langle\tau_c\rangle$) relative to the kinetics of crystal growth (τ_{lc}). To check the generality of the findings, our study is expanded into a series of A-B aliphatic polyesters. $\langle\tau_c\rangle$ and τ_{lc} of the polyesters were investigated by nuclear magnetic resonance (NMR) and polarized optical microscope, respectively. The semicrystalline morphology was monitored by small angle X-ray scattering (SAXS) during isothermal crystallization. Long $\langle\tau_c\rangle$ (not measurable by NMR) was qualitatively differentiated by different crystal thickening slopes (SAXS measurement). The results show that our findings are also valid for the investigated polyesters. The different crystal thickening slopes show that the ICD of polymers slows down due to the formation of layers of ester groups in the crystal. At last, we report on the exponential dependence of shear modulus of the polyesters with long $\langle\tau_c\rangle$ on their crystallinity.

CPP 4.5 Mon 12:30 H34

Self-assembled Peptides Structure Mediated by Solid Interfaces — •Leila Sahebmohammadi[1], Pol Besenius[2], Markus Mezger[3], and Regine von Klitzing[1] — [1]Soft Matter at Interfaces, Department of Physics, Technical University of Darmstadt, Germany — [2]Department of Chemistry, Johannes Gutenberg-Universität Mainz, Germany — [3]Faculty of Physics, Universität Wien, Austria

The self-assembly of amphiphilic, C3-symmetric dendritic peptides is driven by non-covalent interactions and steric limitations. This study focuses on peptides with a thermosensitive moiety. In phosphate buffer, oppositely charged peptide amphiphiles form 1D nanorod-like patterns, confirmed by circular dichroism spectroscopy to follow a ß-sheet structure. Atomic Force Microscopy (AFM) revealed temperature-dependent helical filaments, where higher temperatures increased filament length and pitch due to the hydrophobic thermosensitive moiety, while reducing filament height. Quartz Crystal Microbalance with Dissipation (QCM-D) showed a temperature-responsive, layer-by-layer adsorption process forming stable multilayers. Lysine-based cationic comonomers improved adsorption and coating uniformity on gold (Au) and silicon (Si) surfaces. Extreme pH conditions (2 or 12) caused multilayer removal, revealing a pH-responsive mechanism from weakened electrostatic interactions. This study demonstrates how self-assembly and surface confinement adapt peptide assembly, offering insights for modifying surface properties for diverse applications.

CPP 4.6 Mon 12:45 H34

Crystallization and Pseudo-Isodimorphism in Statistical Co-Polythiophenes — •Alexander Johannes Much[1], Jakob Boris Günther Danziger[1], Qian Wang[2], Michael Sommer[2], and Oleksandr Dolynchuk[1] — [1]Martin-Luther-Universität Halle-Wittenberg — [2]Technische Universität Chemnitz

Statistical copolymerization is a powerful and widely used way to tailor material properties like solubility or mechanical properties. The copolymer properties depend largely on their co-crystallization and the crystal structure formed, which has been studied for polyesters, polyamides, and polycarbonates. The results suggest three co-crystallization scenarios: (1) total exclusion of comonomers, (2) total inclusion of comonomers (isomorphism), and (3) partial inclusion of comonomers into two crystal lattices (isodimorphism).

Here we study the co-crystallization and crystal structure of poly-(3-hexylthiophene)-stat-poly-[3-(6-cyanohexyl)thiophene] statistical copolymers using differential scanning calorimetry (DSC) and wide-angle X-ray scattering (WAXS). The composition-dependent melting temperatures and enthalpies obtained from DSC show minima, which is typical of isodimorphic co-crystallization. However, WAXS clearly indicates single crystal lattices in all copolymers, with a monotonic dependence of lattice constants on composition. This finding is inconsistent with isodimorphism, making the co-crystallization of these statistical copolythiophenes only pseudo-isodimorphic. Hence, our results suggest that the current classification of statistical copolymer crystallization is incomplete and needs to be extended.

CPP 5: Composites and Functional Polymer Hybrids

Time: Monday 11:30–13:00 Location: H38

Invited Talk CPP 5.1 Mon 11:30 H38

Theoretical characterization of sulfur/carbon copolymer cathodes for next-generation batteries via *ab initio* spectroscopy simulations — •Daniel Sebastiani and Pouya Partovi-Azar — Martin Luther University Halle-Wittenberg, Halle (Saale), Germany

The remarkable theoretical specific capacity of elemental sulfur (~1675 mAh/g) and its abundance make lithium-sulfur (Li-S) batteries an attractive alternative to current lithium-ion technology. Nevertheless, their cycle life has so far been limited due to an irreversible capacity fade. To tackle this issue, numerous studies have focused on structural optimization of sulfur cathodes including utilization of sulfur/carbon copolymers. Among others, sulfur-*n*-1,3-diisopropenylbenzene (S/DIB) copolymer, a 3D network of DIB molecules interconnected via sulfur chains, has shown a promising performance as an active cathode material.

In this talk, we will present our recent works employing a quantum-chemical approach for the characterization of S/DIB copolymer cathodes through simulation of their Raman fingerprints during discharge. Theoretically predicted Raman responses, calculated at density-functional theory (DFT) level along with DFT-based *ab initio* molecular dynamics simulations, hint at activities at certain frequencies which can be exploited to experimentally distinguish between the underlying structures involving short or those having longer sulfur chains. These predictions are all proven plausible by experimental Raman measurements on Li-S coin cells.

CPP 5.2 Mon 12:00 H38

Unveiling the Kinetics of Block Copolymer Micelles Close Packing by In Situ GISAXS — •Guangjiu Pan[1], Jinsheng Zhang[1], Altantulga Buyan-Arivjikh[1], Zhuijun Xu[1], Stephan V. Roth[2,3], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]DESY, 22607 Hamburg, Germany — [3]KTH Royal Institute of Technology, SE 100 44 Stockholm, Sweden

Packing spheres has long been a key topic in science. While hard spheres often form dense, close-packed structures like face-centered cubic (FCC) lattices, soft spheres, such as block copolymers in selective solvents, tend to arrange into

less dense structures. However, when using block copolymer templates in the sol-gel method, these soft spheres can achieve close-packed structures. In this study, in situ grazing-incidence small-angle X-ray scattering (GISAXS) is used to examine the self-assembly and co-assembly processes during the formation of close-packing structures. The results reveal that the hybrid films preferentially develop an FCC structure with cluster nuclei. After the polymer template is removed, a superlattice-like mesoporous metal oxide film is obtained, showcasing the potential for advanced applications due to its well-organized nanostructures.

CPP 5.3 Mon 12:15 H38

Optimizing the internal structure of soft elastic composite materials — •Lukas Fischer and Andreas M. Menzel — Institut für Physik, Otto-von-Guericke-Universität Magdeburg, Magdeburg, Germany

We study magnetic gels and elastomers, soft materials composed of magnetic or magnetizable particles embedded in a soft polymeric matrix material. These materials can be controlled by external magnetic fields, which induce deformations (magnetostriction) or changes in the rheological behavior (magnetorheological effect).

In particular, we investigate how these two effects depend on the arrangement of magnetizable particles within the elastic matrix. For the magnetostrictive effect, we consider model systems of spherical shape, for which we can analytically calculate how the volume change and overall elongation or contraction under applied magnetic fields depends on the configuration (within the linear elastic regime) [1]. Based on these formulae, we optimize the structures for maximized deformations, using an adaption of simulated annealing. Additionally, we investigate cubical systems for their magnetorheological effects, also presenting the internal arrangements that maximize these effects. The optimized arrangements are compared to regular lattice configurations.

The method that we present here can be transferred to the investigation of other types of soft elastic composite systems, driving them towards their full potential in light of future applications.

[1] L. Fischer, A. M. Menzel, PNAS Nexus **3**, pgae353 (2024).

CPP 5.4 Mon 12:30 H38

Water dynamics in conductive PEDOT:PSS/cellulose nanocomposite films in dependence of relative humidity — •Lucas P. Kreuzer[1], Marie Betker[2], Marcell Wolf[1], Daniel Söderberg[3], and Stephan Roth[2,3] — [1]Heinz Maier-Leibnitz-Zentrum, Technische Universität München — [2]Deutsches Elektronen Synchrotron DESY — [3]Department of Fibre and Polymer Technlogy, KTH Royal Institute of Technology

Poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS) is a conductive polymer blend widely used in organic electronics. However, pure PEDOT:PSS films absorb significant amounts of water (≈50 V%), causing swelling, degradation, and eventually a decrease in conductivity. Integrating PEDOT:PSS with cellulose nanofibrils (CNFs) overcomes these issues by limiting water absorption and enhancing mechanical stability. However, in humid environments, a minor amount of water is still absorbed, leading to a change in film morphology: the absorbed water induces de-wetting of PEDOT:PSS from the CNFs, reducing conductivity, whereas drying generally leads to a re-wetting of PEDOT:PSS, thereby restoring conductivity. To investigate further the role of water, quasi-elastic neutron scattering is applied, which reveals two water species in the films: mobile bulk water and slower hydration water. Upon drying, bulk water is released completely, while hydration water remains in the films, supporting the re-wetting of PEDOT:PSS. QENS also provides information on the diffusive and hydrogen-bonding behavior of water.

CPP 5.5 Mon 12:45 H38

Enhanced Physical Properties and Shape Recovery in Epoxy-Based Shape Memory Polymer Nanocomposites under Gamma Irradiation for Aerospace Applications — •Eman Taha — 1 Ahmed El-Zomor St, 11727, Cairo, Egypt.

This research explores the impact of gamma irradiation on the structural and functional properties of epoxy-based shape memory polymer nanocomposites, specifically engineered for potential satellite deployment mechanisms in space applications. To enhance durability and adaptability in extreme conditions, multi-walled carbon nanotubes (MWCNTs) were incorporated into the epoxy matrix, with surfactants added to improve dispersion. Using a Cobalt-60 gamma irradiation facility, doses ranging from 250 to 1000 kGy were applied, uncovering dose-dependent changes in thermal stability and mechanical properties. Surface tension tests confirmed effective dispersion with nonionic (Tween 80) and anionic (SDS) surfactants, while cationic surfactants had less impact. Thermogravimetric analysis revealed enhanced thermal stability at moderate doses due to increased crosslinking. Dynamic mechanical analysis showed shifts in viscoelastic behavior and higher glass transition temperatures (Tg), critical for thermal stress resistance. Shape memory performance improved at 250 kGy but declined at higher doses, indicating a balance between radiation exposure and functionality. These findings highlight controlled gamma irradiation as a tool to optimize the performance and stability of epoxy-based nanocomposites with MWCNT reinforcement, advancing their suitability for space applications.

Scattering data of A_4B_4 model networks reveal structure induced apparent interaction and cross-link repulsion — •Reinhard Scholz and Michael Lang — Leibniz-Institut für Polymerforschung, Hohe Str. 6, 01069 Dresden, Germany

Based on computer simulations, we analyze how different forms of labeling the network components allow to extract complementary structural information from scattering data. The analysis relies upon simulations of hetero-complementary bound four-functional star polymers A_4 and B_4. For optimized contrast between A and B stars, the calculated dynamic scattering intensity resembles A-B block copolymers with an apparent repulsion between both components, accounting for ordering effects due to the complementary coupling scheme. The position of the observed scattering peak is compatible with radius of gyration and end-to-end extension of A-B chains connecting adjacent star centers, providing access to the mesh size of the network. In samples with optimum contrast, the static correlation length Ξ is in the same range but somewhat smaller than the respective correlation length for homogeneously labeled polymers. Choices of the scattering contrast focusing on the star centers or on small regions around these reveal a correlation hole. Accordingly, scattering is suppressed towards small wave vectors, allowing for a decomposition of the observed scattering intensity into a product of the form factor of the labeled star sections and a structure factor describing the distribution of cross-links in space.

CPP 6.2 Mon 15:15 H34

Responsive Microgel Based Membranes — •Thomas Hellweg — Universität Bielefeld, Fak. f. Chemie, Physikalische und Biophysikalische Chemie, Universitätsstr. 25, 33615 Bielefeld

If microgels are made with comonomers which can act as (photo-)crosslinkable secondary crosslinker, they can be deposited in thin layers and subsequently be cross- linked by irradiation [1, 2]. Upon cross-linking freestanding membranes are obtained, which still exhibit the temperature response of the original microgels. The present contribution describes the synthesis and properties of the respective microgels, the membrane formation, and the membrane properties. The thermal response of the obtained 2D materials can be exploited to make gating membranes [3] which modulate ion flow by changing temperature which can be used in electrochemical devices. The resistance is found to steeply increase by up to an order of magnitude at the volume transition of the original microgels. Hence, these freestanding microgel membranes might be useful for building self- regulating fuel cells. Moreover, they can be doped with metal nanoparticles granting them catalytic activity and allowing to use them in flow reactors or microfluidic cells for chemical conversion [4].

CPP 6.3 Mon 15:30 H34

Correlation between swelling ability, softness and adhesion of PNIPAM microgels — •Carina Schneider, Kevin Hagmann, Joanne Zimmer, Franziska Braun, and Regine von Klitzing — Departement of Physics, TU Darmstadt, Hochschulstraße 8, 64289, Darmstadt

PNIPAM microgels (poly-N-isopropylacrylamide) are polymeric cross-linked networks with a core-shell structure. Due to their volume phase transition, it is possible to control their swelling and mechanical behavior. However, the concept of softness in these microgels, is highly complex and is not a single, well-defined property. In this study we show that it rather has a multifold characteristic that arises from a combination of several factors, such as their (de-)swelling ability, mechanical properties and adsorption behavior at interfaces. The cross-linker density of the microgels affect their adsorption behavior at interfaces and faceting. For exploring the multifold softness of adsorbed PNIPAM microgels, atomic force microscopy (AFM) is used to directly probe the mechanical and adhesion properties through indentation measurements and related them to their swelling ability. These insights into the microgel behavior could inform the design of next-generation microgels for biomedical applications.

CPP 6.4 Mon 15:45 H34

Deformation and actuation of 3D-printed polymeric microstructures predicted by finite element simulations — •Santiago Gomez Melo and Ulrich Schwarz — Univesität Heidelberg, Heidelberg

Mechanical metamaterials with promising properties can be manufactured via 3D-printing of polymers. Computational modelling, in addition to aiding conceptualization and characterization, opens the gate towards computer rationalized material design. We present two projects to this end. First, we discuss the experimental investigation of 3D-printed tetrahedral polymeric microlattices with X-ray nanotomography. Step-wise loading and image processing allowed us to evaluate the evolution of the displacement fields. Finite element simulations were used to understand the strain accumulation around lattice defects. Second, we demonstrate that the thermomechanical response of printed nematic elastomer microstructures can be controlled via confinement in PDMS-scaffolds. We applied Landau-de Gennes theory combined with nonlinear morphoelasticity to predict the molecular orientation from the scaffold geometry and the actuation upon heating, in excellent agreement with experimental measurements of birefringence patterns.

CPP 7: Active Matter II (joint session BP/CPP/DY)

CPP 7.1 Mon 15:00 H37

Emerging cellular dynamics from turbulent flows steered by active filaments — Mehrana Nejad[1,4], Julia Yeomans[2], and •Sumesh Thampi[2,3] — [1]Department of Physics, Harvard University, Cambridge, MA 02138 — [2]The Rudolf Peierls Centre for Theoretical Physics, Parks Road, Oxford OX1 3PU, UK — [3]Department of Chemical Engineering, Indian Institute of Technology, Madras, Chennai, India 600036 — [4]School of Engineering and Applied Sciences, Harvard University, Cambridge, MA 02138, USA

Describing the mechanics of cell collectives and tissues within the framework of active matter, without resorting to the details of biology is an exciting area. We develop a continuum theory to describe the dynamics of cellular collectives, discerning the cellular force-generating active filaments from cells shape. The theory shows that active flows and straining part of the active turbulence can elongate isotropic cells, which form nematic domains. This is important as cell morphology is not only an indicator of diseases but it can affect the nucleus morphology, gene expression and other biochemical processes inside the cells. Our theory highlights the importance of distinguishing the roles of active filaments from cell shape and explains outstanding experimental observations such as the origin of cell-filament alignment patches. Further, we reconcile how the contractile forces generated by the cytoskeletal network makes the cells to exhibit flow behaviours similar to that of extensile active systems. Revealing the crucial role of activity and rheology to describe the dynamics of cellular layers, our study is in consonance with a number of experimental observations.

CPP 7.2 Mon 15:15 H37

Defects in active solids: self-propulsion without flow — •Fridtjof Brauns[1], Myles O'Leary[2], Arthur Hernandez[3], Mark Bowick[1], and Cristina Marchetti[4] — [1]Kavli Institute for Theoretical Physics, Santa Barbara, USA — [2]Princeton University, Princeton, USA — [3]Leiden University, Leiden, the Netherlands — [4]University of California Santa Barbara, Santa Barbara, California 93106, USA

Topological defects are a key feature of orientational order and act as organizing centers of orientation fields. Self-propulsion of +1/2 defects has been extensively studied in active nematic fluids, where the defects are advected with the fluid through the flow field they generate. Here, we propose a minimal model for defect self-propulsion in a nematic active solid: a linear elastic medium with an embedded nematic texture that generates active stress and in turn is coupled to elastic strain. We show that such coupling gives rise to self-propelled +1/2 defects that move relative to the elastic medium by local remodeling of the nematic texture. This mechanism is fundamentally different from the fluid case. We show that this mechanism can lead to unbinding of defect pairs and stabilize +1 defects. Our findings might help explain how orientational order, e.g. of muscle fibers, is reconfigured during morphogenesis in solid-like tissues. For instance, motility and merging of +1/2 defects play a crucial role in setting up the body axis during Hydra regeneration.

CPP 7.3 Mon 15:30 H37

Isovolumetric dividing active matter — Samantha R. Lish[1], Lukas Hupe[1], Ramin Golestanian[1,2], and •Philip Bittihn[1] — [1]Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — [2]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, Oxford OX1 3PU, United Kingdom

We introduce and theoretically investigate a minimal particle-based model for a new class of active matter where particles exhibit directional, volume-conserving division in confinement while interacting sterically, mimicking cells in early embryogenesis. We find that complex motion, synchronized within division cycles, displays strong collective effects and becomes self-similar in the long-time limit. Introducing the method of normalized retraced trajectories, we show that the transgenerational motion caused by cell division can be mapped to a time-inhomogenous random walk with an exponentially decreasing length scale. Analytical predictions for this stochastic process allow us to extract effective parameters, indicating unusual effects of crowding and absence of jamming. Robustness of our findings against desynchronized divisions, cell size dispersity, and variations in confinement hints at universal behavior. Our results establish an understanding of the complex dynamics exhibited by isovolumetric division over long timescales, paving the way for new bioengineering strategies and perspectives on living matter.

CPP 7.4 Mon 15:45 H37

Tracking plankton-to-biofilm transition in phototrophic bacteria — •Anupam Sengupta — Physics of Living Matter Group, Department of Physics and Materials Science, University of Luxembourg, Luxembourg — Institute for Advanced Studies, University of Luxembourg, Luxembourg

Phototrophic bacteria commonly inhabit natural aquatic and marine ecosystems, exhibiting both motile and sessile lifestyles [1]. Yet, how and when they switch between the two states has remained unknown. Using quantitative imaging, AFM and mathematical modeling, we track the conditions and phenotypic changes across multiple generations in Chromatium okenii, a motile phototrophic purple sulfur bacterium [2]. Enhanced cell-surface adhesion together with changes in the cell shape and cellular mass distribution facilitate the motile-to-sessile shift. Our results, supported by cell mechanics model, establish a synergistic link between motility, mass distribution and surface attachment in promoting biofilm lifestyle. [1] T. Sommer et al., Geophys. Res. Lett. 44, 2017. [2] F. Di Nezio,.., & A. Sengupta, Plos one 19, e0310265, 2024.

CPP 7.5 Mon 16:15 H37

How localized active noises influence the conformations and dynamics of semiflexible filaments — •Shashank Ravichandir[1], Jens-Uwe Sommer[1,2], and Abhinav Sharma[1,3] — [1]Leibniz-Institut für Polymerforschung, 01069 Dresden, Germany — [2]Technische Universität Dresden, 01069 Dresden, Germany — [3]Universität Augsburg, 86159 Augsburg, Germany

The structure and dynamics of active polymers have been recently studied in some detail. In these works all the monomers are considered to be active. However, in most biological systems non-equilibrium fluctuations manifest as activity only at isolated locations within the polymer. There have been only few studies of such polymers, in which the active monomers occur periodically along the polymer contour. We consider arbitrary active-passive copolymers and isolate the effects of the number and locations of active monomers on the conformational and dynamical properties of polymers. We use Langevin dynamics simulations to calculate the end-to-end distance, radius of gyration, and mean-squared displacement of such semiflexible filaments and classify the various states of these polymers based on their conformational properties. We also present preliminary results of polymers in which the location of active monomer moves dynamically along the chain contour. This is an idealized model of biopolymers such as DNA, during DNA transcription, and microtubules, which are driven by kinetic motors that traverse along its length.

CPP 7.6 Mon 16:30 H37

Sequence-specific folding of partially active polymers — •Shibananda Das — Department of Physics, Indian Institute of Science, Bengaluru, India

Biological polymers like actin filaments and microtubules exhibit important physical properties due to their out-of-equilibrium behavior induced by ATP or GTP. In contrast, synthetic polymers rely on energy from their surrounding environment, often using local chemical, electrical, or thermal gradients to remain far from equilibrium. Theoretically, active polymers serve as minimal models for these systems, enabling systematic study of the competition between thermodynamic and active forces while they undergo conformational changes.

Using a combined analytical and numerical approach, we investigate an active polymeric chain composed of multiple self-avoiding units, representing good solvent condition in the absence of active forces. For partially active polymers without orientational constraints, we find that distribution of the active units in distinct sequences along the backbone can induce a significant collapse into folded, globular structures. Detailed analysis shows that this activity-dependent collapse is driven by a reduction in swim pressure of the monomers, linking the

distribution of active forces along the polymer contour to its folded conformations.

CPP 7.7 Mon 16:45 H37

Effect of interactions on the chemotactic response of active-passive chains — •Hossein Vahid[1], Jens-Uwe Sommer[1,2], and Abhinav Sharma[3] — [1]Leibniz-Institut für Polymerforschung, Dresden, Germany — [2]Technische Universität Dresden, Germany — [3]University of Augsburg, Augsburg, Germany

Living organisms, from single cells to populations, exhibit complex behaviors driven by the need to navigate toward favorable environments. These behaviors are often shaped by interactions within clusters or mixed populations, where collective dynamics play a crucial role in the characteristic properties of multicellular systems.

Chemotactic bacteria, found in diverse environments such as the gastrointestinal tract, plant surfaces, and aquatic ecosystems, demonstrate the significance of chemotaxis at the population level. While extensive research has focused on the properties of active polymers in spatially homogeneous activity fields, their behaviors in inhomogeneous fields remain less explored.

This study investigates the behavior of self-propelled polymers in activity gradients, emphasizing the effects of inter- and intra-chain interactions, such as steric and excluded volume effects, on chemotactic responses. These interactions give rise to distinct phases or collective behaviors that influence the stability and persistence of chemotaxis. Additionally, polymer density emerges as a critical factor impacting diffusion and the overall efficiency of chemotaxis. This work aims to study the dynamics of the active polymer populations in non-uniform environments systematically.

CPP 8: Hybrid and Perovskite Photovoltaics I

Time: Monday 15:00–16:00 Location: H38

Invited Talk CPP 8.1 Mon 15:00 H38

The Nanoscale Photovoltaics Laboratory on a Tip — •Stefan Weber — Institute for Photovoltaics, University of Stuttgart — Max Planck Institute for Polymer Research

Electrical scanning probe microscopy (SPM) modes are ideal for nanoscale photovoltaic measurements. I will discuss our recent work on developing specialized SPM techniques to study hybrid perovskite materials. Optimizing perovskite solar cells requires understanding energy losses, instability, and aging processes. These macroscale properties result from the interplay between nanoscale structure and function, including twin domains, grain boundaries, interfaces, and crystal grain orientations. Using static and time-resolved Kelvin probe force microscopy (KPFM), we can map the local surface potential, surface photovoltage (SPV), and cross-sectional potential distributions under operating conditions. With Nano-SPV spectroscopy, we achieve 10-20 nm lateral- and sub-millisecond temporal resolution. Our research aims to address key challenges in perovskite research, such as phase segregation, degradation, and interface heterogeneity, advancing understanding of loss mechanisms and instabilities in MHP solar cells.

CPP 8.2 Mon 15:30 H38

Sputter-Deposited TiOx Thin Film as a Buried Interface Modification Layer for Efficient and Stable Perovskite Solar Cells — •Xiongzhuo Jiang[1], Kun Sun[1], Zerui Li[1], Zhuijun Xu[1], Guangjiu Pan[1], Yusuf Bulut[1,2], Benedikt Sochor[2], Matthias Schwartzkopf[2], Kristian A. Reck[3], Thomas Strunskus[3], Franz Faupel[3], Stephan V. Roth[2], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Science, Chair for Functional Materials, 85748 Garching, Germany — [2]Deutsches Elektronen-Synchrotron (DESY), 22607 Hamburg, Germany — [3]Lehrstuhl für Materialverbunde, Institut für Materialwissenschaft, Christian Albrechts-Universität zu Kiel, 24143 Kiel, Germany

It is crucial to suppress the non-radiation recombination in the hole-blocking layer (HBL) and at the interface between the HBL and active layer for performance improvement. Herein, TiO_x layers are deposited onto a SnO_2 layer via sputter deposition at room temperature, forming a bilayer HBL. The structure evolution of TiO_x during sputter deposition is investigated via in situ grazing-incidence small-angle X-ray scattering. After sputter deposition of TiO_x with a suitable thickness on the SnO_2 layer, the bilayer HBL shows a suitable transmittance, smoother surface roughness, and fewer surface defects, thus resulting in lower trap-assisted recombination at the interface between the HBL and the active layer. With this SnO_2/TiO_x functional bilayer, the perovskite solar cells exhibit higher power conversion efficiencies than the unmodified SnO_2 monolayer devices.

CPP 8.3 Mon 15:45 H38

Dynamics and kinetics of light-induced phase segregation in $MAPbBr_{1.8}I_{1.2}$ perovskites — •Ivan Zaluzhnyy[1], Linus Pithan[2], Rustam Rysov[2], Frederik Unger[1,2], Jakub Hagara[1], Ekaterina Kneschaurek[1], Paul Zimmermann[1], Sebastian Schwartzkopff[1], Lena Merten[1], Dmitry Lapkin[1], Alexander Hinderhofer[1], Fabian Westermeier[2], Michael Sprung[2], Yana Vaynzof[3,4], Fabian Paulus[5,4], and Frank Schreiber[1] — [1]University of Tübingen — [2]Deutsches Elektronen-Synchrotron DESY — [3]Technical University of Dresden — [4]Center for Advancing Electronics Dresden (cfaed) — [5]IFW Dresden

Hybrid organic-inorganic perovskites tend to undergo several structural transformations that can be caused by temperature, humidity and light. Here we use X-ray photon correlation spectroscopy (XPCS) to study the dynamics of light-induced phase segregation in $MAPbBr_{1.8}I_{1.2}$ and the formation of Br-rich and I-rich domains. We observe that the phase segregation is characterized by three distinct time scales corresponding to the rapid formation of small seeds of the I-rich phase, fluctuations of the ion distribution around the quasi-equilibrium state (dynamics), and a directional drift of the ions within the crystal grains (kinetics). We also observe the influence of defects in the halide sublattice on phase separation and find that samples with interstitial halides exhibit slower phase separation as samples with vacancies in the halide sublattice.

CPP 9: Biomaterials and Biopolymers (joint session BP/CPP)

Time: Monday 15:00–16:45 Location: H46

CPP 9.1 Mon 15:00 H46

Ferroelectric Microelectrodes for Hybrid Neuroelectronic Systems — •Maximilian T. Becker[1,2], Roland Thewes[3], and Günther Zeck[4] — [1]Department of Embedded Systems, Hahn-Schickard, Freiburg, Germany — [2]Faculty of Engineering, University of Freiburg, Freiburg, Germany — [3]Chair of Sensor and Actuator Systems, TU Berlin, Berlin, Germany — [4]Institute of Biomedical Electronics, TU Wien, Vienna, Austria

Direct electrical interfacing of semiconductor chips with individual neurons and neural networks forms the basis for a systematic assembly and investigation of hybrid neuroelectronic systems with future applications in information technology and biomedicine. The neuroelectronic interface is realized via microelectrodes to bidirectionally transmit electrical signals between neurons and the semiconductor chip. Here, we introduce the concept of ferroelectric microelectrodes and discuss the physics of ferroelectric interfaces in neuroelectronic applications. As an example, we present neural recordings from retinal ganglion cells (RGCs) interfaced with a ferroelectric complementary metal-oxide-semiconductor microelectrode array (CMOS-MEA) and discuss the results in detail.

CPP 9.2 Mon 15:15 H46

Highly sensitive, specific and label-free detection of SARS-CoV-2, Influenza A and RSV proteins via surface plasmon resonance technique using the biofunctionalization with 1 nm thick carbon nanomembranes — •Ghazaleh Eshaghi[1], David Kaiser[1], Hamid Reza Rasouli[1], Rania Ennaciri[1], Martha Frey[1], Christof Neumann[1], Dominik Gary[2], Tobias Fischer[2], Katrin Frankenfeld[2], and Andrey Turchanin[1] — [1]Institute of Physical Chemistry, Friedrich Schiller University Jena, 07743 Jena, Germany — [2]Forschungszentrum für Medizintechnik und Biotechnologie (fzmb) GmbH, 99947 Bad Langensalza, Germany

Accurate and rapid detection of respiratory viruses like SARS-CoV-2, Influenza A and RSV is crucial for improving global health outcomes. We present a novel surface plasmon resonance (SPR) platform using a biofunctionalized 1 nm-thick carbon nanomembrane (CNM) for enhanced viral protein detection. The azide-modified CNM (N3-CNM) enables covalent antibody binding, ensuring selective immobilization of target proteins. Our platform achieves equilibrium dissociation constants (KD) of 570 * 30 pM and 22 * 3 pM for SARS-CoV-2 nucleocapsid and spike proteins, with detection limits (LODs) of ~190 pM and ~10 pM, respectively. For Influenza A and RSV, KD values are 86 * 4 pM and 3 * 0.2 pM, with LODs of ~90 pM and ~2 pM. Multiplexed detection with no cross-

reactivity supports rapid, accurate point-of-care diagnostics. Validation with nasopharyngeal swabs confirms a LOD of ~40 pM for SARS-CoV-2 spike protein, highlighting CNMs' promise in infectious disease diagnostics.

CPP 9.3 Mon 15:30 H46

Superselective multivalent client recruitment in biomolecular condensates — •Xiuyang Xia and Erwin Frey — Ludwig-Maximilians-Universität München

Biomolecular condensates (BMCs) are membraneless organelles formed via liquid-liquid phase separation, playing a crucial role in organizing cellular functions by selectively concentrating specific molecules. In this talk, I will present a new theoretical framework that models multivalent client recruitment in valence-limited, multicomponent systems like BMCs. We uncover how enthalpic and entropic factors interplay under valence constraints to enable switch-like recruitment and precise compositional regulation.

This work advances our understanding of the principles governing BMC composition and highlights the broader significance of multivalency in biological systems, offering insights into cellular organization and potential therapeutic applications.

CPP 9.4 Mon 15:45 H46

What is the structure of a biomolecular condensate? — •Charlotta Lorenz[1,2], Teagan Bate[1], Takumi Matsuzawa[1], Kaarthik Varma[1], Sully Bailey-Darland[1], George Wang[1], Dana Matthias[1], Harsha Koganti[2], Nicola Galvanetto[2], Matti Valdimarsson[2], Aleksander Rebane[3], Etienne Jambon-Puillet[4], Ben Schuler[2], and Eric R. Dufresne[1] — [1]Cornell University, Ithaca, NY, USA — [2]University of Zurich, Zurich, Switzerland — [3]New York University Abu Dhabi, Abu Dhabi, United Arab Emirates — [4]École Polytechnique Paris, Paris, France

Biomolecular condensates are important for a variety of cellular functions, such as biochemical regulation, structural organization, and RNA metabolism. While the properties and physiology of these condensates depend on their structure, this important aspect has received little experimental consideration. On the other hand, recent simulations of disordered proteins with interactions based on the sticker-and-spacer suggest fascinating structures in the bulk and surface of condensates. We aim to reveal the structure of biomolecular condensates using X-ray scattering. Here, we will present results for a simple model system and apply our approach to the structure of condensates made of disordered proteins. We particularly consider the change in condensate structure due to small molecules.

CPP 9.5 Mon 16:00 H46

Encoding how shear stress during gelation boosts the stiffness of collagen networks — •Pavlik Lettinga[1,2], Lens Dedroog[2], Olivier Deschaume[2], Yovan de Coene[2], Carmen Bartic[2], Erin Koos[2], and Mehdi Bouzid[3] — [1]Forschungszentrum Jülich — [2]KU Leuven — [3]Université Grenoble Alpes

Collagen is one of the main building blocks of the mammalian extracellular matrix, due to its ability to form tough structures with a wide variety of non-linear mechanical properties allowing it to support multiple tissue types. However, the mechanical properties of collagen gels have been extensively studied under static conditions, whereas in nature gelation will mostly take place in the presence of flow. Here we show how the elastic modulus of collagen hydrogels can be increased up to an order of magnitude by applying a stress ramp at a well-defined moment during gelation. Where the first stress block induces most of the final strain and alignment, sequential increases in stress cause a dramatic increase of the modulus. This high modulus is preserved by keeping the high stress until the gel is fully matured. Coarse-grained simulations of a model gel system show that that the microscopic mechanism of inducing high stiffness is due to formation of extra cross bridges and could be very generic. Thus, we not only show that the true non-linear capabilities of biomaterials are tenfold higher than previously assessed, but also provide insight into in vivo structure formation of collagen and potentially other (bio-)polymers.

Invited Talk CPP 9.6 Mon 16:15 H46

In situ control of cells and multicellular structures at the microscale by two-photon lithography — •Christine Selhuber-Unkel — Heidelberg University, IMSEAM, Heidelberg, Germany

In vivo, cells and multicellular assemblies often experience strong confinement by their surrounding tissue environment, particularly in cancer. Thus, replicating these confined environments in situ is essential for investigating their impact on cellular systems. Using two-photon lithography, we printed structures directly within and around multicellular assemblies. For example, we fabricated dome-shaped confinements with micrometer-scale openings to encapsulate cancer spheroids. This enabled us to study how confinement influences cancer cell migration and spheroid behavior. Our findings revealed that confinement slows cell migration and alters actin dynamics. In addition, in situ printed structures can also directly interfere with migrating cellular assemblies. Additionally, elastic structures can be created to mechanically stimulate cells, offering further control over cellular behavior. Therefore, two-photon lithography proves to be a powerful tool for manipulating the growth, migration, and morphology of live cells, making it particularly useful for exploring how changing physical microenvironment in situ affect cell responses.

CPP 10: Wetting, Fluidics and Liquids at Interfaces and Surfaces I (joint session CPP/DY)

Time: Monday 16:15–17:15 Location: H34

CPP 10.1 Mon 16:15 H34

Beyond contact angle measurements of aerophilic surfaces — •Alexander Tesler[1], Wolfgang Goldmann[1], Anca Mazare[2], Ben Fabry[1], Stefan Kolle[3], Robin A.H. Ras[4], Heikki Nurmi[4], George Sarau[5], and Silke Christiansen[5] — [1]Biophysics Chair, Erlangen, Germany — [2]WW4-LKO, Erlangen, Germany — [3]UCSD, San Diego, USA — [4]Aalto University, Epsoo, Finland — [5]Fraunhofer Institute, Forchheim, Germany

Aerophilicity can provide surface resilience to the detrimental effects of wetting-related phenomena. However, the development of such superhydrophobic surfaces with a long-lasting entrapped air layer, called plastron, is hampered by the lack of evaluation criteria and methods that can unambiguously distinguish between stable and metastable Cassie-Baxter wetting regimes. The information to evaluate the stability of the wetting regime is missing from the commonly used contact angle goniometry. Therefore, it is necessary to determine which surface features can be used as a signature to identify thermodynamically stable plastron. Here, I describe a methodology for evaluating the thermodynamic underwater stability of the Cassie-Baxter wetting regime of superhydrophobic surfaces by measuring the surface roughness, solid-liquid area fraction, and Young's contact angle. The method allowed the prediction of passive plastron stability for over one year of continuous submersion,[1] impeding mussel and barnacle adhesion,[2] and inhibition of metal corrosion in seawater.[3] [1] Tesler et al., Commun. Mater. 2024, 5, 112. [2] Tesler et al., Nat. Mater. 2023, 22, 1548. [3] Prado et al., Adv. Funct. Mater. 2024, 35, 2407444.

CPP 10.2 Mon 16:30 H34

Fluid flow inside slit-shaped nanopores: the role of molecular surface morphology — •Giorgia Marcelli[1], Tecla Bottinelli Montadon[1], Roya Ebrahimi Viand[1], and Felix Höfling[1,2] — [1]Institute of Mathematics, Freie Universität Berlin, Germany — [2]Zuse Institute Berlin, Germany

The boundary conditions of nanoscale flows near surfaces can deviate from the no-slip condition observed at macroscopic scales, and used in classical fluid mechanics. In this context, we investigate the influence of surface morphology on fluid flow inside slit-shaped nanopores [1]. Using non-equilibrium molecular dynamics (NEMD) simulations, we demonstrate that the surface morphology effectively controls the slip length, which approaches zero when the molecular structures of the pore wall and the fluid are matched. We examine two types of pore walls, mimicking a crystalline and an amorphous material, that exhibit markedly different surface resistances to flow. The resulting flow velocity profiles are consistent with Hagen–Poiseuille theory for incompressible, Newtonian fluids when adjusted for surface slip and effective viscosity; the latter is found to vary substantially with the pore width. Moreover, analysis of the hydrodynamic permeability shows that the simulated flows are in the Darcy regime. We further show that thermal isolation within the pore causes a linear increase in fluid temperature along the flow, which we relate to strong viscous dissipation and heat convection, utilizing the conservation laws of fluid mechanics.

CPP 10.3 Mon 16:45 H34

How do polymers of different architecture penetrate nanochannels? — •Panagiotis Kardasis[1] and George Floudas[2] — [1]Department of Physics, University of Ioannina, 45110 Ioannina, Greece — [2]Max Planck Institute for Polymer Research, 55128 Mainz, Germany

The way that polymers penetrate narrow pores is of both academic and technological importance. Capillary force can drag polymer chains into nanopores, a process called imbibition. Using in situ nanodielectric spectroscopy (nDS), we report the imbibition and following adsorption kinetics of star cis-1,4-polyisoprenes (SPI) and of bottlebrush polymers directly at the chain length scale by monitoring the evolution of the normal modes, during the flow within in alumina nanopores (AAO), as a function of chain architecture (vs linear), pore size, molar mass, and temperature. We demonstrate that the imbibition kinetics of SPIs proceeds via a slow adsorption mechanism, about 2 orders of magnitude

slower than in linear polyisoprenes (PI). We further demonstrate that the bottlebrush topology results in slower adsorption in nanopores in comparison to linear counterpart, albeit, with different dependence. Additionally, bottlebrushes present weaker temperature dependence comparing to both linear and star polymers. Furthermore, we explore how symmetric star / linear and brush / linear blends penetrate the same nanopores and we demonstrate that differences in the imbibition and adsorption kinetics can be used to separate the homogeneous blend to its components, giving rise to *topology sorting*, based on the relative viscosities and pore diameter.

CPP 10.4 Mon 17:00 H34

Removing particles from hydrophobic surfaces by single water drops — •Franziska Sabath, Stefanie Kirschner, and Doris Vollmer — Max Planck Institute for Polymer Research, 55128 Mainz, Germany

The accumulation of dust on surfaces is a well-known phenomenon in everyday life, for example on windows and solar panels. Both manual cleaning and self-cleaning of hydrophobic surfaces with water can restore the properties of soiled surfaces. However, it is not yet understood how particles are removed by a water drop and which forces play a role for successfully removing the particles. We investigated the removal of two or more particles from hydrophobic coatings by a single water drop. For this purpose, we used a confocal microscope with a sliding drop setup. This implies that the particles was moved at constant velocity while the drop is hold in position by a blade. The sliding drop and the way in which the particles are picked up and pulled along by the water drop can be imaged. From the deflection of the blade, we can determine the force required to pull the particles along with the drop. Here, we focus on the removal of spherical model particles and the impact of drop volume, particles size and particle velocity on the particle removal. At low velocities the particles remain attached to the drop. With increasing velocity we observe that the particle detachment becomes more likely. In case of particle detachment, we observe a correlative effect: after the second particle has reached the rear side of the drop, both particles can detach together.

CPP 11: Hybrid and Perovskite Photovoltaics II

Time: Monday 16:15–17:00 Location: H38

CPP 11.1 Mon 16:15 H38

Structure and morphology investigations on slot-die coated perovskite nanocrystal films — •Thomas Baier[1], Altantulga Buyan-Arivjikh[1], Lixing Li[1], Xiaojing Ci[1], Matthias Schwartzkopf[2], Sarathlal Koyiloth Vayalil[2,3], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany — [3]Applied Sciences Cluster, University of Petroleum and Engergy Studies UPES, Dehradun, Uttarakhand 248007, India

Perovskite quantum nanocrystals hold great potential for contributing to the future renewable energy mix by serving as the active layer in solar cells. This potential arises from quantum confinement effects, which occur when crystal sizes are reduced below the Bohr radius. These nanocrystals achieve high power conversion efficiencies, excellent photoluminescence quantum yield (PLQY), narrow photoluminescence (PL) peaks, and enhanced stability compared to bulk perovskite. Additionally, the choice of X halides (I-, Br-, Cl-) and A-site cations (FA+, MA+, Cs+) within the ABX3 perovskite structure allows precise bandgap tuning. Cesium-formamidinium lead iodide perovskite nanocrystals have been prepared and slot-die coated. These perovskite nanocrystals as active layers are investigated using in-situ grazing incidence small- & wide-angle x-ray scattering (GISAXS & GIWAXS) to better understand the layers formation process.

CPP 11.2 Mon 16:30 H38

Tracking the Crystallization Pathway of Perovskite using Microscopy, Spectroscopy and Machine Learning — •Meike Kuhn[1], Milan Harth[2], Alessio Gagliardi[2], and Eva M. Herzig[1] — [1]Dynamik und Strukturbildung - Herzig Group, Universität Bayreuth, Universitätsstr. 30, 95447 Bayreuth, Germany — [2]Simulation of Nanosystems for Energy Conversion, Technische Universität München, Hans-Piloty-Str. 1, 85748 Garching b. München, Germany

The interest in perovskite materials has grown significantly in recent years due to their diverse applications, with the crystallization process playing a crucial role in determining the final properties of perovskite films. Time-resolved techniques, such as microscopy and spectroscopy, enable detailed analysis of the various stages of perovskite formation.

In this study, we investigated the crystallization of methylammonium lead iodide (MAPbI3) blade coated from dimethylformamide (DMF), using a combined microscopy and spectroscopy approach. This approach allowed us to observe morphological and optical changes during intermediate phase formation and perovskite conversion, influenced by the addition of various additives. By applying a machine learning model to the microscopy data, we developed a predictive framework capable of estimating spectroscopic signals, thus enabling insights into physical properties with time-resolved microscopy.

CPP 11.3 Mon 16:45 H38

Utilizing CsPbBr3 Nanocrystals as Nucleation Seeds for Scalable FAPbI3 Thin Films — •Altantulga Buyan-Arivjikh[1], Jascha Fricker[1], Thomas Baier[1], Xiaojing Ci[1], Lixing Li[1], Matthias Schwartzkopf[2], Sarathlal Koyiloth Vayalil[2], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]DESY, 22604 Hamburg, 22607, Germany

Lead-halide perovskites have gained a significant interest in the scientific community owing to their favorable optoelectronic properties combined with their ease of production and abundance of raw materials. In many cases, polycrystalline thin films are fabricated, where the crystallinity and morphology of the thin film are critical factors influencing the properties and performance of perovskites. In this work, we present a novel approach for improving the quality of FAPbI3 thin films by utilizing CsPbBr3 nanocrystals as nucleation seeds. In-situ optical spectroscopy experiments reveal a faster transition of FAPbI3 into the photactive phase in the seeded thin films as well as a reduced defect density. In-situ grazing incidence wide angle X-ray scattering (GIWAXS) measurements confirm the former and additionally show that the seed crystals improve the thin film texture by inducing a preferred crystallite orientation.

CPP 12: Biomaterials, Biopolymers and Bioinspired Functional Materials I (joint session CPP/BP)

Time: Monday 17:00–18:00 Location: H46

CPP 12.1 Mon 17:00 H46

Polymer Assisted Condensation and Heterochromatin — •Jens-Uwe Sommer — Leibniz-Institut für Polymerforschung Dresden (IPF), Hohe Straße 6, 01069 Dresden, Germany — TU Dresden, Insitut für Theoretische Physik, Zellescher Weg 17, D-01069 Dresden, Germany

Many biomolecular condensates are formed through the co-condensation of proteins and polynucleotides. In most cases, the proteins that constitute the majority of the condensate exhibit a miscibility gap in aqueous solution at elevated concentrations in vitro. Recently, we published the theory of Polymer-Assisted Condensation (PAC), which predicts the formation of the condensate within the polymer's volume of gyration, where interactions with the three-dimensional conformation of the polymer trigger the phase transition of the protein component [1]. A key feature of these liquid condensates is their robustness against changes in parameters, as well as the dominant role played by the condensation free energy of the protein component. The formation and properties of heterochromatin, a genetically silenced region of eukaryotic chromosomes, can be explained by PAC, which resolves several issues present in previously published theories. Recently, we developed a field-theoretic approach to PAC to better understand the adsorption and desorption scenarios of heterochromatin at the nuclear lamina.

CPP 12.2 Mon 17:15 H46

How specific binding induces sol-gel transitions and liquid-liquid phase separation in RNA/protein solutions: Coarse-grained simulations versus Semenov-Rubinstein Theory — •Xinxiang Chen, Jude Ann Vishnu, Pol Besenius, Julian König, and Friederike Schmid — Johannes Gutenberg-University, Mainz, Germany

Liquid-liquid phase separation plays a central role in cellular organization, including RNA splicing. RNA-protein interactions are crucial to these processes. A key factor in controlling the phase behavior of RNA-protein systems is the sequence of binding and neutral domains. Using molecular dynamics simulations, we investigate phase transitions in RNA-protein solutions that are driven solely by specific binding interactions. The model omits nonspecific interactions including electrostatic interactions. We show that specific binding interactions

induce a percolation transition with double reentrant behavior without phase separation, if the neutral linker size is long. Comparing our results with the two-component Rubinstein-Semenov theory, we find that the theory qualitatively reproduces the phase diagram of the percolation transition and the impact of the neutral domains. Phase separation is observed when reducing the neutral linker size in an asymmetric system, resulting in a closed-loop phase diagram. We also study the effect of modulating the sequence and find that blockiness of sticker sites introduces microstructure in the dense liquid phase. These insights enhance our understanding of how specific binding and domain arrangement regulates condensate formation in RNA-protein systems.

CPP 12.3 Mon 17:30 H46

Model particles to study interaction of microplastic particles — •Kai Gossen, Andreas Fery, and Günter Auernhammer — IPF Dresden, Dresden, Germany

Microplastic in the environment is typically coated by natural organic matter forming an ecocorona. We present an approach to model ecocorona on particles with well-defined polymers, synthetic and derived from natural polymers. Polystyrene particles were coated with fluorescent polyelectrolyte multilayer systems, PS(Chitosan/Hyaluronic acid) and PS(Poly(dimethyldiallylammonium chloride) /Polystyrene sulfonate) by the layer-by-layer method. Systems with 2, 4 and 6 bilayers were synthesized. The second layers were fluorescently labelled with SNARF conjugated dextran.

It was found that zeta potentials of the PS(Chi/HS)2/4/6 systems assume values (-20 mV to -35 mV) that are similar to those of PS-ecocorona particles (-40 mV to -5 mV). The pH-dependent fluorescence of particle suspensions and individual particles were measured at pH values between pH 3 and pH 8. A well measurable pH dependence between pH 4.5 and 8 for the PS(Chi/HS) systems and the PS(PDADMAC/PSS) system could be measured. The system could serve to selectively study effects of surface properties of ecocorona coated particles such as surface stiffness or zeta potential.

CPP 12.4 Mon 17:45 H46

Microgels for Enhanced Adsorption of Endothelial Cells on Artificial Networks — •Souraj Mandal[1], Anna Fritschen[2], Alina Filatova[3], and Regine von Klitzing[1] — [1]Soft Matter at Interfaces, Department of Physics, Technical University of Darmstadt, Darmstadt 64289, Germany — [2]BioMedical Printing Technology, Department of Mechanical Engineering, Technical University of Darmstadt, 64289 Darmstadt, Germany — [3]Stem Cell and Developmental Biology, Technical University of Darmstadt, 64287 Darmstadt, Germany

Three-dimensional cellular models hold great promise for drug testing, but their success relies on maintaining a controlled supply of oxygen and nutrients. Artificial vascular networks aim to mimic blood vessel functions, yet ensuring robust endothelial cell (EC) attachment remains a significant challenge. In this study, we designed a mediator between artificial network surfaces and ECs using Poly(N-isopropylacrylamide) (PNIPAM) microgels (MGs) that remain mechanically stable in nutrient solutions. Charged MGs were synthesized and tested for adhesion on plasma-treated model surfaces. The microgel-coated substrates were exposed to cell static culture media and under defined flow. Atomic force microscopy (AFM) confirmed stable adhesion of MG particles before and after exposure. Initial experiments explored EC attachment on positively and negatively charged MG surfaces, followed by mechanical property characterization. The MG coatings were biofunctionalized with integrin-recognized ligands to enhance EC adhesion and proliferation further.

CPP 13: Molecular Electronics and Excited State Properties I

CPP 13.1 Mon 17:15 H38

Revealing the Origin of low-energy Excited State Absorption in the nonlinear Optical Properties of Thiophene — •Mustapha Driouech, Michele Guerrini, and Caterina Cocchi — Carl von Ossietzky Universität Oldenburg

Optical nonlinearities in organic molecules are useful for advanced applications. Among them, optical limiting is particularly relevant to prevent critical damage to the human eyes and artificial sensors from intense radiation. In this ab initio study, we investigate the nonlinear optical properties of thiophene oligomers with a non-perturbative approach based on real-time time dependent density functional theory [1]. We study the optical absorption spectra obtained after applying a broadband instantaneous electric field. For sufficiently high intensities, we observe the appearance of absorption peaks at low energies that are not present in the linear spectra. To investigate in more details the nonlinear mechanisms involved, we perform pump-probe simulations combined with analysis of the population dynamics revealing that the emerging features are due to excited state absorption in the visible region. Our results show that this fully ab initio methodology is able to capture and unravel the fundamental mechanisms of optical nonlinearities in organic molecules.

CPP 13.2 Mon 17:30 H38

Theoretical perspectives on ground- and excited state absorption in organic materials: comparing TDDFT, GW/BSE, and post-Hartree-Fock methods — •Narges Taghizade[1], Andreas Windischbacher[1], Andreas W. Hauser[2], and Peter Puschnig[1] — [1]Institute of Physics, University of Graz, Austria — [2]Institute of Experimental Physics, Graz University of Technology, Austria

Ground- and excited-state absorption (ESA) properties of conjugated organic materials are fundamental to the development of advanced optoelectronic devices. In this contribution, we specifically focus on molecules, which pose challenges to traditional theoretical approaches owing to significant electron correlation resulting in complex charge transfer and multi-reference characteristics, particularly when it comes to excited state properties. To address these complexities, we compute the ground and ESA spectra using a number of complementary, advanced theoretical methods. First, we employ time-dependent density functional theory within the linear and quadratic response frameworks, respectively. Second, we present results from a GW/BSE many-body perturbation theory approach thereby addressing the challenge of accurately accounting for charge transfer excitations. Third, we also apply post-Hartree-Fock methods, such as the multi-configurational self-consistent field method in order to tackle the strong electron correlation and multi-reference effects. The comparison of our results highlights the strengths and limitations of various computational approaches and offers a pathway toward improved theoretical models for the design of efficient optoelectronic materials.

CPP 13.3 Mon 17:45 H38

Charge and energy transfer mechanisms in a singlet fission donor-acceptor complex — •Karin S. Thalmann[1], Johan E. Runeson[1], Pedro B. Coto[2], and Michael Thoss[1] — [1]Institute of Physics, University of Freiburg, Germany — [2]Spanish National Research Council (CSIC), Madrid, Spain

Singlet fission is a photophysical process transforming a singlet excited electronic state to two triplet states [1]. Thus, materials exhibiting singlet fission have the potential to increase the efficiency of solar cells. Adding an acceptor to a singlet fission active molecule enables the extraction of charges and excitation energy. In our work, we study a diazadiborine dimer as donor [2] and tetracyanoquinodimethane as acceptor molecule. Using *ab initio* multireference perturbation theory calculations, we build a vibronic model Hamiltonian and further perform quantum dynamical [3] and mixed quantum-classical simulations [4] to analyse the charge and energy transfer dynamics in the complex. With our techniques, we characterise competing charge and energy transfer processes as well as intramolecular and intermolecular singlet fission. The analysis reveals the role of the different electronic states and vibrational modes in the dynamics of the donor-acceptor complex.

CPP 13.4 Mon 18:00 H38

The Influence of Solvent Nature and Annealing Conditions on the TADF Properties of DMAC-TRZ in Films and Single Crystals — •Anatolii Kuimov[1], Sergey Bagnich[1], Christopher Greve[2], Eva M. Herzig[2], and Anna Köhler[1] — [1]Soft Matter Optoelectronics, University of Bayreuth, Germany — [2]Dynamik und Strukturbildung - Herzig Group, Universität Bayreuth, Germany

We investigated the impact of molecular arrangement and post-processing conditions on the thermally activated delayed fluorescence (TADF) of the donor-acceptor type molecule DMAC-TRZ. Specifically, we studied luminescence at various temperatures and time delays after excitation across different solid-state morphologies, including amorphous films, polycrystals, and single crystals, complemented by X-ray analysis of the single crystal. In single crystals, we observed that emission energy, the singlet-triplet gap, and TADF intensity were influenced by processing conditions, such as aging, thermal and solvent annealing, and the choice of solution for crystal growth. These effects are attributed to changes in the torsion angle between the donor and acceptor moieties. Comparisons with polycrystals and amorphous films reveal that introducing morphological disorder promotes a more orthogonal donor-acceptor arrangement, leading to a smaller singlet-triplet gap and enhanced TADF. Our findings emphasize the pivotal role of molecular conformation in modulating photophysical properties. This study highlights the potential of tailoring material performance through

structural modifications and annealing strategies to optimize TADF efficiency for organic optoelectronic applications.

CPP 13.5 Mon 18:15 H38

Effect of Junction Structure on Quantum Interference in Single-Molecule Junctions — •Aoshi Yamane, Shintaro Fujii, and Tomoaki Nishino — Department of Chemistry, School of Science, Institute of Science Tokyo, 2-12-1 Ookayama, Meguro-ku, Tokyo, Japan

The destructive quantum interference (DQI) effect in single-molecule junctions induces a steep decrease in electron transmission at specific energies, enables high on/off ratios of electrical conductivity, and is expected to be applied to molecular devices such as transistors and switches. Here, we aimed to elucidate the effects of molecular and molecule/metal interface structures on DQI. We focused on disubstituted naphthalene with different types and positions of anchoring groups connecting molecules and electrodes. Break junction measurements of the molecular junctions demonstrated that for naphthalenedithiol (NDT), 2,7-NDT showed significantly lower conductivity compared to 2,6-NDT, indicating the presence of DQI in 2,7-NDT. On the other hand, for naphthalenedicarbonitrile (NDCN), 2,6-NDCN and 2,7-NDCN showed similar conductance. Combined with Flicker noise analysis and DFT-NEGF transmission calculations, we demonstrate that the DQI features in 2,7-NDCN are masked by the contribution of electrode-π coupling, which short-circuit the molecular junctions. The present study provides important insights into the control of unique electron transport properties induced by DQI in single-molecule junctions.

CPP 14: Wetting, Fluidics and Liquids at Interfaces and Surfaces II (joint session CPP/DY)

CPP 14.1 Mon 17:30 H34

Vapor-mediated wetting and imbibition control on micropatterned surfaces — •Ze Xu and Stefan Karpitschka — Fachbereich Physik, Universität Konstanz, Konstanz, Germany

Wetting and evaporation of droplets on micropatterned surfaces are ubiquitous in nature and key to many technological applications, such as water/ice-proof coatings, spray cooling, inkjet printing, and semiconductor surface processing. The wettability of micropatterned surfaces is governed by surface chemistry and topography, and significant effort has been devoted to overcoming this intrinsic behavior, e.g. to dry or coat structures surfaces, by use of external stimuli like electromagnetic fields. However, these methods usually require specific materials, thus limiting their practical use. Here, we show that the spreading behavior of water droplets on hydrophilic surface patterns can be controlled and even temporarily inhibited by the presence of the vapor of a low surface tension liquid. We show that this delayed wicking arises from Marangoni forces due to vapor condensation at the droplet periphery that compete with the capillary wicking force of the surface topography. We further demonstrate how modulating the vapor concentration in space and time can be used to guide droplets across patterns and even extract liquid from fully imbibed films, devising new strategies for coating, cleaning and drying of functional surface designs.

CPP 14.2 Mon 17:45 H34

Gradient dynamics model for volatile binary mixtures including Marangoni flows — •Jan Diekmann und Uwe Thiele — Universität Münster, Wilhelm-Klemm-Straße 9, 48149 Münster

We present a mesoscopic thin-film model in gradient dynamics form for binary liquid mixtures on solid substrates incorporating interface tension-induced flow, and volatility in a narrow gap. Thereby, we use and expand models established in [1-4] by accounting for the two substances in each of two bulk phases - liquid and gas - and for the enrichment of one component at the liquid-gas interface. We discuss the different contributions to the free energy, thereby employing Flory-Huggins theory of mixing for the condensed phase and assuming ideal gases for the vapor phase. The resulting five-field model is then analyzed with numerical time simulations focusing on the interplay of the drop dynamics with the developing lateral concentration gradients, and the resulting Marangoni flows. The results are compared to experimental findings [5].

CPP 14.3 Mon 18:00 H34

Fast dynamics of PNIPAM microgels at fluid interfaces: insights from droplet bouncing and jetting — Atieh Razavi, Suvendu Mandal, Benno Liebchen, Regine von Klitzing, and •Amin Rahimzadeh — Technische Universität Darmstadt, Hochschulstrasse 8, 64289 Darmstadt, Germany

PNIPAM microgels, as cross-linked polymer networks, are known to adsorb at the air-water interface, reducing surface tension. The kinetics of their adsorption, and thus the dynamic surface tension, depend on their cross-linking density, which determines the stiffness of individual microgels. Under interfacial perturbations such as dilation, softer microgels restore surface tension more rapidly, creating interfaces with higher surface elastic moduli, as shown by interfacial rheology studies using profile analysis tensiometry (1-10 s timescales). However, the behavior of microgels under very rapid interfacial deformations (milliseconds) remains unclear. We address this question through experiments involving droplet bouncing and jetting, processes relevant to applications such as inkjet printing and needle-free drug delivery. Our results demonstrate that microgels rapidly respond to fast interfacial deformations, with softer microgels restoring surface tension more efficiently. This quicker response allows greater interfacial extension in the presence of softer microgels. Molecular dynamics simulations corroborate our experimental findings, providing further insight into the mechanisms at play. This study highlights the critical role of microgel stiffness in determining their interfacial dynamics across a wide range of timescales and deformation rates.

CPP 14.4 Mon 18:15 H34

Soft dynamic wetting transition — •Christopher Henkel[1], Vincent Bertin[2], Jacco Snoeijer[2], and Uwe Thiele[1,3] — [1]Institut für Theoretische Physik, Universität Münster, Germany — [2]Physics of Fluids Group, Faculty of Science and Technology, Mesa+ Institute, University of Twente, The Netherlands — [3]Center for Nonlinear Science (CeNoS), Universität Münster, Germany

We investigate the forced receding and advancing dynamics of a three-phase contact line on a viscoelastic substrate, i.e., the wetting transition of a substrate from macroscopically dry to wet or vice versa. Thereby, we use the Landau-Levich (or dip-coating) geometry, where a solid viscoelastic plate is dragged out of or pushed into a liquid bath. We employ a mesoscopic hydrodynamic model in long-wave approximation, i.e. valid at small contact angle and plate inclination. The elastic response of the substrate follows the Winkler foundation with a Kelvin-Voigt relaxation. In particular, we investigate how the shape and stability of the meniscus changes with the plate velocity and the substrate softness. In this we compare numeric results with asymptotic analytic calculations. Finally, we explore whether the occurrence of stick-slip motion in the advancing case can be predicted, using simple scaling arguments.

CPP 15.1 Mon 19:00 P4

Exploring Green Solvent Additives for Enhanced Solubility in Organic Photovoltaics Processing — •Leonhard Schatt, Fabian Eller, and Eva M. Herzig — Dynamik und Strukturbildung - Herzig Group, Universität Bayreuth, Universitätsstr. 30, 95447 Bayreuth, Germany

Organic Photovoltaic (OPV) devices offer the potential for low-cost production of devices that convert light into electricity. These devices are typically processed from solution, which allows for simple, scalable production methods such as printing. However, the solvents used by most research groups are halogenated aromatic solvents, as green solvents often lack good solubility for the solutes used. We are therefore experimenting with additives in green solvents as a method of tuning solubility. We monitor the solubility with in-situ solubility measurements to study the effects of additive type and volume fraction. This will allow us to map the solubility space of the high performance OPV material PM6. Our aim is to contribute to the replacement of halogenated solvents for OPV processing and to make our organic electronic material processing feasible for industrial applications.

CPP 15.2 Mon 19:00 P4

Comparing Machine Learning Force Fields for Proton Transfer Dynamics in Solid Acids — •Jules Oumard, Aaron Flötotto, and Christian Dressler — Technische Universität Ilmenau, Fakultät für Mathematik und Naturwissenschaften, Institut für Physik, Fachgebiet Theoretische Festkörperphysik, Weimarer Straße 32, 98693, Ilmenau

Solid acids are excellent water-free proton conductors and can be used in fuel cells. [1]. The rarity of long-range proton transfer events in ab initio molecular dynamic simulations makes the calculation of converged diffusion coefficients challenging. This can be overcome by accelerating these simulations with machine learning force fields (MLFF). We compare two MLFF approaches: Gaussian Approximation Potentials (GAP) with on-the-fly learning [2] and equivariant graph neural networks [3]. A protocol for fine-tuning GAP models is presented. We evaluate the calculated diffusion coefficients and explain trends in terms of jump rate functions and anion rotation rates.

Towards Theoretical UV/Vis Spectra with Experimental Accuracy. Benchmarks for Spiropyran Photoswitches — •Robert Strothmann[1], Johannes T. Margraf[2], and Karsten Reuter[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]University of Bayreuth

Molecular photoswitches are molecules that undergo an isomerization upon irradiation with specific wavelengths. One key feature for understanding this process are the UV/Vis spectra of the involved species (e.g. the closed and open forms in the case of spiropyran, SP). First-principles methods like density-functional theory (DFT) allow the calculation of UV/Vis spectra within certain approximations. However, the properties of the chosen functional, the description of solvation, as well as the accuracy of conformational and vibrational sampling all contribute to discrepancies between theory and experiment. This motivates us to establish a rigorous theoretical approach to assist in the prediction and analysis of UV/Vis spectra for molecular photoswitches. As a crucial step, we here benchmark different approaches for predicting UV/Vis spectra of SP switches against experimental references. We emphasize the influence of different functional approximations and highlight the role of the conformational ensemble and molecular vibrations sampling (e.g. via by machine learning enhanced molecular dynamics simulations). The importance of these different effects is discussed, with the goal of providing best practice guidelines that enable robust predictions.

CPP 15.4 Mon 19:00 P4

Optical properties of diamondoid organotin sulfur clusters with fluorescent ligands — •Alexander Schauerte[1], Jie Wang[2], Felix Thomas[1], Irán Rojas León[2], Stefanie Dehnen[2], and Marina Gerhard[1] — [1]Faculty of Physics and Material Sciences Center, Philipps-University of Marburg, Renthof 7a, D-35032 Marburg, Germany — [2]Institute of Nanotechnology, Karlsruhe Institute of Technology, Hermann-von-Helmholtz-Platz 1, 76344 Eggenstein-Leopoldshafen, Germany

White light is important in our daily life as well as in technology and research. It has been shown that diamondoid organotin clusters with organic ligands emit a brilliant white light beam when pumped with an infrared laser.

We investigate the fluorescent properties of tin-sulfur/selenium clusters with three phenyl- and one tetraphenylethylene ligands using photoluminescence- and spatially resolved photoluminescenceexcitation- spectroscopy. Through temperature-dependent measurements of compounds prepared as glass and as powder, we conclude that the electron-phonon-coupling and short-range ordering seems to be reduced in a glass state compared to a powder.

Furthermore, we investigate the white light generation (WLG) and second harmonic generation of different cluster compounds, which show a dependence of the WLG-efficiency on the chemical composition. The glass has a lower excitation power threshold for WLG than the powder.

CPP 15.5 Mon 19:00 P4

Electromagnetic Compatibility Measurements of Polymers in the Automotive Industry: Shielding Effectiveness According to ASTM D 4935 — Leopold Handke, Nicola Peranio, and •Verena Cerna — Technische Hochschule Ulm, Ulm, Deutschland

Electromagnetic compatibility (EMC) is a key concern in the automotive industry due to the growing complexity of vehicle electronic systems and the need to prevent electromagnetic interference that could affect their performance and safety. Polymers used in automotive components must meet specific EMC requirements to ensure proper functioning of vehicle electronics. This study investigates the shielding effectiveness (SE) of various polymer materials using standardized measurements according to ASTM D 4935. Shielding effectiveness for both magnetic (B-field) and electric (E-field) fields was measured over a frequency range from 50 kHz to 3 GHz. SE measurements provide valuable insights into the frequency-dependent shielding properties of plastics, offering a basis for selecting appropriate materials for automotive applications to address EMC challenges.

CPP 15.6 Mon 19:00 P4

Time-resolved structure formation in biohybrid coatings revealed by in-situ GISAXS and machine learning — •Julian E. Heger[1], Shachar Dan[2], Yufeng Zhai[2], Stephan V. Roth[2,3], and Peter Müller-Buschbaum[1] — [1]1TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [3]Department of Fibre and Polymer Technology, KTH Royal Institute of Technology, Stockholm, Sweden

Relationships between the structure and property of functional films are at the heart of material science, which makes understanding of how film morphology influences its function essential. Achieving a comprehensive and statistically relevant understanding of the film's characteristics often requires the use of indispensable tools like grazing-incidence small-angle X-ray scattering (GISAXS). GISAXS enables the exploration of the film's characteristic morphology in reciprocal space, such as characteristic size distributions. However, a challenge arises due to the loss of phase information during measurements, which inhibits a direct transformation from reciprocal space to real space via inverse Fourier transform. In addressing this obstacle neural networks (NN) emerge as promising solutions, as they offer potential ways to enable a fast transformation of GISAXS data. Here, we present the results of applying a NN which is trained on synthetic GISAXS data to evaluate the film formation of biohybrid coatings during deposition from in-situ GISAXS synchrotron data.

CPP 15.7 Mon 19:00 P4

Simulation-Based Neural Network with Embedded Prior Knowledge for Predicting Morphological Parameters in GISAXS — •Shachar Dan[1], Eldar Almamedov[2], Matthias Schwartzkopf[1], Sven-Jannik Wöhnert[1], Andre Rothkirch[1], Yufeng Zhai[1], Jose I. Robledo[4], Volker Skwarek[2], and Stephan V. Roth[3] — [1]DESY, Notkestraße 85, D-22607 Hamburg — [2]HAW, Berliner Tor 5, D-20099 Hamburg — [3]KTH, Teknikringen 56 SE-10044 Stockholm — [4]FZ-Jülich, Wilhelm-Johnen- Straße D-52428 Jülich

In-situ grazing-incidence small-angle X-ray scattering (GISAXS) is a powerful technique for analyzing nanoscale structures, yet its interpretation is challenging due to the inverse problem caused by phase information loss. Advances in simulation software and deep learning techniques have opened the door to the idea of using simulations, which can now be generated more efficiently in diverse configurations, to train neural networks (NNs). However, simulations often fail to fully represent experimental data, creating a significant sim-to-real gap. In our work, we tackle this challenge by embedding prior knowledge about the system into the NN training process. By incorporating constraints based on this knowledge, we train models on simulations and apply them to experimental data, enabling reasonable predictions of morphological parameters such as cluster radii, intercluster distances, and grain size distributions. This approach aims to accelerate material characterization at the nanoscale and provide a portable and efficient counterpart to traditional methods.

CPP 15.8 Mon 19:00 P4

Low-Temperature Photoluminescence Characterization of Hybrid Metal Halides — •Anton Krüger[1], Meng Yang[2], Alexander Schauerte[1], Dominik Muth[1], Johanna Heine[2], and Marina Gerhard[1] — [1]Faculty of Physics and Material Sciences Center, Philipps-Universität Marburg, Renthof 5, D-35032 Marburg, Germany — [2]Faculty of Chemistry, Philipps-Universität Marburg, Hans-Meerwein-Straße 4, D-35032 Marburg, Germany

In order to remove the toxic lead component of the otherwise promising perovskite materials, many different approaches have been pursued.

Here, the photoluminescence (PL) and absorption properties of crystalline non-toxic hybrid main group metal halide compounds, $(\alpha\text{-Me-2-NA})_4E_2X_{10}$ (NA=Naphthylmethylammonium, E=Sb/Bi, X=Halide) are investigated by means of time-resolved PL spectroscopy, steady-state PL spectroscopy as well as PL excitation spectroscopy.

It is shown that the absorption and PL properties of these materials depend on the metal/halide composition, giving rise to a variety of absorbers and emitters. Furthermore, temperature dependent spectroscopic experiments reveal a thermochromic behavior of the compounds.

CPP 15.9 Mon 19:00 P4

Effect of fluorinated tail groups on the properties of aromatic self-assembled monolayers — Yangbiao Liu[1], Sonja Katzbach[2], Andreas Terfort[2], and •Michael Zharnikov[1] — [1]Angewandte Physikalische Chemie, Universität Heidelberg, 69120 Heidelberg, Germany. — [2]Institut für Anorganische und Analytische Chemie, Johann Wolfgang Goethe Universität Frankfurt, 60438 Frankfurt am Main, Germany

Electric transport properties of functional self-assembled monolayers (SAMs) are important for interface engineering in organic electronics and molecular

electronics. As was shown recently, substituting only one terminal hydrogen atom in SAMs with a halogen atom changes their electric conductance noticeably. In this context, we studied the respective effects in a series of non-substituted and methyl-substituted biphenylthiolate (BPT) SAMs on Au(111), exchanging the terminal hydrogen atom/atoms for fluorine/fluorines and testing not only single-component but binary SAMs as well. The gradual variation of the work function with the SAM composition was accompanied by a gradual variation of electrical conductance, decreasing, in particular, by two orders of magnitude at going from CH3-BPT to CF3-BPT SAMs. The observed behavior was tentatively explained by the higher projected density-of-states at the position of the terminal tail groups in the CH3-BPT (H-BPT) case compared to CF3-BPT (F-BPT) and by the appearance of an internal electrostatic field in the SAMs, leading to a change and renormalization of the energy level alignments within the junction upon contact of the SAMs to the top EGaIn electrode.

CPP 15.10 Mon 19:00 P4

Charge separation in a porphyrin-based metal-organic framework incorporating fullerene — •Martin Richter[1], Xiaojing Liu[2], Pavel Kolesnichenko[1], Christof Wöll[2], and Petra Tegeder[1] — [1]Physikalisch-Chemisches Institut, Universität Heidelberg, Germany — [2]Institut für Funktionelle Grenzflächen, Karlsruher Institut für Technologie, Germany

Porphyrin-based materials are attracting great interest due to their wide range of potential applications. They can be embedded into metal-organic frameworks (MOF) to manipulate and investigate the relations between function and structure. In conjunction with an electron acceptor, charge separation can be achieved, which is beneficial for applications such as solar cells or photocatalysis. Experiments on ZnTPP (Zinc 5,15-bis-(3,4,5-trimethoxyphenyl)-10,20-bis-(4-carboxyphenyl)) in a surface-anchored MOF (SURMOF) with fullerene C_{60} loaded into the pores, have demonstrated that photoexcitation can enhance the conductivity by up to two orders of magnitude [1]. Here, we investigate excited states dynamics after optical excitation with transient absorption spectroscopy on the femto- to nanosecond time scale. Charge separated states can be identified, which have a lifetime of 212-360 ps. The charge separation occurs after excitation of both the Soret band and the Q band within only a few hundred femtoseconds.

CPP 15.11 Mon 19:00 P4

Structural influences on nonlinear optical activity for supercontinum generation: isolated cubane — •Alexander Kapp and Simone Sanna — Institute for Theoretical Physics, 35392 Gießen, Germany

It has been suggested that adamantane-based molecular clusters can convert a narrowband laser source into a broadband supercontinuum. Unlike thermal emitters, the resulting spectra are coherent and not constrained by Planck's law, making them highly valuable for various applications, such as high-resolution monitoring and spectroscopy.

In order to expand our library of suitable molecules, we investigate the electronic and optical properties of materials with similar symmetry. This involves performing first-principle density functional theory calculations to identify appropriate structures. Here, we focus specifically on isolated cubane (C_8H_8) molecules and their derivatives, analyzing their electronic and structural properties and their correlation with the optical response.

CPP 15.12 Mon 19:00 P4

Impact of Classical and Quantum Light on Donor-Acceptor-Donor Molecules — •Haraprasad Mandal[1,2], Sajal Kumar Giri[3], Sara Jovanovski[1], Oleg Varnavski[1], Malgorzata Zagorska[4], Roman Ganczarczyk[4], Tse-Min Chiang[3], George C. Schatz[3], and Theodore Goodson III[1] — [1]Department of Chemistry, University of Michigan, Ann Arbor, Michigan 48109, United States — [2]Department of Chemistry, University of Graz, Heinrichstrasse 28, 8010 Graz, Austria — [3]Department of Chemistry, Northwestern University, Evanston, Illinois 60208, United States — [4]Faculty of Chemistry, Warsaw University of Technology, Noakowskiego 3, 00-664 Warsaw, Poland

Investigations of entangled and classical two-photon absorption have been carried out for six donor (D)-acceptor (A)-donor (D) compounds containing the dithieno pyrrole (DTP) unit as donor and acceptors with systematically varied electronic properties. Comparing ETPA (quantum) and TPA (classical) results reveals that the ETPA cross section decreases with increasing TPA cross section for molecules with highly off-resonant excited states for single-photon excitation. Theory (TDDFT) results are in semiquantitative agreement with this anticorrelated behavior due to the dependence of the ETPA cross section but not TPA on the two-photon excited state lifetime. The largest cross section is found for a DTP derivative that has a single photon excitation energy closest to resonance with half the two-photon excitation energy. These results are important for the possible use of quantum light for low-intensity energy-conversion applications.

CPP 15.13 Mon 19:00 P4

Correlating molecular properties to the SHG response: Prerequisites for white light generation. — •Ferdinand Ziese and Simone Sanna — Institut für Theoretische Physik and Center for Materials Research (LaMa), Justus-Liebig-Universität Gießen, 35392 Gießen, Germany

Recent studies have demonstrated white light generation from molecular clusters with adamantane-like cores and different substituents [1,2]. Systematic investigations further our understanding of the origin of this behavior, we have investigated structural, electronic, and (nonlinear) optical properties from first principles for isolated molecules [3]. Core modifications mostly change the characteristic of the response in a more subtle manner while the exchange of substituents exhibit a greater impact. Distinct changes to the intensity, energy, and characteristic can be observed. The presented results provide a theoretical foundation for the design of tailored nonlinear optical sources.

CPP 15.14 Mon 19:00 P4

Effect of Deposition Rates on the Morphology and Efficiency of Blue TADF OLEDs — •Tolga Durmus, Marius Schnapp, Ahmed Mohamed, Vladimir Dyakonov, and Andreas Sperlich — Experimental Physics 6, University of Würzburg, 97074 Würzburg, Germany

The efficiency and stability of blue thermally activated delayed fluorescence (TADF) OLEDs are strongly influenced by the structural properties of their active layers. In this study, we investigate the impact of varying deposition rates on the morphology of these layers, focusing on their amorphous or crystalline nature. Atomic force microscopy (AFM) is used to analyze the surface morphology of the deposited layers and we aim to establish a correlation between the deposition conditions, the structural properties of the layers, and the efficiency of the OLEDs. These investigations are expected to provide valuable insights into optimizing fabrication parameters for improved blue TADF-OLEDs.

CPP 15.15 Mon 19:00 P4

Temperature-dependent Transient Electroluminescence of Blue TADF OLEDs — •Klara-Maria Bögle, Felix Kübert, Ahmed Mohamed, Vladimir Dyakonov, and Andreas Sperlich — Experimental Physics 6, Julius-Maximilians-Universität Würzburg, 97074 Würzburg, Germany

Third generation OLEDs use, in contrast to first and second generation OLEDs, ambient thermal energy to increase fluorescence, so-called Thermally-Activated Delayed Fluorescence (TADF). This is achieved via reverse inter-system crossing (*rISC*), which means that non-radiative triplet excitons are up-converted to radiative singlet excitons. This process significantly increases the internal quantum efficiency, up to 100%. In this study, OLEDs with the multiple resonance blue TADF emitter ν-DABNA embedded in an mCP matrix are investigated. Transient electroluminescence (EL) reveals a strong temperature dependence, which we model with rate equations to better understand the TADF process in an OLED under operating conditions. The rate equations describe the population densities of the triplets, singlets and charge carriers using the different rates of *(r)ISC*, triplet-triplet annihilation (*TTA*), triplet-polaron annihilation (*TPA*) as well as the (non-) radiative singlet/triplet decay rates. Traditionally, such analysis is often based on transient photoluminescence at room temperature, which also lacks charge carrier contributions and is thus inconclusive. We therefore aim to get a full picture of *all* population densities and recombination mechanisms to better understand efficiency limiting processes.

CPP 15.16 Mon 19:00 P4

Porous poly(ethylene glycol) films as a versatile platform for ssDNA immobilization and hybridization — Zhiyong Zhao and •Michael Zharnikov — Angewandte Physikalische Chemie, Universität Heidelberg, 69120 Heidelberg, Germany

Poly(ethylene glycol) (PEG) films, fabricated by thermally induced crosslinking of amine and epoxy-terminated four-arm STAR-PEG precursors, were used as porous and bioinert matrix for single-stranded DNA (ssDNA) immobilization and hybridization. The immobilization relied on either the reaction between the amine groups in the PEG matrix and N-hydroxy succinimide (NHS) ester groups of the NHS-ester-decorated ssDNA or the reaction between the epoxy groups in the matrix and thiol groups of the respectively substituted ssDNA. The mixing ratio of the precursors was varied to tune the density of the amine and epoxy groups available for the immobilization. Spectroscopic and electrochemical data confirmed the successful immobilization of the ssDNA probes into the PEG matrix as well as the high hybridization efficiency, selectivity, and sensitivity of the resulting DNA sensors. Whereas these sensors were equivalent to the direct ssDNA assembly in terms of efficiency, they exhibited better selectivity and bioinert properties because of the bioinert character of the PEG matrix.

The above findings place PEG films as a promising platform for highly selective ssDNA sensing, leveraging their flexible chemistry, 3D character, and bioinert properties.

CPP 15.17 Mon 19:00 P4

The effect of spherical nanoceria on the anionic polysaccharides and in vitro behavior as a wound dressing — •Alexandra Feraru[1,2], Zsejke-Réka Tóth[2], Klára Magyari[2,3], Monica Baia[4,5], Tamás Gyulavári[6], Emoke Páll[7], Emilia Licarete[8], Codrut Costinas[1,5], Oana Cadar[9], Ionel Papuc[7], and Lucian Baia[2,4,5] — [1]Doctoral School of Physics, Babes-Bolyai University, M. Kogălniceanu 1, 400084 Cluj-Napoca, Romania — [2]Nanostructured Materials and Bio-Nano-Interfaces Center, Interdisciplinary Research Institute on Bio-Nano-Sciences, Babes-Bolyai University, T. Laurian 42, 400271 Cluj-Napoca, Romania — [3]INSPIRE Research Platform, Babes Bolyai University, 400084, Cluj-Napoca, Romania — [4]Faculty of Physics, Babes-Bolyai University, M. Kogălniceanu 1, 400084 Cluj-Napoca, Romania — [5]Institute for Research-Development-Innovation in Applied Natural Sciences, Babes-Bolyai University, Fântânele 30, 400294, Cluj-Napoca, Romania — [6]Department of Applied and Environmental Chemistry, University of Szeged, Rerrich B. sqr. 1, Szeged 6720, Hungary — [7]Faculty of Veterinary Medicine, University of Agricultural Science and Veterinary Medicine, 400372 Cluj-Napoca, Romania — [8]Faculty of Biology and Geology, Babes-Bolyai University, 400015 Cluj-Napoca, Romania — [9]INCDO-INOE 2000, Research Institute for Analytical Instrumentation, 67 Donath Street, 400293 Cluj-Napoca, Romania

In this study, we aimed to enhance the understanding of how chemical bonds form when sodium alginate and gum arabic interact with nanoceria nanoparticles.

CPP 15.18 Mon 19:00 P4

Programming fibril alignment and mechanical response in electron beam-modified collagen type I fibers — •Friedrich Schütte[1,2], Anastassiya Bublikova[1,2], and Stefan G. Mayr[1,2] — [1]Division of Surface Physics, Department of Physics and Earth System Sciences, University of Leipzig, Linnéstr. 5, 04103 Leipzig — [2]Leibniz Institute of Surface Engineering (IOM), Permoserstr. 15, 04318 Leipzig, Germany

Modifying collagenous systems for tendon and tissue replacements in a controlled manner to produce biomimetic implants has a high potential for future biomedical applications. As a polymeric biomaterial, abundant in human bodies and influencing cellular morphology, collagen type I provides structural integrity and strength to tissues. However, applications are limited because even in crosslinked cases, the biomechanical properties of collagen networks can differ by several orders of magnitude in terms of both elasticity and load capacity. The widely used crosslinker glutaraldehyde has been the subject of controversy due to cytotoxic effects. In contrast, electron-beam-treatment allows reagent free control over a rapid and sterilizing crosslinking method in a non-cytotoxical biomimetic manner, resulting in improved mechanical properties due to high penetration depth and sufficiently high irradiation-induced doses. Subsequently, the modification of collagen type I fibers by energetic electron-beam-treatment during prestrain induced alignment of the inner filaments is shown to achieve and imprint network anisotropies resulting in mechanical properties with Young's moduli bridging orders of magnitude from a kPa range to a MPa range.

CPP 15.19 Mon 19:00 P4

Biopolymer-Templated Deposition of Hierarchical 3D-Structured Graphene Oxide/Gold Nanoparticle Hybrids for Surface-Enhanced Raman Scattering — •Yingjian Guo[1,2], Jungui Zhou[1], Constantin Harder[1,2], Guangjiu Pan[1], Yusuf Bulut[1,2], Gergely Nemeth[3], Ferenc Borondics[3], Benedikt Sochor[1], Sarathlal K. Vayalil[1], Daniel Söderberg[4], Peter Müller-Buschbaum[2], and Stephan V. Roth[1,4] — [1]Deutsches Elektronen-Synchrotron, 22607 Hamburg, Germany — [2]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [3]Synchrotron SOLEIL, Saint-Aubin, France — [4]KTH Royal Institute of Technology, Stockholm, Sweden

Cellulose has emerged as a promising bio-based template for sensors, smart windows, and bioelectronics. Typically, Surface Enhanced Raman Scattering (SERS), an advantageous analytical technique, allows for the rapid detection and structural analysis of chemical compounds through their spectral patterns in nanotechnology. Crucial for SERS is fabricating the substrates with strong enhancements of the Raman signal over large areas. Herein, we present a straightforward approach utilizing the layer-by-layer spray coating method to fabricate films loaded with gold nanoparticles and graphene oxide to serve as SERS substrates. GISAXS combined with nano-FTIR spectroscopy was used to confirm a synergistic Raman enhancement mechanism of localized surface plasmon resonance and interface charge transfer. Our approach provides a reference for facile and scalable production of SERS substrates.

CPP 15.20 Mon 19:00 P4

Analysis of folding/unfolding behavior of micro and nano collagen fibers by SFTIRM — •Selcuk Kaan Haciosmanoglu[1], Gihan Kamel[2,3], and Murat Kazanci[1,4] — [1]Nanoscience and Nanoengineering Program, Graduate School, Istanbul Medeniyet University, Istanbul, Turkey — [2]SESAME (Synchrotron-light for Experimental Science and Applications in the Middle East), Allan, Jordan — [3]Department of Physics, Faculty of Science, Helwan University, Cairo, Egypt — [4]Biomedical Engineering Department, School of Engineering and Natural Sciences, Istanbul Medeniyet University, Istanbul, Turkey

Collagen nanofibers are essential extracellular matrix (ECM) components widely used in regenerative medicine. While both electrospinning and wet-spinning techniques can produce anisotropic collagen micro- and nanofibers from dissolved collagen solutions, electrospun fibers require crosslinking to maintain water stability for cell culture applications. This study investigates in-situ crosslinking during electrospinning using chemical agents and physical methods. Synchrotron Fourier-Transform Infrared Microspectroscopy (sFTIRM) analysis revealed distinct molecular structural changes in the collagen nanofibers based on processing methods. Protein band positions shifted according to the extraction methods employed. Notably, electrospinning inhibited collagen molecule self-assembly, resulting in lower band positions compared to wet-spun fibers. The choice of crosslinking agent significantly influenced collagen's secondary structure, with genipin-mediated in-situ crosslinking better preserving the native structure of electrospun collagen nanofibers compared to UV crosslinking.

CPP 15.21 Mon 19:00 P4

Enhancing Endothelial Cell Attachment on PNIPAM-Based Microgel Coatings with RGD Ligand Functionalization — •Leonie Beer, Souraj Mandal, and Regine von Klitzing — Soft Matter at Interfaces, Department of Physics, Technical University of Darmstadt, Darmstadt 64289, Germany

Endothelial cell (EC) attachment is crucial for capillary formation and the success of artificial vascular networks in tissue engineering. Poly(N-isopropylacrylamide) (PNIPAM) microgels offer a promising platform for this application due to their tunable mechanical properties and ability to incorporate bioactive ligands. This study investigates the use of PNIPAM-based microgel coatings functionalized with the integrin-binding peptide sequence arginine-glycine-aspartate (RGD) to enhance EC adhesion. Successful conjugation of RGD peptides was confirmed using infrared spectroscopy and fluorescence microscopy. To evaluate the impact of ligand configuration, we compared three variations of RGD based peptides. The results reveal that increasing the anchor length significantly improves HUVEC recognition of the ligands, resulting in enhanced cell attachment and proliferation. These findings highlight the critical role of ligand design in optimizing biofunctional coatings. This work presents a straightforward chemical strategy for improving endothelial cell adhesion on PNIPAM-based microgel surfaces, paving the way for advanced artificial vascular networks in tissue engineering and regenerative medicine.

CPP 15.22 Mon 19:00 P4

Green plastics: Direct production from grocery wastes and characterization by using S-FTIR — •Onur Aras[1], Gihan Kamel[2,3], and Murat Kazanci[4,5] — [1]Istanbul Medeniyet University, Nanoscience and Nanoengineering Program, Graduate School, 34700 Istanbul, Turkey — [2]SESAME Synchrotron (Synchrotron-light for Experimental Science and Applications in the Middle East), 19252 Allan, Jordan — [3]Department of Physics, Faculty of Science, Helwan University, Cairo, Egypt — [4]Istanbul Medeniyet University, School of Engineering and Natural Sciences, Department of Biomedical Engineering, Istanbul, Turkey — [5]Istanbul Medeniyet University, Science and Advanced Technologies Research

This study investigates the production of cellulosic bioplastics from four green waste sources: hemp, parsley stem, pineapple leaves, and walnut shell, using either trifluoroacetic acid (TFA) or water as solvents. Synchrotron FTIR Microspectroscopy (SR-*FTIR) was employed to analyze structural modifications during biofilm formation and regeneration.Water-based biofilms retained their native cellulose, hemicellulose, and lignin components. In contrast, TFA-dissolved samples exhibited additional spectral bands in the hemicellulose region, attributed to ester bond hydrolysis and subsequent carboxylic acid formation. Principal component analysis revealed distinct groupings based on solvent type and polymer addition.

CPP 15.23 Mon 19:00 P4

How do stiffness patterns, with no topographical or chemical cues, influence cellular and tissue contact guidance? — •Mathis Grelier[1], Carlos Urena Martin[2], Mark Schvartzman[2], and Ana Suncana smith[1,3] — [1]Puls Group, Institute for Theoretical Physics and Interdisciplinary Center for Nanostructured Films (IZNF), Friedrich-Alexander Universität Erlangen-Nürnberg (FAU), 91058 Erlangen, Germany — [2]Department of Materials Engineering and Ilse Katz Institute for Nanoscale Science and Technology, Ben-Gurion University of the Negev, Beer-Sheva, Israel — [3]Group of Computational Life Sciences, Division of Physical Chemistry, Rudjer Bošković Institut, 10000 Zagreb, Croatia

While current systems cannot disentangle the effects of topography and stiffness

contrasts, our study overcomes this challenge by investigating cell and tissue behavior on substrates with only alternating stiffness stripes. Our experiments and model reveal that wider stripes enhance alignment along stiffer or softer regions due to the higher energy cost of traversing softer substrates. At the cellular level, we employ a stochastic model based on Boltzmann weights applied to possible cell shapes, integrating energy contributions that govern movement across stiffness boundaries. For tissues, we extend this framework using a dissipative particle model to capture collective dynamics and mechanical interactions. To further explore these effects, we applied a Globalized Bounded Nelder-Mead optimization, enabling the efficient recovery of key physical parameters, such as stiffness and contractility, under both untreated and treated conditions.

CPP 15.24 Mon 19:00 P4

Latex film formation investigated by GISAXS and spectral reflectance — •Simon Schraad[1,2], Helder Marques Salvador[4], Nadja Kölpin[1], Nicolae Tomozeiu[4], Peter Müller-Buschbaum[2], and Stephan Volkher Roth[1,3] — [1]Deutsches Elektronen Synchrotron, Notkestraße 85, 22607 Hamburg — [2]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [3]Department of Fibre and Polymer Technology, KTH Royal Institute of Technology, Teknikringen 56, 100 44 Stockholm, Sweden — [4]Canon Production Printing Netherlands B.V., Van der Grintenstraat 10, 5914 HH Venlo, Niederlande

The film formation of latex inks on nanoporous substrates is of high interest for scientific and industrial applications. Inks are multi-component, complex fluids and consist of colloids, pigments and solvents. The film formation is a multistage process. After deposition, solvent begins to evaporate and finally nanoparticles self assembly. To quantitatively analyze latex film formation a combination of in-situ grazing incidence small angle scattering (GISAXS) and light scattering will be employed. Here structural changes during the deformation and coalescence phase of latex colloids will result in changes in the scattering patterns. We present a design of an experimental spray chamber to allow in-situ GISAXS and the spectral reflectance during spray deposition of latex inks to be used at synchrotron facilities.

CPP 15.25 Mon 19:00 P4

Dynamic magnetic response of multicore particles: the role of grain magnetic anisotropy and intergrain interactions — •Ekaterina Novak[1], Elena Pyanzina[1], Andrey Kuznetsov[2], and Sofia Kantorovich[2] — [1]Ekaterinburg, Russia — [2]University of Vienna, Vienna, Austria

This study examines the magnetic properties of multicore magnetic nanoparticles (MMNPs) utilizing Brownian dynamics simulations in conjunction with the Landau-Lifshitz-Gilbert equation. We demonstrate that the magnetic responses of MMNPs, both static and dynamic, are governed by a complex interplay between the cores magnetic anisotropy and the strength of inter-core magnetic interactions. These insights are crucial for refining the design of multicore magnetic particles in various applications, including magnetic hyperthermia, data storage, and targeted drug delivery, where accurate control over magnetic characteristics is vital.

CPP 15.26 Mon 19:00 P4

Kinetics of nanostructure and interface evolution induced by photopolymerization — •Shouzheng Chen[1,2,3], Yufeng Zhai[2], Jungui Zhou[2], Guangjiu Pan[1], Sarathlal Koyiloth Vayalil[2], Rolf A.T.M. van Benthem[4], Johan F.G.A Janssen[5], Mats K. G. Johansson[6], Peter Müller-Buschbaum[1], and Stephan V. Roth[2,6] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]DESY, Notkestraße 85, 22607 Hamburg, Germany — [3]FRM II, Lichtenbergstraße 1, 85748 Garching, Germany — [4]Eindhoven University of Technology, Groene Loper 5, 5600, MB, Eindhoven, the Netherlands — [5]Covestro (Netherlands) B.V., Urmonderbaan 22, 6167, RD, Geleen, the Netherlands — [6]Department of Fibre and Polymer Technology, KTH Royal Institute of Technology, Teknikringen 56, SE-100 44 Stockholm, Sweden

Photopolymerization offers spatial resolution, low energy consumption, and high curing speeds, making it a widely used technology in additive manufacturing. The kinetics of the physical transformation of the resin from liquid to solid (cross-linked) state induced by photopolymerization and the kinetics of the solid-liquid interface formation of resin multilayer are the key to achieving controllable high-precision manufacturing. By modulating precursor resin components and combining grazing incidence small angle X-ray scattering (GISAXS), the UV-curing induced nanostructure and the buried interface of resin multilayer are probed. We reveal how solvents and additive monomers determine in nanostructure and multilayer interface formation during photopolymerization.

CPP 15.27 Mon 19:00 P4

Effect of grafting density on particle distribution in polymer brush/gold nanoparticle composite materials — •Elias Hallenbach, Hayden Robertson, and Regine von Klitzing — Institute for Condensed Matter Physics, Technical University of Darmstadt, Germany

Metal/polymer nanocomposites are versatile hybrid materials and find use in many fields such as photonics, biomedical engineering and catalysis. A promising realization of this type of hybrid material is the controlled self-assembly of gold nanoparticles (AuNPs) inside a polymer brush, which induces color changes upon exposure to environmental changes enabling sensor applications.

The polymer brushes serve as a matrix for the immobilization of AuNPs. Particle uptake into the brush matrix is affected by parameters such as thickness, particle size and the grafting density. Polymer brushes with varying grafting densities are synthesized by a controlled polymerization (SI-ARGET ATRP) directly from a silicon substrate. The nanocomposite materials are fabricated by dip-coating of polymer brushes into a AuNP dispersion. Characterization of the nanocomposites is performed by (in situ) spectroscopic ellipsometry, atomic force microscopy and (in situ) X-ray reflectometry (XRR).

Uptake of nanoparticles has proven to be highest at intermediate grafting densities. I will discuss the influence of particle distribution inside the brush on particle uptake, which can be yielded by XRR measurements.

CPP 15.28 Mon 19:00 P4

Multi-material filament fabrication for 3D printing photoelectrocatalytic carbon nitride composites — •Timo Uhlein and Siowwoon Ng — FAU Erlangen-Nürnberg, Erlangen, Germany

Additive manufacturing of electrochemically active 3D structures is of rising interest. In particular, using fused deposition modeling (FDM) based on filament extrusion concept to produce carbon-polymer-based 3D structures offers several advantages, such as accessibility, low-cost and ease of use. Nevertheless, carbon-based filaments are limited with their applications. Therefore, incorporating additional materials to produce a multi-material filament is of interest, to create 3D-printed electrodes with new or targeted functional properties. In this project, we fabricated a multi-material filament consists of carbon nitride, C3N4, and carbon nanotubes, CNTs, for its photocatalytic properties and high conductivity, respectively, and polymer as the backbone of a FDM filament. We examined the performance of the composite C3N4-CNT electrodes for hydrogen evolution and the photocatalytic degradation of a dye. We indicate that further advancements can be achieved by developing multi-material filaments in order to use them for further electrochemical applications.

CPP 15.29 Mon 19:00 P4

Mechanochemical Behavior and Flow Dynamics of Glycerol Aqueous Solutions Confined between Ferrous Surfaces: Atomic-scale Insights from Reactive Molecular Dynamics Simulations — •Vahid Fadaei Naeini[1,2], Andreas Larsson[1], and Roland Larsson[2] — [1]Applied Physics, Division of Materials Science, Department of Engineering Sciences and Mathematics, Luleå University of Technology, Sweden. — [2]Machine Elements, Division of Machine Elements, Department of Engineering Sciences and Mathematics, Luleå University of Technology, Sweden.

This study explores the tribochemical behavior of glycerol and its aqueous solutions confined between ferrous surfaces using reactive non-equilibrium molecular dynamics simulations. Results show that glycerol reduces friction effectively, with viscosity decreasing as water content increases. Pure glycerol achieves lower friction but exhibits significant wall slip and deviations from a linear velocity profile near the surfaces. Glycerol dissociation, influenced by shear stress and pressure, produces water and organic acid by-products, with dissociation rates decreasing at higher water concentrations. Atomic-scale analysis reveals increased surface wear and iron atom dissociation under elevated stresses. These findings highlight the balance between friction reduction, viscosity, and tribochemical reactivity in glycerol-water mixtures, offering insights for sustainable lubricant design under extreme conditions.

CPP 15.30 Mon 19:00 P4

Evaluating the Properties of Nafion PEMFC Membrane via MD Simulations — •Mateja Jovanović[1], Matthias Baldofski[1], Igor Stanković[2], Marcin Rybicki[1], and Miljan Dašić[2] — [1]Freudenberg Technology Innovation SE & Co. KG, Hoehnerweg 2-4, 69469 Weinheim, Germany — [2]Scientific Computing Laboratory, Center for the Study of Complex Systems, Institute of Physics Belgrade, University of Belgrade, Pregrevica 118, 11080 Zemun, Serbia

Understanding the nanoscale interactions within Nafion membranes is crucial for optimizing their performance in Proton Exchange Membrane Fuel Cells (PEMFC). In present a molecular dynamics study of the structural and dynamic properties of Nafion-water systems under varying hydration levels using molecular dynamics simulations. The density of the Nafion-water system is examined to identify deviations from the ideal additivity rule, providing insights into molecular interactions and structural rearrangements. The radial pair distribution function, radius of gyration, pore-water contact surface, and diffusion coefficients for water and hydronium ions are analyzed to reveal the local organization, solvation quality, porosity, and transport properties within the hydrated Nafion membrane. The methodology used to obtain properties of the Nafion-water mixture builds on techniques previously developed for the study of ionic liquids [1].

CPP 15.31 Mon 19:00 P4

Exploring Polymer Aging: Microscopy and Thermal Analysis — •Judith Bünte, Laila Bondzio, Karsten Rott, and Andreas Hütten — Universität Bielefeld, Dünne Schichten und Physik der Nanostrukturen, Universitätsstr. 25, 33615 Bielefeld

The analysis of polymers and their additives is essential for understanding material performance and longevity, particularly in the context of aging processes. This work emphasizes the synergistic application of advanced microscopy and thermal analysis techniques to investigate polymer composition, structure, and degradation behavior.

Transmission Electron Microscopy (TEM) and Scanning Electron Microscopy (SEM) were utilized to visualize the microstructural features of polymer matrices, as well as the distribution of particles within the polymer. TEM offered high-resolution imaging to reveal morphological details, while SEM enabled surface characterization. These imaging techniques were further augmented by Differential Scanning Calorimetry to analyze thermal properties.

Polymer aging was studied under controlled conditions to evaluate structural and compositional degradation over time. Changes in microstructure and thermal properties were correlated with aging-related alterations.

The integration of these analytical techniques establishes a robust framework for characterizing polymers and their additives. This approach yields valuable insights into the stabilizing role of additives, such as TiO_2, in protecting polymers against environmental and thermal stressors.

CPP 15.32 Mon 19:00 P4

Atomistic simulations of PEDOT:PSS — •Richard Schömig[1,2], Annalena Riffelt[2], and Alexander Schlaich[1] — [1]Institute for Atomistic Modeling of Materials in Aqueous Media, Hamburg University of Technology, Hamburg — [2]SC SimTech, University of Stuttgart, Stuttgart

PEDOT:PSS is by far the best known conjugated polymer with a broad application in e.g. bioelectronics, energy storing devices or neuromorphic computing due to its electrolyte-dependent swelling behavior and extraordinary conductance in the doped (oxidized) state. However, the insolubility of its films once their dried hinders classic experimental studies, thus making molecular dynamics simulations an indispensable tool to understand its electronic and mechanical behavior on an atomic scale. Here, we employ different established force fields to study the influence of a set of parameters such as different water models, dissociation degrees, partial charges and simulation protocols on the structural changes and polymer physics by water uptake for both the PEDOT and the PSS part. We test the validity of these force fields by benchmarking them against ab-initio MD and experimental results.

CPP 15.33 Mon 19:00 P4

Analysis of the Reciprocity Theorem in the DWBA — •Reinhard Sigel — Independent Scientist, D-88677 Markdorf, Germany

The Distorted Wave Born Approximation (DWBA) is a favored theory among X-ray scientists for the analysis of interface scattering experiments [1,2]. Unfortunately, there is no proper clarification which X-ray specific aspects and approximations enter the DWBA and what is the difference to interface scattering of coherent visible laser light. Based on the differing refractive index approaches for X-rays and for visible light, we identify the spot where an X-ray specific equation enters the derivation [1] of the so-called reciprocity theorem. It involves an intermixing of microscopic and macroscopic Maxwell equations. A much simpler correct derivation valid for both wavelength ranges is discussed.

CPP 15.34 Mon 19:00 P4

Dynamic Polarization and Electrostriction of PVDF-Based Copolymer Films as Measured with Double-Modulated Interferometry — Marvin Malchau[1], Philipp Ramming[2], and •Lothar Kador[1] — [1]University of Bayreuth, Institute of Physics and BIMF, 95440 Bayreuth, Germany — [2]University of Bayreuth, Experimental Physics II, 95440 Bayreuth, Germany

Thin films of a ferroelectric copolymer based on polyvinylidene fluoride (PVDF) were exposed to electric ac fields with amplitudes up to 115 MV/m and frequencies between 5 and 100 Hz. The electrical polarization of the material was calculated by integrating the current flow, and the electric-field-induced thickness change (electrostriction) was measured with double-modulated interferometry. Thickness changes up to 60 nm were observed in an 8 μm thick film. The polarization shows a hysteresis loop typical for ferroelectric materials; it is independent of frequency in the investigated frequency range. The electrostriction exhibits a different type of hysteresis with strong frequency dependence. This indicates that the mechanical relaxation of the polymer film is independent of the electric dipole orientation.

CPP 15.35 Mon 19:00 P4

Ternary Organic Solar Cells For Space Applications — •Ivonne A. Zitzmann, Lukas V. Spanier, and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany

It has been demonstrated that organic solar cells (OSC) are capable of achieving high gravimetric power density, making them suitable for space applications. However, they still exhibit insufficient long-term stability, and there are few studies on their performance under space-like conditions. Here we investigate the ternary OSC system PBDB-T-2F:BTP-eC9:$PC_{71}BM$ by optimizing its efficiency and studying its structure and degradation by optical measurements and grazing incidence wide and small angle X-ray scattering. Space conditions were simulated with AM0 illumination. Further, the OSCs were exposed to temperature cycling to assess their stability in a space environment, subject to rapidly changing temperatures. In addition, data from a suborbital rocket flight was examined for performance and degradation of the solar cells. These results may allow for the furthering of our understanding of photovoltaic power generation in harsh environments.

CPP 15.36 Mon 19:00 P4

Degradation of Printed Organic Solar Cells at High Temperatures — •Christoph G. Lindenmeir[1], Simon A. Wegener[1], Christopher R. Everett[1], Julian E. Heger[1], Sigrid Bernstroff[2], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]Elettra, 34149 Basovizza, Trieste, Italy

Organic solar cells (OSCs) have gained significant attention recently due to their non-toxicity, short energy payback times, and fast efficiency improvements. Their high absorbance, potentially flexible design, and easy solution-based manufacturing make them particularly promising. Especially slot-die printing, a fast and low-waste fabrication method, enhances their scalability and potential for various applications, including space use. OSCs are particularly suited for space as their thin, lightweight structure provides a higher power-to-weight ratio than traditionally used solar cells, lowering production and launch costs. However, space conditions like extreme temperatures, high vacuum, and radiation accelerate degradation. This study focuses on the impact of extreme temperature variations on printed OSCs. We optimized their printing process and analyzed their degradation using operando grazing incidence small-angle X-ray scattering (GISAXS), a nondestructive method for studying thin-film morphology. Additionally, we monitored their electrical performance under high vacuum to simulate space conditions.

CPP 15.37 Mon 19:00 P4

Modulate Pre-aggregation to Optimize the Morphology in Organic Solar Cells — •Tim Bohnen, Jinsheng Zhang, and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany

Morphology optimization has emerged as a key strategy to effectively improve device performance and stability in organic solar cells. Due to the solution-processing method, the selection of solvents for precursor solutions is crucial, as it directly affects the ultimate the morphology of active layer. Recent research demonstrates that donor and acceptor molecules form aggregates of varying sizes in precursor solutions, subsequently inducing different phase separation and crystallization behavior during drying process. However, the detailed correlation between pre-aggregation behavior and final morphology has yet to be fully elucidated. In this study, the active layer is composed of PBDB-TF-TTz acting as the donor and BTP-4F-24 as the non-fullerene acceptor. Next, we characterize the resulting morphology using atomic force microscopy (AFM) and grazing incidence small- and wide-angle X-ray scattering (GIWAXS and GISAXS).

CPP 15.38 Mon 19:00 P4

Investigation of quenching in exciplex OLEDs under variation of the giant surface potential — •Clarisse Henriques, Albin Cakaj, Alexander Hofmann, and Wolfgang Brütting — Institut für Physik, University of Augsburg, Augsburg, Germany

An exciplex is a short-lived excited charge transfer state formed between donor and acceptor molecules of different species, in which under radiative decay a photon is emitted. They can either function as efficient host for emitters or directly as emitter because of their apparent thermally activated delayed fluorescence characteristics. Especially the electron accepting materials tend to show a macroscopic film polarization, which is also referred to as giant surface potential (GSP). The presence of GSP in an organic light emitting diode (OLED) promotes charge injection in the electron transport layer (ETL), but causes the accumulation of holes, which can result in exciton quenching. Consequently, studying the impact on the device is of crucial importance. The main interest lies now on the tunability of this parameter by using the material as a co-host or directly as emitter. We investigate OLEDs with different film thickness of the ETL and emission layer. Additionally, devices of donor and acceptor with different mixing ratios were prepared. The major focus is now on studying these systems by current density-voltage-luminance, photoluminescence (PL) and electroluminescence spectra, impedance spectroscopy and their PL quenching under different bias voltages. Such studies are fundamental to understand the impact of SOP in OLEDs for further improvement.

CPP 15.39 Mon 19:00 P4

Tracking degradation of non-fullerene organic solar cells under dynamic environmental conditions — •Lixing Li, Lukas Spanier, Zhaonan Jin, Linus Huber, Guangjiu Pan, and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany

The power conversion efficiency (PCE) of non-fullerene organic solar cells (OSCs) has already approached 20%, but stability and environmental degradation issues have always been one of the biggest challenges limiting their application. Considerable research has been conducted to understand the degradation mechanisms in OSCs, especially under extreme environmental conditions like high and low temperatures. While these studies offer valuable insights, they do not fully represent the dynamic conditions that most organic solar cells face in real-world environments. In practical scenarios, environmental factors such as temperature, humidity, and light fluctuate over time rather than remaining constant. Therefore, it is crucial to investigate how OSCs degrade not only under steady stress but also when exposed to varying environmental conditions. This study explores the degradation of BTP-4F non-fullerene organic solar cells subjected to multiple environmental cycles. Advanced characterization methods, including grazing-incidence X-ray scattering (GIXS) and atomic force microscopy (AFM), are used to monitor both in-situ and ex-situ structural changes in the active layer of OSCs, offering deeper insights into the underlying degradation mechanisms.

CPP 15.40 Mon 19:00 P4

Revealing the Effect of Solvent Vapor Annealing on the Morphology of Non-Fullerene Organic Solar Cells — •Liansong Chu — TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany

Solvent vapor annealing (SVA), as an effective post-treatment technique, has been widely used to optimize the morphology in organic solar cells (OSCs). When exposed to the specific solvent atmosphere, the swelling effect induced by solvent vapor facilitates molecular mobility of both donor and acceptor molecules, leading to modifications in crystallinity and phase separation. Hence, the selection of solvent and annealing duration for SVA is critical for the morphology, which ultimately determines the power conversion efficiency and stability. However, fundamental understanding of solvent selection criteria and the associated kinetic processes during treatment remains unknown. In this work, we systemically investigates the impact of different solvents for SVA on the morphological properties of non-fullerene OSCs (PBDB-TF-TTz as the donor and BTP-4F-24 as the acceptor) using atomic force microscopy (AFM), grazing incidence small- and wide-angle X-ray scattering (GISAXS and GIWAXS). Furthermore, we provide real-time insights into the morphological evolution during SVA through in situ UV-Vis absorption spectroscopy and photoluminescence measurements.

CPP 15.41 Mon 19:00 P4

Impact of the electrode area on the local J-V curves of organic photovoltaics — •Paul Schwanitz[1], Fabian Eller[1], Carsten Deibel[2], and Eva M. Herzig[1] — [1]Dynamik und Strukturbildung - Herzig Group, Universität Bayreuth, Universitätsstr. 30, 95447 Bayreuth, Germany — [2]Institut für Physik, Technische Universität Chemnitz, 09126 Chemnitz, Germany

Organic photovoltaics (OPV) are promising candidates for flexible solar cells, which may be more cost efficient to produce than their silicon counterparts. The organic semiconductor materials can be dissolved and printed on large scale, with the attractive advantage that the geometry of the OPV devices can be chosen on demand. The aim here is to analyze the influence of the top and bottom size of the electrodes on the J-V curve measurements. If the active areas are too small, fluctuations in the performance can occur, which are caused by inhomogeneities in the film. As the active area increases, performance is expected to stabilize as it is averaged over a larger area [1]. The different sizes of the anode and cathode also enable in-line measurements during production. The sizes of the electrodes are systematically varied to estimate the influence on the measurements, to interpret the J-V curves correctly and to account for the dark currents.

CPP 15.42 Mon 19:00 P4

Thin Films of Substituted Benzo[*b*]fluorenes as Emitting Layers for Blue OLED Devices — •Pascal Schweitzer[1], Christopher M. Leonhardt[2], Cazibe Arslan[1], Hermann A. Wegner[2], and Derck Schlettwein[1] — [1]Justus-Liebig-Universität Gießen, Institut für Angewandte Physik, Heinrich-Buff-Ring 16, D-35392 Gießen — [2]Justus-Liebig-Universität Gießen, Institut für Organische Chemie, Heinrich-Buff-Ring 17, D-35392 Gießen

Organic light emitting diodes (OLED), despite widespread application in displays, still exhibit major challenges: The search for stable and efficient blue-emitting molecules continues, as these often suffer from degradation. Here we study substituted benzo[*b*]fluorenes (BF) as an alternative for such emitters. Their modular structure allows for tuning opto-electronic properties. Thin films of different BF were prepared by solution-based methods or physical vapor deposition (PVD). Significant blue emission was found by photoluminescence spectroscopy in solid state. Film growth at device interfaces was studied. In-situ Kelvin-probe force microscopy (KPFM) gave insight into electrical contact formation to typical transport materials: Stranski-Krastanov growth was found in PVD onto hole-conducting poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS), accompanied by the formation of an interface dipole. On the electron-conducting side, a pronounced Volmer-Weber growth of bathocuproine (BCP) on the emissive layer demands a high film thickness for pin-hole-free contacts. Finally, based on these findings, we show a working prototype of a blue OLED based on a substituted BF.

CPP 15.43 Mon 19:00 P4

Excimer as intermediate in singlet fission process for Polydiketopyrrollopyrrole based materials — •Sruthy Asa Rajan, Sergey Bagnich, and Anna Köhler — University of Bayreuth, Bayreuth, Germany

Photovoltaics are essential for renewable energy generation, but the efficiency of conventional solar cells is constrained by the Shockley-Queisser limit, which arises from fundamental and practical losses such as thermalisation loss. Singlet fission (SF), a carrier multiplication process, offers a promising pathway to surpass this efficiency limit. However, a key challenge lies in identifying SF molecules with triplet energy levels that align with the silicon band gap, enabling the efficient formation of correlated triplet pairs, 1(TT) and their subsequent separation into individual triplets.

Polydiketopyrrollopyrrole (PDPP) is a molecule with a comparable triplet energy to the silicon bandgap. We investigate the influence of solvent properties on the optical behaviour of N-substituted pyrene-bridged PDPPs. We employ temperature-dependent steady-state and time-resolved photoluminescence studies on N-substituted pyrene-bridged PDPPs in protic polar and aprotic polar solvents to study the evolution of different species. We observe excimer emission at intermediate temperature and 1(TT) emission at lower temperature. This observation supports the notion that excimers are involved in the formation of 1(TT).

CPP 15.44 Mon 19:00 P4

Solution processed organic solar cells for agrivoltaic applications — •Sebastian Coen, Yunan Chen, Kerstin Märkle, and Christian Sprau — Karlsruhe Institute of Technology, Light Technology Institute

Organic solar cells (OSCs) offer a wide range of applications due to their light weight, low energy payback time, non-toxicity and mechanical flexibility. This work aims to expand these applications by fabricating semitransparent OSCs for agricultural photovoltaic applications, such as greenhouses and foil tunnels.

To facilitate future industrial production, we explore scalable processes and a fully solution-processed architecture based on non-halogenated solvents. The fabricated solar cells are studied in terms of their electrical and spectral properties and their real space morphology.

CPP 15.45 Mon 19:00 P4

Utilizing Ultrasonic Spray for the Integration of Organic Solar Cells on Cellulose Substrate — •Xinyu Jiang[1], Kang An[2], Qin Wang[2], Nadja Koelpin[1], Arik Willner[1], Ning Li[2], and Stephan V. Roth[1,3] — [1]Deutsches Elektronen-Synchrotron DESY, Notkestraße 85, 22607 Hamburg — [2]Institute of PolymerOptoelectronic Materials and Devices, State Key Laboratory of Luminescent Materials and Devices, South China University of Technology (SCUT), Guangzhou, Guangdong 510641, China — [3]Department of Fibre and Polymer Technology, KTH Royal Institute of Technology, Teknikringen 56-58, SE-100 44 Stockholm, Sweden

Cellulose nanofibrils, heralded for their eco-friendly and renewable nature, offer a significant stride toward sustainable energy solutions. Their advantageous attributes such as biocompatibility, flexibility, lightweight nature, transparency, and remarkable mechanical strength render them suitable as a base material for incorporating photovoltaic or electronic devices. We aim to explore the development of functional photovoltaics on transparent cellulose-fabricated curtains, aiming at transforming undesired sunlight into electricity. The inherent flexibility of curtains poses a fabrication challenge for solar cells, adeptly mitigated through ultrasonic spray deposition. This technique manifests as an efficacious means to engender functional layers on a large scale, ensuring a homogeneous surface with minimal roughness. Employing an advanced non-fullerene acceptor system, the resultant organic solar cell curtain showcases the promising performance, delineating a path toward substantial applications in the sustainable energy.

CPP 15.46 Mon 19:00 P4

Multiscale morphological modulation in spray-coated organic solar cells — •Shuxian Xiong[1,2], Benedikt Sochor[1], Constantin Harder[1,2], Sarathlal Koyiloth Vayalil[1], Peter Müller-Buschbaum[2], and Stephan V. Roth[1,3] — [1]Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany — [2]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [3]KTH Royal Institute of Technology, 10044 Stockholm, Sweden

The balance between phase separation and crystallization arising from the aggregations of organic semiconductor molecules defines the film morphology, resulting in multi-length scale phase transitions that enhance device performance. We investigate the morphological evolution driven by molecular self-assembly during the ultrasonic spray-coating of organic functional layers in organic solar cells. An in-depth understanding of phase transition phenomena through an analysis of both temporal (film formation kinetics) and thermal scales (annealing), with the elucidation of the intricate structure-performance nexus linked to morphological evolution and device efficiency, is achieved. We clarify the principles of effective morphological optimization to achieve high-efficiency sprayed organic solar cells, providing valuable guidance for their commercial application.

CPP 15.47 Mon 19:00 P4

Impact of amphiphilic additives on organic solar cells: Enhancing thermal stability for long term performance — •Jose Prince Madalaimuthu[1,2], Tim Matzdorff[1,2], Zhuo Xu[1,2], Md. Moidul Islam[1,2], Yisak Tsegezab Gerase[3], Hassan Ismail[1,2], Rico Meitzner[4], Aman Anand[1,2], Martin Presselt[3], Ulrich S Schubert[1,2], and Harald Hoppe[1,2] — [1]Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich-Schiller-University Jena, Jena, Germany — [2]Laboratory of Organic and Macromolecular Chemistry (IOMC Jena), Friedrich-Schiller- University Jena, Jena, Germany — [3]Leibniz Institute of Photonic Technology (IPHT), Jena, Germany — [4]Helmholtz-Zentrum Berlin GmbH, Hahn-Meitner Platz 1, 14109 Berlin, Germany

The stability of organic solar cells (OSCs) depends not only on the device architecture or effective sealing but also significantly on the morphological stability of the photoactive layer. This stability can be disrupted by alterations in the spatial arrangement of the electron donor and acceptor, which are the fundamental components of OSCs. The extent of phase separation between donor and acceptor regions within the bulk heterojunction (BHJ) plays a pivotal role in determining device performance. Consequently, various strategies have been explored to preserve the distribution of these components. One promising approach is the incorporation of amphiphilic molecules to enhance the stability of the donor-acceptor interface. This method improves thermal resilience, overall OSC performance, and mitigates morphological degradation.

CPP 15.48 Mon 19:00 P4

Interfacial encapsulation of organic solar cells — •Saib Jahan Qazi[1,2], Md Moidul Islam[1,2], Zhou Xu[1,2], Ulrich S. Schubert[1,2], and Harald Hoppe[1,2] — [1]Laboratory of Organic and Macromolecular Chemistry (IOMC Jena), Friedrich Schiller- University Jena, Jena, Germany — [2]Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich-Schiller-University Jena, Jena, Germany

Organic solar cells are emerging as promising prospects in the field of solar energy technology due to their low-cost, light-weight and simple roll to roll fabrication properties. A record power conversion efficiency above 19% has already been reported. However, long-term stability is still the main obstacle for commercialization of these devices. In this study, we demonstrate solution processed interlayer encapsulation of organic solar cells using polymer-based barriers to prevent interlayer migration of impurities as well as the ingress of oxygen and moisture.

CPP 15.49 Mon 19:00 P4

Modifying spacers for higher efficiency and stability of single-component organic solar cells — •Yakun He[1], Peter Baeuerle[2], Weiwei Li[3], Christoph Brabec[4], and Frederic Laquai[1,5] — [1]King Abdullah University of Science and Technology, Saudi Arabia — [2]University of Ulm, Germany — [3]Beijing University of Chemical Technology, China — [4]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — [5]Ludwig-Maximilians-Universität München, Munich, Germany.

Organic solar cells have achieved 20% efficiencies yet still lag regarding stability. Single-component materials incorporating donor and acceptor moieties in a nonconjugated method exhibit intrinsically high stability because of the restriction of morphological evolution. Nevertheless, the efficiency of single-component organic solar cells (SCOSCs) is still low compared to bulk heterojunction structures. We employ a series of dyads with similar structures but modify their spacer type and lengths to investigate the structure-morphology-performance relation. Photophysics has been studied by using steady-state and transient absorption and photoluminescence. Dyad4, with a proper long spacer, has shown the highest efficiency and surprisingly high stability under illumination. Moreover, we investigated the thermal stability of double-cable polymers by tuning the linker length between donor and acceptor moieties. Surprisingly, double-cable polymers do not show a decline of stability with the increase of space linker, and all of them display remarkably excellent stability without degradation after heating for 1000 hours at 90 degree.

CPP 15.50 Mon 19:00 P4

Photoinduced charge transfer and photophysics of functionalized Diethienopyrrole molecules from first principles — •Jannik Theile, Caterina Cocchi, and Michele Guerrini — Physics Department and Center for Nanoscale Dynamics, Carl von Ossietzky Universität Oldenburg, D-26129 Oldenburg, Germany

Donor-acceptor compounds are key components in organic electronics due to their tunable electronic and optical properties. In this work based on time-dependent density functional theory, we examine diethienopyrrole molecules, which act as electron donors, covalently combined with electron-acceptor units, focusing on their charge transfer dynamics induced by femtosecond laser excitations.

In the current symmetric molecule configuration, we find strong fluctuation patterns of the charge after laser excitation across both intensities and with and without nuclear motion, exceeding the initial changes of charge induced by laser excitation and the charge transfer (CT) remains insufficient and inconsistent throughout time evolution. Further considerations include asymmetric molecule configuration.

CPP 15.51 Mon 19:00 P4

Direct stochastic optical reconstruction microscopy (dSTORM) on cationic copolymer microgels — •Evelyn Gettinger and Thomas Hellweg — Physical & Biophysical Chemistry, University Bielefeld, Bielefeld, Germany

Microgels, three-dimensional polymer networks with colloidal dimensions, are promising candidates for catalysis, sensory and drug delivery applications due to their responsive properties. Cationic copolymer microgels, in particular, are gaining increasing attention in research, as they are suitable for conjugation with biomolecules like peptides, antibodies, and nucleic acids. Poly(NNPAM-co-DAPMA) is one such microgel that exhibits thermoresponsiveness through the monomer N-n-propylacrylamide (NNPAM) and pH responsiveness through the cationic comonomer N-3-(dimethylamino)propylmethacrylamide (DAPMA). This study investigates the network structure of Poly(NNPAM-co-DAPMA) microgels using direct stochastic optical reconstruction microscopy (dSTORM), a high-resolution fluorescence technique. Microgels with varying DAPMA concentrations were synthesized and analyzed for swelling behavior and polydispersity using photon correlation spectroscopy (PCS). Morphological properties were examined with atomic force microscopy (AFM). Post-synthetic fluorescence labeling with the anionic dye DY-654-carboxylic acid revealed a gradient of fluorophore localization from the core to the periphery and concentrated fluorophore domains, indicating a heterogeneous network with random comonomer distribution.

CPP 15.52 Mon 19:00 P4

Volume phase transition of NIPAM based copolymer microgels with non-thermoresponsive comonomers — •Jannis Krüger and Thomas Hellweg — Physical and Biophysical Chemistry, Bielefeld University

We conducted photon correlation spectroscopy (PCS) to obtain swelling curves of *N*-isopropylacrylamide (NIPAM)-based copolymer-microgels with varying content of non-thermoresponsive *N*-tert-butylacrylamide (NtBAM). Increasing NtBAM content reduces the hydrodynamic radius and broadens the volume phase transition (VPT). We analyzed the thermoresponsive contribution to the swelling curves with a cooperative Hill-like model for the Flory-Huggins interaction parameter $\chi_{\mathrm{Hill}}(T)$ [1]. This model effectively describes the microgel swelling at various compositions. The Hill parameter ν estimates the number of water molecules leaving a polymer segment at the phase transition. A linear decrease of ν with BIS content suggests that water stays adsorbed on BIS during the VPT due to the lack of an LCST [2]. We fitted PNIPAM-*co*-NtBAM microgel swelling curves [3] with a hybrid model of χ_{Hill} for NIPAM and the original Flory-Huggins parameter χ_{FH} for NtBAM, revealing an exponential decrease in ν with x_{NtBAM}, indicating that NtBAM inhibits water adsorption of neighboring NIPAM units. Based on these results we propose a steric mechanism, which qualitatively describes the observed inhibition of microgel hydration.

CPP 15.53 Mon 19:00 P4

Amphiphilic Monomers Bridge Hydrophobic Polymers and Water — •Guido Kusters[1,2,3], Guogao Zhang[1,4], Zheqi Chen[1,5], and Zhigang Suo[1] — [1]Harvard University — [2]Eindhoven University of Technology — [3]Max Planck Institute for Dynamics and Self-Organization — [4]Xi'an Jiaotong University — [5]Zhejiang University

Water dissolves a hydrophilic polymer but not a hydrophobic polymer. However, many hydrophilic polymer monomers are amphiphilic, with a hydrophobic vinyl group for radical polymerization and a hydrophilic group, and so may form solutions with both water and hydrophobic polymers. Ternary mixtures of amphiphilic monomers, hydrophobic polymers, and water have recently been used as precursors for interpenetrating polymer networks with unusual properties. However, the phase behavior of such ternary mixtures has not been studied. Here we mix the amphiphilic monomer acrylic acid, the hydrophobic polymer

poly(methyl methacrylate) and water. In the mixture, the hydrophobic polymer can form various morphologies, including solution, micelle, gel, and polymer glass. We interpret these findings by proposing that the hydrophobic and hydrophilic groups of the amphiphilic monomer enable it to function as a bridge. That is, the hydrophobic functional group binds to the hydrophobic polymer, and the hydrophilic functional group binds to water. This picture leads to a simple modification to the Flory-Huggins theory, which agrees well with our experimental data. Amphiphilic monomers offer a rich area for the development of materials of self-assembled structures with unusual properties.

CPP 15.54 Mon 19:00 P4

Mechanical Characterization of Epon 862/DETDA Epoxy Networks: Molecular Dynamics Simulations — •Djihed Rezzig[1,3], Wolfgang Verestek[2], Saad Abdeslam[1], Johannes Roth[3], and Siegfried Schmauder[2] — [1]LPMMM, Setif 1 University- Ferhat ABBAS, Algeria — [2]IMWF, Stuttgart University, Germany — [3]FMQ, Stuttgart University, Germany

Epoxy resins are widely used in advanced materials due to their exceptional mechanical properties. Among them, Epon 862/DETDA is a commonly employed thermoset system in aerospace and automotive applications. This study employs molecular dynamics simulations to investigate the mechanical behavior of the Epon 862/DETDA epoxy network. The simulations were conducted using cross-linked molecular models to represent the cured network, incorporating detailed atomic scale interactions. Mechanical behavior was evaluated by simulating stress-strain responses under tensile loading conditions and shear test for the elasticity tensor, revealing the epoxy networks high modulus and strength. Additionally, the study examines the effects of varying cross-link densities and molecular configurations on the materials performance.

CPP 15.55 Mon 19:00 P4

The effect of intracrystalline chain dynamics (ICD) in the stress relaxation of semi-crystalline polymers — •Tonghua Liu, Rose Mary Michell, Albrecht Petzold, and Thomas Thurn-Albrecht — Von-Danckelmann-Platz 3, 06120, Halle(Saale)

The intracrystalline chain dynamics (ICD) plays a significant role in semicrystalline polymers (SC), influencing not only the polymer crystallization and morphology but also the stability of crystals and the mechanical properties, such as drawability. Here we investigate how the ICD affects the stress relaxation of SC polymers.

Plane-strain compression test is used to study the relaxation behavior after yielding point. For crystal-fixed polymers like polycaprolactone (PCL), where ICD is absent or significantly hindered, only one relaxation process is observed. In contrast, crystal-mobile polymers like high density polyethylene (HDPE) exhibit two distinct relaxation processes, which can be attributed to the additional mobility within the crystals. The two relaxation processes in HDPE demonstrate markedly distinct time scales. The faster relaxation process is observed to relax faster with increasing temperature, whereas the slower relaxation process remains unaltered within the chosen temperature range.

CPP 15.56 Mon 19:00 P4

The effect of the intracrystalline chain diffusion on the non-linear mechanical behavior of semicrystalline polymers — •Rose Mary Michell, Albrecht Petzold, and Thomas Thurn-Albrecht — Martin Luther University Halle Wittenberg, Institute of Physics, D-06099 Halle, Germany.

This work studies the influence of intracrystalline chain diffusion (ICD) on the mechanical properties of semicrystalline polymers by comparing PEO with fast ICD and PCL with slow ICD. Mechanical tests were performed under plane strain compression at temperatures from -10 to 55 °C and true strain rates from 0.005 to 10 min^{-1}. At large deformations, the PCL always shows a strain hardening effect, while PEO shows softening when the rate decreases, temperature increases, and molecular weight decreases. The data corresponding to the strain hardening part, which describes the network forces, was fitted using the Gaussian model. The stress-strain curve for PCL showed higher stress than the Gaussian chain model predicted. In contrast, PEO had lower stress values; this difference could be attributed to an effect linked to chain mobility. For slow ICD, the crystals act as physical crosslinking points. Otherwise, the chains can be pulled from the crystals and soften the network. In conclusion, we found systematic differences in non-linear mechanical behavior between crystal-fixed and crystal-mobile polymers. This suggests that the competition between ICD and deformation determines the non-linear mechanical behavior at large deformations of semicrystalline polymers.

CPP 15.57 Mon 19:00 P4

Exploring the role of defects in polymer networks through simulations of 4-armed polymers — •Sayam Bandyopadhyay[1,2], Sebastian Seiffert[3], and Arash Nikoubashman[1,2] — [1]Leibniz-Institut für Polymerforschung Dresden e.V., 01069 Dresden, Germany — [2]Institut für Theoretische Physik, Technische Universität Dresden, 01069 Dresden, Germany — [3]Department of Chemistry, Johannes Gutenberg Universität Mainz, 55128 Mainz, Germany

We simulated polymer networks formed by coarse-grained tetra-PEG (tPEG) macromolecules to investigate the effects of (connectivity) defects on network dynamics. We modeled both homoleptic and heteroleptic systems, where we modeled non-covalent bonds between functionalized end groups using an inverted Gaussian potential to control valency. The network structure was quantified through the fraction of bonded end groups and the radial distribution functions of attractive beads. Polymer mobility was characterized by examining the mean square displacement of individual tPEG molecules after gelation. To explore the impact of defects, we systematically altered the defect density by incorporating tPEG chains with inert end groups in the homoleptic systems and by varying the stoichiometry in the heteroleptic mixtures. Additionally, we examined how the bending stiffness of the polymers influenced network structure and dynamics, finding a marked slowing down with increasing stiffness. These findings provide new insights into the factors governing the role of defects in the structure and dynamics of polymer networks.

CPP 15.58 Mon 19:00 P4

Silicone implementation to car industry — •Yury Ostretsov — Moscow, Russia, Bolshaya Semenovskaya 38

Silicone is a preferred material for manufacturing automotive hoses due to its high heat resistance, resistance to aggressive chemical environments, flexibility, and durability. These properties allow silicone hoses to maintain shape and performance under extreme temperatures and pressure fluctuations, reducing the risk of leaks or failures. Additionally, silicone is lightweight compared to rubber alternatives, contributing to overall vehicle efficiency. Its ability to withstand ozone and UV exposure also enhances longevity, making it a reliable choice for various automotive applications.

CPP 15.59 Mon 19:00 P4

Water flow decrease of track-etched polyethylene terephthalate membranes in filtration applications — •Ana Ambroz[1,2], Zhen Yao[2], Christopher Rojas[3], Polina Angelova[2], Irena Petrinic[1], and Armin Gölzhäuser[2] — [1]Univeristy of Maribor, Maribor, Slovenia — [2]University of Bielefeld, Bielefeld, Germany — [3]CNM Technologies GmbH, Bielefeld, Germany

Track-etched (TE) membranes, with their precise pore size, controlled porosity, and defined pore geometry, are industrially applied as highly sensitive and fast filters for bacteria in the food, cosmetic and pharmaceutical industries, as control barriers in glucose sensors, and as biomolecule selective barrier in implants. Additionally, they are being investigated for their potential in reverse and forward osmosis for water purification and cold concentration. However, their tendency to lose performance over time presents a significant challenge, particularly in high-throughput and durable applications. In this work, we evaluate the performance of track-etched polyethylene terephthalate (TE-PET) membranes as nano- and microfilters in low-pressure reverse osmosis (LPRO) and dead-end filtration systems. Monitoring water flux through the TE-PET membranes at different low pressures (0.02-10 bar) revealed a gradual decrease over time, varying with porosity and pore size. Specifically, membranes with low porosity (<1.5%) and small pore sizes (<1.5 um) exhibited a significant reduction in water flux. The decline is attributed to membrane swelling and the formation of a sol-gel film within the pores, with additional contributing factors discussed.

CPP 15.60 Mon 19:00 P4

Intermolecular bonds - connecting structure and dynamics — •Martin Tress[1], Friedrich Kremer[1], and Jan Philipp Gabriel[2] — [1]Peter-Debye-Institute for Soft Matter Research, Leipzig University, Leipzig, Germany — [2]Institute of Materials Physics in Space, German Aerospace Center, Köln, Germany

Descriptions of the glass transition often consider temperature dependent changes in the specific volume to explain the tremendous increase in relaxation time, and empricial data confirm the general role of thermal expansion [Nat Phys 19 (2023) 694]. However, since glassy dynamics happens on molecular scale, macroscopic thermal expansion might be too coarse. Here we use infrared spectroscopy data to extract inter-molecular hydrogen (H)-bond lengths in wide temperature ranges. For water, the H-bond expansion coefficient differs strongly from the macroscopic one, which is easily assigned to considerable structural reorganization in the water network [JCP 160 (2024) 234502]. Their comparison reveals that the most compact molecular arrangement is formed in the range ~316-331 K (i.e. well above the density maximum). This coincides with several pressure-related anomalies which confirms this characteristic point in the supra-molecular arrangement. These results confirm our earlier approach to deduce inter-molecular H-bond lengths in polyalcohols [JCP 154 (2021) 024503] and open a new alley to investigate the role of inter-molecular expansion as a precursor to structural relaxation on a bond-specific level.

CPP 15.61 Mon 19:00 P4

Single-molecule spectroscopy of organic laser gain media — •Janne Becker, Robert Schmidt, Steffen Michaelis de Vasconcellos, and Rudolf Bratschitsch — Institute of Physics, University of Münster, Germany

Since the first experiments on pentacene [1], single-molecule spectroscopy has been performed for applications ranging from cell biology and medicine to organic laser media and single-photon emission [2]. To design and use these spe-

cialized molecules, their photophysical properties have to be investigated. Here, we perform single-molecule spectroscopy to study organic laser gain media. To isolate single molecules, we dilute the organic material down to concentrations of the order of nmol/L with ultra-pure solvents and measure characteristic fluorescence lifetimes and spectra.

CPP 15.62 Mon 19:00 P4

XPS study of redox mechanism in $Na_{2.5-x}Fe_{1.75}(SO_4)_3$ cathode material for high-voltage sodium-ion batteries — •Neama Imam[1], Karsten Henkel[1], Anna Milewska[2], Janina Molenda[2], Ehrenfried Zschech[1], and Jan Ingo Flege[1] — [1]Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology Cottbus-Senftenberg, Germany — [2]AGH University of Krakow, Faculty of Energy and Fuels, Krakow, Poland

A multiplet splitting model based on the original work by Gupta and Sen has been used to track the redox mechanism and electronic structure of $Na_{2.5-x}Fe_{1.75}(SO_4)_3$, a high-performance cathode material for sodium-ion batteries (SIBs). This high-purity, off-stoichiometric open-channel cathode material with a tailored sodium-ion distribution, synthesized using an optimized solid-state route, demonstrates a high operating voltage of ~3.8 V, surpassing the values reported for other cathode materials in the literature. X-ray photoelectron spectroscopy (XPS) was employed to analyze the evolution of the material's electronic structure at various charging potentials. $Fe2p_{3/2}$ spectra decomposition using the multiplet splitting model revealed the gradual oxidation of Fe^{2+} to Fe^{3+} during battery charging while transitioning from its pristine state ($x = 0$) with the presence of only Fe^{2+} at the cathode surface to the highest sodium deintercalation level ($x = 1.61$). This result is consistent with the electrochemical analysis.

CPP 15.63 Mon 19:00 P4

Multiscale dynamics simulations of amorphous polyethylene terephthalate — •Andoni Ugartemendia[1], Alessandro Mossa[2], and Giorgia Brancolini[3] — [1]Institute of Nanoscience, CNR-NANO S3, via G. Campi 213/A, 41125 Modena, Italy — [2]Institute of Nanoscience, CNR-NANO S3, via G. Campi 213/A, 41125 Modena, Italy — [3]Institute of Nanoscience, CNR-NANO S3, via G. Campi 213/A, 41125 Modena, Italy

In the last decades, multiwall polymers have become widely used in food packaging due to their excellent mechanical and barrier properties. Unfortunately, the recycling of these materials is difficult and costly, leading to environmental problems. An understanding of the polymers properties is crucial towards the development of new recycling technologies. However, their computational modeling poses a great challenge since the dynamics span over several time scales. As a result, a multiscale approach becomes mandatory to gain access to the slower degrees of freedom. In this regard, coarse grained (CG) models have drawn considerable attention recently. CG models neglect the fastest degrees of freedom, flattening the rugged potential and thus, allowing higher time steps. In this work, we adopt a multiscale protocol to characterize several properties of polyethylene terephthalate (PET). First, atomistic molecular dynamics (MD) simulations are performed for amorphous PET systems with varying chain lengths. Then, the atomistic data is employed to derive a CG force field based on the iterative Boltzmann inversion (IBI). Finally, the structural data obtained with atomistic and CG simulaions are compared.

CPP 15.64 Mon 19:00 P4

Fourth-Generation High-Dimensional Neural Network Po- tentials for Molecular Chemistry in Solution — •Djamil Abdelkader Adel Maouene[1,2], Moritz Richard Schäffer[1,2], Moritz Gubler[3], Stefan Goedecker[3], and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany — [3]Department Physik, Universität Basel, Switzerland

Machine learning has become a powerful tool in chemistry and materials science, as high-dimensional neural network potentials (HDNNPs) provide accurate representations of multidimensional potential energy surfaces for atomistic simulations. In this study, we compare the performance of two types of HDNNPs; 2G-HDNNPs and 4G-HDNNPs, in modeling organic molecules in aqueous solution. While 2G-HDNNPs have proven effective in many systems in capturing local interactions based on atomic environments, they fail in scenarios where long-range charge transfer plays a critical role. These cases are better addressed by 4G-HDNNPs, which take into account atomic charge variations caused by structural or electronic changes even at distant regions in the system. Both methods are demonstrated using a model organic molecule.

CPP 15.65 Mon 19:00 P4

Insights into Machine Learning Interatomic Potentials for simple analytical model systems — •Mirko Fischer and Andreas Heuer — Institute for Physical Chemistry, University of Münster, Corrensstraße 28/30, 48149 Münster

During the past 10 years Machine Learning interatomic potentials (MLIP) have gained popularity for Molecular Dynamics simulations with quantum chemical accuracy. Although it is a rapidly evolving field, many questions remain open. These include issues of interpretability, modeling different interaction types and how to select training data properly. MLIPs are rarely applied to simple model systems, for which the interactions of particles can be described analytically, to investigate these questions. Instead, MLIPs are mostly applied directly to realistic molecular systems for which the ground truth interactions must be approximated by methods like Density Functional Theory. By training an Atomic Cluster Expansion as a systematic and generally interpretable model for a Lennard-Jones model system, we aim to study how interaction types, system size and temperature affect the learned model in a systematic manner. The obtained interactions can be directly compared to the known true analytical interactions. Moreover, we fit a MLIP for an amorphous silica system to study structure and dynamics in a glass-forming system, where low-energy states are important. The question emerges, how to select the training data best and if such low-energy (low temperature) states must be explicitly included in it or if the MLIP is able to extrapolate from high-energy (high temperature) states to low energy states.

CPP 15.66 Mon 19:00 P4

Efficient Millisecond Timescale Modeling of Hydroxide Ion Dynamics in Aqueous Systems: A Multiscale Simulation Approach — •Jonas Hänseroth[1,2], Daniel Sebastiani[2], and Christian Dressler[1] — [1]Theoretical Solid State Physics, Institute of Physics, Ilmenau Universitiy of Technology, Ilmenau, Germany — [2]Theoretical Chemistry, Institute of Chemistry, Martin-Luther-University of Halle-Wittenberg, Halle (Saale), Germany

An adapted combined Molecular Dynamics/Lattice Monte Carlo (cMD/LMC) approach models hydroxide ion transport across extended systems and millisecond timescales.[1] The method surpasses classical Molecular Dynamics in efficiency while maintaining the accuracy of ab initio Molecular Dynamics, allowing the study of aqueous potassium hydroxide systems over a wide concentration range (3-61 wt.-%). The cMD/LMC algorithm allows simulations involving thousands of atoms at low computational cost, yielding diffusion coefficients consistent with ab initio benchmarks. This framework can provide insights into the dynamics of hydroxide ion in systems such as anion exchange membranes, which are essential for fuel cell technology. [1] J. Chem. Theory Comput. 2014, 10, 10, 4221-4228

CPP 15.67 Mon 19:00 P4

Confinement-induced dynamics in binary liquid mixtures: insights from molecular simulations — •Anam Sara, Pascal Merle, Siegfried Stapf, and Christian Dressler — Technische Universität Ilmenau, Germany

In this work, we investigate the behavior of binary liquid mixtures confined within silica nanopores, examining how confinement impacts the diffusion and relaxation properties of mixtures such as cyclohexane/acetone, cyclohexane/tetrahydrofuran (THF), water/acetone, and water/THF [1]. Experimental NMR measurements revealed deviations in diffusion coefficients and relaxation times of these mixture under confinement [2,3]. To interpret these observations, we perform molecular dynamics (MD) simulations to get atomistic insights into the structure and dynamics of these mixtures within the pores. Our primary objective is to characterize how confinement alters the microphase separation, component density distribution along the pore axis, and preferential interactions with pore walls.

Density of states in hard disks: Concentration dependency via SAMC simulation — Timur Shakirov[1,2], Malte Kautzsch[1], and •Viktor Ivanov[1] — [1]Martin-Luther-University Halle-Wittenberg, Halle (Saale), Germany — [2]Indivumed GmbH, Hamburg, Germany

We propose a new variant of SAMC sampling for determining the density of states as a function of the concentration of particles. The system is modelled as a set of dimensionless points, i.e., points with zero diameter. The minimal points separation, d_{min}, is chosen as the sampling parameter determining the macrostate. Thus, the density of states and the visiting histogram depend on the minimal distance d_{min} and are accumulated at each step of the algorithm according to the standard SAMC procedure. In a microstate (particular configuration of points' positions) with a given value of the minimal distance between points, d_{min}, one can replace the points with the hard disks of the diameter d_{min} (or less). This creates a system with a specific value of the concentration φ. We apply this algorithm for the two-dimensional system of hard disks to study its phase behaviour at different concentrations and compare the results with KTHNY theory and the previous simulations.

CPP 15.69 Mon 19:00 P4

Multiscale Simulation Framework for Functional Polymer Systems — •Steffen Kampmann[1], Alexander Croy[2], Arezoo Dianat[1], and Gianaurelio Cuniberti[1,3] — [1]Institute for Materials Science and Max Bergmann Center for Biomaterials, TU Dresden — [2]Chair of Theoretical Chemistry, Institute of Physical Chemistry, Friedrich Schiller University Jena — [3]Dresden Center for Computational Materials Science (DCMS)

Functional, mechanically resilient polymer and polymer-based nanocomposite films play an important role for strain gauges or organic light-emitting diode (OLED) displays [1-3]. The modelling and simulation workflow presented here enables the generation of disordered polymer systems and the linking of the mechanical and electronic properties from the atomistic to the microscopic size scale. Here, the focus is on the relationship between deformation and conductivity behavior. To calculate the multi-scale material behavior, we use density functional tight binding (DFTB) calculations, molecular dynamics simulations, and the finite element method. The in-situ processing, evaluation as well as the exchange of the generated data across simulation methods is performed using our Python framework. The multi-scale computational workflow indicated here represents a computationally efficient assessment of the properties of the polymer systems at different scales. [1] K. Grabowski, et al., Computational Materials Science, 135, 169*180, (2017) [2] R. Luo, et al., Progress in Organic Coatings, 162, 106593 (2022) [3] L. CPP 15.70 Mon 19:00 P4

Investigation of electrolyte dynamics with interfaces: Insights from simple MD-models — •Katharina Kintrup[1,2], Youssef Mabrouk[1,2], Diddo Diddens[1,2], and Andreas Heuer[1] — [1]Institut für Physikalische Chemie, Corrensstraße 28/30, 48149 Münster, Deutschland — [2]Helmholtz-Institut Münster, Corrensstraße 48, 48149 Münster, Deutschland

Molecular Dynamics (MD) simulations are a common tool to investigate transport properties of electrolytes. Typically, periodic boundary conditions (pbc) are applied to simulate energetically closed systems, which are contrary to experimental systems with interfaces. Electrophoretic NMR (eNMR) experiments show that the incompressibility is dominating the transport properties of electrolytes, leading to an application of local conservation of volume. [1] Inspired by this, we set up simplified models to simulate binary liquids, imitating ionic liquids (IL), within interfaces, resulting in energetically open systems. After applying external (electric) fields, various properties of the model systems such as average velocities, number densities, volume densities, etc. were evaluated. A transition from local conservation of momentum towards local conservation of volume was observed. The velocities of all systems portrayed oscillations due to sound waves. A general analysis of dynamic processes on different time scales for systems without explicit charges was achieved. A comparison between systems with and without explicit charges was conducted, proving the superiority of the advanced charged model due to higher incompressibility. [1] J. Phys. Chem. Lett, 2022, 13, 8761-8767

CPP 15.71 Mon 19:00 P4

Evidence for unusual solvation shell of aqueous Fe^{3+} at high dilution — •Amrita Goswami, Elvar Örn Jónsson, and Hannes Jónsson — Science Institute and Faculty of Physical Sciences, University of Iceland, VR-III, 107 Reykjavík, Iceland

Solvated Fe^{3+} in water is a particularly important system, relevant, for instance, for the widely studied charge transfer Fe3+/Fe2+. However, the solvation shell of such highly charged cations is still poorly understood, particularly at for concentrations less than 1 M. In this regime of high dilution, experimental data and high-level calculations are sparse. For instance, most density-functional theory calculations are performed at a concentration of 0.8 M or higher, with uniform background charge. Simulations for such dilute solutions can provide insight inaccessible to other techniques. Using extensive molecular dynamics simulations with empirical potentials and DFT geometry optimizations of selected configurations, we study the effect of solution concentration on the solvation structure of aqueous Fe^{3+}. The solvation shell is found to undergo abrupt transitions between two states: an octahedral (OH) state with 6-fold coordination, and a metastable capped trigonal prism (CTP) state with 7-fold coordination. Further, we have developed a QM/MM (quantum-mechanical/molecular mechanical) method to study dilute solutions of aqueous Fe^{3+} with DFT-level accuracy, with a polarizable water model. References: Goswami et al., J. Phys. Chem. Lett., 2024

CPP 15.72 Mon 19:00 P4

Exploring Pathways of Supramolecular Self-Assembly at Liquid-Liquid Interfaces — •Mephin Philip Alamcheril[1], Friederike Schmid[1], and Shikha Dhiman[2] — [1]Institute for Physics, Johannes Gutenberg University Mainz — [2]Department of Chemistry, Johannes Gutenberg University Mainz

A self-assembly process usually occurs through thermodynamic pathways but the co-existence of different intermediates and diverse pathways of self-assembly have been observed. Liquid droplets are one such intermediate in many self-assembly processes, particularly in biological systems, which form through liquid-liquid phase separations (LLPS). Even though LLPS is a very well-known phenomena in polymer chemistry, only little is known about the possible role of LLPS in synthetic small molecule-based self-assembly.

In this project, we aim to study the possible mechanism of self-assembly at the surface of phase separated liquid droplets to explore the structure and dynamics at various stages of self-assembly and provide insights into how it can be controlled and manipulated for various applications. To that end, we develop a simple coarse-grained model for monomers in explicit solvent that self-assemble into fibers. The model is designed to represent BTA-like molecules in water. It is able to capture key characteristics of the experimental system such as the competition of fibril formation and liquid-liquid phase separation. We use it to examine the pathways of fibril formation from phase separated droplets.

CPP 15.73 Mon 19:00 P4

Isoconversional effect in epoxy polymerization process — •Sampanna Pahi[1], Christian Wick[1,2], and Ana Sunčana Smith[1,2,3] — [1]PULS Group, Institute for Theoretical Physics , FAU Erlangen-Nürnberg, Germany — [2]Group of Computational Life Sciences, Division of Physical Chemistry, Ruder Bošković Institute, Zagreb, Croatia — [3]Competence Unit for Scientific Computing (CSC), FAU, 91058 Erlangen, Germany

Isoconversional methods are essential for understanding the kinetics and predicting thermodynamic data in epoxy polymerization. While these methods have been experimentally validated, their computational modeling remains underexplored. In this study, we use molecular dynamics (MD) simulations and Quantum Mechanics/Molecular Mechanics (QM/MM) transition state (TS) analyses to investigate mechanisms and energetic barriers in epoxy thermoset curing, focusing on isoconversional effects. We generated post-a-priori QMMM reactive sites with hydrogen-bonded systems to examine the influence of hydrogen bonding on the curing process. Initial results without hydrogen bonds showed higher activation energies than experimental values, with some outliers showing lower energies. Adding hydrogen bonds, especially hydroxyl (OH) bonds, reduced activation energies and explained these discrepancies. Radial distribution function (RDF) analyses showed OH bond formation is more likely than amine (NH) bonds, highlighting hydrogen bonding*s critical role in isoconversional effects during epoxy curing.

CPP 15.74 Mon 19:00 P4

A Multiscale MD-QM/MM Approach for Modeling Fracture Behavior in Epoxy Resins — •Barişcan Arican[1], Christian Wick[1], and Ana-Sunčana Smith[1,2] — [1]PULS Group, Institute for Theoretical Physics, IZNF, FAU Erlangen-Nürnberg, 91058 Erlangen — [2]Group of Computational Life Sciences, Division of Physical Chemistry, Ruder Bošković Institute 10000 Zagreb, Croatia

Epoxy resins, with their exceptional mechanical properties, are indispensable in advanced engineering applications. However, understanding their fracture behavior at the molecular level remains a challenge. This study presents a multiscale framework that couples molecular dynamics (MD) simulations with quantum mechanics/molecular mechanics (QM/MM) calculations to analyze bond rupture and crack propagation in epoxy networks. The MD component monitors strain accumulation and identifies critical bond elongation thresholds indicative of imminent fracture. When these thresholds are met, the simulation transitions to QM/MM calculations, where bond breakage is determined dynamically by considering the surrounding chemical environment. This on-the-fly approach enables efficient and accurate modeling of fracture events and their impact on larger-scale material behavior, providing a foundation for future studies of epoxy resin failure mechanisms.

CPP 16: Energy Storage and Batteries I

Invited Talk CPP 16.1 Tue 9:30 H34

Multifunctional structural batteries — •Göran Lindbergh — KTH Royal Institute of Technology, Stockholm, Sweden

A multifunctional lightweight material combines several functions in a single material entity able to simultaneously bear mechanical loads by acting as a carbon fibre composite component while providing one or more other functionalities at the same time, e.g. storing energy. In this work, we will show functionalities coming from alkali ion insertion in carbon fibres that goes beyond the battery function, and how these functions can be combined in a single device.

The starting point for these concepts is so called structural batteries, which

are multifunctional composite materials able to carry load while storing electrical energy like lithium-ion batteries. In such a battery, carbon fibres are used as the load carrying material thanks to their excellent strength and stiffness properties, but also as the active negative electrode. They also include a multifunctional matrix system, a structural battery electrolyte (SBE), the material holding the fibres together to make a solid-state load carrying material, but which at the same time is ionically conductive and chemically stable. It includes a multifunctional positive electrode, a composite electrode based on conventional ion inserting materials like lithium iron phosphate (LFP) supported by electrochemically active carbon fibres for load carrying and electrical conduction. This device can then also be used for inherent strain sensing in the material and can also be made to shape-morph with electrical control at low voltages and for harvesting energy by converting mechanical strain to electrical power.

CPP 16.2 Tue 10:00 H34

Structural response of advanced silicon-containing graphite anodes in commercial Li-ion batteries — •Tobias Hölderle[1,2], Dominik Petz[1,2], Vladislav Kochetov[2], Peter Müller-Buschbaum[1], and Anatoliy Senyshyn[2] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]MLZ, TUM, 85748 Garching, Germany

This study explores the structural behavior of graphite anodes containing silicon additives in commercial lithium-ion batteries (LIBs) through detailed X-ray and neutron powder diffraction analyses. Silicon is increasingly utilized in advanced LIB anodes due to its potential to significantly increase energy capacity. However, its substantial volume expansion and amorphization during lithiation, complicate direct observation of lithium redistribution within the anode via diffraction techniques. Nonetheless, an indirect structural response linked to the lithiation of silicon was identified, indicated by a delayed lithium intercalation into the graphite structure. Furthermore, aging effects on high-silicon-content anodes were explored, showing the role of silicon in accelerating electrode degradation over time. These findings enhance our understanding of the complex relationship between the silicon content in the anode, structural stability, and lithium transport in advanced LIBs.

CPP 16.3 Tue 10:15 H34

XPS study of redox mechanism in Na2.5-xFe1.75(SO4)3 cathode material for high-voltage sodium-ion batteries — Neama Imam[1], •Karsten Henkel[1], Anna Milewska[2], Janina Molenda[2], and Jan Ingo Flege[1] — [1]Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology Cottbus-Senftenberg, Germany — [2]AGH University of Krakow, Faculty of Energy and Fuels, Krakow, Poland

A multiplet splitting model based on the original work by Gupta and Sen has been used to track the redox mechanism and electronic structure of Na2.5-xFe1.75(SO4)3, a high-performance cathode material for sodium-ion batteries (SIBs). This high-purity, off-stoichiometric open-channel cathode material with a tailored sodium-ion distribution, synthesized using an optimized solid-state route, demonstrates a high operating voltage of ~3.8 V, surpassing the values reported for other cathode materials in the literature. X-ray photoelectron spectroscopy (XPS) was employed to analyze the evolution of the material's electronic structure at various charging potentials. Fe2p3/2 spectra decomposition using the multiplet splitting model revealed the gradual oxidation of Fe2+ to Fe3+ during sodium de-intercalation while transitioning from its pristine state with the presence of Fe2+ at the cathode surface only to the fully charged state (Na0.89Fe1.75(SO4)3 at 4.5 V). This result is consistent with the electrochemical analysis.

CPP 16.4 Tue 10:30 H34

Multipoint Anionic Bridge: Asymmetric Solvation Structure Improves the Stability of Lithium-Ion Batteries — •Tianle Zheng[1], Ya-jun Cheng[2], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]Ningbo Institute of Materials Technology & Engineering, Chinese Academy of Sciences, Ningbo, 315201, Zhejiang Province, P. R. China

In this study, a novel concept of multipoint anionic bridge (MAB) is proposed and proved, which utilizes anions with different sites to connect with the asymmetric solvation structure (ASS). Compared to usual solvation structures, this study uses the multifunctional groups of difluoro(oxalate)borate anion, which can connect with Li ions. By tailoring the concentration, the anion serves as a bridge between different solvated structures. In-situ techniques and simulations investigate electrolytes to draw correlations between solvation structures and reaction pathways. The proposed design demonstrates remarkable high-temperature performance on both the anode and cathode sides, enabling stable cycling of lithium cobalt oxide (LCO)||graphite (0.5 Ah, 1.0 C) pouch cell for over 200 cycles at 80 °C, and facilitating Li||MCMB and Li||lithium iron phosphate (LFP) cells to deliver stable performance for 200 cycles at 100 °C. This work paves a way to develop high-performance electrolyte systems by designing and using new multipoint anions to construct ASSs.

CPP 16.5 Tue 10:45 H34

In situ Mechanochemical Synthesis of Organic Anodes in Electrode Processing for Ultra-long Sodium Storage — •Ying Qi, Huaping Zhao, and Yong Lei — TU Ilmenau

Currently, hard carbon is commonly used as an anode material in sodium-ion batteries (SIBs). However, hard carbon anodes face several challenges, including time-consuming and energy-intensive synthesis processes, low-voltage operating platforms, and capacity storage with a steep slope. These issues contribute to severe dendrite growth and reduced full-cell capacity, negatively affecting electrochemical performance. In contrast, organic anodes are becoming a focal point in SIBs research due to their abundant availability, low cost, simple synthesis, and stable potential plateaus. In this study, we directly prepared a series of acid anhydrides including perylene-3,4,9,10-tetracarboxylic dianhydride (PTCDA), 1,4,5,8-naphthalenetetracarboxylic dianhydride (NTCDA), and pyromellitic dianhydride (PMDA) into electrodes using a one-step milling process during slurry preparation. The prepared Na4PTC electrodes show low potential plateaus and ultra-stable cycling performance in SIBs. It exhibited exceptional performance, demonstrating ultra-long cycling stability lasting nearly one year. Additionally, the assembled full cell delivered a high energy density of ~200 Wh kg-1.

CPP 16.6 Tue 11:00 H34

Localized highly concentrated electrolytes with perfluorocarbonate diluents enable high-energy-density lithium/sodium metal batteries — •Zhuijun Xu[1], Yinghui Li[2], Yajun Cheng[2], Yonggao Xia[2], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]Ningbo Institute of Materials Technology & Engineering, Chinese Academy of Sciences, Ningbo, Zhejiang, 315201, P. R. China

Localized high-concentration electrolytes (LHCEs) have been widely recognized for their critical role in managing the reversible plating/stripping of alkali metals. multi-functional diluents with more stable physical and chemical properties are crucial for enhancing battery performance and safety. In this study, a variety of solvents, including 4-fluoro-1,3-dioxolan-2-one, 4,4-difluoro-1,3-dioxolan-2-one, cis-4,5-difluoro-1,3-dioxolan-2-one, trans-4,5-difluoro-1,3-dioxolan-2-one, 4,4,5-trifluoro-1,3-dioxolan-2-one, and 4,4,5,5-tetrafluoro-1,3-dioxolan-2-one, were analyzed using Density Functional Theory (DFT) calculations. Further, molecular dynamics (MD) simulations were conducted on the aforementioned solvents and their corresponding LHCEs for lithium/sodium metal batteries (LMBs/ SMBs). A comprehensive set of physical and chemical properties was examined, including the density of the solvent molecules, their highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) energies, and their binding energies with lithium or sodium ions, distinct solvation structures within various LHCEs.

CPP 17: Modeling and Simulation of Soft Matter I

Time: Tuesday 9:30–11:15 Location: H38

Invited Talk CPP 17.1 Tue 9:30 H38

Continuum models for water's peculiar behavior on the nanoscale — •Alexander Schlaich — Institute for Atomistic Modeling of Materials in Aqueous Media, Hamburg University of Technology, Germany

Water at the nanoscale exhibits unexpected properties relevant to many soft matter applications, ranging from the hydration forces that stabilize biological matter, via interfacial viscous effects that dominate wear behavior, to the unique dielectric behavior. Atomistically, these effects can be linked to the strong hydrogen bonding network and the corresponding water orientation and density at interfaces and in confinement – observables directly accessible from molecular simulations. However, relating these properties to experimental, typically macroscopic or at least averaged quantities is a tedious task. Here I will discuss some of the progress we have made in the last few years in deriving effective descriptions of the microscopic details that can be used to apply continuous descriptions and thereby extract, for example, experimentally accessible hydration pressure, permeance, or capacitance. Our recent work has focused on combining concepts from solid state theory and soft matter physics to accurately treat the electrode/electrolyte interface, and I will present our analysis of the unusually high capacitance of pure water capacitors.

CPP 17.2 Tue 10:00 H38

Coupled self and collective dynamics in highly charged colloidal Yukawa-systems — •Daniel Weidig and Joachim Wagner — University of Rostock, Rostock, Germany

We investigate binary mixtures of highly charged colloidal particles employing Brownian dynamics simulations. In mixtures of identically charged, but differently sized particles solely the Stokes-Einstein diffusion coefficients differ, while the interactions are practically size-independent. Due to these identical interactions the static structure of all species are identical and independent on dynamical properties of the particles, as observed in partial static pair correlation functions. A dynamical coupling of both self and collective motion is observed in these systems. The long-time self-diffusion coefficient of a larger species is enhanced by the presence of a smaller, more mobile species and vice versa. Similar coupling effects are as well observed in the initial correlation decay of partial, distinct intermediate scattering functions, quantified by relaxation rates and stretching exponents of stretched exponentials. For all the here mentioned parameters, in the limit of strongly electrostatically coupled colloidal systems in first approximation linear dependencies on the size-ratio and reduced number density are observed. Despite we investigated highly dilute colloidal suspensions, where normally hydrodynamic interactions are neglectable, we found especially in binary mixtures an enhancement of the self and collective diffusion coefficients due to hydrodynamic interactions. Contrary, in one-component systems, hydrodynamic interactions do not have significant influence on time-dependent diffusion coefficients.

CPP 17.3 Tue 10:15 H38

Grand canonical molecular dynamics simulation of surface-initiated polymerization — •Bhuwan Poudel and Kurt Kremer — Max Planck Institute for Polymer Research, Mainz, Germany

The post-characterization of polymer brushes prepared from surface-initiated polymerization (SIP) is challenging because of their unique morphology and limitations in experimental techniques. However, in simulation counterparts, it is much easier to gain control over SIP processes. In this work, we used grand canonical molecular dynamics simulations to investigate the growth kinetics and characterization of polymer brushes. The SIP was studied by varying the grafting density. At low grafting densities, nearly monodisperse brushes were obtained. The dispersity was found to be increased with increasing grafting density; as a result, brushes with broad molecular weight distribution were obtained. We also showed that parameters such as thickness, molecular weight, and dispersity can be precisely controlled during SIP. The results suggests that the method presented here provides strategies to synthesize polymer brushes and tailor their properties more efficiently.

CPP 17.4 Tue 10:30 H38

IR Spectroscopy and Electric Field Simulations Enabled by the Atomic Polar Tensor Neural Network — •Philipp Schienbein — Lehrstuhl für Theoretische Chemie II, Ruhr-Universität Bochum, 44780 Bochum, Germany — Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, 44780 Bochum, Germany

Vibrational spectroscopy is a vital technique for uncovering microscopic structure and dynamics of condensed phase systems. However, interpreting such spectra at the microscopic level often requires theoretical support. While ab initio molecular dynamics (AIMD) has proven effective for this purpose, its high computational cost – especially when using electronic structure methods beyond GGA DFT – can be prohibitive. We have recently introduced a machine learning molecular dynamics (MLMD) approach for accurately calculating IR spectra using the atomic polar tensor, a size-intensive physical observable that can uniquely be defined for each atom and is thus broadly applicable across diverse systems. Notably, the atomic polar tensor also rigorously enables MLMD simulations under external electric fields. In this work, I benchmark this method against explicit AIMD simulations demonstrating comparable accuracy with significantly reduced computational cost and present applications of the atomic polar tensor neural network. These examples highlight its potential to drive novel physical insights, particularly in scenarios requiring large-scale MD simulations or computationally intensive electronic structure methods.

CPP 17.5 Tue 10:45 H38

Reducing dynamical helical polymers to 1D Ising models: long-range effects from polymer self-avoidance — •Keerti Chauhan[1], Marcus Müller[2], and Kostas Daoulas[1] — [1]Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany — [2]Georg-August-Universität Göttingen, Institute for Theoretical Physics, 37077 Göttingen, Germany

Cooperative chiral order in dynamic helical polymers (DHP) is commonly understood by reducing them to 1D Ising chains. Each spin can switch between $\sigma = -1$ and $\sigma = +1$ to represent rapid interconvertion between left-handed (M) and right-handed (P) helical twist. Spins are ferromagnetically coupled to capture the energetic disadvantage of boundaries between P and M domains. Currently, all 1D Ising models of DHP assume nearest-neighbor (NN) spin-spin interactions. We use a minimal model to challenge this assumption and investigate whether polymer self-avoidance, due to excluded volume, leads to effective non-local coupling between spins. Polymers are represented by freely-jointed chains with reversible hinges and helicity is described by a NN 1D Ising Hamiltonian with coupling strength J. Ideal and self-avoiding DHP are generated via a Monte Carlo scheme. First, we verify that in ideal chains the spins reproduce the statistics of a NN 1D Ising model with coupling strength J. Next, we find that chain self-avoidance does create effective long-range interactions between spins, as demonstrated by spin-spin correlation functions and free-energy calculations. These interactions renormalize J and create finite-size effects that are inconsistent with a NN 1D Ising behavior.

CPP 17.6 Tue 11:00 H38

Stabilization of Sodium Dodecyl Sulfate Reverse Micelles in Acid Solutions and Toluene from Molecular Dynamics Simulations — •Qixuan Li — Ruhr University Bochum, Bochum, Germany

The anionic surfactant Sodium dodecyl sulfate (SDS) forms reverse micelles (RMs) in two non-miscible components above the critical micelle concentration. Although the RMs in salt or alkali solution has been investigated in previous studies, less is known on the working mechanism of acids in SDS RMs. Here, we employ all-atom molecular dynamics simulations using Generalized Amber Force Field (GAFF) to investigate the effects of chloroauric acid (HAuCl4), fluoroboric acid (HBF4), phosphoric acid (H3PO4) and perchloric acid (HClO4) solutions on the stability of the RMs through spontaneous self-assembly in toluene. We find that all kinds of acids can stabilize micellar structure, and in particular high concentration of acids can significantly enhance the stability of RMs. In addition, H2PO4- anions tend to accumulate close to the RM surface, because they can form stable hydrogen bonds with the sulfate-based headgroup of SDS molecules or hydrated protons. Our findings can help to rationalize the impact of different acids on the RMs stability and in turn on the metallic nanoparticles synthesis where the RMs are used as nanoreactors.

CPP 18: Biomaterials, Biopolymers and Bioinspired Functional Materials II (joint session CPP/BP)

Time: Tuesday 9:30–11:15 Location: H46

Invited Talk CPP 18.1 Tue 9:30 H46

Hybrid materials from colloidally stable nanocellulose and nanoparticles - scattering techniques are needed for characterization — •Eva Malmström[1], Åsa Jerlhagen[1], Benedikt Sochor[2], Korneliya Gordeyeva[1], and Stephan Roth[1,2] — [1]KTH Royal Institute of Technology, Stockholm, Sweden — [2]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany

Cellulose nanofibrils (CNFs) have rendered increasing interest during the last decades as their high stiffness, strength, and aspect ratio are attractive features to further explore on the pathway to a more sustainable society.

Controlled radical polymerization procedures allow for the synthesis of well-defined, nearly monodisperse, block-copolymers. The development of the polymerization-induced phase self-assembled (PISA) technique enables the production of well-defined nanoparticles (nanolatexes), with controlled size (typically with a diameter smaller than 200 nm), charge density, chemical functionality, and glass transition temperature.

The combination of CNFs and well defined nanolatexes allows for the design of novel materials with unique properties. Scattering techniques have proven very useful to characterize the corresponding materials, for instance, a method to assess cross-section orientation.

CPP 18.2 Tue 10:00 H46

In situ GISAXS investigation of different protein-templated titania nanostructures — •Linus Fidelis Huber and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany

Nanostructured titania thin films have been studied for a large variety of applications. An environmentally benign and scalable synthesis route for this material class could be of interest to many state-of-the-art devices, from solar cells to battery materials. Protein-assisted sol-gel synthesis is a low-temperature, low-cost, and highly scalable technique, that can be used to achieve a nanostructured titania thin film. It has been shown that the bovine whey protein β-Lg forms differently shaped aggregates at different solution pH values. With simple changes to the solution chemistry, different domain sizes, porosities, and morphologies are possible. Therefore, it is a promising candidate to create tunable and mesoporous

titania structures. In this work, we investigate the film formation with in situ small-angle/wide-angle grazing incidence X-ray scattering (GISAXS/GIWAXS) techniques. It is found that films printed at acidic pH form significantly different final bulk morphologies than films printed at neutral pH. The crystallite phase is strongly reduced in average domain size and domain-domain distance. Agglomerate size is increased for the acidic template. The in situ data is complemented by SEM, PL, UV-Vis and static GISAXS/GIWAXS measurements.

CPP 18.3 Tue 10:15 H46

With digital luminescence towards minimalistic, biodegradable information storage — •Sebastian Schellhammer, Heidi Thomas, Tim Achenbach, and Sebastian Reineke — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute for Applied Physics, Technische Universität Dresden, Dresden, Germany

Materials showing persistent luminescence, characterized by extended excited state decay times in the millisecond range and beyond, have gained much attention. Recently, we have reported a photonic device architecture based on organic functional materials called programmable luminescent tag (PLT) that is well suited for sensing, labelling, and information exchange applications. Information can be erased and rewritten repeatedly by using the design principle of digital luminescence, i.e. the control of the local oxygen concentration in a polymer:emitter blend and accordingly the emission by room temperature phosphorescence (RTP). We present the design of PLTs made from industrially compostable, ready-to-use materials (bioPLTs). As natural emitters, quinoline alkaloids show sufficient RTP when being embedded in a polymer matrix. Polylactic acid is used as matrix material and flexible substrate. RTP can be controlled adding oxygen blocking layers made from Exceval. Although organic semiconductors provide the potential of biodegradable technologies, prototypes do only rarely exist. With this work, a promising technology for compostable information storage and sensing systems is introduced.

CPP 18.4 Tue 10:30 H46

Enhancing drug release at interfaces with photoresponsive surfactant-polyelectrolyte mixtures — •Ipsita Pani, Michael Hardt, and Björn Braunschweig — Institute of Physical Chemistry, Center for Soft Nanoscience (SoN), University of Münster, Corrensstraße 28-30, Münster 48149, Germany

Using micellar nanocarriers of a photoresponsive arylazopyrazole (AAP) surfactant, we have recently demonstrated the drug release at air-water interface.[1] In this work, we use a biopolymer poly-L-lysine (PLL) to form surfactant-polyelectrolyte mixtures to enhance the drug release of a chemotherapeutic drug doxorubicin. We observe a strong binding between the negatively charged AAP and the positively charged PLL at equimolar ratio. The information from UV-visible spectroscopy, light scattering studies, surface tensiometry and SFG spectroscopy has been utilized to identify the concentration of PLL at which the light-induced drug release is enhanced at the interface. We found that at higher PLL:AAP ratio, the complexes have low net charge and colloidal stability and the release of Dox from the bulk solution to the air-water interface is not observed. However, at lower PLL:AAP ratio, when the system is colloidally stable with a net negative charge, the drug release to the air-water interface is significantly enhanced. Further, the kinetics of drug release to the interface is faster in presence of PLL-AAP mixtures in comparison to pure AAP micelles.

CPP 18.5 Tue 10:45 H46

Proteins as foam stabilizers: From single foam lamellas to macroscopic foams — •Kevin Gräff, Sebastian Stock, Luca Mirau, Matthias Kühnhammer, Olaf Soltwedel, and Regine von Klitzing — Terchnische Universität Darmstadt, Darmstadt, Germany

Foams consist of foam lamellas, which separate single air bubbles from each other. Investigation of lamellas is crucial to understand foam properties. In order to untangle electrostatic, steric and network stabilization effects, we compare two globular proteins (β-lactoglobulin and Lupine Protein Isolate) and a disordered, flexible protein (whole casein) at different pH values. The Thin Film Pressure Balance (TFPB) device based on image intensity measurements generates spatially resolved disjoining pressure isotherms. We introduce feature tracking for the measurement of interfacial mobility and stiffness of lamellas as a novel method. Around the isoelectric point, Newton Black Films (NBFs) form, which are stable for the globular proteins while they are unstable for the disordered flexible one. This difference in film stability is explained by different characteristics of network structures in the lamellas from the respective protein solutions. Small-Angle Neutron Scattering (SANS) evaluation with a new model for foams proves the presence of NBFs within macroscopic foams. For a complete picture we compare the TFPB findings with X-ray reflectometry as well as with Brewster Angle Microscopy on single interfaces.

CPP 18.6 Tue 11:00 H46

What makes a polysaccharide biomaterial a good candidate for tissue engineering applications? — •Emma Bobu Cimpoi[1], Codrut Costinas[1], Emilia Licarete[2], Tamás Gyulavári[3], Klara Magyari[4], and Monica Baia[4,5] — [1]Doctoral School of Physics, Babes-Bolyai University, Cluj-Napoca, Romania — [2]Centre for Systems Biology, Biodiversity and Bioresources "3B", Cluj-Napoca, Romania — [3]Department of Applied and Environmental Chemistry, University of Szeged, Hungary — [4]INSPIRE Research Platform, Babes Bolyai University, Cluj-Napoca, Romania — [5]Faculty of Physics, Babes-Bolyai University, Cluj-Napoca, Romania

Biomaterials are inovative systems used to solve medical issues. Daily, injuries produce major bleeding that affects people and, without proper care, leads to other health problems. Traditional care methods are limited and outdated, so the focus is on natural materials with hemostatic properties, that are biocompatible and non-toxic. The aim of this work was to develop biomaterials based on pullulan, alginate and gelatin in various combinations, which could stop the bleeding and regenerate the wound. The developed sponge-like materials were characterized by FT-IR spectroscopy and X-ray diffraction. Then they were evaluated in vitro in terms of porosity, toxicity, swelling and charge on the surface, using SEM, cell viability assays, water up-take and mechanical tests. The investigations revealed good results as the synthesis was succesfull, the samples swell a lot, have good shape memory properties, are porous and non-toxic. These indicate their potential to stop bleeding, and therefore further in vivo tests will be carried out.

CPP 19: Active Matter III (joint session DY/BP/CPP)

Time: Tuesday 9:30–13:00 Location: H47

CPP 19.1 Tue 9:30 H47

From micro to macro: systematic coarse-graining of active particle models and implications on phase separation — •Sumeja Burekovic[1], Filippo De Luca[2], Cesare Nardini[1,3], Ananyo Maitra[4,5], and Michael E. Cates[2] — [1]CEA, Paris-Saclay, France — [2]DAMTP, University of Cambridge, UK — [3]LPTMC, Sorbonne Université, France — [4]LPTM, CY Cergy Paris Université, France — [5]LJP, Sorbonne Université, France

Significant insights into collective phenomena of active systems, such as phase separation, have been obtained through minimal field theories developed in a top-down manner. In contrast, the bottom-up approach seeks to link these continuum models to the microscopic dynamics of active particles, often formulated as Langevin equations for their position and orientation. This connection is typically achieved via explicit coarse-graining and allows active field theories to be expressed in terms of physically meaningful parameters. A major challenge in coarse-graining is the consistent elimination of irrelevant fast degrees of freedom to derive closed equations for the hydrodynamic variables or order parameters, such as the density field. We propose a systematic extension of standard homogenization/projection-operator techniques. As we show in minimal examples with few degrees of freedoms, our technique allows to go beyond the state of the art of homogenization in the mathematical literature. We then discuss the predictions of our coarse-graining methods for the large-scale phenomenology of non-aligning active particles, including cases in which microphase separation - rather than full phase separation - emerges due to activity.

CPP 19.2 Tue 9:45 H47

Active Quadrupolar Dumbbells — •Margaret Rosenberg[1], Marco Musacchio[1], Lorenzo Caprini[2], and Hartmut Löwen[1] — [1]Heinrich-Heine University Düsseldorf, Universitätsstraße 1, 40225 Düsseldorf — [2]Università di Roma Sapienza, P.le Aldo Moro 2, 00185 Rome, Italy

The field of Active Matter has thrived in recent years, driven both by the insight that it underlies fundamental processes in nature, and by its vast potential for applications. Although the self-propulsion mechanisms of Active Matter allow us to consider and control a wide range of motions, there is - by default - no obvious control over the orientation and rotation of the particles. One approach to resolve this is the use of anisotropic particles and interactions. This contribution presents a computational study of a novel system composed of active, quadrupolar dumbbells, the phase behavior of which is determined by the competition between active motion and the orthogonal alignment favored by quadrupolar attraction. We explore the novel phase behavior unlocked by these anisotropic interactions, and discuss options for experimental realizations and applications.

CPP 19.3 Tue 10:00 H47

Order by disorder in a swarm with obstacles — Pradeep Kumar[1], Sanjay Puri[1], and •Martin Weigel[2] — [1]School of Physical Sciences, Jawaharlal Nehru University, New Delhi – 110067, India — [2]Institut für Physik, Technische Universität Chemnitz, 09107 Chemnitz, Germany

Simple models of swarming and active matter such as the Vicsek model [1] have been studied in detail, and the phase diagram as a function of noise strength and particle density is by now well understood. Real active systems are usually affected by impurities and random disorder, however. The presence of a quenched distribution of disc-like obstacles in the domain of the Vicsek model is observed to have a dramatic effect on the ordering behavior [2]: in contrast to the model without obstacles, where the strongest alignment is observed for the lowest noise, as soon as obstacles are added only the presence of a certain amount of noise leads to a global alignment of particles. This order by disorder phenomenon for active systems is traced back to the interplay of multiple length scales in the system: the typical inter-obstacle distance, the typical cluster size, and the resulting mean-free-paths of cluster-obstacle and cluster-cluster collisions. We present scaling arguments explaining these connections and provide an outlook towards similar phenomena in related systems.

[2] O. Chepizhko, E. G. Altmann, and F. Peruani, Phys. Rev. Lett. 110, 238101 (2013).

CPP 19.4 Tue 10:15 H47

Autonomous navigation in synthetic microswimmers: solving mazes with chemical echolocation — •Aritra K. Mukhopadhyay[1], Linhui Fu[2], Kai Feng[2], Ran Niu[2], and Benno Liebchen[1] — [1]Technische Universität Darmstadt, Darmstadt, Germany. — [2]Huazhong University of Science and Technology, Wuhan, China.

Motile microorganisms like bacteria and algae combine self-propulsion, cooperation, and decision-making at the micron scale. Inspired by these biological systems, synthetic microswimmers are emerging as human-made counterparts capable of self-propulsion. Recent breakthroughs provide a platform to integrate additional functionalities, bridging the gap between biology and synthetic systems.

We propose and experimentally demonstrate a mechanism enabling synthetic microswimmers, such as autophoretic colloids, droplet swimmers, and ion-exchange-driven modular swimmers, to make autonomous navigational decisions. These swimmers generate chemo-hydrodynamic signals that interact with boundaries, creating echoes that carry structural information about the environment. Remarkably, these echoes invoke automatic responses, such as synthetic chemotaxis, enabling the swimmers to avoid dead ends and autonomously find paths through complex mazes.

Our findings illustrate how simple physical principles can endow synthetic systems with advanced navigation functionalities, which could be useful for developing self-navigating micromachines with potential applications in targeted drug delivery and environmental sensing.

CPP 19.5 Tue 10:30 H47

Active Particles in Tunable Colloidal Environments — •Abhimanyu Nowbagh[1], Venkata M.S.G. Tanuku[2], Thomas Palberg[2], and Ivo Buttinoni[1] — [1]Institute of Experimental Colloidal Physics, Heinrich-Heine University, 40225 Düsseldorf — [2]Institute of Physics, Johannes-Gutenberg University, 55128 Mainz

Active colloids are microscopic particles which propel through aqueous media by converting the externally available energy into directed motion. Using non equilibrium thermodynamics to understand biological systems: interactions of active colloids with crowded systems, and emergent phenomena of ensembles of active particles, remain an important and open question.

In this work, we investigate the dynamics of active particles in crowded environments subjected to alternating-current (AC) electric fields. The AC electric field is used to control: i) the velocity of active particles and ii) the inter-particle interaction between passive colloids. As we increase electric field strength, the velocity of active particles increases and the inter-particle interaction between passive colloids becomes stronger. We study the behaviour of active particles as a function of: i) the frequency of the applied AC electric field, ii) the area fraction of the passive crowd, iii) the active to passive particle number ratio, and iv) the velocity of the active particles.

Our experimental findings show that the active particles reorient faster with an increasing electric field strength. With an increase in the active to passive particle ratio, we show that cluster formation is non-monotonically sensitive to the passive crowd density.

Invited Talk CPP 19.6 Tue 10:45 H47

Beyond spheres - active matter in new shapes — •Juliane Simmchen — University of Strathclyde, Cathedral street 295, Glasgow UK

Surface minimisation for a given volume is energetically favourable on the small scale - this is why most colloidal particles are spherical. In active matter they have the added advantage of facilitating comparison between experiment and theory, one of the reasons why spherical Janus particles dominate the field.

However, broadening the range of materials has led to interesting discoveries - behaviour that would not have been observable in the spherical regime. This talk will give an overview of the intriguing behaviour of non-spherical active materials at the microscale - from plates to truncated bipyramids and rods.

15 min. break

CPP 19.7 Tue 11:30 H47

Modeling Filamentous Cyanobacteria — •Elias Fischer and Holger Stark — Institute Of Theoretical Physics, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin, Germany

Filamentous cyanobacteria play an important role in many ecosystems and the carbon cycle of our planet, both in the present and the past. They triggered the great oxygenation event about 2.5 billion years ago, generating the atmospheric oxygen of our planet while contributing large parts of our fossil fuel record.

Filamentous cyanobacteria exhibit gliding motility when in contact with solid surfaces or each other. Despite their ecological relevance and increased use in biotech applications, the exact nature of the force-generating process remains not fully understood. Furthermore, the gliding of cyanobacteria is strongly affected by external cues, most importantly light. They aggregate in regions with the highest light intensity, which means best environmental conditions for photosynthesis.

Following recent advances in understanding the self-organization of cyanobacteria, we present a novel approach for modeling the mechanical and behavioral aspects of individual cyanobacteria filaments, including force synchronization and response to light. Each filament is modeled as a bead-spring chain in 3D with bending and torsional elasticity, as well as a hard-core repulsion between the filaments. Notably, the propulsion forces that drive the individual parts of the filament forward are only considered locally where the filament comes into contact with another surface. First results on the 3D bending and twisting motion of a filament and its reaction to light are presented.

CPP 19.8 Tue 11:45 H47

Self-assembly and control of active and passive triblock Janus colloids — •Juri Franz Schubert, Salman Fariz Navas, and Sabine H. L. Klapp — Institut für Theoretische Physik, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin

Triblock Janus colloids belong to the family of patchy particles, interacting with hydrophobic attraction at opposite poles and electrostatic repulsion in the equatorial region. They are known to self-assemble into a colloidal kagome crystal from experiments [1] and theory [2,3,4]. However, investigating the self-assembly of such systems via Brownian Dynamics can result in timescales inaccessible to brute force simulations, often requiring complex sampling techniques [3]. Recently, it has been shown that introducing self-propulsion can significantly accelerate self-assembly and enhance the Kagome yield [4]. Here, we study the model introduced in [4] and further investigate the self-assembled structures in active and passive systems. Using simple time-dependent activity protocols, we are able to sample a temperature-density state diagram of the passive system. Our results closely match with earlier studies [2,3], where different triblock models and sampling techniques were used.

CPP 19.9 Tue 12:00 H47

Enhanced Diffusion and Universal Rouse-like Scaling of an Active Polymer in Poor Solvent — Suman Majumder[1], Subhajit Paul[2], and •Wolfhard Janke[3] — [1]Amity Institute of Applied Sciences, Amity University Uttar Pradesh, Noida 201313, India — [2]Department of Physics and Astrophysics, University of Delhi, Delhi 110007, India — [3]Institut für Theoretische Physik, Universität Leipzig, IPF 231101, 04081 Leipzig, Germany

By means of Brownian dynamics simulations we study the steady-state dynamic properties of a flexible active polymer in a poor solvent condition. Our results show that the effective diffusion constant of the polymer D_{eff} gets significantly enhanced as activity increases, much like in active particles. The simulation data are in agreement with a theoretically constructed Rouse model of active polymer, demonstrating that irrespective of the strength of activity, the long-time dynamics of the polymer chain is characterized by a universal Rouse-like scaling $D_{\text{eff}} \sim N^{-1}$, where N is the chain length. We argue that the presence of hydrodynamic interactions will only have an insignificant effect on the observed scaling behavior.

CPP 19.10 Tue 12:15 H47

A Pulsating Active Solid — •Umang A Dattani[1], Francesco Serafin[1], Jonas Ranft[2], and Etienne Fodor[1] — [1]Department of Physics and Materials Science, University of Luxembourg, L-1511 Luxembourg City, Luxembourg — [2]Institut de Biologie de l ENS, Ecole Normale Superieure, CNRS

Active matter has garnered significant attention in recent decades due to its numerous parallels with biological systems. Inspired by recent studies of biological tissues, such as cardiac cells, where constituent cell sizes periodically vary, a new form of activity termed "pulsating active matter" has been introduced recently. We propose a model of a pulsating active solid, consisting of size-changing particles linked by a triangular spring network. Despite the fixed connectivity, our model exhibits a variety of patterns and topological phase defects, akin to previous studies. Additionally, we explore the elastic continuum limit, which successfully predicts several essential features of the microscopic model. We conclude by highlighting intriguing properties of this system and its different potential parallels.

Invited Talk CPP 19.11 Tue 12:30 H47

Emergent correlations and boundary fluctuations in epithelial cell sheets — •Silke Henkes — Lorentz Institute, Leiden University, Leiden, The Netherlands

In soft active materials, the driving motion of individual constituents competes with their mechanical interactions, giving rise to active liquids, solids or glasses. An especially important example of this are epithelial cell sheets, which form a barrier function in the body and where the active crawling motion of cells over the substrate acts against cell-cell adhesion and repulsion.

I will show that a minimal model of cell sheets with uncorrelated activity, based on active Brownian dynamics and a vertex model, is a good quantitative match to data from two experiments on corneal and MDCK cell sheets. Its core feature is an emergent correlation length, arising from the diffusive spread of active forces through an elastic solid. This is a very general result that emerges in many active solids.

The boundary of such cell sheets exhibits a 'fingering instability' where the initially straight boundary develops large, spatiotemporally correlated fluctuations. Despite previous interpretations within many frameworks as an instability, I will show that it can be fully explained as arising from the active correlations of the cell sheets driving the boundary.

CPP 20: Interfaces and Thin Films I

Invited Talk CPP 20.1 Tue 11:30 H38

Tailored polymer thin films enabled by initiated chemical vapor deposition (iCVD): From fundamentals to functional applications — •Stefan Schröder — Christian-Albrechts-Universität zu Kiel, Kiel, Germany

Functional polymer thin films are of great interest in vast application fields ranging from electronic devices to biomedical interfaces. Device miniaturization and the consequent need for new polymer films on the nanoscale demand precise thickness control and defect free films. Solvent-free initiated chemical vapor deposition (iCVD) meets these demands, because it circumvents de-wetting and surface tension effects encountered in conventional solution-based polymer thin film fabrication. The process provides conformal polymer coatings on the nanoscale on large-area substrates as well as complex geometries. In addition, it enables deposition on delicate substrates like flexible organic substrates, copy paper and biomedical patches at room temperature. This talk demonstrates the versatility of the iCVD process and highlights recent results from fundamental studies based on density functional theory (DFT) on the underlying reaction processes up to the application of iCVD films in sensors, biomedicine and electronic devices.

CPP 20.2 Tue 12:00 H38

Highly Electrically Conductive PEDOT:PSS films via Layer-by-Layer Electrostatic Self-Assembly — •Muhammad Khurram, Sven Neuber, Annekatrin Sill, and Christiane A. Helm — muhammad.khurram@uni-greifswald.de

Electrically conductive films of Poly(3,4-ethylenedioxythiophene): poly(styrenesulfonic acid) (PEDOT:PSS) are usually formed by spin coating of aqueous dispersions with PEDOT:PSS nanoparticles. The adsorption conditions are investigated using dip coating and a flow cell with different flow rates. Multilayer films are formed by sequential adsorption of oppositely charged macromolecules. PEDOT:PSS serves as polyanion, and PDADMA is the polycation. In dip coating, the first layer consists of approximately 70 nm thick monolayer of PEDOT:PSS nanoparticles. Subsequent PDADMA/PEDOT:PSS bilayers have a low, constant thickness (9.5 nm). Using the flow cell (0.2 mL/min) for film preparation also resulted in a constant PDADMA/PEDOT:PSS bilayer thickness (7.5 nm). PEDOT:PSS nanoparticle monolayers could also be observed with the flow cell, but only if the washing step after PEDOT:PSS adsorption was omitted. The films prepared by flow cell showed the highest conductivity (230 kS/m) and the lowest roughness (2 - 4 nm). We propose that the adsorption in a flow cell leads to a nearly flat orientation of the PEDOT molecules, increasing charge carriers' mobility. We also find that the relative humidity strongly influences the volume density and mobility of the charge carriers

CPP 20.3 Tue 12:15 H38

DFT Study of Catalyst-Ionomer Interactions in Hydrogen Fuel Cells — •Johanna Weidelt[1], Fabian Tipp[1], Tobias Binninger[1], and Michael Eikerling[1,2] — [1]Theory and Computation of Energy Materials (IET-3), Institute of Energy Technologies, Forschungszentrum Jülich GmbH, 52425 Jülich, Germany — [2]Chair of Theory and Computation of Energy Materials, Faculty of Georesources and Materials Engineering, RWTH Aachen University, 52062 Aachen, Germany

Proton exchange membrane fuel cells (PEMFCs) are promising devices for electricity generation from hydrogen. High efficiencies at low temperatures are achieved with platinum (Pt) as catalyst and Nafion as ionomer material. Because of the environmental persistence of the perfluorinated Nafion chains, fluorine-free ionomer materials are searched that maintain PEMFC performance and durability. To this end, the influence of the ionomer on the catalysis of the oxygen reduction reaction (ORR) in the cathode catalyst layer must be considered. Previous studies suggested that interactions between ionomer and Pt surface can compete with the adsorption of oxygenated ORR intermediates and negatively affect the catalytic activity. In this talk, we present a computational study investigating the competitive adsorption of ionomer species and reaction intermediates at a Pt(111) surface using grand-canonical density functional theory simulations. The Pt-adsorbate interaction strength was evaluated and surface phase diagrams were derived from adsorption energies calculated in implicit water environment under constant electrode potential.

CPP 20.4 Tue 12:30 H38

Dynamical and morphological changes of polyethylenimine thin films in relation to its CO2 absorption performance — •Maximilian Brückner[1], Martin Tress[1], Soma Ahmadi[2], and Shiwang Cheng[2] — [1]Peter Debye Institute for Soft Matter Research, Physics Department, Leipzig University, Germany — [2]Department of Chemical Engineering and Materials Science, Michigan State University, United States

Chemical reactions between carbon dioxide (CO2) and amine have been extensively characterized, however, their influence on the dynamics of polyamines remains largely unexplored. In this work, we compare the dynamics of polyethylenimine (PEI) before and after CO2 absorption through broadband dielectric spectroscopy (BDS). The molecular processes of bulk PEI are very different from those of thin film PEI, highlighting an interesting interface and nanoconfinement effect. Detailed analyses show CO2 absorption slows down the PEI dynamics, which is consistent with an elevated glass transition temperature of PEI upon CO2 absorption. Further aspects of thin-film-preparation, namely the impact of molecular weight, film thickness, used solvent and plasma treatment of the substrate on surface roughness were investigated by atomic force microscopy and reveal pronounced de-wetting which did not occur in high-molecular-weight PEI on plasma-treated surfaces. The observed changes in dynamics and morphology are likely to reduce the performance of large-scale CO2 capture devices based on low-molecular weight PEI in porous silica, thus suggesting modifications of this approach.

CPP 20.5 Tue 12:45 H38

Thermo-Responsive Surface Structure and Wetting of Polymer Brushes with Octadecyl Side Chains — •Billura Shakhayeva[1], Franziska Neuhaus[1], Luciana Buonaiuto[2], Sander Reuvekamp[2], Sissi de Beer[2], Frieder Mugele[2], and Björn Braunschweig[1] — [1]University of Münster, Institute of Physical Chemistry, Münster (Germany) — [2]University of Twente, Physics of Complex Fluids, Enschede (The Netherlands)

Polymers are extensively studied as coatings due to their ability to respond to environmental changes, such as temperature or humidity variations, which greatly influence their wettability. This study investigates the effect of temperature on the molecular structure of poly-octadecylmethylacrylate (P18MA) brushes and their wetting behavior with hexadecane. Vibrational sum-frequency generation (SFG) spectroscopy was used to examine the molecular structure at the brush surface, both in air and in contact with hexadecane, by recording in situ SFG spectra near the three-phase contact line. The SFG spectra showed strong CH stretching bands of the octadecyl side chains at the air interface, indicating partial chain ordering that varies with temperature. For brushes in air, a phase transition at 311 K was identified as the surface melting temperature, 3 K higher than the bulk melting point. In the presence of hexadecane, surface melting occurred at 309 K, likely due to liquid penetration. Optical microscopy also revealed halo formation around the drop, suggesting local brush swelling. Below the surface melting point, the contact angle gradually decreased, while crossing the melting point enhanced hexadecane spreading.

CPP 21: Modeling and Simulation of Soft Matter II

CPP 21.1 Tue 14:00 H34

Hard anisotropic particles: Excluded volume and second virial coefficients in arbitrary dimensions of space — •Markus Kulossa and Joachim Wagner — University of Rostock, Rostock, Germany

Precondition for investigations of phase behavior and equation-of-state data of many-particle systems are closed expressions for their free energy. The virial series gives access to the compressibility factor and therewith to the excess free energy of real supercritical fluids formed by hard, anisometric particles. Using Parson's approach, in many cases expressions solely based on the second virial coefficient accounting for the initial departure from ideal-gas behavior are used. In this contribution, we provide analytical expressions for the excluded volume of hard convex particles in arbitrary-dimensional Euclidean spaces. In addition to the detailed influence of the geometry and aspect ratio, we investigate the influence of singularities in the surface curvature. Analytical expressions for the excluded volume and second virial coefficients are of crucial importance for numerical calculation of higher-order virial coefficients. We provide so far unknown expressions for geometrical measures of uniaxial solids of revolution such as hyperellipsoids, hyperspherocylinders, hypercylinders, and hyperdoublecones in higher-dimensional Euclidean spaces.

CPP 21.2 Tue 14:15 H34

Navigating Chemical Space: An Active Learning Strategy Using Multi-Level Coarse-Graining — •Luis Walter and Tristan Bereau — ITP, Heidelberg University

Exploring the vast chemical compound space remains a significant challenge due to the immense number of possible molecules and limited scalability of conventional screening methods. To approach chemical space exploration more effectively, we have developed an active learning-based method that uses transferable coarse-grained models to compress chemical space into varying levels of resolution. By using multiple representations of chemical space with different coarse-graining resolutions, we balance combinatorial complexity and chemical detail. To identify target compounds, we first use an autoencoder to transform the discrete molecular spaces into continuous latent spaces. We then perform Bayesian optimization within these latent spaces, using molecular dynamics simulations to calculate target free energies of the coarse-grained compounds. This multi-level approach allows for an effective balance between exploration at lower and exploitation at higher resolutions. We demonstrate the effectiveness of our method by optimizing molecules to enhance phase separation in phospholipid bilayers. Our funnel-like strategy not only suggests optimal compounds, but also provides insight into relevant neighborhoods in chemical space. We show how this neighborhood information from lower resolutions can be used to guide the optimization at higher resolutions, thereby providing an efficient way to navigate large chemical spaces for free energy-based molecular optimization.

CPP 21.3 Tue 14:30 H34

Tuning Pore Size in Integral-Asymmetric, Isoporous Membranes via Bidisperse Diblock Copolymers — •Jiayu Xie and Marcus Müller — Institute for Theoretical Physics, Georg August University Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

Integral-asymmetric isoporous membranes, widely used in water filtration, are fabricated using a combination of evaporation-induced self-assembly (EISA) and nonsolvent-induced phase separation (NIPS). Membranes must have pores of an optimal size; small enough to block target substances but not so small as to cause excessive water resistance. While pore size can technically be adjusted by varying the copolymer's degree of polymerization, this approach requires synthesizing new copolymers for each desired pore size. A more economical alternative is blending polymers, where tuning the blending ratio of different components offers a feasible way to control pore size. However, mixing different copolymers could lead to macrophase separation. In this study, we focus on bidisperse diblock copolymers, and employ self-consistent field theory and particle-based simulations to explore the range of pore sizes over which this blending strategy is effective in fabricating membranes. Specifically, we aim to (1) establish correlations between system parameters and pore size and (2) elucidate the effects of these parameters on the dynamic behavior during SNIPS and the resulting membrane morphologies. Our findings provide valuable insights for the cost-effective fabrication of filtration membranes with tailored pore sizes.

CPP 21.4 Tue 14:45 H34

Machine-Learning potentials to understand pairing and stacking at the origin of life — •Laurie Stevens[1], Riccardo Martina[2], Alberta Ferrarini[2], and Marialore Sulpizi[1] — [1]Faculty of Physics and Astronomy, Ruhr-Universität Bochum, Germany — [2]Chemical Science Department, Università degli Studi di Padova, Italy

When exploring the origin of life, one main question remains open: how did we get from single nucleotides to long RNA and DNA chains which then led to more complex biological structures, following the RNA world hypothesis. More specifically, we are interested in how the nucleotides interactions are able to promote the synthesis of long polynucleotides. Experimental studies suggest that free nucleotides in water spontaneously organize into small molecular columnar phases, promoting the ligation of nucleic acid chains. To uncover the mechanisms behind this self-assembly, we use Molecular Dynamics simulations combined with Machine-Learning approaches.

Ab initio methods are too computationally expensive for the timescale of interest and for the complexity of the investigated systems. To overcome this limitation, we use Neural Network Potentials (NNPs) trained with DeepMD-kit and reinforced by metadynamics. After mastering the static and dynamical properties of a single Adenosine Monophosphate (AMP) in water, we are now investigating the stacking and pairing interactions between several AMPs by predicting the free energy landscape of this system as a function of the relevant degrees of freedom.

CPP 21.5 Tue 15:00 H34

Influence of hydroxyl groups on the dielectric constant of polyethylene — •Roshal Perepadan Shaju[1], Guido Roma[1], and Xavier Colin[2] — [1]Université Paris-Saclay, CEA, Service de recherche en Corrosion et Comportement des Matériaux, SRMP, Gif sur Yvette, 91191, France — [2]PIMM, Arts et Métiers Institute of Technology, CNRS, CNAM, HESAM University, 151 Boulevard de L'Hôpital, 75013 Paris, France

Polyethylene (PE) is widely used as an insulation for electric cables in various environments, including nuclear power plants. PE is susceptible to chemical modifications when exposed to ionizing radiation and oxidative environments. Introducing polar functional groups to this semi-crystalline PE, such as carbonyls and hydroxyl (OH) groups, has been observed to modify its dielectric response. However, the precise influence of hydroxylation on the dielectric properties of semi-crystalline PE is still inadequately understood. In this paper, we employ DFT and Density Functional Perturbation Theory (DFPT) to systematically investigate the effect of OH groups on the dielectric properties of semi-crystalline PE. By modeling PE with distinct surface, amorphous, and crystalline regions, the complexity of its semi-crystalline nature is explored. The static and high-frequency dielectric constants of polyethylene systems with different concentrations of OH groups were determined. The orientation of the OH defect relative to various crystallographic axes is thoroughly examined in order to determine how the alignment of the defects in the crystal lattice may affect the dielectric tensor.

CPP 21.6 Tue 15:15 H34

Load-induced shear band formation in microscale epoxy materials — •Julian Konrad, Janina Mittelhaus, Bodo Fiedler, and Robert Meissner — Hamburg University of Technology

Thin epoxy films ($\approx 30\ \mu$m) exhibit unexpected ductile behavior under mechanical load, challenging the conventional view of thermoset materials as inherently brittle. This behavior is characterized by the formation of shear bands, as revealed by mechanical testing and infrared spectroscopy. Analysis of vibrational spectra shows redshifts in *para*-phenylene stretching vibrations due to bond elongation, and blueshifts in out-of-plane hydrogen vibrations, resulting from polarization effects in the aromatic backbone. Molecular dynamics simulations support these findings, revealing a cascade of molecular realignments driven by deformation. Notably, these structural changes are reversible upon heating, suggesting a form of frozen entropy elasticity rather than plasticity. To further investigate, we employed a novel method using the MACE neural network potential to compute vibrational spectra with *ab initio* accuracy. This approach captures strain-dependent spectral shifts, accounts for interface and size effects, and highlights key implications for the design of composite materials.

CPP 22: Organic Electronics and Photovoltaics II

Time: Tuesday 14:00–15:15 Location: H38

CPP 22.1 Tue 14:00 H38

Spontaneous orientation polarization in mixed films of organic semiconductors — •Albin Cakaj, Alexander Hofmann, and Wolfgang Brütting — Experimental Physics IV, Institute of Physics; University of Augsburg, 86135 Augsburg, Germany

Small organic molecules processed by physical vapor deposition (PVD) can exhibit a preferential alignment, despite their tendency to form glassy amorphous films. This alignment can additionally lead to a macroscopic polarization of the film, if the molecules have a permanent dipole moment (PDM). The additional field, also referred to as giant surface potential (GSP), can impact the properties of organic light emitting diodes (OLEDs) significantly. Therefore, understanding the formation and control of this effect is of crucial importance.

We investigated different GSP forming polar molecules mixed with non-polar organic compounds. We found combinations with enhanced PDM alignment, where the impact of suppressed dipole-dipole interactions by dilution is far more significant than the effect on the film-formation process by a change in the effective glass temperature of the blend. Additionally, our data hint to the conclusion that molecules with an already high degree of PDM alignment keep their magnitude of alignment in mixed films without significant enhancement. Therefore, we can conclude that mixing of polar molecules with a non-polar compound can enhance the degree of PDM alignment significantly, if the polar molecules exhibit only a small degree of PDM alignment in the first place.

CPP 22.2 Tue 14:15 H38

Ultrafast Response in Unbalanced Mobility Organic Photodetectors — •Felix Hergenhan, Tianyi Zhang, Karl Leo, and Johannes Benduhn — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute of Applied Physics, TU Dresden, Dresden, 01187 Germany

Organic photodetectors (OPDs) have attracted growing interest due to their potential in various optoelectronic applications. However, the slower response speed of OPDs compared to their inorganic counterparts, primarily influenced by low charge carrier mobilities, has hindered their application in high-speed technologies. In this presentation, we will discuss the dynamic behavior of OPDs, focusing on how ultrafast response times can still be achieved despite significant mobility imbalance and overall low mobility. Importantly, the role of RC (resistance-capacitance) limitations is emphasized, as they significantly impact the achievable response speed of the devices. We systematically investigated the effects of device design, device dimensions, light intensity, and applied bias on OPD performance and its dynamic behavior. Notably, special features could be identified in their dynamic response that led to improved rise and fall times of only a few nanoseconds and a cutoff frequency beyond 10 MHz. We propose a model explaining the origin of these features and demonstrate how to utilize them to achieve faster response times. By exploring the entire picture of device design, material choice, and operational conditions, we provide an outlook on the future development of ultrafast OPDs.

CPP 22.3 Tue 14:30 H38

Systematic variation of acceptor and donor moieties in donor-accerptor-donor small molecules for efficient room-temperature phosphorescence — •Uliana Tsiko, Sebastian Kaiser, Sebastian Schellhammer, and Sebastian Reineke — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute for Applied Physics, Technische Universität Dresden

Room-temperature phosphorescence (RTP) from purely organic materials promises unique application in diverse fields including molecular sensing, bioimaging, information storage, and anti-counterfeiting. With the design of programmable luminescent tags (PLTs), we recently reported a novel photonic device architecture that is well suited for various labelling and information exchange applications and even allows a biodegradable design. However, improved RTP emitters are required to fully exploit this technology.

In our contribution, we systematically analyze the impact of the acceptor and donor moieties on the photophysical properties of newly synthesized RTP emitters to gain an understanding of structure-property relationships. While the electron-accepting character does not significantly affect the emission properties, the electron-donating ability of the donor unit can strongly improve RTP emission, leading to pronounced sky-blue phosphorescence in purely organic materials, which has been rarely observed before. These emitters are further characterized in PLTs as a prototypical excitonic application scenario.

CPP 22.4 Tue 14:45 H38

Efficient room-temperature phosphorescence in small-molecule hosts for applications in information storage — •Yana Bui Thi, Sebastian Schellhammer, and Sebastian Reineke — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute for Applied Physics, Technische Universität Dresden

Room-temperature phosphorescence (RTP) from organic materials promises unique applications in molecular sensing, bioimaging, and information storage. Typically, RTP is achieved by embedding emitter molecules in a rigid matrix to suppress non-radiative decay. The integration of such emitters into polymer hosts has enabled advancements in photonic technologies, such as programmable luminescent tags. However, a comprehensive understanding of host-guest interactions, particularly with small-molecule hosts suitable for vacuum processing, is widely missing. This work investigates the photophysical properties of RTP emitters embedded in wide bandgap small molecules, typically used in OLEDs. Thin films are fabricated either by spin coating or thermal evaporation, the latter offering superior film quality and compatibility with patterning techniques. RTP can be promoted or impaired depending on the choice of the host material, partially even allowing for RTP in the presence of oxygen. A significant enhancement of photoluminescence can be obtained due to favorable energy transfer from host to emitter. These results highlight the importance of the host selection in optimizing emitter performance and present valuable insights for polymer-free RTP-based photonic devices.

CPP 22.5 Tue 15:00 H38

Regulated Growth of Benzoperylene-TCNQ Charge-Transfer Complex Crystalline Networks — •Kirill Gubanov, Yana Reva, Stevie Furxhiu, Fabian Streller, Yifan Bo, Phillip Greissel, Dirk M. Guldi, and Rainer H. Fink — Department of Chemistry and Pharmacy, Friedrich-Alexander-Universität Erlangen Nürnberg, Egerlandstraße 3, 91058 Erlangen, Germany

Highly ordered luminescent organic micro- and nano-crystals of charge-transfer complexes (CTC) are generating a considerable interest due to their prospective applications in miniaturized and multifunctional optoelectronics. We propose a strategy of controlled crystallization growth of Benzoperylene (BP)-TCNQ-CTC nanorods network. As a result of the distinct polarity-based solubility of BP and TCNQ, 2D microsheets of BP of tunable sizes can be used as templates for the CTC nanorod meshes growth in solution. The optical and electronic properties of the respective CTC were additionally investigated. Emission spectroscopy revealed a significant quenching of the BP strong fluorescence upon CTC formation: electron excitation in BP leads to a charge transfer to a non-emissive TCNQ and to non-radiative relaxation. Using NEXAFS micro-spectroscopy, we examined the electronic structure and a temperature-dependent band gap modification. Thus, collective insights into the BP-TCNQ CTC properties provide valuable information for material optimization for future applications in optoelectronic devices. The research is funded by the BMBF (contract 05K19WE2) and SolTech initiative.

CPP 23: Polymer and Molecular Dynamics, Friction and Rheology

Time: Wednesday 9:30–11:15 Location: H34

Invited Talk CPP 23.1 Wed 9:30 H34

Advanced combined rheometer setups to in-situ correlate molecular dynamics and molecular structure formation with mechanical properties — •Manfred Wilhelm — Karlsruhe Institut für Technologie, Karlsruhe, Germany

Molecular understanding of mechanical properties over a broad length and time scale is crucial to develop advanced materials. Our research aims to design and built unique combined rheometer setups that can monitor in-situ molecular observables, such as molecular dynamics or chemical functional groups that are directly correlated to the macroscopic mechanical responses. These combined experimental setups overcome the experimental challenges associated with offline measurements and facilitate the understanding of structure-property relationships.

CPP 23.2 Wed 10:00 H34

Nonequilibrium Dynamics of the Helix-Coil Transition in Polyalanine — •Maximilian Conradi[1], Henrik Christiansen[1,2], Suman Majumder[3], Fabio Müller[1], and Wolfhard Janke[1] — [1]Institut für Theoretische Physik, Universität Leipzig, IPF 231101, 04081 Leipzig, Germany — [2]NEC Laboratories Europe GmbH, Kurfürsten-Anlage 36, 69115 Heidelberg, Germany — [3]Amity

Institute of Applied Sciences, Amity University Uttar Pradesh, Noida 201313, India

In this work, the nonequilibrium pathways of the collapse of the helix-forming biopolymer polyalanine are investigated. To this end, the full time evolution of the helix-coil transition is simulated using molecular dynamics simulations. At the start of the transition short 310-helices form, leading to the molecule becoming more rod-like midway through the collapse. Afterwards, α-helix formation becomes the prevalent ordering mechanism leading to multi-leg hairpin structures, representative for the equilibrium behavior of longer chains. The dynamics of this transition is explored in terms of the power-law scaling of various associated relaxation times as a function of the chain length.

CPP 23.3 Wed 10:15 H34

Porous Particles Formation in the Drying of Polymer Solution Droplets — •Mengmeng Wu, Hsiao-Ping Hsu, and Kurt Kremer — Max-Planck-Institut für Polymerforschung, Mainz, Germany

Due to the unique properties such as large specific surface area, high permeability and low density, porous polymer nano- or micro-spheres are promising for various applications including biomedical, pharmaceutical, tissue engineering and degradable electronic applications. We develop a coarse-grained polymer solution droplet model to study the particle structure formation of drying polymer solution droplets. By maintaining below the glass transition temperature, highly porous particles are generated followed by a fast evaporation and cavitation of solvents. For a drying droplet in an environment with low thermal conductivity, the temperature experiences a decrease owing to solvent vaporization. Such temperature reduction results in a decrease in evaporation rate during evaporation, consequently impacting the drying dynamics of polymer droplets. Our investigation explores how the cooling of droplets during solvent evaporation influences the final morphology of polymer particles.

CPP 23.4 Wed 10:30 H34

Polymer chains under oscillatory force in solvents of variable quality — •Bogumiła Szostak[1,2], Ron Dockhorn[2], Jens-Uwe Sommer[2], and Jarosław Paturej[1,2] — [1]University of Silesia in Katowice, Bankowa 12, 40-007 Katowice, Poland — [2]Leibniz Institute of Polymer Research Dresden, Hohe Straße 6 D-01069 Dresden, Germany

Polymers are key materials in soft condensed matter with diverse applications. Recently, significant attention has been given to understanding the micromechanical behavior of single macromolecules under applied forces. Using molecular dynamics, we examined how constant and periodic forces affect polymer chain conformations in dilute solutions, modeled for good and poor solvents. We systematically calculated the projection of the end-to-end vector in the force direction as a function of the applied force. This analysis led to the construction of force-extension diagrams, which revealed conformational transitions of polymers from a globular state to an extended chain. Analysis of hysteresis loops for periodic forces showed that longer force periods allowed more time for the system to respond, resulting conformational reorganization. These results were compared with analytical solutions of the Rouse model under periodic perturbation and scaling laws, providing a valuable benchmark and deeper insight into the observed dynamics. We also characterized the relationship between dissipated energy and the frequency of the applied sinusoidal stretching force. These findings provide new insights into the mechanical behavior of polymer chains under oscillatory forces, enhancing our understanding of their dynamic properties and potential applications.

CPP 23.5 Wed 10:45 H34

Role of Trapped Water Molecules at Sliding Contacts in Lattice-Resolved Friction Investigated with Molecular Dynamics — •Miljan Dašić and Igor Stanković — Scientific Computing Laboratory, Center for the Study of Complex Systems, Institute of Physics Belgrade, Pregrevica 118, 11080 Belgrade, Serbia

Understanding nanoscale friction within an environment which contains water, is crucial for engineering friction-based mechanisms and characterizing surfaces. From the point of view of Friction Force Microscopy (FFM) experiments, it has been understood that the lattice resolution in water environments originates from a dry contact state, in case of which all water molecules get expelled from the gap between the microscope's tip and the studied substrate.

We have developed an All-Atom Molecular Dynamics simulation setup, for revisiting this understanding by performing a detailed analysis of the impact of water molecules present in the system on the dynamic behavior of the nanotribological contact between an amorphous SiO2 probe and a monolayer MoS2 substrate.

Our analysis of stick-slip patterns shows the entrapment of water molecules at the contact interface. These trapped water molecules act as an integral part of the probe and participate in its interaction with the substrate, hence affecting the probe's dynamics and preventing long slips. Surrounding water molecules from the capillary or layer of water exhibit a replenishing effect, acting as a water reservoir during the sliding process. Such a phenomenon enables the preservation of lattice-scale resolution across a range of normal loads.

CPP 23.6 Wed 11:00 H34

The analytical investigation of star polymers in confined geometries — •Zoriana Danel[1], Joanna Halun[2], and Maciej Dudek[3] — [1]Cracow University of Technology — [2]Institute of Nuclear Physics — [3]Academy WSB

The analysis of the influence of star polymer topology on the depletion interaction potentials, the depletion forces and Pincus force was carried out analytically. The method of calculation of the dimensionless depletion interaction potentials and the dimensionless depletion forces for a dilute solution of ideal star polymers with f=3, 4, 5 legs in a Θ - solvent confined in a slit geometry of two parallel walls with repulsive surfaces and for the case of one repulsive and the other inert surface was proposed. Besides, we performed the investigation of the elastic properties of star polymers with different number of legs in a semi-infinite space confined by single wall with different boundary conditions and calculated Pincus force in the above mentioned cases. Calculations were carried out for star polymers with f=3,4,5 legs attached to the substrate by one or two arms. The acquired results showed that the Pincus force is affected by the number of arms attached to the surface. The obtained results are interesting from scientific and industrial point of view, because of their potential use in the production of paints, varnishes and new functional materials. Star polymers, due to their topology and shape can find practical application in nano - technology, as well as in biotechnology and medicine for drug and gene transmission.

CPP 24: Hybrid and Perovskite Photovoltaics III

Time: Wednesday 9:30–11:15 Location: H38

CPP 24.1 Wed 9:30 H38

Tailored perovskite crystallization by passivation molecule engineering for efficient light-emitting diodes — •Jungui Zhou[1,2], Min Zhu[1], Yufeng Zhai[2], Shouzheng Chen[2,4,5], Benedikt Sochor[2], Sarathlal Koyiloth Vayalil[2], Lei Cai[3], Man-Keung Fung[1,6], Peter Müller-Buschbaum[5], and Stephan V. Roth[2,7] — [1]Soochow University, Suzhou, China — [2]DESY, Hamburg, Germany — [3]Shandong normal university, Shandong, China — [4]FRM II, Garching, Germany — [5]TUM School of Natural Sciences, Garching, Germany — [6]MUST, Macau, China — [7]KTH Royal Institute of Technology, Stockholm, Sweden

Metal halide perovskite light-emitting diodes (PeLEDs) are regarded as alternative candidates for next-generation display technologies.Various additives have been widely used in perovskite precursor solutions, aiming to improve the as-obtained perovskite film quality through passivating defects and controlling the crystallinity. Although the defect passivation of additives has been intensively investigated, a deep understanding of how additives influence the crystallization process of perovskites during the spin-coating and annealing processes is still lacking. Here, by combining In-situ photoluminescence (PL) and grazing-incidence wide/small-angle X-ray scattering (GIWAXS/GISAXS) techniques, a systematic study of the perovskite film-formation process, perovskite structure, and inner morphology of CsPbBr3 perovskite films modified by various additives is conducted, revealing the influence of additives on the formation of high-quality perovskite films and efficient PeLEDs.

CPP 24.2 Wed 9:45 H38

Optical In-Situ Methods as Process Optimization Toolbox — •Lennart Reb — Helmholtz-Zentrum Berlin, Hahn-Meitner-Platz 1, 14109, Berlin

In the field of perovskite photovoltaics, precursor optimization is often guided by the visual inspection of film quality by experienced researchers. However, combined optical in-situ techniques can help shift toward rational, evidence-based process design. In-situ characterization methods are frequently used for studying the reaction kinetics during processing: Optical techniques to monitor solvent evaporation, such as spectral absorption, reveal changes in halido-plumbate spectral signatures that correlate with the increasing density of polynuclear plumbate species. Photoluminescence (PL) measurements further elucidate early perovskite nucleation during quenching processes and crystal growth. Structural insights from grazing-incidence X-ray scattering (GIWAXS) track intermediate phases, the formation of perovskite structures, and the evolution of secondary phases. This work briefly reviews the state-of-the-art multimodal in-situ characterization techniques and introduces the multimodal μ slot-die coater, a small-scale platform integrating UV-vis, PL, imaging, and GIWAXS capabilities. Initial results of combined measurements demonstrate its power for studying perovskite film formation during scalable processing, offering insights into reaction kinetics and showcasing the capabilities of in-situ imaging techniques in scalable perovskite deposition. For example, in-situ PL measurements show the changes of PL signal over time upon the inclusion of chloride-based additives.

CPP 24.3 Wed 10:00 H38

Metal halide perovskite solar cells under space like temperature conditions — •Simon Alexander Wegener[1], Altantulga Buyan-Arivjikh[1], Kun Sun[1], Zerui Li[1], Xiongzhuo Jiang[1], Matthias Schwarzkopf[2], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]Deutsches Elektronen-Synchrotron (DESY), 22607 Hamburg, Germany

Perovskite solar cells hold great promise for space applications due to their exceptional properties, including high power-to-weight ratios and efficiencies comparable to silicon cells. Their solution processability lowers both manufacturing and launch costs, presenting a cost-effective alternative to gallium arsenide cells. However, their viability in space is challenged by harsh conditions such as high vacuum, extreme temperatures, and radiation. This study investigates the impact of extreme temperature fluctuations in low Earth orbit, ranging from -100*C to +100*C, on perovskite solar cell performance. Operando GIWAXS measurements enable real-time analysis of the crystal structure under simultaneous illumination and thermal cycling. Measurements of I-V curves and optical absorption spectra further assess electrical and optical properties. Results reveal temperature-dependent efficiency variations and degradation influenced more by device layers and interfaces than the active layer itself. Understanding the mechanical, optical, and electrical behavior of the entire cell assembly under such conditions is key to optimizing durability and performance.

CPP 24.4 Wed 10:15 H38

Simulation of the impact of processing conditions for solution-processed thick perovskite layers — •Martin Majewski[1], Shudi Qiu[2], Larry Lüer[2], Vincent M. Le Corre[2], Tian Du[2], Olivier J.J. Ronsin[1], Christoph J. Brabec[2], Hans-Joachim Egelhaaf[2], and Jens Hartin[1] — [1]Helmholtz Institue Erlange-Nuernberg, Cauerstraße 1, 91058 Erlangen, Germany — [2]Institute of Materials for Electronics and Energy Technology (i-MEET), Friedrich-Alexander Universitaet Erlangen Nuernberg

Fabricating thick (1000 nm) solution-processed perovskite layers is expected to increase the efficiency of carbon-contact-based solar cells compared to thinner (500 nm) films. However, increasing only the deposited layer thickness often results in buried voids inside the dry film. Recently, we have developed a theoretical framework based on Phase Field simulations. With the help of the simulations, it is possible to explain why voids form in the film. The crystals nucleate at random spots inside the liquid film. The movement of the condensed-vapor interface, due to evaporation, leads to an agglomeration of the crystals at the film surface. The crystals block further evaporation and the remaining solvent is the origin of the buried voids inside the dry film. We explain how adding seeds on the substrate before coating the thick film can prevent this. In this case, processing conditions have to be modified compared to standard operating procedures for thin films. The theoretical expectations can be verified experimentally, leading to a performance improvement of the devices.

CPP 24.5 Wed 10:30 H38

First-principles modelling of hybrid perovskites — •Udo Schwingenschlögl and Aleksandra Oranskaia — King Abdullah University of Science and Technology (KAUST), Thuwal 23955-6900, Saudi Arabia

The photoconversion efficiency record of silicon-perovskite solar cells exceeds 30% owing to hybrid perovskites with organic cations that stabilize the perovskite by non-covalent bonding. To address the electronic properties and stability issue from the perspectives of the bulk crystal phases, point defects, and surfaces and interfaces (requiring large simulation cells) the computational methods must be chosen carefully: (1) For the structural relaxation an exchange-correlation functional is required that adequately describes materials rich in NH$\cdots$I bonding (between organic cations and I) and I$\cdots$I bonding (between PbI_6 octahedra or between PbI_6 octahedra and I-related defects). (2) For the electronic structure calculation an exchange-correlation functional is required that adequately describes the spin-orbit coupling of the Pb and I electrons. Comparing the PBE, PBE-TS, PBE-D3, PBEsol, vdW-DF2, and rVV10 functionals for relaxing FAI, $C_4N_2H_{12}(I_3)_2$, $C_6H_7NI(I_3)$, I_2, In, $Cs(I_3)$, $Cs_2(I_3)_2(I_2)$, and PbI_2 crystals, we show that the rVV10 functional provides the most balanced prediction for the types of non-covalent bonding relevant for hybrid perovskites. We also discuss problems related to the HSE06 functional and show that the PBE functional with a Hubbard correction for the Pb 6p and I 5p orbitals (together with fully relativistic pseudopotentials) provides promising results.

CPP 24.6 Wed 10:45 H38

An effective Population balance model for evaporation-driven precursor-mediated crystallization — •Kai Segadlo, Olivier Ronsin, and Jens Harting — Helmholtz Institute Erlangen-Nürnberg for Renewable Energy (IET-2), Erlangen, Germany

Although tremendous progress has been made in recent years in Experimental and Material Design for solution-processed photoactive Perovskite thin films, this progress has not likewise been followed by a corresponding improvement in the theoretical understanding of these systems. In particular, the high computational demands arising from the plethora of potentially relevant thermodynamic processes, such as evaporation, crystallization, chemical reactions, demixing, and advection, as well as the high costs of in situ multichannel screening experiments, lead to uncertainties about the underlying physical mechanisms, which in practice often facilitate the use of narrow empirical models. As a first step towards theoretical coherence, we combine empirical mass transport models into a single population balance model accounting for evaporation, crystallization, and chemical reactions. We validate the drying subpart against drying curves, and the crystallization subpart against crystallinity curves from Ultraviolet Imaging Spectroscopy, and Phase field simulations, respectively. The model allows us to gauge the relevances of the processes during precursor-mediated methylammonium lead iodide crystallization measured with in situ Grazing Incidence Wide Angle X-ray scattering and to shed light on the experimentally highly relevant but hard-to-access coupling between evaporation and crystallization.

CPP 24.7 Wed 11:00 H38

Modeling and Analysis of Spectral and Thermal Effects in 2-Terminal Perovskite-CIGSe Tandem Solar Cell Configurations — •Yokozuna Schirmer[1], Nicolas Otto[1], Guillermo Farias Basulto[2], Rutger Schlatmann[1,2], Bert Stegemann[1], and Christof Schultz[1] — [1]HTW Berlin - University of Applied Sciences, Wilhelminenhofstr. 75a, D-12459 Berlin, Germany — [2]PVcomB / Helmholtz-Zentrum Berlin für Materialien und Energie, Schwarzschildstr.3, D-12489 Berlin, Germany

Tandem solar cells are being developed to exceed the efficiency limits of single-junction cells. Typically, they are designed in a 2-terminal (2T) current-matched configuration, which can result in a reduced energy yield due to current mismatch caused by spectral variations throughout the day. To overcome this limitation, tandem solar cells can be configured in a 2T voltage-matched setup, which could mitigate the impact of spectral sensitivity on performance. The aim of this work is the development of a computational model to analyse the energy yield of each configuration. This model combines temperature-dependent electrical cell parameters with spectrally resolved real-world outdoor data to simulate the operational behaviour and to evaluate the advantages of each interconnection approach. The model is validated by measured I-V cell data from single- and multi-junction cells. Moreover, a comprehensive analysis of the calculated results provides valuable insights into the performance trade-offs under real-world conditions, enabling the identification of the optimum design for specific applications.

CPP 25: Poster: Active Matter, Soft Matter, Fluids (joint session DY/CPP)

Time: Wednesday 10:00–12:00 Location: P3

CPP 25.1 Wed 10:00 P3

Enhanced stability and chaotic condensates in multi-species non-reciprocal mixtures — •Laya Parkavousi[1], Navdeep Rana[1], Ramin Golestanian[1,2], and Suropriya Saha[1] — [1]Max Planck Institute for Dynamics and Self-Organization (MPI-DS), D-37077 Göttingen, Germany — [2]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, Oxford OX1 3PU, United Kingdom

Random non-reciprocal interactions between a large number of conserved densities are shown to enhance the stability of the system towards pattern formation. The enhanced stability is an exact result when the number of species approaches infinity and is confirmed numerically by simulations of the multi-species non-reciprocal Cahn-Hilliard model. Furthermore, the diversity in dynamical patterns increases with increasing number of components and novel steady states such as pulsating or spatiotemporally chaotic condensates are observed. Our results may help to unravel the mechanisms by which living systems self-organise via metabolism.

CPP 25.2 Wed 10:00 P3

Non-reciprocal Model B and the role of mobilities and non-reciprocal interfacial forces — •Bibhut Sahoo[1] and Peter Sollich[1,2] — [1]Institut für Theoretische Physik, Georg-August-Universität Göttingen, 37077 Göttingen — [2]Department of Mathematics, King's College London, London

Recently the effects of non-reciprocal interactions have been widely studied in the Cahn-Hilliard model for phase separation, which is based on a magnetic analogy. Here we explore the corresponding nonreciprocal model B, as the continuum theory for non-reciprocal particle mixture. We focus on the effect of mobility matrix on topology of the phase diagram and find that changing mobility can change stability of a homogeneous state, which for reciprocal interactions

would be impossible. We study spinodal dynamics in regions of instability, where static or travelling spinodal patterns can occur. This aspect is as in non-reciprocal Cahn-Hilliard but, the transitions between these instabilities are novel: they occur not via exceptional points, but via first order transitions in the length scale of the dominant unstable modes. At transition, a static and a travelling spinodal pattern with two different scales coexist. We show that more complicated transitions involving coexistence of three length scales can also occur. We finally argue, based on a nonreciprocal version of Dean's equation, that coarse graining into a model B description should lead to non-reciprocal interface terms, rather than only in the bulk as assumed in theories to date. We show that such interfacial terms can significantly enlarge the travelling spinodal regions in the phase diagram.

CPP 25.3 Wed 10:00 P3

Mixed active fluids of two kinds — •Astik Haldar — Universität des Saarlandes, Saarbrücken 66123, Germany

We explore here the polar active fluids of two types, characterizing by their different aligning and propulsion strengths. We example here the fluids as the collections of moving living creatures, which could fuel itself through chemical reactions in their body . We called this system as active system, and consider their brilliant interactions. We here try to model those through considering some parameters and physically observable quantities. We find the parameters region where they have their oriented flocking as parallel or antiparallel, ordered rotating phase coherently meaning chiral phase. Our study finds the transition between the phases as saddle node as well as pitchfork bifurcation in mean field theory scheme. We find different kind of pattern formed states appear through the analytical as well as numerical study.

CPP 25.4 Wed 10:00 P3

Verification, efficiency analysis and extension of the kinetic Event-Chain Algorithm — •Nico Schaffrath, Tobias Kampmann, and Jan Kierfeld — TU Dortmund, Dortmund, Germany

The novel cluster kinetic Monte-Carlo algorithm, which is based on the event-chain Monte-Carlo method, is specifically designed to simulate systems of two-dimensional self-propelled hard particles. We verify this algorithm from scratch by analysing various single-, two- and many-body systems, as well as some algorithm-specific quantities. To gain insight about the applicability of the algorithm, we compare its performance to that of an Event-Driven Brownian-Dynamics simulation. Finally, we investigate the possibility to simulate particles with soft interaction energies as well as an extension to three-dimensional systems. Regarding the latter, the phase diagram of self-propelled hard spheres is calculated.

CPP 25.5 Wed 10:00 P3

AMEP: Analyzing Active Matter Simulations in Python — Kay-Robert Dormann[1], Lukas Hecht[1], Kai Luca Spanheimer[2], Aritra K. Mukhopadhyay[1], Mahdieh Ebrahimi[1], Suvendu Mandal[1], and •Benno Liebchen[1] — [1]Institut für Physik kondensierter Materie, Technische Universität Darmstadt, Darmstadt, Germany — [2]Institut für Theoretische Physik II, Heinrich-Heine-Universität, Düsseldorf, Germany

The **A**ctive **M**atter **E**valuation **P**ackage (AMEP)[1] is an easy-to-use Python library for analysing simulation data of particle-based and continuum simulations. It provides a powerful interface for handling complex analysis of large data sets from different simulation software such as LAMMPS, HOOMD-blue, GROMACS and others. A plethora of methods to calculate observables and visualise results make AMEP suitable to calculate complex observables not only for beginners but also for advanced studies of active and soft matter. AMEP is written in pure Python and leverages powerful and well-known libraries such as NumPy, SciPy and Matplotlib. Computationally expensive methods are parallelized to run on laptops and workstations as well as high-performance computing clusters.

The methods range from order parameters, cluster methods, spatial and time correlation functions to thermodynamic properties and coarse-graining methods. More information and examples are available at https://amepproject.de. AMEP can be installed via conda and pip.

CPP 25.6 Wed 10:00 P3

Fluctuation induced network patterns in spatially correlated noise — •Sebastian Fehlinger[1], Kai Cui[2], Arooj Sajjad[1], Heinz Koeppl[2], and Benno Liebchen[1] — [1]Technische Universität Darmstadt, Institut für Physik Kondensierter Materie, Hochschulstraße 8, 64289 Darmstadt — [2]Technische Universität Darmstadt, Selbstorganisierende Systeme, Merkstraße 25, 64283 Darmstadt

Fluctuations play an important role in many fields of physics, from quantum electrodynamics to statistical mechanics. In active matter physics, so far, most works have focused on active particles that are subject to thermal fluctuations caused by the surrounding solvent. Here, we explore the collective behaviour of active particles under the influence of spatially correlated noise, that can arise, e.g., from fluctuating external fields. Therefore, we introduce a minimal model which describes the dynamics of (chiral) active particles with alignment interactions in a time-dependent Gaussian random field, that features a characteristic spatial correlation length, but no temporal correlations. Using Brownian dynamics simulations, we find, that the active particles aggregate to system spanning, percolated networks. These structures are (i) fluctuation-induced, (ii) feature local alignment of the contained particles, but no global alignment, and (iii) hardly show any coarsening. We systematically characterize the emerging patterns with tools from topological data analysis (persistence diagrams, Vietoris-Rips complexes and Betty numbers).

CPP 25.7 Wed 10:00 P3

Reconfiguring hydrodynamic flow fields of active particles by light — Lisa Rohde, Tom-Hannes Hemann, Gordei Anchutkin, and •Frank Cichos — Molecular Nanophotonics Group, Peter Debye Institute for Soft Matter Physics, University Leipzig, Leipzig, Germany

Microscopic active particles propel themselves via localized energy conversion, generating hydrodynamic flow fields that govern their boundary interactions and collective behaviour. The long-range behaviour of the flow patterns classifies them as either pushers, which expel fluid along their swimming axis, or pullers, which draw fluid inward. In nature, some microorganisms can adaptively switch between pusher and puller modes in response to their environment. However, synthetic active particles are currently limited to a fixed pusher or puller configuration during fabrication, constraining our ability to study their dynamic responses to environmental cues. Here, we present a self-thermophoretic active particle that can reconfigure its flow field on demand during the experiment. This is achieved by illuminating the particle with an inhomogeneous light field shaped by a spatial light modulator. The illumination patterns create surface temperature fields inducing thermo-osmotic flow fields that propel the particle and shape the hydrodynamic interactions. By using gold nanoparticles, we trace and characterize the hydrodynamic flow field of the active particle. The ability to dynamically alter the propulsion characteristics will enable us to investigate and control their interactions and collective dynamics.

CPP 25.8 Wed 10:00 P3

Brainbots as smart autonomous active particles with programmable motion — •Isa Mammadli[1], Martial Noirhomme[2], Nathan Vanesse[2], Jayant Pande[3], Ana-Sunčana Smith[1], and Nicolas Vandewalle[2] — [1]PULS, Institute for Theoretical Physics, FAU Erlangen-Nürnberg, 91058, Erlangen, Germany — [2]GRASP, Institute of Physics B5a, University of Liege, B4000 Liege, Belgium — [3]Department of Physical and Natural Sciences, FLAME University, Pune, India

We introduce an innovative robotic device designed to enable controlled motion for the study of active matter. Motion is driven by an internal vibrator, powered by a compact rechargeable battery. The system integrates acoustic and magnetic sensors alongside a programmable microcontroller. Unlike conventional vibrobots, this device employs a motor that generates horizontal vibrations, producing cycloidal trajectories that have been thoroughly characterized and optimized. Specific segments of these trajectories can be harnessed to create tailored motion patterns. As a proof of concept, we demonstrate how this versatile system can be used to develop active particles exhibiting diverse dynamics, ranging from ballistic motion to run-and-tumble diffusive behavior. Based on experimental data, we provide a simulation routine capable of replicating these trajectories, enabling the generation of extended datasets and the exploration of various input velocity configurations. This approach facilitates the determination and prescription of optimized input parameters for applications such as enhanced search strategies and precise path following.

CPP 25.9 Wed 10:00 P3

Fundamental Measure Theory for active hard discs — •Jonas Buba and Michael Schmiedeberg — Theoretical Physics: Lab for Emergent Phenomena, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

The behavior of active soft particles has been studied extensively and provides a good model for many active matter systems [1]. However, some systems might be described more accurately by considering hard particles instead. While active soft particles have been described with a Phase Field Crystal approach (e.g., in [2]), a similar description of active hard particles is still lacking. In our approach we use Fundamental Measure Theory [3] to model hard discs and add activity. We expect to gain further insight into the role that the particle type can play in dynamical pattern formation.

CPP 25.10 Wed 10:00 P3

Many-Body Dynamics of actively rolling fibers — •Alex Arnhold[1], Falko Ziebert[1,2], and Igor M Kulic[3,4] — [1]Institute for Theoretical Physics, Heidelberg University, Philosophenweg 19, 69120 Heidelberg, Germany — [2]BioQuant, Heidelberg University, Im Neuenheimer Feld 267, 69120 Heidelberg, Germany — [3]Institut Charles Sadron UPR22-CNRS, 67034 Strasbourg, France — [4]Institute Theory of Polymers, Leibniz-Institute of Polymer Research, D-01069 Dresden, Germany

Fiberboids are active filaments, capable of self-propulsion, whose dynamics were recently described in [A. Bazir, A. Baumann, F. Ziebert, I. M. Kulić, Soft Matter 2020]. So far, only single and simple 2-body dynamics of fiberboids were described.

In this work we will take a first look at the many-body dynamics. Specifically, we analyze a system of multiple nylon-rods, which when heated from below display self-propelled rolling motion. Confining the rods to roll on a single axis only, implements a simple realization of an 1D active gas. We analyze the experiments concerning clustering and nonequilibrium fluctuations and rationalize the system by simple lattice models.

CPP 25.11 Wed 10:00 P3

Pumping currents and formation of flocks in 1D Ising model — •Adrian Morais Cabral and Achim Rosch — Institute for Theoretical Physics, University of Cologne, Germany

Non equilibrium systems create phenomena that are not observed in equilibrium counterparts, such as long range order in two or less dimensions and breaking of detailed balance.

We use an effective description of coupled Langevin equations to study a 1D system where an Ising order parameter is coupled to a charge density. Our assumption is that the charge current has a contribution proportional to the order parameter for the driven system. The formation of domain walls leads to a source of dynamical frustration for the charge. Driving disallows the formation of domain walls and creates flocking blob like states in addition to constant ordered and disordered states and a non moving spike phase. These solutions are studied numerically in 1D for $T \geq 0$.

At $T = 0$, we characterize existing flocking solutions and compare analytical predictions to numerical simulations which agree well with only one fitting parameter.

At finite temperatures we find new dynamics for the flocking state such as reversals similar to the active Ising model and (quasi) crossings. However, we have not yet been able to answer whether the existing ordered phase is stable in 1D.

CPP 25.12 Wed 10:00 P3

Statistical Field Theory for Vicsek-type models — •Carsten Littek, Falko Ziebert, and Matthias Bartelmann — Institut für Theoretische Physik, Universität Heidelberg, Germany

Dry, aligning, dilute active matter systems display a wide range of emergent phenomena such as collective, orientationally ordered motion and phase separation. The self-propelled particles in such systems undergo noisy aligning interactions with their neighbours, but they do not exchange momentum with their surrounding. While microscopic and hydrodynamic descriptions, whose connection involves approximations, exist, their predicted behaviour - such as scaling exponents - do not match.

Here we present a microscopic statistical field theory for active Brownian particles inspired by Mazenko (2010). In our formulation we interpret the particles' two-dimensional positions and their direction of motion as Martin-Siggia-Rose (MSR) fields to obtain a path integral representation of the N-particle partition function. The MSR action is augmented by a two-particle interaction that aligns particle directions either ferromagnetically as in the Vicsek model or nematically. Similar to quantum many-body theory the benefit of our field theoretic formulation of Vicsek-type models is that it allows for developing a self-consistent perturbation theory and using renormalization techniques. Our aim is the calculation of density and velocity correlation functions in the homogeneous ordered phase and the transition into the ordered phase.

CPP 25.13 Wed 10:00 P3

Coupling reaction-diffusion and locomotion in vegetative cells — •Blaž Ivšić[1], Piotr Nowakowski[2], Igor Weber[2], and Ana Sunčana Smith[3,2] — [1]Institut za fiziku, Zagreb, Croatia — [2]Institut Ruđer Bošković, Zagreb, Croatia — [3]Friedrich-Alexander- Universität, Erlangen, Germany

Cellular locomotion involves the dynamic interplay between signaling molecules, cytoskeletal activity, and membrane deformation. We present a computational model coupling protein Rac1 reactiondiffusion dynamics to cell locomotion to study vegetative state of amoeba Dictyostelium discoideum. Rac1 regulates actin polymerization via effectors like WASP and Arp2/3, while GAP modulates its activity. The model captures Rac1 dynamics on a deforming membrane, reproducing experimentally observed spatiotemporal patterns.

Cell shape is modeled using a Level-set method to track membrane dynamics, driven by forces linked to Rac1 concentration. Specifically, surface tension and normal forces (due to interaction of the cell with the substrate) proportional to Rac1 concentration influence membrane movement. The dynamics are conveyed through a fluid velocity field obtained by solving a time-dependent Stokes equation.

Our model replicates Rac1 activity patterns seen in live-cell imaging and links these patterns to cell motility. By bridging Rac1 reactiondiffusion dynamics with membrane mechanics, the model provides insights into the mechanisms of actin-driven locomotion in vegetative cells.

CPP 25.14 Wed 10:00 P3

Numerical Simulation of Microplastic Permeation in Soil: from Solutes to Particles — •Hao Liu[1], Yifan Lu[2], Christina Bogner[2], Martin Lörder[1], and Stephan Gekle[1] — [1]University of Bayreuth, Bayreuth, Germany — [2]University of Cologne, Cologne, Germany

Microplastics have become significant environmental pollutants, raising concerns about their accumulation and distribution across ecosystems. Although terrestrial environments, particularly soils, often exhibit high levels of microplastic contamination, they remain relatively understudied. Microplastic transport in soil involves complex interactions among particle properties, soil structure, and fluid dynamics. Understanding mechanisms such as permeation, aggregation, and degradation is essential for effective environmental risk assessments and strategies to control microplastic pollution.

This study aims to simulate and predict soil hydraulic conductivity in microplastic-laden flows. Challenges include modeling behaviors of microplastic particles as they transport in soil with complex porous structures. High-resolution μCT scans of soil samples will provide the necessary porous media data, and simulations will be conducted using FluidX3D software. The research progresses in two phases: first, disregarding particle size and shape to analyze solute transport mechanisms; second, incorporating detailed particle properties to study transport and accumulation in pores. The goal is to model microplastic dynamics for accurate predictions of microplastic distribution in soil systems.

CPP 25.15 Wed 10:00 P3

Thermo-Osmotic Flows via Anti-Stokes Cooling — •akshay kallikkunnath[1], kamil bruchal[2], pawel karpinski[2], and frank cichos[1] — [1]Molecular Nanophotonics, Peter Debye Institute for Soft Matter Physics, Faculty of Physics and Earth System Sciences, Leipzig University, Germany — [2]Faculty of Chemistry, Institute of Advanced Materials, Wroclaw University of Science and Technology, Poland

Fluidic manipulation has gained huge interest over time especially with the studies on metal nanoparticles as optically controlled heat sources generating temperature gradients. With recent developments in the synthesis of lanthanide doped crystals which can be cooled by anti- stokes cooling, we try to bring laser cooling of microcrystals to the field of fluidics. In this work, we optically trap and cool ytterbium doped NaYF4 crystals by means of anti-stokes cooling. Temperature measurements for such microscale cooled crystals are done using a technique which utilizes the phase transition of liquid crystals. With such a thermal gradient created using cold sinks in liquid, we study and provide for the first time experimental and numerical results for flows generated at solid-liquid boundary, i.e., thermo-osmotic flows. The results will provide further scope for studying dipolar thermo-osmotic and corresponding thermo-electric fields in an electrolyte solution generated by arranging optically heated and cooled particles together. Our findings can have direct implications on the study of temperature-dependent biochemical processes which inhibit with lower temperature or on response of a biological specimen to low temperature stress or may even find application in local cryotherapy.

CPP 25.16 Wed 10:00 P3

Thermodynamically consistent coarsening model of crossover placement in meiosis — •Marcel Ernst[1,2] and David Zwicker[1] — [1]Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — [2]Universität Göttingen, Germany

Crossovers play an important role in meiosis, ensuring correct segregation of homologous chromosomes and increasing genetic variability. A recently proposed model suggests that crossover placement is determined by biomolecular condensates that coarsen by exchange and diffusion of a protein along chromosomes, consistent with experiments. We here present an extended model including exchange with the nucleoplasm based on thermodynamic principles. We study theoretically and numerically the initial protein loading onto the chromosome, the droplet growth regime, the coarsening regime, and the final equilibrium. We derive scaling laws for the number of crossovers analogous to Lifshitz-Slyozov-Wagner theory in different limits. Finally, we investigate the effect of protein exchange with the nucleoplasm on crossover placement and compare the results with empirical data from several species. In conclusion, our model allows us to explain key features of meiotic crossover placement in wild type and several mutants.

CPP 25.17 Wed 10:00 P3

A lattice Boltzmann approach to electrolytic multiphase flows — •Alexander Reinauer and Christian Holm — Institute for Computational Physics, Stuttgart, Germany

Simulating electrolytic multiphase flow presents significant challenges, often requiring either the detailed modeling of large numbers of particles or solving complex, nonlinear partial differential equations, such as the Navier-Stokes and Nernst-Planck equations. While particle-based simulations provide molecular details, continuum-scale approaches, including the Navier-Stokes and Nernst-Planck equations, enable the study of larger systems relevant to applications in oil recovery, biological processes, and waste treatment.

In this work, we extend the Lattice Boltzmann Method using a Color-Gradient approach to simulate immiscible two-phase flow, coupled with a custom Nernst-Planck solver for the transport of dissolved charged species. This coupling allows to incorporate the preferential solubilities of chemical species.

Our implementation, based on the pystencils/lbmpy framework, generates highly optimized code for both CPU and GPU architectures. To validate the model, we performed simulations of freely suspended liquid droplets subjected to an external electric field. Additionally, we explored contact angle models and initiated studies on applying the approach to porous media under varying conditions.

CPP 25.18 Wed 10:00 P3

Coarsening of chemically active droplets — •Stefan Köstler[1,2], Yicheng Qiang[1], and David Zwicker[1] — [1]Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, 37077 Göttingen, Germany — [2]University of Göttingen, Institute for the Dynamics of Complex Systems, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

Droplets formed by phase separation play an important role in cellular organization and are widely used in the design of synthetic cells and lab-on-chip devices. Droplet emulsions typically coarsen due to surface tension and hydrodynamic effects, which generally prevents precise control over droplet sizes. While coarsening can be suppressed by active chemical reactions, it is unclear how these reactions affect the coarsening dynamics and control droplet sizes. To elucidate this, we numerically simulate a binary mixture that phase separates and undergoes reactions. We find three different dynamical regimes: Small droplets are dominated by coalescence due to hydrodynamic advection, then transition to an Ostwald ripening regime dominated by diffusion, and finally exhibit size control by active chemical reactions. We predict the transition from ripening to size control analytically, and we validate our analytical estimate of the final size using a numerical minimization of a surrogate equilibrium free energy. Our theory provides an improved understanding of coarsening mechanisms, allowing to achieve greater control of emulsions.

CPP 25.19 Wed 10:00 P3

Zetapotential of Gold Surfaces in a Flow Cell — •Mattis Rasenat, Peter Vogel, Marcus Witt, and Thomas Palberg — Johannes Gutenberg Universität Mainz

We present a case study on the zeta-potential of gold surfaces in a continuous flow cell. The charge of dielectric surfaces is of high interest for technological applications. Therefore, we measure the zeta potential of polymer particles in a custom-made electrokinetic flowthrough cell with exchangeable sidewall. The zeta potential is measured with a super-heterodyne light scattering setup.

CPP 25.20 Wed 10:00 P3

Use of molecular CO_2 for surface charge regulation — Peter Vogel[1], Markus U. Witt[1], David Beyer[2], Christian Holm[2], Muhammad Navaz Qaisrani[3], Marialore Sulpizi[4], and •Thomas Palberg[1] — [1]Inst. of Physics, JGU, Mainz, Germany — [2]Inst. of Computational Physics (ICP), U Stuttgart, Stuttgart, Germany — [3]MPI for Polymer Research, Mainz, Germany — [4]Dept. of Physics, RU Bochum, Bochum, Germany

In deionized water CO_2 forms carbonic acid which partially dissociates. Such 'realistic' salt free systems contain a significant background electrolyte concentration and a pH of 5.5. Both lowers the effective charge of dielectric surfaces. Surprisingly, the remaining molecular CO_2 causes an additional drastic decharging effect, even to complete decharging in water equilibrated against pure CO_2. Molecular CO_2 acts directly on the degree of dissociation and thus lowers the bare charge, while effective charges merely follow suit. MD simulations show the formation of a diffusely adsorbed monolayer of CO_2, which locally lowers the dielectric constant. Based on this we suggested dielectric charge regulation as novel decharging mechanism. If then salts are added to the carbonized surfaces, one finds recharging by co-ion adsorption. This process is favoured by hydrophobicity, by co-ion size and, most important, also by the amount of adsorbed CO_2. Given the ubiquity of dielectric surfaces in contact with aqueous electrolytes, this very general charge regulation processes appear to be of great fundamental and practical importance.

CPP 26: Nanostructures, Nanostructuring and Nanosized Soft Matter I

Time: Wednesday 11:30–13:00 Location: H34

Invited Talk CPP 26.1 Wed 11:30 H34

Polyelectrolytes in the confined space of mesopores for transport regulation — •Annette Andrieu-Brunsen — Technische Universität Darmstadt, Macromolecular Chemistry - Smart Membranes, Germany

Nanopores are a key component in various technologies from oil production, separation and sensing, to drug delivery or catalysis and energy conversion. In contrast to technological pores, biological pores and channels demonstrate highly precise transport being directed, highly selective, and gated. A key factor to this performance is their nanoscale structure, and their local control on charge regulation and polarity in confined space. Inspired by this performance and precision we are interested in understanding the relation between the design of polymers in nanoscale space and its resulting properties to for example understand and advance transport performance of technological pores.

This talk will give insights into the interplay of polymer functionalization of mesoporous layers and resulting ionic mesopore accessibility. Among others, the effect of increasing polyelectrolyte amount and thus increasing charge density as well as the influence of polymer chain composition and the observation of confinement-induced pKa shifts will be discussed. Furthermore, ionic transport regulation by gradually adjusting the wettability of mesopores will be demonstrated including the influence of nanoscale wettability step-gradients in mesoporous silica layers. To indicate next steps our activities towards increasing precision in polymer functionalization of mesoporous silica materials will be outlined.

CPP 26.2 Wed 12:00 H34

Infrared Scanning Near-Field Spectroscopic Insights into Self-Assembled Block Copolymer Nanostructures — •Nadine von Coelln[1], Britta Weidinger[2], Christian Huck[1], Irene Wacker[3], Ronald Curticean[3], Rasmus R. Schröder[3], Eva Blasco[2], and Petra Tegeder[1] — [1]Institute for Physical Chemistry — [2]IMSEAM — [3]BioQuant, Heidelberg University, Germany

Block copolymers (BCPs) are known for their ability to self-assemble into a variety of morphologies on the nanometer scale. While the self-assembly of 2D thin films has been extensively investigated, less attention has been paid to 3D bulk morphologies. In this work, the internal nanostructure of long-range ordered 3D bulk morphologies of a well-defined diblock copolymer consisting of polystyrene and a methacrylate-based copolymer is studied by means of infrared scanning near-field optical microscopy (IR-SNOM). We demonstrate that by irradiation at an absorption band specific to one polymer block, it is possible to chemically image the blocks nano-ordered spatial arrangement [1]. Representative images were successfully correlated with scanning electron microscopy (SEM) data. By altering the molar fraction of polymer blocks, a variety of nanostructures was imaged. For some polymer compositions, the nanostructure formed was observed to change upon post-functionalization. Additionally, nanotomography of the bulk material is approached by imaging and volume reconstruction of serial sections.

CPP 26.3 Wed 12:15 H34

Star-like molecular brushes with poly(2-oxazoline)-based amphiphilic diblock copolymer side arms — •Wenqi Xu[1], Laura Fietzke[2], Rustam A. Gumerov[3], Feifei Zheng[1], Peiran Zhang[1], Cy M. Jeffries[4], Dmytro Soloviov[4], Rainer Jordan[2], and Christine M. Papadakis[1] — [1]TUM School of Natural Sciences, Technical University of Munich, Garching, Germany — [2]Faculty of Chemistry and Food Chemistry, Technical University of Dresden, Dresden, Germany — [3]DWI Leibniz Institute for Interactive Materials, RWTH Aachen University, Aachen, Germany — [4]EMBL at DESY, Hamburg, Germany

Poly(2-oxazoline)s (POx) are synthetic, non-toxic, and biocompatible polymers developed to replace the increasingly immunogenic poly(ethylene glycol) in biomedicine. Among many architectural variants of POx, studies on POx-based star brushes are still scarce. In the present work, we investigate molecular brushes, in which diblock copolymers from hydrophilic poly(2-methyl-2-oxazoline) and hydrophobic poly(2-*n*-butyl-2-oxazoline) are grafted onto star-shaped poly(methyl methacrylate) backbones with the stars having functionalities ranging from 2 to 5. The size and shape of the star brushes were investigated in dilute aqueous solutions using computer simulation, dynamic light scattering, and synchrotron small-angle X-ray scattering. Our results show that these star brushes form ellipsoids with different degrees of elongation. Moreover, a size growth is found for the star brushes at high temperatures, which is attributed to the aggregation of the amphiphilic side arms.

CPP 26.4 Wed 12:30 H34

STED-inspired optical lithography beyond acrylates — Sourav Islam, Georgii Gvindzhiliia, and •Thomas A. Klar — Institut für Angewandte Physik, Johannes Kepler Universität Linz, Austria

STED-inspired[1], and hence sub-diffractional, nanolithography was so far restricted to free radical polymerizations, predominantly of (meth)acrylates.[2] We now expand the STED-inspired toolkit to cationic[3, 4] and oxidative polymerizations,[5] comprising the technologically important classes of epoxides and pi-conjugated polymers. In both cases, we achieved structure sizes below 100 nm using transient-state absorption depletion (TAD) in systems comprising depletable photosensitizers, optionally combined with onium salts. The pi-conjugated nanostructures are particularly intriguing, because they potentially will allow for sub-diffractional organic electronic devices.

CPP 26.5 Wed 12:45 H34

In-situ investigation of the lateral and vertical structure of PNIPAM-microgels at the air-liquid and solid-liquid interfaces — Olaf Soltwedel, Joanne Zimmer, •Hayden Robertson, and Regine von Klitzing — Institut für Physik Kondensierter Materie, Technische Universität Darmstadt, D-64289 Darmstadt, Germany

The novel surface characterisation approaches presented here highlight, for the first time, the use of both specular and off-specular X-ray reflectivity (XRR) to probe the vertical and lateral structure of adsorbed polymer microgels particles at various interfaces, offering *in situ*, non-invasive insights without the need for doping or transfer-induced artefacts. In particular, we demonstrate the complementarity of two readily accessible laboratory techniques on characterising the structure of adsorbed microgels: atomic force microscopy (AFM) and XRR. Initial *ex situ* AFM scans of Langmuir-Blodgett deposited microgels at the solid interface revealed strong lateral 2D hexagonal ordering across a broad range of surface pressures. However, for the first time, these results are confirmed by off-specular XRR, demonstrating the existence of the hexagonal long-range ordering at low and intermediate surface pressures for *in situ* conditions at the air-water interface. Upon uniaxial compression of the interface, the microgel lattice constants decrease monotonically, indicating tighter packing. At these higher surface pressures, both AFM and off-specular XRR also reveal the formation of microgel domains; hexagonal short-range ordering is maintained whereas long-range ordering is diminished.

Break-junctions beyond single-molecule conductance — •Joseph Hamill — Department of Chemistry and Nanoscience Center, University of Copenhagen, Denmark

The challenge in nanosciences is to reliably manipulate and probe objects on the atomic and molecular scale. Single-molecule break junctions cleverly integrate a single molecule into an electric circuit, enabling measurement of its thermal, electrochemical, and electrical properties. These studies explore candidates for waste heat capture, quantum information technologies, sensors, nanomedicine, and other novel materials applications. Over the past 20 years, single-molecule break junction methods have advanced to measure current, resistance, rectification, and thermopower. Despite this progress, they are not yet a staple in every chemist's toolbox like NMR spectroscopy. Recent studies using these junctions to monitor and induce chemical reactions may change this. I will present two recent studies demonstrating their sensitivity to changes in bonding chemistry and the tautomer state of single molecules in the junction. This sensitivity is unlocked through frequency domain spectroscopy using flicker noise analysis[1] and improved machine learning approaches, such as principal component analysis and k-means clustering.[2]

CPP 27.2 Wed 11:45 H38

Charge transport in organic semiconductors with a mapping approach to surface hopping — •Johan Runeson[1], Thomas Drayton[2], and David Manolopoulos[2] — [1]Institute of Physics, University of Freiburg, Germany — [2]Physical and Theoretical Chemistry Laboratory, University of Oxford, UK

Coupled charge-phonon systems are challenging to simulate in the intermediate regime between traditional delocalized band theory and localized polaron theory. In particular, it remains unclear which methods are suitable to describe organic semiconductors. Conventional trajectory-based methods, such as Ehrenfest dynamics and surface hopping, do not capture the correct equilibrium of mixed quantum-classical systems. In this talk, I will present a simple solution to this problem. Based on a recently developed "mapping approach to surface hopping" [1,2], we propagate trajectories on the adiabatic state with the highest population, which in contrast to previous methods is consistent with the correct quantum-classical equilibrium. We applied this methodology to charge diffusion in crystalline rubrene [3] and obtained a well-defined diffusion constant, without having to introduce the phenomenological relaxation time approximation (RTA). Our results give 30-60 % higher charge mobilities than conventional RTA calculations and shed light on experiments of the optical conductivity.

CPP 27.3 Wed 12:00 H38

Influence of Classical Molecular Motion on Energy Transport in Molecular Aggregates — •Ritesh Pant[1], Sebastian Wüster[2], and Alexander Eisfeld[1] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Indian Institute of Science Education and Research, Bhopal, India

Molecular aggregates can transport electronic excitation energy over large distances due to dipole-dipole interactions [1]. We explore the impact of classical thermal motion of entire monomers on this transport, considering a chain of molecules [2]. Such motion induces changes in the aggregate's geometry, thereby altering the exciton states and enabling, in certain regimes, the adiabatic transport of excitation energy. We find that, in the absence of intramolecular vibrations, the interplay between molecular motion and exciton dynamics induces oscillatory behavior in site populations, which are coupled to the motion. These oscillations occur specifically when the molecular motion is slow enough to be considered adiabatic with respect to the exciton dynamics, and their characteristics depend on the chain length, with shorter chains exhibiting more pronounced effects. We also explore the effect of intramolecular vibrations on this oscillatory behavior and investigate the conditions under which the oscillations persist or are suppressed.

CPP 27.4 Wed 12:15 H38

Enhancing excitonic properties in organic semiconductors by aqueous ions — •Filip Podjaski — Department of Chemistry and Centre for Processable Electronics, Imperial College London, UK

While organics semiconductors (OSC) promise tailorable structure-function relationships for enhanced solar energy conversion abilities, advancement is often hindered by limiting knowledge of interwoven photo-physical processes and properties that lead to recombination losses on ultrafast time scales.[1] Herein, I discuss possibilities to measure and modify functionalized OSC' exciton behaviour, to address their recombination. For photocatalysis, interactions with aqueous ions, which are also relevant for enabling sea water use, are typically disregarded. Our time-resolved optical spectroscopy study on suspended polymer nanoparticles in presence of different salts shows how they can improve stabilization of excitons. We further introduce Terahertz permittivity measurements as convenient tool to probe the complex permittivity / dielectric properties of OSCs on ps-time scales. The permittivity defines exciton binding energy and is hence relevant for charge carrier photogeneration and transport. But its highly frequency dependent values are commonly extracted orders magnitude off the ps-regime. Our study focussing on carbon nitrides now reveals dielectric screening and transport properties at the early time scales of solar energy conversion process chains, and illustrates environmental enhancements enabled by ions.[2]

CPP 27.5 Wed 12:30 H38

Computational insights into open-shell molecules for applications in molecular electronics — •Susanne Leitherer[1] and Gemma C. Solomon[1,2] — [1]Department of Chemistry and Center of Nanoscience, University of Copenhagen, Denmark — [2]Niels Bohr Institute, University of Copenhagen, Denmark

Recent studies have explored a range of molecules with unpaired electrons, represented by their spin. These investigations focused on the charge transport characteristics of the molecules when interfaced with electrodes, as well as their structural rearrangements in electric fields and interactions with surfaces. The theoretical analysis of these systems frequently employs spin-polarized or symmetry-broken unrestricted density functional theory (DFT). This method has proven effective in modeling oxidized molecules exhibiting highly conductive low-energy states, characterized as 1D topological insulators[1]. However, it is well known that DFT can pose challenges for open-shell structures due to their multiconfigurational nature. We demonstrate how for a selection of polycyclic aromatic hydrocarbons - previously investigated in recent scanning probe experiments[2] - the ground state can be accurately determined using a multiconfigurational short-range DFT approach[3]. [1] High Molecular Conductance and Inverted Conductance Decay over 3nm in Aminium-Terminated Carbon-Bridged Oligophenylene-Vinylenes, Krieger et al, JACS (2024); [2] Atomically resolved single-molecule triplet quenching, Peng et al., Science 373 (2021); [3] Multiconfigurational sr-DFT for open-shell systems, Hedegard et al, J. Chem. Phys. 148, 214103 (2018)

CPP 27.6 Wed 12:45 H38

Exceptionally High Two-Photon Absorption Cross Sections in Quinoidal Diazaacene-Bithiophene Derivatives — •Gabriel Sauter[1], Antonia Papapostolou[2], Audrey Pollien[1], Kathleen Fuchs[3], Kerstin Brödner[3], Jan Freudenberg[3], Uwe H. F. Bunz[3], Andreas Dreuw[2], and Petra Tegeder[1] — [1]Physikalisch-Chemisches Institut — [2]Interdisziplinäres Zentrum für Wissenschaftliches Rechnen — [3]Organisch-Chemisches Institut, Universität Heidelberg

In nonlinear optics, materials with high two-photon absorption (2PA) cross sections are crucial for bioimaging, photodynamic therapy, and 3D nanoprinting [1]. Our study highlights quinoidal diazaacene-bithiophene derivatives with exceptional 2PA cross sections, reaching 53,600 GM (850-950 nm) and 4,100 GM (1400-1600 nm), unmatched by organic chromophores of this size [3].

Using experimental z-scan techniques and TDDFT calculations, we attribute these properties to the chromophores acceptor-π-donor-π-acceptor structure, which ensures high oscillator strength and strong state coupling. These features optimize transition dipole moment alignment, maximizing 2PA efficiency.

These findings advance the development of efficient NIR-2PA materials for photonic and biomedical applications.

CPP 28: Modeling and Simulation of Soft Matter III

Time: Wednesday 15:00–16:00 Location: H34

CPP 28.1 Wed 15:00 H34

Many-body potentials and optimized mapping schemes for systematic coarse-graining of small conjugated molecules — •Sayan Dutta[1,2,3], Muhammad Nawaz Qaisrani[4], Denis Andrienko[4], and Arash Nikoubashman[1,2,3] — [1]Johannes Gutenberg-Universität, Mainz, Germany — [2]Leibniz-Institut für Polymerforschung, Dresden, Germany — [3]Technische Universität Dresden, Dresden, Germany — [4]Max-Planck Institut für Polymerforschung, Mainz, Germany

Bottom-up coarse-graining approaches frequently focus on reproducing structural order parameters, ensuring consistency with structural properties from the underlying atomistic model. However, these methods often struggle to predict thermodynamic quantities accurately, leading to challenges in transferability. Furthermore, the coarse-grained (CG) potential is typically highly sensitive to the mapping scheme, introducing representability issues. Recent CG models increasingly enhance traditional pair potentials by incorporating a potential that depends on the local density around each CG particle, which effectively includes many-body interactions in a mean-field approximation. We introduce local density dependent potentials based framework in the CG force-field for small conjugated molecules, which are widely used in the field of organic photovoltaic materials. Our framework captures the local density around each mapped CG site to ensure structural and thermodynamic accuracy, while enhancing computational efficiency compared to its atomistic counterparts.

CPP 28.2 Wed 15:15 H34

Simulation of the fabrication of integral asymmetric polymer membranes using continuum modeling — •Gregor Häfner and Marcus Müller — University of Göttingen, Germany

Integral asymmetric polymer membranes represent a promising class of functional macromolecular systems with a wide range of potential applications, including water purification and protein separation. Their synthesis is achieved through a two-step procedure: (i) the controlled self-assembly of diblock copolymers upon solvent evaporation, to form a cylindrical morphology that is oriented perpendicular to the solution-gas interface. (ii) a solvent-non-solvent exchange, raising the polymer concentration above its glass transition, thereby freezing the matrix phase while allowing the entry of the non-solvent through the cylindrical minority domains. Below, the non-solvent macrophase separates from the polymer to form a porous sub-structure.

In order to gain insight into the physical processes, we perform computer simulations. A continuum model is employed which treats the local concentrations as order parameters and minimizes a free-energy functional. In the limit of high viscosity, the dynamics are purely diffusive, enabling comparison with a particle-based model. We use the continuum model to optimize the final membrane morphology and identifying optimal parameter regions and dependencies. Additionally, this model enables the treatment of finite viscosities. We demonstrate that in the presence of a bariocentric flow, the frozen top layer can be transported downwards to prevent the formation of macro voids beneath the isoporous top layer.

CPP 28.3 Wed 15:30 H34

Highways in pore networks — •Werner Napetschnig[1], Ekaterina Baikova[1,2], Maximilian Fuchs[1,2], and Karin Zojer[1,2] — [1]Institute for Solid State Physics, Graz University of Technology, Austria — [2]Christian Doppler Laboratory for Mass Transport through Paper

When simulating Stokes flow of gases through porous media, the volume flow is often explained by microstructural properties. However, most of these properties do not adequately account for the arrangement of pathways, which is strongly material dependent. Here, we highlight the importance of considering these pathways and explore different techniques to identify flow paths. A pore network model based on micro-computed tomography scans of paper samples serves as the basis for air flow simulation. Two methods are evaluated to identify transport pathways and locate the most critical flow regions. In the first method, the maximum flow rate between individual pores determines the paths. It is shown that the highest flow rate travels between fiber network layers and clusters at a few exit pores. The second method identifies paths iteratively through a stochastic approach where the flow rate is the weighting factor. We identified the most frequently used highway regions. In addition, we studied the orientation and geometric properties of these highways. Our results show that only a few segments within the highways significantly influence the overall flow. Therefore, these highways need to be numerically represented when defining the explanatory microstructure properties.

CPP 28.4 Wed 15:45 H34

A lattice Boltzmann study of bijels as a novel type of catalyst support structure — •Johannes Martinus Peter Beunen and Jens Harting — Helmholtz-Institut Erlangen-Nürnberg für Erneuerbare Energien, Cauerstraße 1, 91058 Erlangen, Germany

Due to their high surface area to volume ratio porous media are very suitable as catalyst support materials. However, the stochastic morphology of commercially available supports generally results in poor reaction product transport and inefficient use of the therein-contained catalyst material. These issues can be alleviated by making use of catalyst supports acquired from spinodally derived architectures due to their beneficial percolation properties. In particular, architectures obtained from bicontinuous interfacially jammed emulsion gels (bijels) seem to provide a viable route to manufacture stable catalyst supports that resolve the aforementioned issues. In this work, this type of porous support is further investigated by means of the three-dimensional lattice Boltzmann method. First, we simulate the formation of bijels by an extension of the lattice Boltzmann method, to allow for multi-component fluids and particles with non-neutral wetting properties. We report on the improved properties of the resulting porous structures compared to stochastic equivalents for usage in chemical reactors. Hereafter, the lattice Boltzmann method is employed again to further validate the enhanced performance of bijel-derived geometries by means of reactive flow simulations. Our findings suggest that bijel-derived catalyst support structures allow for an almost threefold increase in reactor effectiveness.

CPP 29: Organic Electronics and Photovoltaics III

Time: Wednesday 15:00–16:00 Location: H38

CPP 29.1 Wed 15:00 H38

Energy band structure of image potential states of organic semiconductor on graphite studied by angle-resolved low-energy inverse photoelectron spectroscopy — •Tomoko Onishi[1] and Hiroyuki Yoshida[1,2] — [1]Chiba university, Chiba, Japan. — [2]Chiba university MCRC, Chiba, Japan.

The image potential state of the organic semiconductor molecule on the conductive surface is of particular interest because the image potential states can be sensitive probes of interfacial electronic states. Their energy band structure (the energy-momentum relation) provides detailed information about the electron behavior. Recently, we have developed the angle-resolved low-energy inverse photoelectron spectroscopy (AR-LEIPS) [1,2]. This technique allows direct observation of the unoccupied states without sample damage and with the resolution better than 0.3 eV. In this study, we applied AR-LEIPS to a monolayer of copper phthalocyanine (CuPc) on highly oriented pyrolytic graphite (HOPG). The observed band structure of the image potential state was parabolic, indicating that its nature is free-electron-like along the surface plane. By fitting the band structure to a quadratic function, we obtained the effective masses of the image potential states on HOPG and CuPc/HOPG to be (1.14 * 0.02) m0 and (1.33 * 0.08) m0, respectively, where m_0 is the electron mass. The effective mass becomes heavier due to the periodic potential induced by the CuPc molecule.[1] H. Sato, H. Ishii, H. Yoshida, et al., Nature Mat. 21, 916 (2022) [2] Y. Kashimoto, H. Yoshida et al, Rev. Sci. Instrum., 94, 063903 (2023).

CPP 29.2 Wed 15:15 H38

Fluorination of Thieno-quinoxalines enables tunable excitonic and electronic bandgaps — •Md Moidul Islam[1,2], Arthur Markus Anton[3], Shahidul Alam[4], Patrick Irmisch[3], Alexander J. Much[7], Ulrich S. Schubert[1,2], Christos Chochos[5,6], and Harald Hoppe[1,2] — [1]IOMC, FSU Jena, Humboldtstrasse 10, 07743 Jena, Germany — [2]CEEC Jena, Philosophenweg 7a, 07743 Jena, Germany — [3]Peter Debye Institute for Soft Matter Physics, Universität Leipzig, Linnéstraße 5, D-04103 Leipzig — [4]KAUST Solar Center, PSE, MSE, Thuwal 23955-6900, Kingdom of Saudi Arabia — [5]Institute of Chemical Biology, National Hellenic Research Foundation, 48 Vassileos Constantinou Avenue, Athens 11635, Greece — [6]Advent Technologies SA, Patras Science Park, Stadiou Street, Platani-Rio, 26504, Patra, Greece — [7]Experimental Polymer Physics, Martin Luther University Halle-Wittenberg, Von-Danckelmann-Platz 3, 06120 Halle, Germany

Thieno-quinoxaline conjugated polymers are an interesting class of organic semiconductors. While it is known that fluorination causes shifts in the molecular energy levels to deeper binding energies, the mechanisms behind are, so far, not well characterized. In this study, six thieno-quinoxaline polymers with a systematically increased number of fluorinated sites were investigated in solutions and films. Our results indicate a strong correlation between the extend of fluorination, the molecular planarity, and its ability to form aggregates. We also demonstrate, in unprecedented detail, how these structural properties influence various behaviors related to optical and electronic properties.

CPP 29.3 Wed 15:30 H38

Extending the design space of carbazole-based TADF emitters: From photophysical insights to OLED performance — •Karolis Leitonas[1], Łukasz Łapok[2], Sebastian Schellhammer[1], and Sebastian Reineke[1] — [1]Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute for Applied Physics, Technische Universität Dresden — [2]Department of Physical Chemistry and Electrochemistry, Faculty of Chemistry, Jagiellonian University, Kraków, Poland

Although organic light-emitting diodes (OLEDs) dominate the market for mobile displays, e.g., in smartphones, designing efficient and long-lasting blue pixels remains challenging. Enhancing OLED efficiency requires effective singlet and triplet exciton harvesting - a key mechanism to minimize energy losses via non-radiative decay. Emitter materials exhibiting thermally activated delayed fluorescence (TADF) can achieve up to 100 % internal quantum efficiency (IQE) providing a promising approach for the design of efficient OLEDs. Still, their potential is not yet fully exploited due to incomplete insights into the underlying structure-property relationships and chemical design challenges. We discuss the photophysical properties of new emitters extending the class of carbazole-based TADF emitters introduced by Adachi et al. [1] and analyze their application in OLEDs.

[1] Uoyama et al. Nature 2012

CPP 29.4 Wed 15:45 H38

Predicting the molecular arrangement of organic optoelectronic materials — •Alexey Gudovannyy[1], Julia M. Schäfer[2], Olga Gerdes[2], Dirk Hildebrandt[2], Gunter Mattersteig[2], Martin Pfeiffer[2], and Frank Ortmann[1] — [1]Department of Chemistry, TUM School of Natural Sciences, Technical University of Munich, 85748 Garching, Germany — [2]Heliatek GmbH, 01139 Dresden, Germany

The morphology of the most promising molecular semiconductor materials remains highly challenging to predict from scratch. If possible, it would still require a lot of computational time and sometimes experimental data. The main obstacle here is the exponential growth with the number of molecular degrees of freedom for bulky side groups, which forces one to search on extremely complex energy surfaces. However, organic semiconductors mostly exhibit a limited set of structural motifs, primarily herringbone and two-dimensional brickwork patterns. Constraining the search to such dimensionally reduced packing possibilities simplifies the process while preserving 3D structural features. Here, we present a cost-efficient workflow for predicting thermodynamically stable 2D arrangements of molecular periodic associates, where only the molecular structural formula is required. We theoretically and experimentally investigated a set of known and newly crystallized compounds of evaporable flexible molecules with interesting optoelectronic properties, predicted their packing in two-dimensional layers, and compared them with experimentally resolved crystal structures, obtaining a very good agreement in the packing.

CPP 30: Emerging Topics in Chemical and Polymer Physics, New Instruments and Methods I

Time: Wednesday 16:15–18:30 Location: H34

Invited Talk CPP 30.1 Wed 16:15 H34

Challenges and Opportunities in Bringing Machine Learning to a Synchrotron — •Alexander Hexemer[1], Tanny Chavez[1], Wiebke Köpp[1], Dylan McReynolds[1], Stephan Roth[2], Tim Snow[3], and Sharif Ahmed[3] — [1]Lawrence Berkeley National Lab, Berkeley, CA 94720 — [2]DESY, Hamburg, Germany — [3]Diamond Light Source, Didcot, UK

Artificial intelligence (AI) and machine learning (ML) are transforming scientific research, offering innovative solutions to longstanding data collection, analysis, and interpretation challenges. Synchrotron facilities, which generate vast amounts of complex, high-dimensional data, present unique opportunities to leverage ML to advance materials science. Building on this potential, significant progress is being made at the Advanced Light Source (ALS) to integrate ML tools into various synchrotron applications, including tomography segmentation, autonomous scattering analysis, and multimodal data fusion. Efforts are focused on implementing ML as a service, simplifying adoption by providing web-based solutions designed for seamless use across facilities. These tools aim to enable reliable and scalable ML applications for tasks such as the segmentation of complex 3D tomography datasets and automated experimental feedback in scattering experiments. This talk will explore the evolving role of ML at synchrotrons while addressing key challenges.

CPP 30.2 Wed 16:45 H34

Deep Learning-Driven GISAXS Data Processing for Nanostructure Characterization — •Yufeng Zhai[1], Shachar Dan[1], Julian Heger[2], Peter Müller-Buschbaum[2], and Stephan Roth[1,3] — [1]Deutsches Elektronen-Synchrotron (DESY), Hamburg, Notkestr. 85, Germany — [2]Technical University of Munich, TUM School of Natural Sciences, Department of Physics, Chair for Functional Materials, Garching 5, Germany — [3]Royal Institute of Technology (KTH), Stockholm, Sweden

Nanostructured materials, are at the forefront of advanced applications in various fields, owing to their unique physical and chemical properties. Grazing incidence small-angle X-ray scattering (GISAXS) has emerged as a powerful technique for probing the morphology of these nanostructures, offering valuable insights into electron density distributions both at the surface and within thin films. In our approach, we first simulate GISAXS pattern using the Distorted Wave Born Approximation (DWBA) model to generate high-quality training datasets. We then apply deep learning techniques, specifically convolutional neural networks (CNNs), to predict size distributions from GISAXS data. Our results demonstrate that CNNs are highly robust under varying noise conditions and present a promising, time-efficient approach for overcoming the challenges of conventional scattering analysis. This study highlights the potential of integrating advanced computational methods and new analytical tools to enhance the characterization of nanostructures.

CPP 30.3 Wed 17:00 H34

Towards Closing the Autonomous Loop at Multiple Facilities: Developing Web-based User Interfaces and Data Infrastructure for Autonomous Experiments and Automated Data Reduction Workflows — •Benedikt Sochor[1,2], Wiebke Koepp[2], Tanny Chavez[2], Runbo Jiang[2], Dylan McReynolds[2], Marcus Noack[3], Raja Vyshnavi Sriramoju[2], Aidan Coffey[2], Ronald Pandolfi[3], Eric Schaible[2], Chenhui Zhu[2], Frank Schlünzen[1], Stephan V. Roth[1,4], Alexander Hexemer[2], and Sarathlal Koyiloth Vayalil[1,5] — [1]Deutsches Elektronen-Synchrotron DESY, Notkestr. 85, 22607 Hamburg, Germany — [2]Advanced Light Source, Lawrence Berkeley National Laboratory, 6 Cyclotron Rd, Berkeley, 94720, CA, USA — [3]Applied Mathematics and Computational Research Division, Lawrence Berkeley National Laboratory, 1 Cyclotron Road, Berkeley, 94720, CA, USA — [4]KTH Royal Institute of Technology, Teknikringen 56, 100 44 Stockholm, Sweden — [5]UPES, Applied Science Cluster, 248007 Dehradun, India

This project focuses on establishing a robust infrastructure for autonomous scattering experiments at two different synchrotrons: X-ray scattering beamlines at PETRA III (DESY, Hamburg) and at the Advanced Light Source (ALS, Berkeley), initially beamline P03, the micro- and nano-focus small- and wide-angle X-ray scattering beamline (MiNaXS) at DESY, and the SAXS/WAXS/GISAXS/GIWAXS beamline 7.3.3 at the ALS. For selected science cases, the infrastructure's capabilities to handle large datasets during time-resolved and scanning X-ray scattering experiments will be highlighted.

CPP 30.4 Wed 17:15 H34

Imaging techniques for characterization of organic photonic devices utilizing digital luminescence — •Sebastian Kaiser, Sebastian Schellhammer, and Sebastian Reineke — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute for Applied Physics, Technische Universität Dresden

The generally spin-forbidden T_1-S_0 transition of organic molecules gives access to pronounced long-lived room temperature phosphorescence in surprisingly many molecules, but is easily quenched by environmental oxygen. Controlling and utilizing these competing processes has led to the development of digital luminescence as a photonic design principle and its usage in programmable luminescent tags (PLTs) for application in sensing and information storage. To study and utilize this persistent luminescence, a spatially and temporal resolved imaging technique allows us to extend the characterization of these phenomena beyond spectroscopic measurements. By analyzing high-resolution images, differences in intensity and activation time within a single PLT can be detected, allowing conclusions as to structural irregularities. Evaluating each pixel individually also provides great insight into the statistical distribution of these values without the extensive need for samples and measurements. Thus, imaging techniques offer an excellent extension to the characterization of material systems for digital luminescence and by that allowing us to understand and optimize structure-property relationships. This represents an important step towards the use of PLTs for information storage and exchange.

CPP 30.5 Wed 17:30 H34

3D Nanoprinted Polarization Optics Directly on Optical Fibers — •Tim Stechel — Leibniz Institute of Photonic Technology, Albert-Einstein-Str. 9, 07745 Jena, Germany

Polarization is a fundamental property of electromagnetic radiation, influencing numerous areas of physical sciences and optical technologies. Developing functional interfaces that seamlessly integrate polarization control with fiber optics opens new opportunities for advancing these technologies. Using two-photon polymerization, we fabricate 3D structures on the sub-micron scale, directly on optical fibers. This high-resolution additive manufacturing technique enables the creation of tailored microstructures that can precisely control the polarization state of light as it enters and exits fibers. These custom interfaces are highly adaptable to different fiber types and optical configurations, allowing for enhanced polarization shaping and analysis. In this talk, we present the design process, fabrication process and characterization of the fabricated structures. Our approach combines the versatility of 3D printing with the precision required for nanoscale optical engineering, providing a robust platform for research into light-matter interactions and advancing fiber-based photonic technologies. Potential applications span diverse fields, from telecommunications to advanced optical metrology, demonstrating the broad impact of integrating 3D-printed microstructures with fiber optics.

CPP 30.6 Wed 17:45 H34

Phase-cycling and double-quantum two-dimensional electronic spectroscopy using a common-path birefringent interferometer — Daniel Timmer[1], •Daniel C. Lünemann[1], Moritz Gittinger[1], Antonietta De Sio[1], Cristian Manzoni[2], Giulio Cerullo[2], and Christoph Lienau[1] — [1]Carl von Ossietzky Universität Oldenburg, Germany — [2]Politecnico di Milano, Italy

Ultrafast coherent spectroscopy techniques provide unique insights into the coherent dynamics of atomic, molecular and solid state quantum systems. For this, an experimentally challenging but all the more powerful technique is two-dimensional electronic spectroscopy (2DES), which allows to selectively probe coherent and incoherent couplings and to isolate individual excitation pathways by controlling the absolute phases of the ultrashort optical pulses that interact with the system (phase-cycling, PC). Its experimental implementation can be greatly simplified by employing birefringent in-line interferometers (TWINS) which are inherently phase stable. However, TWINS is so far considered to be incapable of this phase control. Here, we demonstrate PC capabilities for 2DES using an adapted TWINS interferometer by recording rephasing, non-rephasing, zero-quantum and double-quantum 2DES on a molecular J-aggregate. This extension is easy to implement and enables new experimental capabilities for TWINS-based 2DES in multidimensional all-optical and photoemission spectroscopy and microscopy.

CPP 30.7 Wed 18:00 H34

Real-time structure-transport investigation under mechanical strain in flexible carbon-based conductive polymer nanocomposites — •Sarathlal Koyiloth Vayalil[1,2], Vaishnav B[2], Benedikt Sochor[1], Stephan V. Roth[1,3], Ajay Gupta[2], Tobias Kraus[4,5], and Debmalya Roy[6] — [1]Deutsches Elektronen-Synchrotron DESY, 22607, Hamburg, Germany — [2]Department of Physics, Applied Science cluster, UPES, Dehradun 248007, India — [3]Division of Coating Technology, KTH Royal Institute of Technology, 100 44 Stockholm, Sweden — [4]INM Leibniz-Institute for New Materials, 66123 Saarbruecken, Germany — [5]Colloid and Interface Chemistry, Saarland University, 66123 Saarbruecken, Germany — [6]DMSRDE, Kanpur 208013, India

In this work, an in situ ultra-small angle X-ray scattering combined with electrical transport measurements under mechanical strain has been carried out in flexible, conductive carbon polymer nanocomposite to observe the real-time structural variations in nanofiller morphologies and distribution. For this purpose, the non-polar and polar elastomers viz. polydimethylsiloxane and polyurethane respectively, loaded with 0D Carbon black, 1D Carbon nanotubes, and 2D Graphene has been employed. The study has elucidated that, it is the filler′s fractal dimension that varies rather than aggregate distribution upon stress that decides PNC′s electrical conduction. Further, a novel relationship has been established between fractal dimension and composite′s conductivity, which invincibly guides in designing wearable and flexible conductors.

CPP 30.8 Wed 18:15 H34

In Situ Synchrotron X-Ray Computed Tomography Studies of Specialty Optical Fibers — •Ali Karatutlu[1], Zehra Gizem Mutlay[1], Andriy Budnyk[1], Gianluca Iori[2], Philipp Iori[3], and Bülend Ortaç[1] — [1]Bilkent University, Institute of Materials Science Nanotechnology and National Nanotechnology Research Center (UNAM), Ankara, 06800 Turkey — [2]Paul Scherrer Institute PSI Forschungsstrasse 111 5232 Villigen PSI Switzerland — [3]SESAME - Synchrotron-light for Experimental Science and Applications in the Middle East, Allan, 19252, Jordan

Specialty fibers have complex structures due to their geometry, including glass core and cladding, multilayered polymer coatings, and the variations of their elemental compositions. Such complex structures of the specialty and microstructured fibers with air holes and the deformation due to manufacturing fiber lasers during fiber splicing can be investigated by X-ray computed tomography (XCT). The fiber fabrication process includes deposition and post-processes with a subsequent fiber drawing. Here, we present the first official results performed at the station BEATS, SESAME, for the synchrotron XCT imaging of specialty optical fibers all in one, such as polarization-maintaining, active, and photonic crystal fibers. In addition, temperature-dependent XCT measurements provided information on how inner structures, such as polymer coatings, could evolve for PM fibers. The conditions of the XCT measurements and the inner structure of the same type of fibers were found to be crucial and act as the guidelines that will be presented for the structures with sizes close to the voxel size.

CPP 31: Responsive and Adaptive Polymers

Moving with minimum effort – Optimal work protocols for systems with memory — •Sarah Loos[1], Samuel Monter[2], Felix Ginot[2], and Clemens Bechinger[2] — [1]DAMTP, University of Cambridge, UK — [2]University of Konstanz

Energy optimization is crucial in engineering and may also govern nonequilibrium processes in chemical and biological systems. Finding optimal solutions for microscale processes–dominated by thermal or nonthermal fluctuations and often displaying memory effects arising from internal degrees of freedom or coupling to viscoelastic environments–posses additional challenges, necessitating general guiding principles. We demonstrate such a general principle for the fundamental problem of dragging a harmonic trap containing a single particle over a finite distance within a given time while minimizing work input. We show that the optimal dragging protocol and the corresponding mean particle trajectory both exhibit time-reversal symmetry, which is a universal and exclusive feature of the optimal solutions. The symmetry principle holds across all media described by a linear generalized Langevin equation, irrespective of the memory kernel or noise properties, including glassy, granular, and active media. For intrinsically driven systems, such as active particles, we show that the optimal protocols remain identical to those for passive systems, but work fluctuations are always increased [2]. CPP 31.2 Wed 16:45 H38

Influence of Azobenzene Moieties on the Swelling Behavior of Poly(Dimethylacrylamide) Films in Water Vapor under UV-Irradiation — •David P. Kosbahn[1], Julija Reitenbach[1], Morgan P. Le Dû[1], Lukas V. Spanier[1], René Steinbrecher[2,3], André Laschewsky[2,3], Robert Cubitt[4], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]Institut für Chemie, Universität Potsdam, 14476 Potsdam-Golm, Germany — [3]Fraunhofer Institut für Angewandte Polymerforschung, 14476 Potsdam-Golm, Germany — [4]Institut Laue-Langevin, 38000 Grenoble, France

This study investigates the swelling behavior of p(AzAm-co-DMAm) films in both isomeric states of the photoswitchable molecule azobenzene (Az). The impact of UV irradiation on swelling in water vapor is examined, with the aim of controlling water uptake, expansion, and nanoscale morphology. This material shows potential for applications in light sensors, photo-actuators, and drug delivery systems. We employ time-resolved FTIR spectroscopy to monitor group vibrations during swelling and irradiation, gaining insights into molecular interactions throughout the isomerization process. Additionally, in situ time-of-flight neutron reflectometry on a thin film provides time- and depth-resolved data on the water distribution along the surface normal. The results shed light on the influence of azobenzene moieties on the polymer's microscopic properties.

CPP 31.3 Wed 17:00 H38

Critical analysis of adhesion work measurements from AFM-based techniques for soft contact — Dmitrii Sychev[1,2], Simon Schubotz[1,2], Quinn A. Besford[1], Andreas Fery[1,3], and •Günter K. Auernhammer[1] — [1]Leibniz-Institut für Polymerforschung Dresden e.V., Dresden, Germany — [2]TU Dresden, Germany — [3]Chair of Physical Chemistry of Polymeric Materials,TU Dresden, Germany

The work of adhesion is a thermodynamic quantity that is frequently measured by atomic force microscopy (AFM). Its determination requires quasi-equilibrium measurements. Here, we address the question of to what extent atomic force microscopy qualifies for quasi-equilibrium measurements. To measure the work of adhesion, we combined soft colloidal probe AFM (SCP AFM) with reflection interference contrast microscopy (RICM). We extract the work of adhesion either from the pull-off force or from the contact radius to measure the adhesion behavior of poly(N-isopropylacrylamide) (PNIPAM) polymer brushes in the swollen and solvent-induced collapsed state. In the swollen state, the adhesion to the PNIPAM brush was fivefold larger and exhibited significant time dependencies when measured with SCP AFM. A strong rate dependence of the pull-off force method was indicative of a non-equilibrium process. In order to reliably determine the equilibrium work of adhesion, the contact radius method was found to be the better because it is not rate dependent. In summary, using optical measurements to determine the contact radius is beneficial when deriving the works of adhesion between colloidal probes and polymer brush surfaces.

CPP 31.4 Wed 17:15 H38

Chain conformation of thermo- and photo-responsive polymers — •Peiran Zhang[1], René Steinbrecher[2], Cy M. Jeffries[3], André Laschewsky[2], Peter Müller-Buschbaum[1], and Christine M. Papadakis[1] — [1]TUM School of Natural Sciences, Technical University of Munich, Garching, Germany — [2]Institute of Chemistry, University of Potsdam, Potsdam-Golm, Germany — [3]European Molecular Biology Laboratory, DESY, Hamburg, Germany

Endowing thermoresponsive polymers with additional photoresponsivity is of interest for applications such as drug delivery and soft robotics, owing to the non-invasive nature of these stimuli and the high temporal and local resolution of the photostimulus. The lower critical solution temperature (LCST) behavior in aqueous solution, characterized by a coil-to-globule transition at the cloud point (CP), can be finely tuned by incorporating photoswitches. Among these, azobenzene (AB) is the most widely used due to its pronounced trans-cis isomerization without side reactions. However, due to the weak change of dipole moment, its influence on the CP is only small. To enhance this photo effect, we used various amino acids as flexible linkers between the thermoresponsive backbone and the AB moiety. Dynamic light scattering reveals that a higher AB content leads to a larger shift of the CP, while small-angle X-ray scattering indicates that the amino acid linker reduces the influence of the inherent rigidity of the AB side groups, making the entire polymer chain more flexible. This approach allows adjusting the CP in wide ranges of temperature, thereby enhancing the range of applications.

CPP 31.5 Wed 17:30 H38

Acoustic levitation for dynamic studies of poly(N-isopropylacrylamide) microgels at the air-water interface — •Atieh Razavi[1], Regine von Klitzing[1], Romain Bordes[2], and Amin Rahimzadeh[1] — [1]Soft Matter at Interfaces, Institute for condensed Matter Physics, Technical University of Darmstadt, Hochschulstraße 8, 64289 Darmstadt, Germany — [2]Applied Surface Chemistry, Chalmers University of Technology, Gothenburg, Sweden

Acoustic levitation provides a unique platform for studying the surface dynamics of an air-water interface covered with poly(N-isopropylacrylamide) (PNIPAM) microgels. By utilizing standing acoustic waves, droplets are trapped at nodal positions, creating a contact-free environment to examine the effects of microgel stiffness, droplet evaporation, and amplitude modulation on droplet deformation. The research focuses on quantifying the aspect ratio (AR) of levitated droplets as a function of frequency of amplitude modulation, microgel concentration, and cross-linker content over time. In addition, we modulate the amplitude of the acoustic pressure at different frequencies (0.005 Hz0 to 05 Hz) to get insight into the interfacial rheology. With this new method, we can qualitatively characterize the interfacial behavior of microgels at the air-water interface such as the elastic modulus of the interface and adsorption kinetics[1].

CPP 31.6 Wed 17:45 H38

Structure and dynamics in injectable hydrogels from thermoresponsive triblock terpolymers — •Feifei Zheng[1], Pablo A. Álvarez Herrera[1], Wenqi Xu[1], Joachim Kohlbrecher[2], Sohila Abdelhafiz[3], Anna P. Constantinou[4], Theoni Georgiou[4], Aristide Dogariu[3], and Christine M. Papadakis[1] — [1]Technical University of Munich, TUM School of Natural Sciences, Garching, Germany — [2]Paul Scherrer Institut, Villigen, Switzerland — [3]CREOL, University of Central Florida, Orlando, USA — [4]Imperial College London, Department of Materials, London, UK

Block copolymers with blocks featuring lower critical solution temperature behaviour have attracted great interest for 3D bioprinting because they form a runny solution at room temperature, but a hydrogel at body temperature. The structure of the solution and the hydrogel as well as dynamic information and their changes upon gelation are essential for understanding. Here we address an ABC triblock terpolymer consisting of a hydrophilic A block, a hydrophobic B, and a thermoresponsive C block. The results from small-angle neutron scattering on 15 wt% polymer solutions indicate that ABC form spherical core-shell micelles, that transform into cylinders in the gel state and form a more compact structure upon heating. By the combination of dynamic light scattering (DLS) and spatiotemporal coherence-gated DLS measurements, the dynamic information of gelation process was retrieved, which reveals the thermoresponsive C block contracts and the micelles aggregate to from the gel upon heating.

CPP 32: Poster Session II

Time: Thursday 9:30–12:00 Location: P3

CPP 32.1 Thu 9:30 P3

Influence of Salt Addition on the Ionic Conductivity, Hydration Behavior, and Structure of Poly(sulfobetaine) Hydrogels for Electrolyte Applications — •Friederike Ganster[1], Marcell Wolf[2], Gilles Wittmann[2], Peter Müller-Buschbaum[1], and Lucas P. Kreuzer[2] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]Forschungs-Neutronenquelle Heinz Maier-Leibnitz (FRM II), 85748 Garching, Germany

Polyzwitterionic hydrogels are promising candidates for electrolytes in aqueous solid-state batteries, such as zinc-ion batteries (ZIBs), due to their ability to retain water molecules that facilitate ionic transport. The retained water acts as a lubricant, coordinating with the charged groups of the polyzwitterion and reducing interactions with mobile Zn^{2+} ions, thereby promoting the dissociation of ions and improving ion mobility. We systematically investigate how the addition of cosmotropic $ZnSO_4$ or rather chaotropic Zn(acetate) affects the ionic conductivity of poly(sulfobetaine)-based hydrogels. Our findings reveal that while ionic conductivity is generally increased, the extent and nature of this enhancement strongly depend on the specific salt type. We attribute this to unique and salt-type sensitive structural and hydration changes. X-ray scattering techniques resolve the electrolyte structure, and FTIR and Raman spectroscopy provide insights into the altered hydration behavior. Electrochemical impedance spectroscopy correlates these structural and hydration changes with variations in ionic conductivity and ion transport efficiency.

CPP 32.2 Thu 9:30 P3

Exploring pressure effects on the coil-globule transition of a pH sensitive polymer — •Ved Mahajan, Varun Mandalaparthy, and Nico F. A. van der Vegt — Technical University, Darmstadt

Macromolecules like polymers and proteins are essential to everyday life, with their structure and function influenced by environmental changes. The coil-globule transition is ubiquitous and is influenced by factors like hydrophobic interactions. External conditions, such as pressure, impact this transition differently in proteins and thermoresponsive polymers like PNiPAM[1].

This study investigates the effect of pressure on the coil-globule transition of a pH-sensitive hydrophobic polymer using constant-pH molecular dynamics. Our Results show that both pH and pressure significantly influence the transition. While pressure and charge both cause chain swelling, charge counteracts pressure-induced chain extension at high pressure. We observe distinct water structuring around positively and negatively charged sites with consequence to the polymer's pressure response. Additionally, we explore zwitterionic polymers under pressure, providing insights into biologically relevant secondary structures.

[1] Papadakis, C. M.; Niebuur, B.-J.; Schulte, A. Thermoresponsive Polymers under Pressure with a Focus on Poly(N-isopropylacrylamide) (PNIPAM). Langmuir 2024, 40 (1), 1* 20, DOI: 10.1021/acs.langmuir.3c02398

CPP 32.3 Thu 9:30 P3

Microscopic Insights into NaTFSI Based Thermoelectric Polymer Electrolyte by Raman Spectroscopy — •Julian-Steven Schilling[1] and Jens Pflaum[1,2] — [1]University of Wuerzburg, 97074 Würzburg — [2]Center for Applied Energy Research (CAE Bayern e.V.), 97074 Würzburg

The variety of chemical components, solution-based processability, and intrinsically low thermal conductivity have positioned polymers as leading materials in the field of organic thermoelectrics. Since materials facilitating ionic transport provide significantly higher thermoelectric voltages compared to electronic ones, we have analyzed the thermoelectric transport properties of a methacrylate-based solid polymer electrolyte. This study pursued our previous work [1] on this solution processed electrolyte by revealing new insights into the interaction of the conducting NaTFSI salt and the polymer backbone on microscopic length scales. By means of Raman spectroscopy, we use e.g. the S-C stretching modes and their salt concentration dependency to identify free TSFI Ions inside the polymer matrix which are responsible for the thermoelectric properties. In addition, we highlight the concentration dependent characteristics of the liquid versus solid electrolyte phase as well as the impact of the photoinitiator used for UV-curing on the electrolyte behaviour. [1] arxiv:2403.09340

CPP 32.4 Thu 9:30 P3

Ion Transport in Block Copolymer Electrolytes: Insights from Atomistic MD Simulations — •Jignesh Dhumal[1], Diddo Diddens[2], and Andreas Heuer[3] — [1]IGS BACCARA, Universität Münster — [2]Helmholtz Institute Münster (IEK-12), Forschungszentrum Jülich GmbH — [3]Institut für physikalische Chemie, Universität Münster

Electrolytes are essential in batteries to facilitate ion transport between electrodes. Block copolymer electrolytes, have emerged as a promising class due to their high ionic conductivity and enhanced mechanical strength. However, despite several experimental and computational studies demonstrating their significance, an atomistic-level understanding of ion transport in Lithium bis(trifluoromethanesulfonyl)imide (LiTFSI)-doped polystyrene-block-poly(ethylene oxide) (PS-b-PEO) block copolymers remain limited. In this study, we employ atomistic molecular dynamics simulations over extended timescales up to a microsecond examining the structural stability of the polymeric system and determine ion co-ordination within. We also quantify ion dynamics and transport properties in the PEO bulk region and the behavior at the PS/PEO interface, providing new insights into the mechanisms governing ion transport in this material.

CPP 32.5 Thu 9:30 P3

Advanced Synchrotron Characterization of NDI based acceptor thin films — •Subhalakshmi Suresh Kumar[1,2], Eva M. Herzig[1], and Christopher R. McNeill[2] — [1]Dynamik und Strukturbildung - Herzig Group, Universität Bayreuth, Universitätsstr. 30, 95447 Bayreuth, Germany — [2]McNeill Research Group, Department of Materials Science and Engineering, Monash University, Wellington Road, Clayton, Victoria, 3800 Australia

The transition to renewable energy has brought polymer solar cells (PSCs) to the forefront due to their lightweight, flexible, and environmentally friendly properties. The alignment of conjugated polymers within PSCs is critical for improving charge transport and overall device performance. This study aims to enhance the alignment of NDI-based acceptor thin films by employing fabrication methods such as blade coating and post-treatment annealing. Thin films were methodically prepared by varying coating speeds, substrate temperatures, and annealing conditions, followed by characterization using UV-Vis spectroscopy, Near-Edge X-ray Absorption Fine Structure (NEXAFS), and Grazing Incidence Wide-Angle X-ray Scattering (GIWAXS). The analyses demonstrated a significant enhancement in molecular alignment after annealing, particularly in PNDITBT films, which showed pronounced backbone alignment. These findings highlight the potential of synchrotron-based techniques in optimizing thin-film microstructures, paving the way for the production of highly efficient laminated organic solar cells with bilayer heterojunctions.

CPP 32.6 Thu 9:30 P3

Morphologies in Thin Films of Charged Pentablock Terpolymers During Solvent Vapor Annealing — •Yujia Gu[1], Constantinos Tsitsilianis[2], and Christine M. Papadakis[1] — [1]TU Munich, TUM School of Natural Sciences, Soft Matter Physics Group, Garching, Germany — [2]University of Patras, Department of Chemical Engineering, Patras, Greece

Thin films from block copolymers containing charged blocks offer enhanced possibilities for precise structural modulation. In our previous work on thin films from a symmetric ABCBA pentablock terpolymer with cationic B and C midblocks and hydrophobic end blocks A, the pH-dependent degree of ionization of the charged midblocks was found to significantly influence the thin-film morphology [1]. In this study, we explore the possibilities to tune the thin film structures during solvent vapour annealing (SVA) using the same ABCBA pentablock terpolymer. Spin-coated films are prepared at various pH values and are subjected to SVA using selective solvents. Depending on the solvent selectivity, SVA may alter the film structure, e.g. by promoting reorganization toward equilibrium morphologies. We utilize in-situ atomic force microscopy (AFM) and spectral reflectometry (SR) to monitor structural transitions during SVA. By systematically examining the effects of pH and solvent selectivity, this study aims to provide insights into controlling nanostructure morphology in charged pentablock copolymers, with implications for advanced thin-film design.

CPP 32.7 Thu 9:30 P3

Adaptive Air-Water Interfaces with Spiropyrans and Arylazopyrazoles — •Michael Hardt[1], Javier Carrascosa-Tejedor[2], Philipp Gutfreund[2], Richard A. Campbell[3], and Björn Braunschweig[1] — [1]University of Münster (Germany) — [2]Institut Laue-Langevin (France) — [3]University of Manchester (UK)

Interfaces that can be tuned in their properties by external stimuli such as light or temperature are of great interest to drive macroscopic properties of interface-controlled soft matter materials. Using molecular switches that respond to orthogonal triggers, the properties of fluid interfaces can be preconditioned, and a low level of adaptivity can be integrated, extending the possibilities of soft matter interfaces beyond responsive functions. We explore the adaptive behaviour of air-water interfaces decorated by spiropyran (SP) and arylazopyrazole (AAP) photo-responsive surfactants. When exposed to UV light, the SP surfactants become more surface active, while the AAP surfactants undergo E/Z photoisomerization, significantly reducing their surface activity. By adjusting the intensity and duration of the UV exposure, the interfacial properties can be shifted from a simple responsive state (upon weak UV irradiation) to a more complex conditioned response (upon intense UV irradiation), accompanied by a dramatic

alteration in interfacial chemistry. Vibrational sum-frequency generation (SFG) and neutron reflectometry suggest that prolonged UV exposure induces SP and AAP surfactant aggregation at the air-water interface, driving the conditioned response where thick SP layers up to 5 nm form in the presence of Z-AAP.

CPP 32.8 Thu 9:30 P3

Is Anomalous Underscreening Detectable via AFM? — •Esther Ohnesorge, Thomas Tilger, Michalis Tsintsaris, and Regine von Klitzing — Department of Physics, Technische Universität Darmstadt, Darmstadt, 64289, Germany

Since colloidal dispersions have a significant importance in our daily life, it is of special interest to gain a deeper understanding of which interfacial forces govern their stability and how this stability can be tailored.

For aqueous electrolyte solutions, the DLVO theory is a powerful and well-established framework to describe these interactions at low and intermediate ionic strengths. In contrast, the situation at high ionic strength is less understood and the main methods for direct force measurements give inconsistent results. While the surface force apparatus (SFA) provides clear evidence for a reentrant behavior of the double layer repulsion in the highly concentrated regime - termed anomalous underscreening - for a wide range of different electrolytes, similar observations weren't possible with the atomic force microscope (AFM) to date. The reason for this fundamental difference is still unclear.

To elucidate the underlying mechanism, we performed colloidal probe AFM (CP-AFM) measurements in aqueous salt solutions. We systematically varied the type of salt, the surface chemistry of the confining surfaces (silica vs mica) as well as their curvature to bridge the gap between CP-AFM and SFA.

CPP 32.9 Thu 9:30 P3

Dynamic Wetting of Adaptive Polyelectrolyte Substrates: A multiscale approach — •Mona Meltschoch, Tünde Benedek, and Regine von Klitzing — Soft Matter at Interfaces, Institute for Condensed Matter Physics, TU Darmstadt, Hochschulstraße 8, D-64289 Darmstadt, Germany

Wetting phenomena are of great importance across various scientific disciplines and the wettability dynamics of adaptive substrates, such as polyelectrolyte (PE) multilayers (PEM), have gained significant attention. An interesting property of PE substrates is their propensity to swell in a liquid environment. However, complexities like the disparity between time and length scales make experimental investigations quite challenging. We prepared PE substrates by the layer-by-layer method, with a focus on their wettability at the nanoscale. We used atomic force microscopy (AFM) as the main characterisation technique. An optical contact angle (CA) tensiometry method is used for macroscopic measurements, layer thickness is determined by ellipsometry and X-ray reflectometry (XRR). Previous results show a decrease in water CA on silicon wafers coated with polystyrene sulfonate (PSS) as outermost layer in water-saturated atmosphere. To investigate the dependence on thickness, chain length and charge of the outer layer, different PEMs were fabricated and characterised. Here, the substrates were investigated with an AFM and showed to exhibit smooth surfaces while linearly increasing in thickness. The decrease in water CA is more pronounced with an increasing thickness and differs if PSS or PAH are outermost layer.

CPP 32.10 Thu 9:30 P3

Molecular Imprinting of PEDOT in Polyelectrolyte Multilayers — •Martin Hunger, Muhammad Khurram, Sven Neuber, and Christiane A. Helm — martin.hunger@uni-greifswald.de

Electrically conductive films of Poly(3,4-ethylenedioxythiophene): poly(styrenesulfonic acid) (PEDOT:PSS) are formed by sequential adsorption of oppositely charged macromolecules. PEDOT:PSS serves as polyanion, and PDADMA is the polycation. When the top layer is PEDOT:PSS, the electrical conductivity is large (8 kS/m), when the top layer is PDADMA, the electrical conductivity is three orders of magnitude lower. In addition, vis-IR absorption spectroscopy shows that the PEDOT density in PEDOT:PSS-terminated films is high, while it is low in PDADMA-terminated films. When a PDADMA layer is adsorbed, turbidity measurements of the adsorption solution show that PEDOT diffuses out of the film. This can be explained entropically: a few PDADMA molecules with many positive charges replace many small molecules with few positive charges. Furthermore, exposure to solutions with divalent or trivalent cations reduce the conductivity of PEDOT-PSS-terminated films. We discuss whether PSS returns to previous binding sites upon adsorption of PEDOT:PSS, a behaviour that is typical for molecular imprinting.

CPP 32.11 Thu 9:30 P3

Extension of initiated chemical vapor deposition to new polymers via silylation — •Lynn Schwäke[1], Artjom Businski[2], Thomas Strunskus[1], Franz Faupel[1], Rainer Herges[2], and Stefan Schröder[1] — [1]Chair for Multicomponent Materials, Department of Materials Science, Kiel University, 24143 Kiel, Germany — [2]Otto Diels Institute of Organic Chemistry, Kiel University, 24143 Kiel, Germany

Initiated Chemical Vapor Deposition (iCVD) is a powerful technique for the solvent-free and conformal deposition of polymer thin films on sensitive substrates and complex geometries. The utilisation of a variety of monomers enables the fabrication of films with specifically tailored properties and functionalities. However, the evaporation of monomers is a prerequisite for iCVD processes. Consequently, this limits its applicability, for example, in the synthesis of hydrogels. The hydrophilic nature of potential monomers and the presence of other strong intermolecular interactions result in low vapor pressures, which in turn hinders their use in iCVD. A well-known strategy, e.g. in the context of drug detection by gas chromatography-mass spectrometry (GC-MS), is silylation, which is used to weaken inter-molecular forces. Here silylation was employed to enhance the vapor pressure of hydrophilic 2-hydroxyethyl methacrylate (HEMA), an important monomer in the synthesis of hydrogels. Consequently, silylation is proposed as a general route for the introduction of low vapor pressure monomers into iCVD systems, which would lead to a significant expansion of the available monomer toolbox.

CPP 32.12 Thu 9:30 P3

In-Situ Neutron and Raman spectroscopy on polymer thin films at varying humidity — •Marcell Wolf[1], Lucas Kreuzer[1], Friederike Ganster[2], Christopher Garvey[1], and Peter Müller-Buschbaum[2] — [1]Heinz Maier-Leibnitz Zentrum (MLZ), Technische Universität München, Lichtenbergstraße 1, 85748 Garching, Germany — [2]Lehrstuhl für Funktionelle Materialien, Physik Department, Technische Universität München, James-Frank-Straße 1, 85748 Garching, Germany

Here we present a new sample environment for in-situ neutron and Raman spectroscopy on polymer thin films at varying humidities and temperatures. The combination of in-situ Raman and neutron spectroscopy shows the advantage that no difference within the sample composition, temperatures and humidity variations at the sample can be neglected, compared to separated single measurements. The structural changes can be directly related to the dynamic changes while varying the environment. We plan to describe our setup and present the first results of this new sample environment measured at the neutron time-of-flight spectrometer FOCUS at the PSI, Switzerland. For our knowledge this is the first time, that both spectroscopy techniques in comibination with varying humidity are applied at in-situ measurements. The new sample environment will be available to all users at time-of-flight spectrometer TOFTOF at the MLZ, as soon as the reactor restarts. Different variations of the sample cell, especially designed for different neutron experiments are available at other neutron instruments at the MLZ.

CPP 32.13 Thu 9:30 P3

Second order nonlinear optical properties of hexagonal boron nitride nanosheets h-BNNs — •Dina Atwa Khalil and G. Omar — Laser Institute for Research and Applications, Beni-Suef University, Egypt

The superior optical characteristics of hexagonal boron nitride nanosheets (h-BNNs) have been drawing more attention in the past few years. However, scientists have not yet thoroughly studied the nonlinear optical (NLO) properties of such innovative material. Here, NLO characteristics of h-BNNs are investigated for the first time utilizing the Z-scan approach that had been irradiated with 100 fs laser pulses using different excitation wavelengths that started from 740 to 820 nm at a constant incident power of 1 W. The studied 2D nanomaterial was prepared by a straightforward and effective technique for producing (h-BNNs), which is mechanical exfoliation. Their morphology and crystal structure have been investigated using different techniques, including UV-vis spectroscopy, scanning electron microscopy (SEM), transmission electron microscopy (TEM), and Raman spectroscopy. The measurements of nonlinearity show that by increasing the excitation wavelength, the nonlinear absorption coefficient decreases in a linear trend. The as prepared h-BNNs performed fascinating optical limiting with excellent two-photon absorption. This innovative optical nanomaterial makes them promise for sensitive optical components and laser protection applications.

CPP 32.14 Thu 9:30 P3

Highly oxidized Graphene Oxide as a Drug Delivery platform: Functional Group Interactions and Controlled Release Mechanisms — •Codrut Costinas[1], Liviu Cosmin Cotet[2], Monica Baia[1], Klara Magyari[3], and Lucian Baia[1] — [1]Faculty of Physics, Babes-Bolyai University, Cluj-Napoca, Romania — [2]Faculty of Chemistry and Chemical Engineering, Babes-Bolyai University, Cluj-Napoca, Romania — [3]Interdisciplinary Research Institute on Bio-Nano-Sciences, Babes-Bolyai University, Cluj-Napoca, Romania

Graphene oxide (GO) presents a promising platform for drug delivery, given its versatile surface chemistry and high surface area that enable effective drug loading and controlled release. Our study investigates the capabilities of an in-house produced, highly oxidized GO as a carrier by examining its interactions with two model compounds: methylene blue and methyl orange, as well as two drugs: doxorubicin and gentamicin sulfate. Through spectroscopic investigations (UV-VIS, FT-IR, and Raman), potentiometric titrations, and drug loading and release experiments we successfully identify the functional groups and bond types involved in drug-GO interactions in different pH media, most notably hydrogen bonding, electrostatic interactions, and π-π stacking. Furthermore, by taking into consideration the pKa values between GO acidic groups and the drugs ion-

izable groups, we can estimate both loading and pH-responsive release behavior in simulated physiological pH conditions. These findings highlight the flexibility of GO as a drug carrier, supporting its application in the development of customizable drug delivery systems for various therapeutic needs.

CPP 32.15 Thu 9:30 P3

Electronic Properties of a Naphthalene Diimide (NDI)-based Covalent Organic Framework (COF) — •Johann Olbrich[1], Laura Fuchs[1], Bibhuti Bhusan Rath[2], Bettina V. Lotsch[2], and Frank Ortmann[1] — [1]TUM School of Natural Sciences, Technische Universität München, Germany — [2]Nanochemistry Department, Max-Planck-Institute for Solid State Research, Stuttgart, Germany

Covalent organic frameworks (COFs) are a versatile class of porous polymers that exhibit exceptional tunability and electronic properties, making them attractive for various applications including water splitting [1], solar batteries [2] or other optoelectronic applications. We investigated the electronic properties of a naphthalene diimide (NDI)-based COF, which demonstrates robust photoinduced charge separation in aqueous environments, by using density functional theory (DFT) calculations. We provide theoretical insights into the stability of the charges in NDI-based COFs under hydrated conditions, highlighting their potential for advanced electronic and material applications. For this, we determined the formation of a stable radical on the NDI unit through the addition of a hydrogen atom. Further modeling of interactions of small water clusters with the COF indicated the emergence of a radical anion on the NDI, accompanied by the stabilization of H+ in an H2O cluster.

[2] Y. Wang, Y. T. Chan, T. Oshima, V. Duppel, B. V. Lotsch, J. Am. Chem. Soc. 2024, 146(37), 25467-25476.

CPP 32.16 Thu 9:30 P3

Lithium Distribution Heterogeneity in the Graphite Anode of 21700-Type Cylindrical Li-Ion Cells during Aging — Dominik Petz[1,2], •Peter Müller-Buschbaum[2], and Anatoliy Senyshyn[1] — [1]Heinz Maier-Leibnitz-Zentrum (MLZ), 85748 Garching, Germany — [2]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany

Electrochemical cycling in lithium-ion batteries involves an active exchange of lithium ions and electrons between the cathode and anode materials. In addition to material properties, this exchange is influenced by cell parameters such as electrode dimensions and geometry, current density, temperature, pressure, reaction rate, and others. These parameters are generally neither uniformly distributed nor static, thereby contributing to the stabilization of heterogeneous states in Li-ion batteries, typically seen in the lithium concentration distribution across the electrodes.

Previous studies have shown that, with cell aging, the distribution of lithium ions in the graphite anode of 18650-type lithium-ion batteries shifts over time. In this study, the heterogeneity of a fresh and an aged 21700-type Li-ion battery was examined using multiple diffraction techniques with both synchrotron and neutron radiation. Laboratory-based techniques such as SEM and incremental capacity analysis were also employed. The findings revealed a notable lithium distribution after cell aging, prompting the question of how cell format impacts cell aging behavior.

CPP 32.17 Thu 9:30 P3

Steering sulfur reduction kinetics of lithium-sulfur batteries by interfacial microenvironment modulation — •Cheng Yuan[1,2], Liang Zhang[2], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]Institute of Functional Nano & Soft Materials (FUNSOM), Soochow University, Suzhou 215123, China

Catalytic conversion of lithium polysulfides (LiPSs) is considered as an effective avenue to suppress the shuttle effect of lithium-sulfur (Li-S) batteries, for which the interfacial microenvironment constructed by the interaction between electrocatalysts and LiPSs plays a pivotal role in modulating the sulfur reduction kinetics. However, most of previous reports mainly focused on modulating the band structure of electrocatalysts or LiPSs alone to enhance the catalytic activity rather than considering the interfacial microenvironment as a whole. Herein, we propose a binary descriptor composed of the energy difference between d-band of electrocatalysts and p-band of LiPSs ($\Delta\epsilon$M-S) and the antibonding filling degree (ϵABF), which capture the energy band contributions from both electrocatalysts and LiPSs, to reveal the influence of interfacial microenvironment on sulfur reduction kinetics. Among different designed electrocatalysts, NiO presents a moderate LiPSs anchoring capacity and rapid electron transfer kinetics owing to the optimal $\Delta\epsilon$M-S and decreased ϵABF after interacting with LiPSs, which lead to a robust interfacial microenvironment and thus guarantee a continuous catalytic conversion of LiPSs in the long-term cycling.

CPP 32.18 Thu 9:30 P3

Polymer of intrinsic microporosity as the silicon-based anode electrode additive — •Ming Yang[1], Ruoxuan Qi[1], Ya-Jun Cheng[2], Yonggao Xia[2], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]Ningbo Institute of Materials Technology & Engineering, Chinese Academy of Sciences, 1219 Zhongguan West Rd, Ningbo, 315201, Zhejiang Province, P. R. China

Silicon-based anodes are promising alternatives due to their high theoretical specific capacity and low voltage platform to traditional graphite anodes for high-energy-density lithium-ion batteries (LIBs). However, their performance is significantly hindered by silicon's substantial volume expansion during cycling, which often leads to electrode degradation. Therefore, it is crucial to design a robust electrode structure and establish a stable solid electrolyte interface (SEI) to address these challenges. Herein, an intrinsic microporosity polymer PIM-COOH is prepared, which has good compatibility with the polyacrylic acid (PAA) binder as a silicon-based anode additive. The microporous structure of the PIM-COOH molecule can effectively improve the transport of lithium ions and improve the electrochemical kinetics. In addition, due to the inherent microporous properties of PIM-COOH additives, the affinity between the electrode and the electrolyte is enhanced. As a result, good lithium-ion transport and mechanical integrity are maintained, resulting in improved long-term stability and high-rate performance.

CPP 32.19 Thu 9:30 P3

In-situ interface film forming on the high-voltage LiCoO2 cathode by a tiny amount of nanoporous polymer additives — •Ruoxuan Qi[1], Ming Yang[1], Tianle Zheng[1], Xingchen Liu[2], Yonggao Xia[2], Ya-Jun Cheng[2,3], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]NIMTE, CAS, Zhejiang Province, P. R. China — [3]College of Renewable Energy, Hohai University, Jiangsu Province, P. R. China

The LiCoO2 (LCO) cathode has been foreseen for extensive commercial applications owing to its high specific capacity and stability. Therefore, there has been considerable interest in further enhancing its specific capacity by increasing the charging voltage. However, single-crystal LCO suffers from a significant capacity degradation when charged to 4.5 V due to the irreversible phase transition and unstable structure. Herein, an ultra-small amount (0.5 %wt in the electrode) of multi-functional PIM-1 (a polymer with intrinsic microporosity) additive is utilized to prepare a kind of binder-free electrode. PIM-1 modulates the solvation structure of LiPF6 due to its unique structure, which helps to form a stable, robust, and inorganic-rich CEI film on the surface of LCO at a high voltage of 4.5 V. This reduces the irreversible phase transition of LCO, thereby enhancing the cyclic stability and improving the rate performance, providing new perspectives for the electrodes fabrication and improving LCO-based high-energy-density cathodes.

CPP 32.20 Thu 9:30 P3

Ionic transport race between lithium and sodium in non-aqueous electrolytes — •Chinwendu Nancy Anabaraonye[1,2], Diddo Diddens[3], and Andreas Heuer[1,3] — [1]Institute of Physical Chemistry, University of Münster, Corrensstraße 28/30, 48149 Münster, Germany — [2]International Graduate School for Battery Chemistry, Characterization, Analysis, Recycling and Application (BACCARA), University of Münster, Corrensstr. 40, 48149 Münster, Germany — [3]Helmholtz Institute Mnster (IEK-12),Forschungszentrum Jülich GmbH, 48149 Münster,Germany;

The need to meet the storage requirements of energy systems safely and efficiently has led to research into electrolytes other than the commonly used lithium-ion batteries. While the lithium-ion battery is the clear market leader, there is increasing interest in sodium-ion batteries, which are cheaper and more abundant. The present work is a comparative study of the transport properties of lithium hexafluorophosphate ($LiPF_6$) and sodium hexafluorophosphate ($NaPF_6$) in carbonate electrolytes consisting of ethylene carbonate (EC) and ethyl methyl carbonate (EMC). Using molecular dynamics simulations, we analyse the influence of EC ratio and salt concentrations on the solvation structure and how this affects the ionic transport properties such as diffusivity and ionic conductivity of the system. Our results show higher conductivity and diffusivity of Na compared to Li for the analysed systems. Optimal ionic conductivity for Na was achieved above 1 M concentration, in contrast to Li. Overall, we observed differences in the coordination and mobilities of lithium and sodium cations.

CPP 32.21 Thu 9:30 P3

3D Electrodeposition of Porous Cu for long-cycling Lithium-Metal Batteries — •Lyuyang Cheng[1], Zhuijun Xu[1], Tianle Zheng[1], Yingying Yan[1], Fabian Apfelbeck[1], Yuxin Liang[1], Yajun Cheng[2], and Peter Müller-buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]Hohai University, 213022 Changzhou, China

Lithium (Li) metal is the ultimate anode for rechargeable batteries. Its high specific capacity (3860) and low voltage (3.04 V vs standard hydrogen electrode) warrant optimal cell energy density. However, these anodes rely on repeated

plating and stripping of Li, which leads to consumption of Li inventory and the growth of dendrites that can lead to self-discharge and safety issues. To address these issues and problems related to the volume change of these anodes, a number of different porous conductive scaffolds have been reported to create high surface area electrodes on which Li can be plated reliably. While impressive results have been reported in literature, current processes typically rely on either expensive or poorly scalable techniques. Herein, we report a scalable fabrication method to create porous Cu anodes using a one-step electrodeposition process. The areal loading, pore structure, and electrode thickness can be tuned by changing the electrodeposition parameters, and we show the in-situ nano WAXS images with lithium growth, which can help to explain the mechanism. We also provide a feasible method to fabricate the porous Cu cathodes with different electrodeposition solution concentrations.

CPP 32.22 Thu 9:30 P3

Operando study on structure-activity relationship between electrolyte components and electrochemical performance for all-solid-state lithium batteries — •Yingying Yan[1], Liangzhen Liu[2], Yuxin Liang[1], Fabian A.C. Apfelbeck[1], Guangjiu Pan[1], Lyuyang Cheng[1], Roland A. Fischer[2], and Peter Müller-buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]TUM School of Natural Sciences, Chair of Inorganic and Metal-Organic Chemistry, 85748 Garching, Germany

All-solid-state lithium-ion batteries (ASSLIBs) are the most promising power sources for high-safety and high-energy-density energy storage devices. However, the practical application of ASSLBs has been hindered by poor interfacial stability and inferior ionic conductivity. Herein, a layered-double-hydroxide (LDH) reinforced poly(ethylene oxide) (PEO) composite polymer electrolyte is designed, which delivers a wide electrochemical window, high ionic conductivity, and superior Li+ transference number with a low LDH loading. The Li symmetric cells show ultra-long cycling stability at 0.1 mAh/cm2. The all-solid-state Li//LiFePO4 exhibits an excellent cycling stability with a high capacity retention of 90.1% at 0.1 C over 250 cycles. Furthermore, the structure-activity relationship between the component structure of the electrolyte and the electrochemical performance was elucidated by operando nanofocus wide-angle X-ray scattering (nWAXS).

CPP 32.23 Thu 9:30 P3

Organic polyaniline-based cathode materials — •Meriem N. Boudjenane[1], Friederike Ganster[2], Sebastian Mühlbauer[1], and Lucas P. Kreuzer[1] — [1]Forschungs-Neutronenquelle Heinz Maier-Leibnitz (FRM II), 85748 Garching, Germany — [2]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany

Organic cathode materials feature tuneable structures, abundant active sites, and compatibility with multivalent charge carriers, thereby allowing to overcome challenges typically faced in inorganic cathode systems such as structural instability, and environmental hazards. We focus on the development of polyaniline (PANI) based cathodes. PANI, a conductive polymer, has demonstrated high capacity, excellent rate capability and fast ionic diffusion. Cellulose-based materials such as carboxymethyl cellulose (CMC) are used as binders and enhance the overall stability and electrochemical performance. By tuning parameters such as material composition, ionic strength, water content, and temperature, we elucidate how the conductivity and electrochemical stability of the PANI-based cathode can be optimized. Advanced techniques like X-ray diffraction, scanning and transmission electron microscopy, and electrochemical analysis provide deep insights into the structure-function relationship of the cathode materials while operando Raman spectroscopy will give insights into the charge/discharge mechanism and respective redox reactions, guiding the development of high-performance organic cathodes.

CPP 32.24 Thu 9:30 P3

Consistent Electrostatics in Bottom-Up Modeling of Electrode-Fluid Systems: Determining the Capacity from Ab-Initio to Continuum Models — •Philipp Stärk[1,2], Henrik Stooss[3], Philip Loche[4], and Alexander Schlaich[3] — [1]Stuttgart Center for Simulation Science (SC SimTech), University of Stuttgart, 70569 Stuttgart, Germany — [2]Institute for Computational Physics, University of Stuttgart, 70569 — [3]Institute for Atomistic Modeling of Materials in Aqueous Media, Hamburg University of Technology, 1073 Hamburg, Germany — [4]Laboratory of Computational Science and Modeling, IMX, Ecole Polytechnique Federale de Lausanne,1015 Lausanne, Switzerland

Detailed understanding of electro-catalysis, batteries and supercapacitors, often requires modeling these systems on an atomistic scale. However, at this length scale and level of detail, most continuum assumptions about electrodes are clearly no longer valid. This is problematic for physical models and methods of analysis which rely on concepts from continuum electrostatics. We demonstrate in this work that a realistic Constant Potential Method model based on DFT data for gold can still consistently be described by concepts of continuum electrostatics, provided the electrostatic boundary condition is modeled correctly. Furthermore, we apply this description to determine the dielectric behavior of water in nanoporous gold. We systematically investigate the difference between conducting and inert confinement on the static dielectric response.

CPP 32.25 Thu 9:30 P3

Evaluating the Impact of Electrode Defects on PEMFC Performance and Durability — •Faezeh Mehdizadeh siahroudi[1], Sebastian Prass[1], and Andreas Bett[2] — [1]Division Hydrogen Technologies Department Fuel Cell Fraunhofer Institute for Solar Energy Systems ISE 79110 Freiburg, Germany — [2]Fraunhofer-Institut für Solare Energiesysteme ISE

According to previous research, imperfect membrane electrode assembly (MEA) manufacturing processes can lead to catalyst layer and membrane defects. Therefore, we have decided to investigate the impact of missing areas in cathode and anode electrodes on the performance and durability of polymer electrolyte fuel cell (PEMFC). Missing areas with varied sizes and configurations are used to determine a threshold at which a missing area can be considered as a crucial defect that degrades MEA components. In our work, several in-situ electrochemical techniques were used, including polarization curves, linear sweep voltammetry (LSV), cyclic voltammetry (CV), and electrochemical impedance spectroscopy (EIS) experiments. The structural changes in the electrodes and the membrane are visualized through SEM cross-sectional imaging.

CPP 32.26 Thu 9:30 P3

Hybrid electrolyte LLZO/PEO-systems: Impact of salt concentration and temperature on the structural properties close to the interface — •Laura Hölzer[1], Melania Kozdra[2], Daniel Brandell[2], and Andreas Heuer[1] — [1]Institut für physikalische Chemie, Universität Münster, Corrensstr. 28-30, 48149 Münster, Germany — [2]Department of Chemistry - Ångström Laboratory, Uppsala University, Box 538, 75121 Uppsala, Sweden

Composite electrolytes are an opportunity for creating new and improved materials as ideally they combine the advantages of different types of electrolytes. One example for this being the LLZO/PEO-system. Insights into the properties and dynamics at and around the interface can be gained by looking at the system with atomistic simulations. Previously it could be seen that over the course of a simulation there is a movement of the Li^+ ions into the crystal.[1] Here, we analyse under which conditions equilibration is possible on the simulation time scales. Molecular dynamic simulations are performed. Three different concentrations and temperatures between 400K and 700K are studied. One could see the formation of a well-defined structure around the interface, which includes an additional layer of Li ions on both sides of the crystal that in equilibrium at 700K is independent of concentration, indicating structure formation via strong enthalpic driving forces. Furthermore, interesting insight into the reorganization of the polymer and the salt due to the presence of the LLZO can be gained.

[1] Kozdra, M.; Brandell, D.; Araujo, C. M. G.; Mace, A. Physical Chemistry Chemical Physics 2024, 26, 6216-6227.

CPP 32.27 Thu 9:30 P3

Structural investigation of lithium deficient metal chlorides solid electrolytes — •Francesco Falsina — TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany

The strong demand for new and emerging sustainable energy solutions to address climate change and the requirements for increased high energy and power density have positioned solid-state batteries as a key research area. Lithium metal chlorides (LiMCl) are considered as promising candidates for next-generation batteries due to their high ionic conductivity, thermodynamic stability, and favourable mechanical properties. In this study, we investigated Li(3-3x) M(1+x)Cl6 compounds with M = Dy, Ho, Tb, and Tm using X-ray diffraction (XRD), confirming that all samples crystallize in the space group P3m1, though exhibiting partial crystallinity and high disorder without post-synthesis annealing. The effect of lithium deficiency was explored on the ionic conductivity employing Electrochemical Impedance Spectroscopy (EIS), offering further insights into their potential for solid-state battery applications.

CPP 32.28 Thu 9:30 P3

Morphology and intracrystalline dynamics of semicrystalline polyester Poly(3-hydroxy-2,2-dimethylbutyrate) — •Johann C. Holz[1], Arman Edalat[1], Kay Saalwächter[1], Thomas Thurn-Albrecht[1], and Eugene Chen[2] — [1]Martin-Luther-University, Halle, GER — [2]Colorado State University, Fort Collins, USA

Semicrystalline polymers are classified as crystal-fixed (non-diffusive) or crystal-mobile (diffusive) based on polymer chain mobility within the crystal. Crystal-fixed polymers exhibit lower crystallinity, thinner lamellae ($d_a > d_c$), and less variation in thickness ($\sigma_a > \sigma_c$). Finding a biodegradable alternative for crystal-mobile polyethylene (PE) remains a priority for sustainable research. Poly(3-hydroxybutyrate) (P3HB), a biodegradable polyester, was recently found to be crystal-mobile, but suffers from poor mechanical properties.

We here study Poly(3-hydroxy-2,2-dimethylbutyrate) ($P3H(Me)_2B$), a structurally similar polyester with methyl-groups substituted for the two α-hydrogens, to improve mechanical toughness, thermal stability, and recyclability. Our analysis of $P3H(Me)_2B$ by Small-Angle X-ray Scattering (SAXS) re-

vealed that it crystallizes in a crystal-fixed mode. This finding contrasts with the crystal-mobile behavior observed in P3HB. Wide-Angle X-ray Scattering (WAXS) corroborated the crystal structure that has already been described in literature, while also revealing previously undetected diffraction peaks. Furthermore, Nuclear Magnetic Resonance (NMR) spectroscopy enabled precise quantification of the polymer's crystallinity, facilitating accurate determination of the melting enthalpy H_f for a 100% crystalline sample.

CPP 32.29 Thu 9:30 P3

Optical properties of biosynthesized nanoscaled Eu_2O_3 for red luminescence and potential antidiabetic applications — •Hamza Mohamed — iThemba LABS, Cape Town, South Africa

This contribution reports on the optical properties of biosynthesised Eu_2O_3 nanoparticles bioengineered for the first time by a green and cost effective method using aqueous fruit extracts of Hyphaene thebaica as an effective chelating and capping agent. The morphological, structural, and optical properties of the samples annealed at 500˚C were confirmed by using a high-resolution transmission electron microscope (HR-TEM), x-ray diffrac tion analysis (XRD), UV-Vis spectrocopy, and photoluminescence spectrometer. The XRD results confirmed the characteristic body-centered cubic (bcc) structure of Eu_2O_3 nanoparticles with an average size of 20 nm. HRTEM revealed square type morphology with an average size of ≈6 nm. Electron dispersion energy dispersive x-ray spectroscopy spectrum confirmed the elemental single phase nature of pure Eu_2O_3. Furthuremore, the Fourier transformed infrared spectroscopy revealed the intrinsic characteristic peaks of Eu-O bond stretching vibrations. UV-Vis reflectance proved that Eu_2O_3 absorbs in a wide range of the solar spectrum from the VUV-UV region with a bandgap of 5.1 eV. The luminescence properties of such cubic structures were characterized by an intense red emission centered at 614 nm. It was observed that the biosynthesized Eu_2O_3 nanoparticles exhibit an efficient red-luminescence and hence a potential material as red phosphor.

CPP 32.30 Thu 9:30 P3

Green synthesis of nanocellulose for archaeological wood preservation: a case study of cheops' second solar boat — •Ihab Abdelbaki — Cairo University, Egypt

The preservation of ancient wooden artifacts presents significant challenges due to environmental degradation and biological deterioration. This study addresses these challenges through the development of an eco-friendly nanocellulose-based preservation method, specifically targeting the deterioration observed in the second solar boat of king khufu (cheops), one of egypt's most significant archaeological wooden artifacts. Nanocellulose was synthesized via a green approach using controlled acid hydrolysis of agricultural waste cellulose, followed by mechanical ultrasonication. the degradation assessment of the second solar boat revealed severe biological infestation, structural weakening, and dimensional instability, particularly in areas exposed to fluctuating humidity levels. The prepared nanocellulose, characterized by TEM, FTIR and XRD, exhibited crystallite sizes of 20-30 nm and a crystallinity index of 82%. when applied to degraded wood samples from similar archaeological contexts, the nanocellulose treatment demonstrated significant improvements in mechanical strength (40% increase), dimensional stability (65% reduction in swelling), and biological resistance. Importantly, the treatment maintained the artifact's aesthetic and historical integrity while providing a sustainable, reversible preservation solution. this study presents a promising green approach for the conservation of ancient wooden artifacts, offering implications for cultural heritage preservation worldwide.

CPP 32.31 Thu 9:30 P3

Investigation of photoelectrochemically induced degradation of III-V nanowires — •Chris Y. Bohlemann, Juliane Koch, David Ostheimer, Peter Kleinschmidt, and Thomas Hannappel — Technische Universität Ilmenau, Faculty of Mathematics and Natural Sciences, Fundamentals of Energy Materials, Gustav-Kirchhoff-Str. 5, 98693 Ilmenau

Over the past two decades, nanoscale structures like III-V nanowires (NWs) have become versatile components in electronic and photonic applications [1]. The large surface-to-volume ratio of NWs enhances reaction efficiency by providing more active sites for light-driven processes. To explore NWs' potential in photoelectrochemical solar energy conversion, we investigated their optoelectronic behavior. First, GaAs NWs were grown via Vapor-Liquid-Solid growth mode using Metal-Organic Vapor Phase Epitaxy. We performed Linear Sweep Voltammetry measurements where the III-V sample was brought into direct contact with the electrolyte. However, a major challenge is the degradation in performance due to the limited durability of NWs in electrolytes compared to planar surfaces. To evaluate the corrosion of NWs in electrolytes, we analyzed the NW structures before and after two hours of stability testing measurements by Scanning Electron Microscopy. Our results indicate that under continuous illumination no significant degradation besides surface roughening is observed while samples under chopped illumination, are nearly completely etched, with few or no NWs remaining intact.

CPP 32.32 Thu 9:30 P3

Fabrication of Gas Sensors with High Sensitivity to NO_2 Based on Photoactivation of Porous Carbon Materials — •Laura Pascual[1], Berta Pérez-Román[2], Jesús López-Sánchez[2], M. Alejandra Mazo[2], Álvaro Peña[3], David G. Calatayud[4], Daniel Matatagui[3], and Fernando Rubio-Marcos[2] — [1]Instituto de Catálisis y Petroleoquímica (ICP-CSIC), Madrid, España — [2]Instituto de Cerámica y Vidrio (ICV-CSIC), Madrid, España — [3]Instituto de Magnetismo Aplicado, (IMA-UCM-ADIF), Madrid, España — [4]Departamento de Química Inorgánica, Universidad Autónoma de Madrid (UAM), Madrid, España

The rise in gas emissions harms public health, with nitrogen dioxide (NO_2) being particularly dangerous due to its impact on the lungs and respiratory conditions. This emphasizes the need for highly selective gas sensors capable of detecting concentrations below 1 ppm in real time, while being miniaturised and operable at room temperature (RT).

Carbon-derived materials from carbides (CDC) are created through high-temperature chlorination, achieving surface areas over 2000 m^2/g. These materials feature hierarchical porosity (micro- to mesopores) and abundant active sites that support redox reactions for NO_2 detection. Incorporating heteroatoms improves charge transfer and electron-hole trap formation. The results show exceptional selectivity and sensitivity to NO_2, with detection below 1 ppm and room temperature operation using UV excitation (275 nm).

CPP 32.33 Thu 9:30 P3

Bimetallic Core-Shell-Nanoparticles for enhanced Raman spectroscopy — •Moritz Willems[1], Steffi Stumpf[1,2], and Stephanie Hoeppener[1,2] — [1]Jena Center for Soft Matter (JCSM) — [2]Institute of Organic and Macromolecular Chemistry (IOMC)

Bimetallic Core-Shell-Nanoparticles have emerged as a versatile tool for advanced sensing applications, particularly in surface-enhanced Raman spectroscopy and tip-enhanced Raman spectroscopy. The combination of two metals in a Core-Shell configuration enhances the plasmonic properties and allows for extended plasmonic bandwidths, as well as superior electromagnetic field amplification in comparison to the monometallic nanoparticles. Silver nanoparticles have been demonstrated to offer effective enhancements for Raman spectroscopy. However, they do present certain challenges, including a narrow spectral range, poor chemical stability, and a relatively short lifespan. The coating of silver nanoparticles with a thin gold shell promises precise control over localised surface plasmon resonance, expanding spectral ranges for Raman spectroscopy measurements, especially between the peaks of gold and silver, by changing the relative thickness of the shell. Furthermore, the gold coating allows for measurements in water, while also providing a prolonged lifespan. The synthesis of these nanoparticles utilizes chemical reduction by microwave irradiation, providing fast, energy efficient and uniform heating. Various methods have been tested to overcome the problems of synthesising a gold shell on silver, and detailed transmission electron microscopy and UV-Vis spectroscopy analysis complement the Raman spectroscopy results.

CPP 32.34 Thu 9:30 P3

Classical simulation studies of dissociation equilibria in nanoconfined systems — •Kira Fischer, Henrik Stooss, and Alexander Schlaich — Institute for Atomistic Modeling of Materials in Aqueous Media, Hamburg University of Technology, Germany

Dissociation equilibria in nanoconfinement are relevant to the chemistry of nanostructured catalysts, aerosols and protein pockets. Experiments indicate that nanoconfinement affects the dissociation of water, however to date a comprehensive understanding is still lacking. Here, we investigate dissociation equilibria in nanoconfinement from a classically. Using molecular dynamics and free energy methods we study hydrochloric acid in diamond nanoconfinement in the dilute limit at ambient conditions.

Our studies reveal a depletion of hydrochloric acid in nanoconfinement, with a negative excess by up to a factor of 100. The negative excess is attributed to the balance between hydronium adsorption and chloride depletion at the interface. Additionally, we propose that hydronium is adsorbed to the diamond interface by dipole orientation within a local electric field. Notably, in the smallest pore, the pK_a is increased by 1. We also introduce useful concepts for analysing dissociation equilibria in confinement. This includes the chemical potential in confinement, which enables quantification of ionic excess in the dilute limit. Furthermore, we demonstrate how to derive the chemical potential from the potential of mean force, thereby decomposing the different energetic contributions to the excess chemical potential.

CPP 32.35 Thu 9:30 P3

Gas quenching under ambient conditions for efficient and stable inverted perovskite solar cells with surface treatment — •Zhaonan Jin, Xiongzhuo Jiang, Zerui Li, Xiaojing Ci, Guangjiu Pan, Kun Sun, and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany

Inverted perovskite solar cells have gained significant attention due to their potential for high efficiency and stability. In the process, the active layer fabri-

cation plays a key role in determining the performance of the solar cells. Gas quenching is an important technique in the preparation of perovskite solar cells as it enhances the film quality and solar cell performance by precisely controlling the crystal growth and minimizing defects. As for the post-treatment of the active layer, surface passivation plays a crucial role in enhancing the performance of perovskite solar cells by reducing surface defects of perovskite interfaces. This study explores the influence of different passivation materials on the morphology of perovskite films and the performance of gas-quenching assisted FA0.8Cs0.2Pb(I0.6Br0.4)3 solar cells. This work provides a practical solution for the production of low-cost and high-performance inverted perovskite solar cells while maintaining operational stability in real-world environments.

CPP 32.36 Thu 9:30 P3

Facet-dependent photovoltaic efficiency and stability variations in mixed Sn-Pb perovskite solar cells — •Xiaojing Ci, Xiongzhuo Jiang, Guangjiu Pan, Jinsheng Zhang, Zerui Li, Kun Sun, and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany

Since the first breakthrough of perovskite solar cells using a solid-state structure, the solar cell power conversion efficiency has increased from 9.7% to 26%. These exciting improvements are mainly attributed to achieving a pinhole-free thin film at the beginning and an increased understanding of microstructures on perovskite thin films. In addition, the rapid PCE improvement has been accompanied by an increased understanding of microstructures on perovskite thin films. The photovoltaic performance of PSCs has been found to correlate strongly with their facet orientations. For example, the charge carrier lifetime, open-circuit voltage deficit and device hysteresis of PSCs are related to the structure and density in (111) crystal facets of perovskite. Besides, different crystal facets have different atomic arrangements and coordination, which lead to different atomic potential landscapes and, subsequently, to different electronic, physical, and chemical properties. Nevertheless, the deep understanding of perovskite thin films, especially the crystal facets of the thin film, still lags behind that of single-crystal samples or other inorganic thin films. In this work, we prepare the mixed tin-lead perovskite film with different orientations according to the facet engineering. We research the role of the different perovskite crystal facets in stability and optoelectronic properties.

CPP 32.37 Thu 9:30 P3

Processing-property relationships in printed hybrid halide perovskites — •Manuel Lippert[1], Meike Kuhn[1], Maximilian Spies[2], Anna Köhler[2], and Eva M. Herzig[1] — [1]Dynamik und Strukturbildung - Herzig Group, Universität Bayreuth, Universitätsstr. 30, 95447 Bayreuth, Germany — [2]Optoelektronik weicher Materie, Universität Bayreuth, Universitätsstr. 30, 95447 Bayreuth, Germany

Solution processable hybrid halide perovskites solar cells have been extensively studied over the last ten years and great advances in efficiency have been achieved. An important factor for the performance of the final solar cell is the morphology of the perovskite layer. Therefore, control of structure formation mechanisms is highly desirable. [1] We investigate systematically the processing of the active layer to determine processing parameters that are decisive for structure formation. To reliably study the effect of time relevant processing steps on the perovskite layer, we use automated processing. Applying photoluminescence, optical microscopy and grazing incidence wide angle X-ray scattering (GIWAXS) allows us to determine the morphology on the nano and micron scale and detect the correlations between processing and efficiency.

CPP 32.38 Thu 9:30 P3

Simulating light induced phase separation in $MAPbBr_{1.8}I_{1.2}$ perovskites — •Sebastian Schwartzkopff, Ivan Zaluzhnyy, Ekaterina Kneschaurek, Paul Zimmermann, Dmitry Lapkin, Hans Mauser, Alexander Hinderhofer, and Frank Schreiber — University of Tübingen

By changing the ratio of halides within mixed organic halide perovskites, such as $MAPbBr_{1.8}I_{1.2}$ (MA -methylammonium), one can adjust the band gap. This is quite desirable for solar cell applications where precisely tunable bandgaps enable the creation of high efficiency solar cells. However, when illuminated with visible light, these materials undergo a phase separation into Br-rich and I-rich phases, which destroys the tuned band gap. To better understand; and hopefully control this process, we utilize phenomenological approaches, such as Cahn-Hilliard and Monte Carlo models, to simulate the light-induced phase separation. We compared the results of our simulations with the experimental diffraction data. Cahn-Hilliard simulations presented quite a few difficulties in replicating the observations. The Monte Carlo simulations on the other hand allow us to investigate the influence of various material parameters on the phase separation, such as iodine-to-bromine ratio, charge carrier density and intensity of illumination. In general, we found that Monte Carlo simulations with the right choice of model parameters are quite capable of reproducing the experimental observations.

CPP 32.39 Thu 9:30 P3

Enhanced Stability of Perovskite Solar Cells via Double-End Coupling Silane — •Xinwei Tian, Xiongzhuo Jiang, and Peter Müller-Buschbaum — TUM School of Natural Science, Chair for Functional Materials, 85748 Garching, Germany

Containing reactive triethoxysilyl groups, 1,4-bis(triethoxysilyl)benzol (BTEB) has high thermal stability by forming robust siloxane networks through hydrolysis and condensation reaction. Besides, BTEB has good hydrophobicity, so it can function as a protective barrier to prevent moisture ingression into the sample, which ensures long-term operation of the perovskite solar cells (PSCs). BTEB can also passivate the interface defect, thus reducing non-radiative recombination. On the other hand, because of the surface passivation effect of BTEB, a smoother and more uniform film layer can be obtained, which can enhance light absorption and reduce scattering loss effectively. In this way, the power conversion efficiency (PCE) can also be improved. In our work, we aim to apply BTEB as the interface modification material, ethyl acetate as antisolvent, to construct inverted perovskite solar cells with higher efficiency and stability.

CPP 32.40 Thu 9:30 P3

Morphology Control and Optical Modelling of $CsPbBr_3$ Nanocrystal Films for Emission Orientation Studies — •Lea Kolb, Roshini Jayabalan, and Wolfgang Brütting — Universität Augsburg, 86135 Augsburg, Germany

The remarkable properties of $CsPbBr_3$ perovskite nanocrystals, exhibiting a high photoluminescence quantum yield (PLQY) and a narrow emission linewidth with size- and composition-tunable bandgap, render them promising for the application as emitters in light-emitting diodes (LEDs). While PLQY and charge carrier transport for perovskite LEDs have been in the focus of extensive studies, the orientation of the emissive transition dipole moment (TDM) has not been investigated thoroughly yet. However, for TDM analysis, determining the complex refractive index of the nanocrystal films is crucial. In this work, variable angle spectroscopic ellipsometry (VASE) was used to obtain the optical constants of various samples containing $CsPbBr_3$ nanocrystals. To avoid scattering effects, VASE measurements require homogeneous films with minimal roughness. For this reason, the substrates on which the nanocrystal films were spin-coated had to be modified and the sample fabrication process was optimized. In order to describe the measured data accurately with optical fit models, the morphology and thickness of the films were studied comprehensively by atomic force microscopy (AFM). Finally, angular dependent photoluminescence (ADPL) measurements have been performed and modelled in order to obtain information about the TDM-orientation.

CPP 32.41 Thu 9:30 P3

PIN-type perovskite solar cells for space applications — •Ruodong Yang, Simon A. Wegener, and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany

Perovskite solar cells have advantages such as low costs and high power-to-weight ratio, which render them to be promising candidates for space applications, where the mass is crucial for launch costs. In this study PIN-type solar cells are investigated. With its inverted p- and n-type structure, it has great research potential. However, solar cells in space also face challenges, such as vacuum, extreme temperature fluctuations during each orbit, and high radiation levels. The purpose of this study is to optimize the manufacturing procedure of PIN-type perovskite solar cells to address these challenges. We investigate the power conversion efficiency of the solar cells under similar environmental conditions to the low Earth orbit with illumination from an AM0 light source and thermal cycling by using optical microscopy to observe the structural changes during the operation. With the results of the measurements, the manufacturing procedure will be optimized, to determine the key factors to improve the performance and efficiency of PIN-type cells under space conditions.

CPP 32.42 Thu 9:30 P3

Perovskite solar cells temperature dependence under space-like conditions — •Anthony Vizcaino, Simon Alexander Wegener, and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair of Functional Materials, 85748 Garching, Germany

In recent years, perovskites have attracted the scientific community's attention due to their properties and possible applications, making their use in solar cells one of the most relevant. Their high-power conversion efficiency, power-to-weight ratio, and manufacturing compared to the to-date used multi-junction devices make them a promising device for space applications, where it is possible to take advantage of all the intensity of sunlight that at the Earth*s surface is lost by absorption or scattering by the atmosphere. However, in this scenario, radiation and high temperatures would affect the solar cell. This study focuses on one of these problems and tries to understand how extreme temperatures and thermocycling through large periods of heating and cooling encountered in low Earth*s orbit affect perovskite solar cell performance and degradation.

Operando studies allow to simulate thermal cycling conditions and measure the transmittance of solar cells, which combined with electrical characteristics from I-V measurements and active layer morphology from GIWAXS give us a robust knowledge of the temperature dependence of perovskite-based solar cells.

CPP 32.43 Thu 9:30 P3

In-situ Monitoring for Optimizing Perovskite Solar Cell Fabrication: Correlating Process Parameters with Power Conversion Efficiency — •Yuxin Liu, Alexander Tarasov, Maxim Simmonds, and Eva Unger — Department Solution Processing of Hybrid Materials and Devices, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, 12489 Berlin, Germany

Halide perovskite solar cells need dependable, reproducible production to reach commercialization. For stable perovskite photovoltaic manufacture and research, deposition processes must be monitored. In-situ photoluminescence (PL) monitoring compares the PL during spin-coating and annealing with absolute PL measurements obtained after annealing of the sample. Examples demonstrating how process conditions and variables like anti-solvent type and drip timing significantly influence PL signatures. We demonstrate that insight during processing can serve as feedback to stabilize the perovskite solar cell fabrication. In-situ PL monitoring shows two distinct peaks within one second of anti-solvent treatment, revealing perovskite nucleation and growth mechanism. All Helmholtz association perovskite PV research uses a standard operating procedure (SOP) for solar cell samples. Absolute PL measurements for thin-film samples quantify Quasi-Fermi Level Splitting, reflecting the opto-electronic quality of the absorber and losses at selective contacts. The absolute PL is correlated to the in-situ PL to establish how far in-situ PL during processing can predict solar cell performance. This study highlights the potential of optical process monitoring to enhance material and interface quality.

CPP 32.44 Thu 9:30 P3

The Construction of Temperature Gradient during Annealing to Guide Crystallization Direction — •Yiran Shi — Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany

Perovskite solar cells have gained significant attention as promising candidates for next-generation photovoltaics due to their outstanding advantages. The quality of the perovskite layer is a crucial determinant of the efficiency and stability of photovoltaic devices. As a polycrystalline thin film, the size and compactness of crystals are key quality metrics, closely linked to the annealing process. Conventional annealing typically involves placing the thin film, post-nucleation, on a fixed-temperature heating platform for crystal growth. Without external guidance, crystallization usually progresses top-down, preferentially completing at the upper surface. This sequence often traps solvents within the film, hindering evaporation and leading to void formation, which negatively affects film quality and device performance. To address this issue, we propose an improved annealing strategy by introducing a vertical thermal gradient to guide a bottom-up crystallization process. This approach aims to delay top-surface crystallization, allowing solvents to escape more effectively and reducing void formation. From the results about SEM and GIWAX, it is improved film quality, with enhanced structural integrity and reduced defects, offering a pathway to optimize perovskite photovoltaic performance.

CPP 32.45 Thu 9:30 P3

Optimizing RbCsFAMA perovskite solar cells with piperazine-inspired passivation technique — •Bashudev Bhandari[1,2,3], Zekarias Teklu Gebremichael[1,2], Niklas Manikowsky[2,3], Chikezie Williams Ugokwe[1,2], Ulrich S Schubert[1,2], and Harald Hoppe[1,2] — [1]Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich-Schiller-University Jena — [2]Faculty of Physics and Astronomy, Friedrich-Schiller- University Jena, Jena, Germany — [3]Laboratory of Organic and Macromolecular Chemistry (IOMC Jena), Friedrich-Schiller- University Jena, Jena, Germany

Perovskite solar cells (PSCs) have emerged as a promising photovoltaic technology, with extraordinary optoelectronic properties. However, stability and defects are the challenges of perovskite solar cells. This work explores the role of piperazine as a novel passivating agent to address these limitations. Piperazine's bifunctional structure enables effective defect passivation at the grain boundaries and interfaces of RbCsFAMA perovskite films, significantly reducing non-radiative recombination losses. Different characterization and imaging techniques photoluminescence spectroscopy, X-ray diffraction and scanning electron microscopy demonstrate improved crystallinity and electronic properties of the RbCsFAMA perovskite films after passivation. This improvement is shown to be transferred into solar cell devices.

CPP 33: Modeling and Simulation of Soft Matter IV

CPP 33.1 Thu 11:45 H34

Understanding COF/Electrode interfaces for electrocatalysis using DFT and molecular simulations — •Henrik Stooss[1], Philip Stärk[1,2], and Alexander Schlaich[1] — [1]Institute for Atomistic Modeling of Materials in Aqueous Media, Hamburg University of Technology, Hamburg — [2]SC SimTech, University of Stuttgart, Stuttgart

This study explores the complex dynamics at electrode/electrolyte interfaces under constant potential, crucial for advancing electrocatalysis and designing efficient energy systems, by combining advanced computational techniques to gain insights into mechanisms at these interfaces. We perform Density Functional Theory (DFT) simulations while maintaining a constant electrode potential. Despite challenges and computational costs, the DFT simulations provide insights into the electronic structure and behavior of electrode surfaces. We then parameterize a classical model based on the DFT data, enabling simulations of larger systems over longer timescales for comprehensive comparison with experimental ATR-SEIRAS data. This approach offers a detailed understanding of adsorption and transport phenomena at the electrode interface, potentially leading to better electrolyte compositions and improved electrode designs. This work advances the connection between first-principles calculations and experimental observations for material design.

CPP 33.2 Thu 12:00 H34

Porous microstructure of fibrous sheets in two transport regimes — Alexandra Serebrennikova[1], Phillip Gräfensteiner[2], Matthias Neumann[1], Volker Schmidt[2], Andoni Rodriguez[3], Peter Leitl[3], Werner Napetschnig[1], Ekaterina Baikova[1], Maximilian Fuchs[1], and •Karin Zojer[1] — [1]Graz University of Technology, Graz, Austria — [2]Ulm University, Ulm, Germany — [3]bionic surface technologies, Graz, Austria

In many applications, a porous material serves multiple functions. For example, paper sheets in packaging bags should allow excess air to escape quickly while minimizing moisture migration. Although the underlying physics are different, both transport processes depend on porosity. However, each function it is likely to be supported by additional, possibly different, microstructural properties. Can these microstructural properties be optimized for all functions or is this not possible due to inherently dependent properties? To answer this question for Stokes flow and reactive diffusive transport through paper, we simulate flow through μ-CT-determined microstructures using physics-informed neural networks, computational fluid dynamics, and pore network modeling. We combine these simulations with statistical morphological analysis including dependency quantification to provide the relevance and dependence of structural properties in both transport processes. Our study suggests that the two transport scenarios do not rely on the same set of structural properties, even when fiber swelling due to moisture transport is considered.

Nuclear Quantum Effects in Clays — Sam Shepherd, Pawan Kurapothula, Nataly Realpe, Gareth Tribello, and •David Wilkins — Queen's University Belfast, Belfast, United Kingdom

Clay materials consist of layers, whose structure is heavily influenced by hydrogen-bonding interactions. Given the importance of nuclear quantum effects such as zero-point energy in water, a hydrogen-bonded liquid, a natural question to ask is how important these effects are in clays themselves.

I describe some work done by my group to understand the importance of nuclear quantum effects in clays and clay-water systems, and to interpret these effects in the same terms used to understand water. I also demonstrate a fully quantum-mechanical description of the interactions and dynamics in kaolinite clay.

CPP 33.4 Thu 12:30 H34

Protonated water clusters by stochastic approaches: probing machine learning resilience against quantum Monte Carlo noise — •Matteo Peria, Antonino Marco Saitta, and Michele Casula — Sorbonne Université, 4 place Jussieu Paris, France

A complete understanding of the hydrogen bond and proton transfer mechanism in water is still lacking, since it requires an accurate potential energy surface (PES) and very expensive quantum mechanical simulations of the nuclear part. Reproducing this high-dimensional surface with current high-level computational chemistry methods is infeasible for the largest clusters. We test gradient-based kernel ridge regression methods and neural networks to reproduce the PES starting from a dataset of energies and forces of the protonated water clusters obtained via simulations combining classical molecular dynamics (MD) for the nuclei and quantum Monte Carlo (QMC) for the electrons. The QMC+MD

approach yields very accurate results for the classical dynamics, which are however affected by the intrinsic noise inherent in the stochastic sampling of both nuclear and electronic phase space. We prove that QMC multivariate noise is not necessarily detrimental to the learning of energies and forces and we determine under which conditions one can derive accurate and reliable MLIPs from QMC data.

CPP 33.5 Thu 12:45 H34

Effect of solid fillers on the thermodynamics and electrical properties of diblock copolymers and polymer blends. — •Alexander Chervanyov — University of Münster, Münster, Germany.

By making use of the developed theory we study the effect of solid fillers on the thermodynamics, phase behaviour and electrical properties of diblock copolymers (DBC) and polymer blends (PB). The theory relies on the combination of the liquid state approach, phase-field model for polymers, Monte-Carlo simulations, and the resistor random network model for fillers. Using the developed approach, we prove that the correlations imposed by the variations of the composition of PB cause a significant non-osmotic contribution to the polymer mediated interaction between fillers immersed in this blend. The effect of fillers on the stability and miscibility of compressible PB is studied in detail. We show that the presence of non-adsorbing fillers can be used to enhance the stability of a PB that shows low critical solution temperature (LCST) behavior. Finally, as an important practical application of the developed theory, we study the electrical response of an insulating DBC filled with conduictive fillers. In particular, the order-disorder transition in the host DBC system is found to be accompanied by the conductor-insulator transition in the filler network. The order-order transition between the lamella and cylindrical microphases of DBC proves to co-occur with a spike of the composite conductivity caused by restructuring of the conductive filler network.

CPP 34: Focus Session: Interactions Between Water and Cellulose I

Understanding Nanocellulose-Water Interactions to Engineer Advanced Functional Materials — •Valentina Guccini — Uppsala University, Lägerhyddsvägen 1, Uppsala, Sweden

Water interactions are a central topic in the field of nanocellulose due to their pivotal role in nanocellulose's chemical reactivity, processability and physical properties. Yet, a key challenge that remains is bridging the fundamental understanding of nanocellulose-water interactions with the design and engineering of advanced functional materials. This presentation will address this challenge by summarizing the main characteristics of water-nanocellulose interactions and how these can be leveraged to engineer nanocellulose-based materials, in which water has both a structural and functional role. We will analyze the structure-property relationship in nanocellulose-based hydrogels, films and membranes for biotechnological and fossil-free energy applications (e.g. fuel cells and lithium-ion batteries). This presentation offers a new perspective on using nanocellulose-water interactions as a tool to enhance and tailor material performance and functionalities.

CPP 34.2 Thu 15:30 H34

Using Nanocellulose Hygroscopicity for Conductive 3D Paper Structures — •Marie Betker[1,2], Tim Erichlandwehr[3], Benedikt Sochor[1,4], Elisabeth Erbes[1,5], Yamit Alon[2], Alisher Kurmanbay[2], Yanan Li[6], Irene Fernandez-Cuesta[3], Peter Müller-Buschbaum[6], Simone Techert[1,5], Daniel Söderberg[2,7], and Stephan Roth[1,2,7] — [1]Deutsches Elektronen Synchrotron, Notkestrasse 85, 22607 Hamburg, Germany — [2]KTH Royal Institute of Technology, Teknikringen 56, 10044 Stockholm, Sweden — [3]Hamburg Advanced Research Centre for Bioorganic Chemistry, Universität Hamburg, Luruper Chaussee 149, 22761 Hamburg, Germany — [4]Lawrence Berkeley National Laboratory, 6 Cyclotron Rd, Berkeley, CA 94720, USA — [5]Institute for X-ray Physics, Goettingen University, Friedrich Hund Platz 1, 37077 Göttingen, Germany — [6]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [7]Wallenberg Wood Science Center, Teknikringen 52, 10044 Stockholm, Sweden

We report the fabrication of the, to this date, thinnest sprayed nanopaper foils. For that, we spray aqueous nanocellulose dispersions layer-by-layer on a hot substrate. The foils are only 2 um thin with an average basic weight of 1.9 g/square metre. We specifically exploit the hygroscopicity of paper-based materials to rearrange our water-soaked foils into three-dimensional, free-standing shapes. We further demonstrate the applicability of our foils by making them conductive via integration of silver nanowires. This approach is a step towards more sustainable, 3D organic electronics.

CPP 34.3 Thu 15:45 H34

A simulation study of the structure and mechanical properties of cellulose and callose hydrogels — •Robinson Cortes-Huerto[1], Nancy C. Forero-Martinez[2], and Pietro Ballone[1] — [1]Max-Planck-Institut für Polymerforschung, Ackermannweg 10, 55128 Mainz, DE — [2]Institut für Physik, Johannes Gutenberg-Universität, Staudinger 9, 55128 Mainz, DE

The cell wall of plants is a complex, self-organized and continuously evolving structure playing important roles in the life cycle of individual cells and the plant as a whole. It consists primarily of cellulose, which is the main responsible for its mechanical properties. Under environmental stress, a crucial role is played by callose, a polysaccharide closely related to cellulose and a minority component of the cell wall. A recent study (*Plant Signal. Behav.* **2019**, *14*, e1548878) suggested that the enhancement of mechanical properties by callose is due to its ability to order neighbouring water molecules, giving origin to solid-like water-callose domains. This hypothesis is tested by atomistic MD simulations using models representing cellulose and callose hydrogels. The results highlight systematic differences in the coordination and H-bonding of callose and cellulose by water, reflected in different dynamical properties of water in callose or cellulose hydrogels, partly validating the hypothesis. However, mechanical properties, characterized by the Young's modulus of the polysaccharide / water gels, are the same in callose/ and cellulose/water samples, suggesting that callose's ability to link cellulose nanofibres into networks is the main responsible for the strengthening of the plant cell wall.

CPP 35: Microswimmers and Microfluidics (joint session DY/BP/CPP)

Invited Talk CPP 35.1 Thu 15:00 H37

Light-Driven Manipulation of Passive and Active Microparticles — •Svetlana Santer — Institute of Physics and Astronomy, University of Potsdam, Germany

Chemical gradient near a solid/liquid can result in lateral long-range fluid transport termed diffusioosmotic (DO) flow. For instance, when photosensitive surfactant is irradiated with light converting the majority of the molecules in one of the possible isomers, emerging concentration gradient of isomers generates an osmotic pressure gradient tangent to the wall actuating the surrounding liquid to flow. [1-3] In my talk I will show how one can manipulate microparticles and even induce their self-propulsion by light urtilizing light driven diffusioosmotic (LDDO) phenomenon. Depending on the applied wave length one can either disperse/remove or gather particles. We will discuss how to establish light-driven hydrodynamics as a useful and versatile tool for investigating collective motion of self-propelled particles and aggregation

[3] Arya, P.; Umlandt, M.; Jelken, J.; Feldmann, D.; Lomadze, N.; Asmolov , E. S.; Vinogradova, O. I.; Santer, S. A. The European Physical Journal E, 44(50) (2021), 1-10.

CPP 35.2 Thu 15:30 H37

Regulated polarization of active particles in local osmotic flow fields — •Lisa Rohde, Desmond Quinn, Diptabrata Paul, and Frank Cichos — Molecular Nanophotonics Group, Peter Debye Institute for Soft Matter Physics, University Leipzig, Leipzig, Germany

Regulation in living systems is a fundamental principle for achieving robust functionality and maintaining specific non-equilibrium states. The control of certain properties and functionalities of systems on the microscale presents particular challenge since thermal fluctuations and environmental perturbations dominate. While synthetic active matter has demonstrated remarkable self-organization capabilities, examples of autonomous regulation processes at the single-particle level remain scarce. Here, we show experimentally that the interplay of two non-equilibrium processes leads to a regulated polarization state of

active particles in local osmotic flow fields. Based on thermophoretic repulsive and attractive forces that are generated by a single heat source at the boundary, the active particles encircle the heat source at a stable distance depending on the heat source temperature. The balance of these temperature-induced processes causes a polarization of the active particles that is independent of the heat source temperature. The individual control of heat source and active particles in the experiment allows detailed investigation of the self-regulated polarization effect in which we find hydrodynamic interactions to dominate. As the effects rely on osmotic flows and phoretic interactions, we expect that the observed phenomena can be generalized to other active systems and flow fields.

CPP 35.3 Thu 15:45 H37

Active particle steering in three dimensions — •Gordei Anchutkin and Frank Cichos — Molecular Nanophotonics Group, Peter Debye Institute for Soft Matter Physics, Leipzig University, Leipzig, Germany

Synthetic active particles serve as a model system that mimic the self-propulsion of living matter to explore fundamental aspects of non-equilibrium physics. Various collective phenomena of active agents have been studied, but mostly in the presence of hydrodynamic and physicochemical boundary effects. While theoretical works predict different collective dynamics in 3D, experimental investigations remain limited due the lack of experimental control over active swimmers in three dimensions.

Here we introduce three-dimensional control to the study of synthetic active matter. We demonstrate simultaneous control of thermophoretic microswimmers in 3D using single-particle tracking through digital holography and dark-field pattern tracking, with real-time wavefront shaping for steering. With the help of these experiments, we explore the interplay of thermophoretic propulsion, gravity, and optical forces for the active particles. By creating a three-dimensional active ensemble, we reveal how bulk interactions and boundary effects shape the collective behavior of active particles.

CPP 35.4 Thu 16:00 H37

***Trypanosoma brucei* in microchannels: the role of constrictions** — •Zihan Tan, Julian I. U. Peters, and Holger Stark — Institute of Theoretical Physics, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin, Germany

Trypanosoma brucei (*T. brucei*), a single-celled parasite and natural microswimmer, is responsible for the fatal sleeping sickness in infected mammals, including humans. Understanding how *T. brucei* interacts with fluid environments and navigates through confinements is crucial for elucidating its movement through blood vessels and tissues, and across the blood-brain barrier.

Using a hybrid multiparticle collision dynamics (MPCD)–molecular dynamics (MD) approach, we investigate the locomotion of an in-silico *T. brucei* in three types of fluid environments: bulk fluid, straight cylindrical microchannels, and microchannels with constrictions. We observe that the helical swimming trajectory of the in-silico *T. brucei* becomes rectified in straight cylindrical channels compared to bulk fluid. The swimming speed for different channel widths is governed by the diameter of the helical trajectory. The speed first slightly increases as the channel narrows and then decreases when the helix diameter is compressed. An optimal swimming speed is achieved when the channel width is approximately twice the bulk helix diameter. Furthermore, *T. brucei* notably slows down when entering the narrow constriction in a microchannel and strongly speeds up upon exiting due to a release of deformation energy of the straightened cell body.

CPP 35.5 Thu 16:15 H37

Helical motion of microorganisms can be more persistent than straight motion — •Leon Lettermann[1], Falko Ziebert[1], Mirko Singer[2], Freddy Frischknecht[2], and Ulrich S. Schwarz[1] — [1]BioQuant & Institute for Theoretical Physics, Heidelberg University — [2]Center for Integrative Infectious Disease Research, Heidelberg University

The movement of microorganisms has been extensively modeled by stochastic active particle models. In three dimensions, both swimming microorganisms, like sperm cells and some bacteria, and gliding microorganisms, like malaria sporozoites in the skin, often exhibit helical trajectories. If the internal driving force is the primary source of noise in the system, it induces random, yet time-correlated variations in the torque. To investigate this effect, we introduce a three-dimensional active rotational Ornstein-Uhlenbeck particle model. We find that the presence of a rotational component and the resulting helical path can mitigate the effect of intrinsic noise in the drive, allowing for larger long-time mean square displacements than straight movement at the same speed. The model not only provides qualitative insights into the constraints faced by microbes that may have led to the evolutionary selection of certain motility patterns, but also presents an analytical, quantitative tool for extracting information from these movements. We present and analyze corresponding data for malaria parasites gliding through hydrogels.

CPP 35.6 Thu 16:45 H37

Corrugated channels can filter ciliated microorganisms based on the metachronal wavelength — •Gonçalo Antunes and Holger Stark — Technische Universität Berlin, Institute of Theoretical Physics, Hardenbergstr. 36, 10623 Berlin, Germany

Many microorganisms (e.g. Paramecium) move by a carpet of cyclically beating cilia that cover their surface. These cilia often beat in an organized fashion, such that the beating phases form a traveling wave, referred to as a metachronal wave. In this study, we investigate the swimming of such microorganisms in corrugated microchannels. We model the motion of the cilia via a time-varying effective slip velocity applied on the microorganism's surface, which we approximate as an infinite slab. By employing the lubrication approximation, we show analytically that the swimming speed of ciliated microorganisms placed inside a corrugated channel is sensitive to the corrugation height, provided that the wavelength of the corrugation matches that of the metachronal wave. Indeed, the direction of motion itself may invert with respect to swimming in bulk fluid, with the channel acting as a virtual barrier which blocks microorganisms under specific conditions for corrugation and slip-velocity modulations, but allow others to pass through. We also show that the interplay between the corrugation and the slip velocity profile allows for the swimming of microorganisms with zero time-averaged slip velocity, which thus cannot swim in bulk fluid. Finally, we complement our theory with preliminary results from hydrodynamic simulations for radially-symmetric microorganisms of finite length in radially-symmetric corrugated channels.

CPP 35.7 Thu 17:00 H37

Motion of a single particle partially exposed in a simple shear flow — •Dominik Geyer[1,2], Aouane Othmane[1], and Jens Harting[1,2] — [1]Helmholtz-Institut Erlangen-Nürnberg for Renewable Energy (IET-2), FZ Jülich — [2]Department of Physcis, FAU Erlangen-Nürnberg

Sand immersed in the water can be imagined as a wet granular matter. Besides sedimentation, friction, and surface roughness are two relevant physical phonemes within this system. Many body systems in a turbulent regime have been studied using discrete elements methods for a long time, but a single particle in the Stokes flow regime is particularly interesting for biological systems and microfluidic devices.

A layer of quadratic-arranged spheres models the rough surface. The question arises of how to describe the motion of a single traveling particle over this substrate.

We choose a combined numerical and analytical approach. The Stokes equation is solved analytically for the sphere near a rough wall. Lattice Boltzmann simulations with momentum-exchange particle coupling are performed for different wall roughness and friction coefficients.

Although, the Stokes equation assumes that the particle Reynolds number is zero. Surprisingly, the numerical results match our theoretical description until a particle Reynolds number of two. In this regime, friction between the moving particle and the substrate significantly influences the angular velocity but has a minor influence on the traveling velocity in the flow direction.

CPP 35.8 Thu 17:15 H37

Rational Design of Smart Microfluidics in Responsive Channels — •Arwin Marbini — Albert-Ludwigs Universität Freiburg

Responsive microfluidics offers exciting potential for self-regulating biomimetic systems. This study explores bifurcating microchannel networks with pressure-sensitive resistances, combining experiments with simulations based on the Hagen-Poiseuille equation and a linear model. These methods extract critical, experimentally inaccessible parameters under steady-state and dynamic conditions. Our findings enable the design of adaptable microfluidic networks, unlocking precise flow control for future applications in biology, soft robotics, and advanced material systems.

CPP 35.9 Thu 17:30 H37

Blue Water: A passive, reusable microfiltration device for water purification — •Tim R. Baumann, Ioannis Gkekas, Martina Viefhues, and Dario Anselmetti — Experimental Biophysics, Bielefeld University

Water is the most vital resource for life on Earth. Due to pollution of freshwater and oceans, this valuable resource has become globally endangered. The effects of microplastic pollution are widely discussed in scientific, political, and socioeconomic contexts. Despite regulations on single-use plastics and microplastic output, efforts should also focus on reintegrating microplastics to achieve a sustainable circular economy. Furthermore, microplastic-sized particles can migrate through organic tissue and can therefore be classified as contaminants of emerging concern. However, filtering plastics of this size is a challenging task.

Thus, this work examines and extends the findings of Divi et al. regarding the suspension feeding mechanisms of various ray species. We studied the filtration performance and efficiency for different geometric ratios of channel widths in simulations and laboratory environments. First, we have the main inner channel connected to the pressure inlet. From this, two rows of tilted lamellae structures branch off laterally to the outer secondary channels.

By applying sufficiently high pressure ($> 6 \cdot 10^5\ Pa$) to the inlet and achieving flow and particle velocities of $> 35\ \frac{m}{s}$, we can purify 82 % of half of the initial fluid. To prevent rupturing of our microfluidic chip under this pressure, we further investigated using glass fiber reinforced PDMS and lowering the operating pressure.

How to Capture and Release Fullerene from an Azobenzene-Bithiophene Nanolayer? — Dmitry A. Ryndyk and •Olga Guskova — IPF Dresden, Hohe Str. 6 01069 Dresden

Optimizing organic photovoltaic devices involves the strategic use of well-defined monolayers of azobenzene-bithiophene (Azo-BT) switches. These monolayers serve as a bridge between inorganic and organic components, allowing precise nanoscale control over electrode morphology [1]. Previous studies have demonstrated that cis- and trans-Azo-BT switches chemisorbed on a gold surface exhibit distinct geometrical, electronic, and charge transport properties. We further investigate the behavior of cis- and trans-Azo-BT monolayers, with a particular focus on "nanotraps" nanometer-sized nanopores formed within the monolayers and their ability to capture&release fullerene. Our findings confirm that the photoswitchable "closed" and "open" configurations of Azo-BT nanotraps remain stable at room temperature under experimentally relevant surface densities. Energy calculations reveal that C60 molecules preferentially stabilize inside the open nanotrap near the pore surface, effectively capturing the fullerene. Additionally, a local energy minimum for C60 near the electron-donating BT block suggests charge transfer from the BT fragment to the fullerene, enhancing the interaction between the trap and the captured molecule. To expel the fullerene from the monolayer, we applied an alternating voltage electric field and determined the optimal parameters required to displace the nanoparticle, demonstrating the feasibility of controlled capture and release. [1] Savchenko, V. et al., Processes, 11 (2023) 2625.

CPP 36.2 Thu 15:15 H38

Deciphering vibronic interactions in NDI-T2 based donor-acceptor type oligomers with theoretical and experimental spectroscopy — •Maximilian F.X. Dorfner[1], Marko Medugorac[1], Ajeet Kumar[2], Jürgen Hauer[1], and Frank Ortmann[1] — [1]TUM School of Natural Sciences, Technische Universität München, 85748 Garching b. München, Germany — [2]Department of Chemistry, Lund University, Naturvetarvägen 14 222 62 Lund, Sweden

In this study, we investigate the alternating Naphthalendiimide-bithiophene co-oligomer (T2-NDI2OD-T2), a fundamental building block of the high charge-mobility polymer-semiconductor PNDI(2OD)2T. This class of materials has garnered significant attention for its exceptional charge transport properties, making it a promising candidate for applications in field-effect transistors and as non-fullerene acceptors in organic photovoltaics. We use Density Functional Theory (DFT) and Time-Dependent DFT (TD-DFT) to examine the ground and singlet excited state properties to understand the electronic structure and vibrational excitations. Additionally, we analyze the coupling between electronic and vibrational degrees of freedom by means of a Linear Exciton-Vibrational Coupling Model parameterized by DFT. We compare the computed optical observables to the experiment and discuss the role of molecular vibrations in this system.

CPP 36.3 Thu 15:30 H38

Grain Boundaries and Charge Mobility in Organic Semiconductors: A Non-Adiabatic Molecular Dynamics Approach — •Sonali Garg[1], Farhad Ghalami[1], Sebastian Schellhammer[2], and Marcus Elstner[1] — [1]Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]Technische Universität Dresden, Germany

Organic semiconductors have emerged as crucial materials in the development of electronic and optoelectronic devices due to their exceptional mechanical flexibility, lightweight nature, and cost-effectiveness. However, the presence of grain boundaries (GBs) can significantly impede device performance by introducing traps or potential barriers that reduce charge carrier mobility. This study investigates the influence of the GB characteristics, including misorientation angles and GB width, on charge carrier mobility and compares the results with intrinsic mobility. Non-Adiabatic Molecular Dynamics (NAMD) simulations, employing Fewest Switches Surface Hopping (FSSH) approach[1,2,3], were used to model charge transport dynamics. The charge transfer Hamiltonian was constructed using a fragment orbital approach, with its elements computed via the Density Functional Tight Binding (DFTB) method[4,5]. These insights provide a deeper understanding of the effects of GB on charge carrier mobility in organic semiconductors.

CPP 36.4 Thu 15:45 H38

Single-particle spectra of pentacene from exact simulations of Green's functions in the time-domain — •Michel Panhans[1], Frank Ortmann[1], and Hiroyuki Yoshida[2] — [1]TUM School of Natural Sciences, Technische Universität München, 85748 Garching b. München, Germany — [2]Graduate School of Engineering, Chiba University, 1-33 Yayoicho, Inage-ku, Chiba, 263-0043, Japan

The investigation of single-particle spectra using experimental techniques such as photo-electron spectroscopy and inverse-photoelectron spectroscopy reveal the nature of the charge carriers close to the Fermi energy. In particular for organic crystals such as pentacene, the single-particle spectra are strongly affected by the electron-phonon coupling (EPC) and crucially deviate from the theoretical spectra based on ab initio band-structure calculations associated with the HOMO and the LUMO of the pristine crystal.

To model these experiments more accurately, Green's-function approaches including the EPC are a suitable methodology to describe what is seen in experiments. In our present study, we calculated the HOMO and the LUMO spectra of pentacene single-crystals and compared them to experimental results. We find that the quantum mechanical treatment of the EPC has a crucial impact on the fine structure of the spectra and explains the band features of the experimental spectra for HOMO and LUMO of pentacene.

CPP 37: Focus Session: Interactions Between Water and Cellulose II

Modelling Hygroexpansion of Compression and Opposite Wood of Conifer Branches: Bridging the Gap between Molecular and Cell Wall Level — Marie Hartwig-Nair, Sara Florisson, Kristofer Gamstedt, and •Malin Wohlert — Dep of Materials Science and Engineering, Uppsala University

Softwood branches develop compression wood (CW) in the lower and opposite wood (OW) in the upper part exhibiting different hygro-mechanical properties and differ in structure at several length scales. Distinctive differences are found at cell level, cell wall level and at the level of chemical composition of the lignin and hemicellulose matrix.

The effect each of these respective differences have on tissue level of wood hygromechanical properties is not yet clear. Here, a hierarchical multiscale modelling approach is employed, where the impact composition, MFA and lignin chemical difference have on wood hygro-expansion is studied by the means of hierarchical modelling as support to tissue level experimental investigation of CW and OW hygro-expansion [1]. With atomistic models and Molecular Dynamics simulations of lignin at different levels of hydration, swelling coefficients for the different lignin matrices are obtained [2] and implemented in a Finite Element (FE) model of the cell wall. The FE model also accounted for differences in MFA and composition.

The results of the FE model will be discussed and connected to the MD and tissue level results.

CPP 37.2 Thu 16:45 H34

Exploring Hygroexpansion of Cellulose Based Fibers via μCT — •Maximilian Fuchs[1,2], Raimund Teubler[2,3], Alexandra Serebrennikova[1,2], and Karin Zojer[1,2] — [1]Institute for Solid State Physics, Graz University of Technology, Austria — [2]Christian Doppler Laboratory for Mass Transport through Paper — [3]Institute of Analytical Chemistry and Food Chemistry, Graz University of Technology, Austria

Understanding the swelling of cellulose-lignin-based fibers is crucial for describing the processes involved in the uptake of water or other volatile organic compounds in paper. Microcomputed tomography (μCT) promises to monitor the

hygroexpansion on a paper sheet level. However, extracting and analyzing individual fibers from the interwoven fiber network in these μCT images is challenging. We present a new approach to identify, extract, and analyze hollow fibers by focusing on the fiber lumen as the structural backbone. Using this approach, we quantify changes in fiber shape as the paper sheet absorbs water and another polar solvent, dimethyl sulfoxide (DMSO), from the vapor phase. We continue to observe these changes long after saturation, when no further mass is absorbed in the fibers. With both water and DMSO, the fiber wall thickness continues to increase even after reaching saturation. Furthermore, when exposed to water, the fibers tend to become rounder during swelling, suggesting fiber decollapse. In contrast, the data for DMSO indicates that the outermost fiber layer gets damaged, leading to unrestricted swelling once saturation is exceeded.

CPP 37.3 Thu 17:00 H34

Structure and dynamics of water adsorbed to amorphous cellulose: a comparison of experimental and simulated neutron scattering data — •Veronika Reich[1], Martin Müller[1,2,3], and Sebastian Busch[1] — [1]German Engineering Materials Science Centre (GEMS) at Heinz Maier-Leibnitz Zentrum (MLZ), Helmholtz-Zentrum hereon GmbH, Garching, Germany — [2]Institute of Materials Physics, Helmholtz-Zentrum hereon GmbH, Geesthacht, Germany — [3]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, Kiel

Neutron scattering experiments provide valuable insights into the nanoscopic properties of matter, a scale that is also accessible through Molecular Dynamics (MD) simulations. If the simulations reproduce the experiments, they can give greater insight into the material properties on the nanoscopic scale than traditional data analysis methods. In our work we establish a connection between published experimental data about water absorbed to amorphous cellulose from neutron experiments [1] and MD simulations. Special focus was put on the comparison of the structure factor of non-crystalline water and the dynamics as a function of temperature. The MD simulations were designed to be close to the experimental data from literature to achieve a meaningful comparison.

CPP 38.2 Thu 16:45 H38

PNIPAM Microgel-Stabilized Foam Films: Effect of Crosslinker Content and Purification State — •Luca Mirau, Joanne Zimmer, Kevin Gräff, Matthias Kühnhammer, and Regine von Klitzing — Institute for Condensed Matter Physics, TU Darmstadt, Germany

Aqueous foams find widespread application in fields such as cosmetics, food industry, oil recovery and fire-fighting. Their stabilization requires the presence of surface-active molecules or colloidal particles. In this study, thermoresponsive microgels (MGs) composed of poly(N-isopropylacrylamide) (PNIPAM) with varying crosslinker contents are applied as foam stabilizers, resulting in temperature-sensitive foams. Foam films serve as the fundamental building blocks of foams. The structuring of MGs within these films is analyzed using the Thin Film Pressure Balance (TFPB) technique. Foam films are formed within a pressure chamber, and their thickness is determined through interferometric methods under a light microscope. The foam films display an inhomogeneous structure comprising significant pattern formation, i.e. a network-like, several 100nm thick region containing MGs, interspersed with thin MG-depleted zones less than 100nm thick. The findings indicate that the crosslinking content plays a crucial role in MG layering within these thick network regions, influencing the film thickness. Additionally, the purification state of the MGs, monitored through interfacial tension measurements, governs the formation of thin zones in the foam films, which strongly affects their stability.

CPP 38.3 Thu 17:00 H38

Ion Specific Effects and Photo-Switching of Surfactants at Interfaces — •Dana Glikman and Björn Braunschweig — Institute of Physical Chemistry and Center for Soft Nanoscience, University of Münster, Busso-Peus-Str. 10, 48149 Münster (Germany)

Understanding surface charging and molecular structure changes at oil/water (O/W) interfaces in nanoemulsions is critical for enhancing colloidal properties. In previous work, we demonstrated that photo-switchable surfactants could modulate interfacial behavior. Specifically, we studied an arylazopyrazole (AAP) derivative that undergoes photoisomerization between E and less surface-active Z isomers. In nanoemulsions with droplets showing an average radius of 90 nm, no significant changes in drop size or ζ-potential were observed upon E/Z photoisomerization. However, second-harmonic scattering (SHS) revealed substantial changes in surfactant coverage which were attributed to ion condensation at the interface [1]. In this contribution, we now focus on the role of specific ion effects and the structural influence of the surfactants' head group. By systematically varying between Li, Na, and Cs cations and by using surfactants with different head group architectures, we aim to dissect the interplay between ionic specificity and head group structure. To study the adsorption of the surfactants at the interface, we are analyzing SHS profiles combined with measurements of the ζ-potential at the shear plane, in order to reveal a detailed mechanisms of ion-specific effects and ion condensation in these nanoemulsions. [1] Glikman et al. J. Am. Chem. Soc. 146, 8362 (2024).

CPP 38.4 Thu 17:15 H38

Anomalous Screening Behavior of Superchaotropic Ions — •Thomas Tilger, Esther Ohnesorge, Michalis Tsintsaris, and Regine von Klitzing — Department of Physics, Technische Universität Darmstadt, Darmstadt, 64289, Germany

Due to their special properties, which make them suitable for many applications such as wastewater treatment, separation of nuclear waste and the stabilization of foams, the interest in superchaotropic nano ions grew during the last years. Especially for the last application, it is crucial to understand how the presence of these ions modifies the interaction between interfaces.

To directly measure the forces between well-defined interfaces, colloidal probe atomic force microscopy (CP-AFM) has proven to be a powerful tool. As model system for nano ions we chose Keggin ions as well as dodecaborate clusters and investigated their influence on the interaction between colloidal silica beads in aqueous solutions.

It turned out that - despite the large ion size of up to one nanometer - the interaction between the silica beads can still be described by the classical DLVO-theory of electrolyte solutions, consisting of a van der Waals attraction and an electrostatic double layer repulsion. However, the obtained screening lengths exhibit a significant deviation from the ones expected according to the nominal ionic strength of the solutions. This might be a hint for an ion aggregation. The magnitude of the deviation depends on the type of nano ion as well as the concentration of the solution.

CPP 38.5 Thu 17:30 H38

The Physics of Water-based Inkjet Printing: Fundamentals in a Nutshell — Helder Savaldor[1,2] and •Nicolae Tomozeiu[1,2] — [1]Canon Production Printing, P.O Box 101, Van der Grintenstraat 1, 5914HH Venlo, The Netherlands — [2]Fluids & Flows Group, Department of Applied Physics, Eindhoven University of Technology, The Netherlands

The printing industry is rapidly evolving, driven by advances in understanding physical-chemical processes and societal needs. Digital inkjet printing, especially with water-based inks, has become a cornerstone of sustainable and cost-effective printing, with Canon Production Printing (CPP) leading innovations in this field. The interaction between ink droplets and porous paper is crucial to achieving high-quality prints, and understanding these processes is essential for improving print performance and durability.

This work explores key scientific domains involved in CPP water-based inkjet technology. We focus on: (i) ink formulation through chemical and polymer

physics for optimal droplet formation and film creation; (ii) the dynamics of thin films, including ink spreading, evaporation, and imbibition in porous paper; (iii) surface science's role in ink absorption and spreading. We will show the use of Optical Spectroscopy, Scanning Electron Microscopy (SEM), Nuclear Magnetic Resonance (NMR) and uGISAXS to provide deeper insights into ink film formation at the micro- and nano-level. These findings optimize print quality, durability, and color properties, advancing both industrial development and academic knowledge in inkjet technology.

Nanoscale Agglomeration Mechanisms of BF-DPB:BPyMPM Donor-Acceptor Systems for Organic Optoelectronic Devices — •Milena Merkel[1], Philipp Wiesener[1], Robert Schmidt[1], Rishi Shivhare[2,3], Rudolf Bratschitsch[1], Saeed Amirjalayer[4], Koen Vandewal[2,3], and Harry Mönig[1] — [1]Physikalisches Institut, Münster University, Münster, Germany — [2]Institute for Materials Research (imo-imomec), Hasselt University, Hasselt, Belgium — [3]imec, imo-imomec, Diepenbeek, Belgium — [4]Interdisciplinary Center for Scientific Computing, Heidelberg University, Heidelberg, Germany

The molecular order of photo-active molecules of organic optoelectronic devices has major impact on their performance. However, it is usually investigated only by indirect measurements or simulations. Here we use low-temperature scanning probe microscopy to image the molecular assembly and interfaces of the donor and acceptor molecules BF-DPB and BPyMPM with submolecular resolution. We illustrate the crucial effect of the substrate and the position of the nitrogen atoms in the BPyMPM molecules on the formation of intermolecular C-H..N hydrogen bonds, metal coordination bonds and corresponding self-assemblies. Using scanning tunneling spectroscopy, we are able to correlate the increasing disorder at the BF-DPB:BPyMPM interface with an increase in the HOMO-LUMO gap of BF-DPB. Photoluminescence measurements on BF-DPB indicate a significant increase in intersystem crossing due to molecule-substrate interactions. Our results provide new insights for a tailored design of active molecules and contact layers for organic optoelectronic devices.

CPP 40.2 Fri 9:45 H34

Multi-layered electrodes for flexible solid-state super capacitors with polymer-based gel electrolyte — •Reyhaneh Bahramian[1,2,3] and Yaser Abdi[3] — [1]Department of Cognitive Sciences, Faculty of Psychology and Education, University of Tehran, Tehran, Iran — [2]Condensed Matter National Laboratory, Institute for Research in Fundamental Sciences, Tehran 19395-5531, Iran — [3]Nanophysics Research Laboratory, Department of Physics, University of Tehran, Tehran 14395-547, Iran

Flexible solid-state supercapacitors are gaining popularity due to their advantages, including flexibility, lightweight design, high power density, rapid charge and discharge rates, broad operating temperature ranges, long cycle life, safety, and ease of fabrication. The use of gel polymer electrolytes enhances ionic conductivity while addressing safety concerns associated with liquid electrolytes.

This research focuses on developing nanocomposite electrodes using Ag-decorated zinc oxide, synthesized through a chemical deposition method on carbon paper, and ferrite applied via a drop-casting technique. The goal is to create electrodes that can operate across a wide voltage range in a non-aqueous electrolyte.

Advanced characterization techniques, such as atomic force microscopy, X-ray diffraction, field emission scanning electron microscopy, and Raman spectroscopy, are employed to analyze the structural properties of the electrodes. The findings reveal an effective specific capacitance of approximately 70 milliFarads per square centimeter.

CPP 40.3 Fri 10:00 H34

Dual-cation pre-intercalated hydrated vanadium oxide achieves 20,000 cycles in aqueous zinc-ion batteries — •Yan Ran and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Aqueous zinc-ion batteries (AZIBs) have broad application prospects in energy storage due to their low cost and high safety. However, cathode materials still face challenges such as low specific capacity and decreased long-cycle performance. In this work, hydrated vanadium oxide with pre-intercalated K and Mn ions (K0.07Mn0.13V2O5*1.47H2O) was synthesized via a one-step hydrothermal method, demonstrating an excellent specific capacity of 524.7 mA h g-1 at 0.1 A g-1, and outstanding stability with 82.47% capacity retention after 20,000 cycles at 5 A g-1. The co-intercalation of dual cations increases the interlayer spacing while stabilizing the material structure, expanding the ion transport channels, and improving both the specific capacity and long-cycle stability. Moreover, the Zn2+/H+ co-intercalation mechanism was confirmed by ex-situ characterization. This work will provide insights for the development of competitive cathodes in high-performance aqueous batteries.

CPP 40.4 Fri 10:15 H34

Temperature-resolved Crystal Structure of Ethylene Carbonate — •Lea Westphal[1,2], Vladislav Kochetov[2], Volodymyr Baran[3], Maxim Avdeev[4,5], Peter Müller-Buschbaum[1], and Anatoliy Senyshyn[2] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]MLZ, TUM, 85748 Garching, Germany — [3]DESY, 22607 Hamburg, Germany — [4]ANSTO, NSW 2234, Sydney, Australia — [5]School of Chemistry, University of Sydney, NSW 2006, Sydney, Australia

Lithium-ion batteries (LIBs) have been a dominant power source for portable electronics for over three decades and are of interest for applications in electric vehicles and large-scale energy storage systems. Despite significant advancements in LIB design, the main solvents used in the liquid electrolytes, responsible for the charge transfer between the electrodes, have largely remained the same. A key class of these solvents are linear and cyclic carbonates, which, when two or more solvents are combined with lithium salts and additives, exhibit favorable physical/chemical properties. Ethylene carbonate (EC) is a common solvent in commercial batteries due to its high dielectric constant and its ability to form the protective solid-electrolyte interphase (SEI) layer. However, it has to be mixed with other solvents because of its high melting point. Following the determination of EC's crystal structure from single crystals, this study presents temperature dependent Neutron and Synchrotron Powder Diffraction data, studying the sample from 3 K up to its melting point and investigations by Synchrotron Total Scattering and Pair Distribution Function analysis.

CPP 40.5 Fri 10:30 H34

Polymer-nano-tufts: A hairy story of limited conductivity — •Martin Tress, Alaa Yussef Hassan, Nico Junkers, and Wing Kit Or — Peter-Debye-Institute for Soft Matter Research, Leipzig University, Leipzig, Germany

Here we present an approach to study conductivity in small polymer aggregates of as few as ten chains using dielectric spectroscopy [Macromol Chem Phys, 224 (2023) 2200452]. For that, a nano-structured electrode arrangement is combined with several physico-chemical surface modifications to deposit a regular pattern of gold nanoparticles onto which end-functionalized polymer chains are grafted to create tuft-like ensembles of individualized chain aggregates. For polyethylene, pronounced changes in conductivity are observed in tufts compared to bulk with details indicating an alteration of the type of charge transport. This might signal a switch from fast inter-chain ion hopping, dominating in bulk, to slower intra-chain ion hopping in the tufts attributed to the chain configurations and orientation forced by the grafting. Consequently, this could be a more general phenomenon of polymer-solid interfaces that may explain significantly increased electrode polarization and interfacial resistance in ion-conducting polymers, potentially diminishing their performance. Hence, the hypothesis, that bottle-brush architectures could reduce these unwanted effects, was developed. Supported by preliminary results, this might be a step to improve polymeric electrolytes for various fields ranging from solid-state electrolyte batteries to ion-conducting fuel cell membranes.

CPP 40.6 Fri 10:45 H34

Interpretation of the Impedance Signal of Composite Materials using a 3D Electrical Network Model — •Felix Schug[1,2], Sascha Kremer[2,3], Christian Heiliger[1,2], and Janis K. Eckhardt[1,2,3] — [1]Institute for Theoretical Physics, Justus-Liebig-University Giessen, 35392 Giessen, Germany — [2]Center for Materials Research (ZfM), Justus-Liebig-University Giessen, 35392 Giessen, Germany — [3]Institute of Physical Chemistry, Justus-Liebig-University Giessen, 35392 Giessen, Germany

All solid-state batteries (aSSBs) are promising candidates for next-generation energy storage systems, offering high energy and power densities as well as improved device safety compared to the established lithium-ion batteries. Electrochemical impedance spectroscopy (EIS) is one of the key methods to determine charge transport characteristics of the material components in an aSSB. Many of these components are composed of multiple phases, with various transport processes affecting the impedance response signal. Furthermore, the microstructure of the material manifests as a signal within the impedance spectrum. The interpretation of an impedance spectrum is therefore not straightforward, as many signals overlap or are indistinguishable from each other. We therefore employ a microstructure-resolved 3D electrical network to modulate charge transport on microscopic length scales. This approach reveals how microstructure affects the impedance response, as well as the potential and current distributions within a system. It is used to investigate the impedance of composite materials and to develop guidelines for its interpretation.

CPP 40.7 Fri 11:00 H34

Measuring Local Electrochemical Properties with Scanning Probe Microscopy — •Alexander Klasen and Andrea Cerreta — Park Systems Europe GmbH, Mannheim, Germany

Electrochemical (EC) applications, ranging from novel energy storage systems to advanced catalysts, are defined on an ever-decreasing length scale. Investigating these systems requires to map key functional features with sufficient resolution, such as the local structure, electronic properties and electrochemical response. Scanning probe microscopy-based techniques are well established to investigate surface parameters using the physical interaction with a nanometer-sized probe allows studying properties such as the topography, work function, or adhesion at high resolution. One such technique, Scanning Electrochemical Cell microscopy (SECCM), was first introduced by E. Daviddi, P.R. Unwin, et al. and uses a pipette-based SPM approach to probe local EC features. When brought in close proximity to the sample, the electrolyte-filled pipette pipette creates a small electrolyte meniscus between the pipette aperture and the surface of interest . This confined volume of solution constitutes a small electrochemical cell that allows for local measurements of electrochemical characteristics. In this talk, we discuss the basics of SECCM, present recent examples from literature, discuss the limitations of the technique and outline potential pathways to overcome those.

CPP 41: Charged Soft Matter, Polyelectrolytes and Ionic Liquids I

Invited Talk CPP 41.1 Fri 9:30 H38

Simulations of reaction equilibria in macromolecular systems — •Peter Košovan — Department of Physical and Macromolecular Chemistry, Faculty of Science, Charles University, Prague, Czechia

Most molecular simulations are performed assuming a fixed chemical composition, focusing on structural and conformational changes and intermolecular interactions, while neglecting the possible chemical changes which may occur simultaneously. In this lecture, we present an overview of our modeling work, addressing how reversible chemical reactions affect the properties of macromolecular solutions and gels. In particular, we discuss the effect of acid-base equilibria on the net charge of peptides, synthetic polyelectrolytes, polyelectrolyte hydrogels, and proteins. By comparing with experiments, we show that our models can quantitatively predict how this net charge depends on pH of the solution. Next, we show that a change in the pH can trigger attraction between macromolecules, resulting in the formation of condensates, precipitation or gelation. Finally, we show how changes in the pH can be used to control the uptake of charged proteins into coacervates, and how the pH affects the properties of protein solutions during purification processes used by the pharmaceutical industry: dialysis and ultra- or dia-filtration.

CPP 41.2 Fri 10:00 H38

Surface Charged Polymeric Micelles - A Tunable Model System Studied by SANS — Lingsam Tea[1], Luis Willner[1], Christin Waldorf[1], Olga Matsarskaia[2], Ralf Schweins[2], Stephan Förster[1], Lutz Willner[1], and •Jörg Stellbrink[1] — [1]JCNS-1, Forschungszentrum Jülich GmbH, 52425 Jülich, Germany — [2]Institut Laue-Langevin, 38042 CEDEX 9 Grenoble, France

We investigate surface charged micelles in aqueous solution formed by carboxy terminated n-octacosyl-poly(ethylene oxide) block copolymers, C-PEO5-COOH with 5 the PEO molar mass in kg/mol, by small angle neutron scattering (SANS), zeta-potential measurements and rheology. The -COOH end group was introduced by selective oxidation of the CH_3OH end group of a C-PEO5-OH precursor using Bobbitt's salt. Micellar solutions of different concentrations in the dilute and semidilute range were investigated at pH 2, 6 and 12 to vary ionic strength and the number of effective surface charges Z. Z was further varied by using mixtures of C-PEO5-COOH and C-PEO5-OH at different mixing ratios. SANS measurements reveal that the intramicellar form factor is identical at the different pH-values which implies that the individual micellar structure is unaffected by the number of surface charges. On the contrary, the intermicellar structure factor and the phase behavior show a strong dependence on Z. In particular, we observe a distinct shift of the liquid - fcc crystal phase boundary. A quantitative analysis in terms of a screened Hard Sphere Yukawa potential reveals a very good agreement between experiment and theory.

Macromolecules 2024, 57, 5818-5830

CPP 41.3 Fri 10:15 H38

Orientation analysis in polyelectrolyte multilayer and brush coatings by dichroic ATR-FTIR spectroscopy — •Martin Müller, Mirjam Hofmaier, Patricia Flemming, Olga Guskova, Alexander Münch, and Petra Uhlmann — Leibniz-Institut für Polymerforschung Dresden e.V.

Dichroic ATR-FTIR spectroscopic data on two types of thin oriented polyelectrolyte (PEL) coatings relevant for life science are presented. Trapezoidal silicon multiple internal reflection elements, sealed in-situ cell in ATR mirror attachment with polarizer and commercial FTIR spectrometer were used. (i) At first dichroic ATR-FTIR data on thin PEL multilayer (PEM) coatings composed of a-helical poly(L-lysine) and various polyanions (PLL/PA) at unidirectionally texturized silicon substrates are presented. Based on experimental dichroic ratios RATR, the known angles theta between transition dipole moment (TDM) of Amide I and Amide II vibration and a-helix axis (38°, 73°) and on calculated electrical field components Ex,y,z high in-plane y-axial orientation of PEM was identified. (ii) Secondly, thin cationic PEL brushes with three different grafting densities at silicon substrates were characterized by dichroic ATR-FTIR. Using concept of (i) and angle theta between TDM of n(C=O) vibration of PDMAEMA and molecular main axis (69°), which was determined by atomistic simulations, high out-of-plane z-axial orientation was identified. Swelling in water increased the orientation if compared to dry state. Both PEL coating types may be used as bioactive platforms towards proteins and microorganisms.

CPP 41.4 Fri 10:30 H38

Vertical Polyelectrolyte and Site Diffusion of PSS in PSS/PDADMA Multilayers — Annekatrin Sill, •Per-Ole Hilken, and Christiane A. Helm — Institute of Physics, University of Greifswald, Germany

The spontaneous formation of polyelectrolyte multilayers or polyelectrolyte complexes depends on the (inter)diffusion of polyelectrolytes. We investigate the transport of extrinsic sites - charged polyelectrolyte repeat units balanced by counterions - and their relationship to polymer diffusion. We determine the vertical diffusion coefficient D_{PSS} of polystyrene sulfonate (PSS) repeat units in polyelectrolyte multilayer films from poly (diallyldimethylammonium) (PDADMA) and PSS using a quartz crystal microbalance with dissipation (QCM-D) and analyze the observed film growth. Varying the NaCl concentration c_{NaCl} results in $D_{PSS} = 3.2{\cdot}10^{-20}\ \mathrm{m^2/s}{\cdot}e^{\alpha \cdot c_{NaCl}}$. As known from the free volume model, the prefactor is constant for each system. For site diffusion, the exponent is also constant ($\alpha \approx 4.9\ \mathrm{M^{-1}}$). For polymer diffusion, however, α increases linearly with M_{PSS}, the molecular weight of PSS. The results for site diffusion quantitatively agree with those of Fares and Schlenoff (JACS (2017) 139; 14656). Polymer diffusion occurs when $M_{PSS} < 65$ kDa (for $M_{PDADMA} = 117$ kDa). For these low PSS molecular weights, the diffusion coefficient is $D_{PSS} = B \cdot M_{PSS}^{-\gamma}$. The dependence of B on c_{NaCl} is a power law, while γ increases linearly with c_{NaCl}.

CPP 41.5 Fri 10:45 H38

Understanding the Mechanisms of pH-Sensitive Collapse of Hydrophobic Polymers — •Varun Mandalaparthy and Nico F. A. van der Vegt — Technical University, Darmstadt

The hydrophobic effect is a important contributor to the stability of proteins and may be influenced by many factors including the pH of the solution. To simplify the study of pH effects on proteins, we parameterize biologically motivated titratable monomers which we insert into the sequence of a hydrophobic polymer and study via constant pH molecular dynamics (MD) simulations. We calculate the potential of mean force of the polymer at different pH values and observe that the collapsed state of the polymer is destabilized when the titratable monomer is more charged (high pH for an acid and low pH for a base). Further, the extent of the destabilization is influenced by the position of the titratable monomer along the polymer sequence. The pK_a value of the titratable monomer is also observed to be sensitive to polymer conformation, in agreement with studies of proteins. We further study a zwitterionic polymer with an acidic and a basic monomer in the same sequence which presents a pH-dependent hairpin formation. Our

model provides a simplified yet powerful framework to study pH effects on the hydrophobic effect, providing insights into mechanisms governing the behavior of intrinsically disordered proteins (IDPs) and pH-sensitive drug delivery, among other applications.

CPP 41.6 Fri 11:00 H38

Machine learning potentials for redox chemistry in solution — •Redouan El Haouari[1,2], Emir Kocer[1,2], and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany

Machine-Learning Potentials (MLPs), which can offer the accuracy of quantum mechanics at a fraction of the costs, have been applied with great success in atomistic simulations of many systems. Still, most MLPs rely on environment-dependent atomic energies, and are thus unable to distinguish different oxidation states of simple ions in solution. Here, we show for the example of ferrous (Fe2+) and ferric (Fe3+) chloride in aqueous solution that this limitation can be overcome with 4th-Generation High-Dimensional Neural Network Potentials (4G-HDNNPs), in which the local atomic energies are complemented with global charges from a charge equilibration scheme. We find that the iron oxidation states match the total number of chloride ions in the system irrespective of their positions. Furthermore, the model captures charge transfers between ferrous and ferric ions, enabling the general simulation of redox chemistry in solution involving different oxidation states.

Invited Talk CPP 42.1 Fri 9:30 H44

Wave propagation in systems of active filaments — •Kirsty Y. Wan — Living Systems Institute, University of Exeter, UK

Active hair-like protrusions called cilia are found in many eukaryotes where they produce physiological flows for a variety of functions. Cilia assume a myriad of configurations both external to an organism for the purposes of feeding or swimming motility, but also internally where they mediate mucociliary clearance in vertebrate tissues. Single cilia can propagate large-amplitude non-decaying bending waves, even in the absence of a cell body. These waves assume a variety of stereotyped forms and frequencies, depending on the species. Multiple cilia also interact to produce different types of local and global coordination patterns, including robust metachronal waves. Do these dynamic states of coordination arise spontaneously, or do they require some form of internal control by the cell or animal? We propose new and emerging organisms to address these questions.

CPP 42.2 Fri 10:00 H44

Metabolic activity controls the emergence of coherent flows in microbial suspensions — •Florian Böhme[1], Alexandros Fragkopoulos[1,2], Nicole Drewes[2], and Oliver Bäumchen[1,2] — [1]University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany — [2]Max Planck Institute for Dynamics and Self-Organization (MPIDS), 37077 Göttingen, Germany

Photosynthetic microbes have evolved and successfully adapted to the spatio-temporal variations of environmental parameters within their habitat. In the absence of light, they can still sustain their biological functionality and metabolic activity through aerobic respiration. However, for the soil-dwelling microalga *Chlamydomonas reinhardtii*, their environment may be deprived of both oxygen and light, resulting in a significant reduction of their swimming velocity [1]. Here, we study the effect of motility and cell density of *C. reinhardtii* in a confined system, on the emergence of bioconvection [2]. This collective phenomenon can be reversibly switched by light and arises due to the natural tendency of the bottom-heavy cells to move against gravity. We show that the rate at which the system evolves, as well as the dominant wavelength of the instability can both be directly controlled by the number density of cells. Further, we provide insights on the internal flow fields and density profiles of single bioconvection plumes for different parameters.

CPP 42.3 Fri 10:15 H44

Tumbling *E.coli* in bulk and close to surfaces — •Pierre Martin[1], Tapan Chandra Adhyapak[2], and Holger Stark[1] — [1]Institute of Theoretical Physics, Hardenbergstr. 36, 10623 Berlin, Germany — [2]Indian institute of science education and research (IISER), Tirupati, India

Escherichia coli (*E. coli*) swims by rotating multiple flagella which are connected to the cell body forming a thick bundle. To change direction, *E. coli* performs tumble events by reversing the rotation of one or more flagella. The involved filaments undergo a series of polymorphic transformations, altering both their helicity and handedness. This complex phenomenon involves the interplay of semiflexible filaments and hydrodynamic flow fields.

Here, we have developed a detailed numerical framework to simulate *E. coli*, capturing the full dynamics of flexible flagella, including their polymorphism and their hydrodynamic interactions. The filaments and the cell body are embedded in a viscous fluid, which we model using multi-particle collision dynamics. We analyzed a large number of tumble events, with fixed tumble time or taken from a gamma distribution, exploring the roles of hook and flagellar flexibility as well as flagellar polymorphism. We find that they strongly influence the distribution of tumble angles. Finally, we also show that close to a flat surface the mean tumble angle is strongly shifted to smaller values. This indicates that tumble events may not be recognized, which could give the impression of suppressed tumbling near surfaces.

CPP 42.4 Fri 10:30 H44

***Trypanosoma brucei* (un)chained - effects of confinement on a parasitic microswimmer** — •Hannes Wunderlich[1], Marinus Thein[2], Lucas Brehm[2], Klaus Ersfeld[2], and Matthias Weiss[1] — [1]Experimental Physics I, University of Bayreuth — [2]Laboratory of Molecular Parasitology, University of Bayreuth

Trypanosoma brucei is a parasitic unicellular microswimmer that causes the African sleeping sickness. An active spiral movement of the parasite, mediated by a microtubule-driven flagellum that wraps around the cell body, is mandatory to evade the host's immune system while exploring tissues and blood vessels. In addition, the nematic subpellicular micotubule array plays a pivotal role in the elasticity, propulsion, and navigation of the parasite. To study the features and mechanisms behind the cell's motion in such complex environments, we have mimicked spatial confinement in microfluidic devices with different geometries. Our data show that spatial constraints in narrow channels and channel networks can improve cell locomotion of wild-type trypanosomes, supposedly due to the interaction of the elastic cell body and nearby walls. The addition of microtubule-disrupting drugs or the use of mutant strains with altered post-translational modifications of microtubules resulted in significantly altered swimming velocities and marked changes in the intermittent switching between run and tumble phases. Shape analyses of individual cells suggest that microtubules in the sub-pellicular array, the corset that keeps trypanosomes in their native spindle-like shape, are most affected in these cases.

CPP 42.5 Fri 10:45 H44

Micro-swimmer motility in presence of signaling factors — Agniva Datta, Robert Grossmann, and •Carsten Beta — Institute of Physics and Astronomy, University of Potsdam, Germany

The navigation of bacteria through aqueous environments, driven by the rotation of helical flagella, has been a significant region of interest in the biophysics community for the last few decades. In this study, we focus on the motility of our model organism, Pseudomonas putida, which exhibits persistent mobile episodes (Active Brownian motion) interrupted by stochastic reorientation events (turns), driven by flagellar self-propulsion, thereby leading to a run-and-turn motility.

Key motility parameters including tumbling rates, run lengths, trajectory persistence (rotational diffusion coefficient), and the characteristics of the self-propulsion force*are hypothesized to depend on the density of quorum-sensing autoinducer molecules, produced by the bacteria themselves as signaling factors. To test this hypothesis, we expose swimming bacteria to aqueous environments with controlled autoinducer concentrations and analyze the resulting changes in motility patterns. Through a combination of experimental data and theoretical modeling, we aim to elucidate the principles of micro-swimmer motility in presence of signaling molecules.

CPP 42.6 Fri 11:00 H44

Collective dynamics of active dumbbells near a circular obstacle — •Chandranshu Tiwari[1] and Sunil Singh[2] — [1]Department of Physics, Indian Institute of Science Education and Research, Bhopal 462066, India. — [2]Department of Physics, Indian Institute of Science Education and Research, Bhopal 462066, India.

We present the collective dynamics of active dumbbells in the presence of a static circular obstacle using Brownian dynamics simulation. The active dumbbells aggregate on the surface of a circular obstacle beyond a critical radius, and the aggregate size increases with the activity and the curvature radius. The dense aggregate of active dumbbells displays persistent rotational motion with a certain angular speed, which linearly increases with activity. Furthermore, we show a strong polar ordering of the active dumbbells within the aggregate. The polar ordering exhibits long-range correlation, with the correlation length corresponding to the aggregate size. Additionally, we show that the residence time of an active dumbbell on the obstacle surface increases rapidly with area fraction due to

many-body interactions that lead to a slowdown of the rotational diffusion. This article further considers the dynamical behavior of a tracer particle in the solution of active dumbbells. Interestingly, the speed of the passive tracer particle displays a crossover from monotonically decreasing to increasing with the size of the tracer particle upon increasing the dumbbells' speed. Furthermore, the effective diffusion of the tracer particle displays non-monotonic behavior with the area fraction; the initial increase in diffusivity is followed by a decrease for a larger area fraction.

CPP 42.7 Fri 11:15 H44

Free growth under tension — •Chenyun Yao and Jens Elgeti — Forschungszentrum Jülich GmbH, Jülich, Germany

Ever since the ground breaking work of Trepat et al. in 2009, we know that cell colonies growing on a substrate can be under tensile mechanical stress. The origin of tension has so far been attributed to cellular motility forces being oriented outward of the colony. Works in the field mainly revolve around how this orientation of the forces can be explained, ranging from velocity alignment, self-sorting due to self-propulsion, to kenotaxis.

In this work, we demonstrate that tension in growing colonies can also be explained without cellular motility forces! Using a combination of well established tissue growth simulation technique and analytical modelling, we show how tension can arise as a consequence of simple mechanics of growing tissues. Combining these models with a minimalistic motility model shows how colonies can expand while under even larger tension. Furthermore, our results and analytical models provide novel analysis procedures to identify the underlying mechanics.

CPP 42.8 Fri 11:45 H44

A route to active turbulence in circular activity spots — •Arghavan Partovifard and Holger Stark — Institute of Theoretical Physics, Institut für Theoretische Physik, Technische Universität Berlin, Hardenbergstr. 36, 10623Berlin, Germany.

Active nematics exhibit distinctive behavior such as active turbulence and regular flow patterns under spatially varying activity [1]. Utilizing the Doi-Edwards theory supplemented by an active stress tensor [1], we investigate active nematics confined to a circular spot by switching off activity outside the spot. The open boundary allows topological defects to enter and leave the spot.

We calculate the total topological defect charge inside the spot using three approaches: counting all defects, measuring the rotation of the director field along the rim of the spot, and integrating the diffusive charge density. All methods agree that for spot radii just larger than the nematic coherence length, the system has a total topological charge of +1, where two +1/2 defects perform a regular swirling motion. As the radius increases, more defects enter and their motion becomes more and more chaotic. Ultimately, the charge per unit area saturates at the value characteristic of bulk active turbulence. For the range of radii where the total charge in the spot is +1, the nematic director exhibits shear-induced anchoring at an angle of 45° with respect to the tangent at the spot rim. With increasing radius, when more defects enter, the anchoring angle deviates from 45° but its distribution still peaks around this value.

Cognitive flocks: order-disorder transitions and threat evasion — •Priyanka Iyer[1], Cecilia Soroco[2], and Gerhard Gompper[1] — [1]Forschungszentrum Jülich — [2]University of British Columbia, Canada

Directed self-propulsion is ubiquitous in living organisms. From E.Coli dispersing in biofilms to migrating bird flocks, living organisms are constantly out-of equilibrium. By sensing their environment and adjusting their movement, organisms can exhibit emergent patterns and collective behaviors, such as self-organization in human crowds [1], bird flocks, and fish schools. The Inertial Spin Model (ISM) was introduced to explain the fast and robust propagation of information in bird flocks [2], when only alignment interactions are considered. However, more generally, agents exhibit a variety of interactions like local avoidance, cohesion and threat evasion. We show how such behaviors can be incorporated within the framework of the ISM. It is found that local avoidance introduces emergent noise in the system, triggering an order-disorder transition. Exploring the flock dynamics near this transition reveals a complex interplay between cohesion, alignment, and local avoidance, resulting in diverse behaviors such as pronounced shape and density fluctuations, and diffusive motion of the flock. Lastly, by applying the model to a stationary threat scenario, we analyze flock properties that govern threat information propagation in the flock.

Myosin-independent amoeboid cell motility — •Winfried Schmidt, Alexander Farutin, and Chaouqi Misbah — Univ. Grenoble Alpes, CNRS, LIPhy, F-38000 Grenoble, France

Mammalian cell motility is essential for many physiological and pathological processes, such as the immune system, embryonic development, wound healing, and cancer metastasis. Cells have developed the amoeboid migration mode which allows them to move rapidly in a variety of different environments, including two-dimensional confinement, three-dimensional matrix, and bulk fluids. We introduce a model for an amoeboid cell where the cortex is described as a thin shell along the cell surface. The cell shape evolves due to polymerization of actin filaments and the forces acting on the cortex. We find analytically and numerically that the state of a resting, non-polarized cell can become unstable for sufficiently large actin polymerization velocities, resulting in the spontaneous onset of cell polarity, migration, and dynamical shape changes. Notably, this transition only relies on actin polymerization and does not necessitate molecular motors, such as myosin. These findings yield a deeper understanding of the fundamental mechanisms of cell movement and simultaneously provide a simple mechanism for cell motility in diverse configurations.

CPP 42.11 Fri 12:30 H44

Active membrane deformations of a synthetic cell-mimicking system — Alfredo Sciortino[1], •Dmitry Fedosov[2], Gerhard Gompper[2], and Andreas Bausch[1] — [1]Physik Department, Technische Universität München, Garching bei München, Germany — [2]Institute for Advanced Simulation, Forschungszentrum Jülich, Jülich, Germany

Biological cells are fascinating micromachines capable of adapting their shape due to the complex interaction between a deformable membrane and the dynamic activity of the cytoskeleton. We investigate the behavior of an active synthetic cell-mimicking system using simulations and experiments. In simulations, the model consists of a fluid vesicle with a few encapsulated growing filaments. In experiments, giant vesicles contain an active cytoskeletal network composed of microtubules, crosslinkers, and molecular motors. These active vesicles show strong shape fluctuations reminiscent of shape changes of biological cells. We analyze membrane fluctuations and show how the intricate coupling between soft confinement and internal active forces results in fluctuation spectra with distinct spatial and temporal scales, differing significantly from those of passive vesicles. Simulations demonstrate the universality of this behavior, quantifying the impact of correlated activity on the dynamics of membrane deformations. This model makes a step toward quantitative description of shape-morphing artificial and living systems.

CPP 42.12 Fri 12:45 H44

Force Generation by Enhanced Diffusion in Enzyme-Loaded Vesicles — Eike Eberhard, •Ludwig Burger, Cesar Pastrana, Giovanni Giunta, and Ulrich Gerland — Physik komplexer Biosysteme, Technische Universität München, Deutschland

Recent experiments show that the diffusion coefficient of some metabolic enzymes increases with the concentration of their cognate substrate, a phenomenon known as enhanced diffusion. In the presence of substrate gradients, enhanced diffusion induces enzymatic drift, resulting in a non-homogeneous enzyme distribution. In this work, we study the behavior of enzyme-loaded vesicles exposed to external substrate gradients using a combination of computer simulations and analytical modeling. We observe that the spatially inhomogeneous enzyme profiles generated by enhanced diffusion result in a pressure gradient across the vesicle, which leads to macroscopically observable effects, such as deformation and self-propulsion of the vesicle. Our analytical model allows us to characterize dependence of the velocity of propulsion on experimentally tunable parameters. The effects predicted by our work provide an avenue for further validation of enhanced diffusion, and might be leveraged for the design of novel synthetic cargo transporters, such as targeted drug delivery systems.

From Cavitation in Soft Matter to Erosion on Hard Matter — •Claus-Dieter Ohl — Institute of Physics, Otto-von-Guericke University, Magdeburg, Germany

Cavitation is the technical term for the formation of empty spaces in a liquid. These unstable voids eventually implode and focus energy on small volumes. Shock wave emission, light emission, erosion, and even nuclear reactions are the consequence of this near singular energy focusing. Here, I will present recent research related to cavitation not only in liquids but also in elastic solids and particularly at the interface of both materials. Singularities developing on the axis of symmetry in non-spherical collapses near boundaries are able to amplify shock waves through self focusing. We think that this mechanism is the primary cause for erosion. In contrast, the non-spherical collapse and shock wave focusing near a tissue allows for the penetration of the tissue with liquid jets at 1000m/s and above. The mechanism at play may be relevant in sports and battle zones, as they could lead to traumatic brain injuries.

CPP 43.2 Fri 10:00 H47

Shape switching and tunable oscillations in adaptive droplets — •Tim Dullweber[1,2], Roman Belousov[1], Camilla Autorino[1,4], Nicoletta Petridou[1], and Anna Erzberger[1,3] — [1]European Molecular Biology Laboratory, Heidelberg, Germany — [2]University Heidelberg, Heidelberg, Germany — [3]Institute for Theoretical Physics, Heidelberg University, Heidelberg, Germany — [4]Faculty of Biosciences, Heidelberg University, Heidelberg, Germany

Soft materials can undergo irreversible shape changes when driven out of equilibrium. When shape changes are triggered by processes at the surface, geometry-dependent feedback can arise. Motivated by the mechanochemical feedback observed in multicellular systems, we study incompressible droplets that adjust their interfacial tensions in response to shape-dependent signals. We derive a minimal set of equations governing the mesoscopic droplet states, controlled by just two dimensionless feedback parameters. We find that interacting droplets exhibit bistability, symmetry-breaking, excitability and tunable shape oscillations ranging from near-sinusoidal to relaxation-type. We apply our framework to model shape measurements in zebrafish embryos and identify a shape-switching mechanism promoting boundary formation. The underlying critical points reveal novel mechanisms for physical signal processing through shape adaptation in soft active materials, and suggest new modes of self-organization at the collective scale.

CPP 43.3 Fri 10:15 H47

Impact of the history force on the motion of droplets in shaken liquids — •Frederik Gareis and Walter Zimmermann — Theoretical Physics, University of Bayreuth

The Basset-Boussinesq history (BBH) force acts on droplets and solid particles in flows, alongside stationary viscous friction, inertia, and gravitational forces. This force arises from vortex shedding around objects undergoing unsteady acceleration. In this study, we analytically calculate the BBH force for spherical, sedimenting heavy particles in horizontally shaken (periodically accelerated) fluids at low Reynolds numbers and identify the parameter ranges where BBH effects are significant. Our results reveal that BBH can increase particle displacement amplitude by over 60 percent, particularly in the transition region between the low-frequency viscous Stokes regime and the high-frequency inertia-dominated regime. Additionally, we derive a power law for the oscillatory displacement amplitude of a particle around its mean position in a horizontally shaken fluid, facilitating clear experimental identification of BBH effects.

CPP 43.4 Fri 10:30 H47

Bubble Dynamics and Transport in Porous Structures: Insights from Mesoscale Simulations — •Qingguang Xie[1], Othmane Aouane[1], and Jens Harting[1,2] — [1]Forschungszentrum Jülich GmbH, Helmholtz-Institut Erlangen-Nürnberg (IET-2), Erlangen, Germany — [2]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany

Bubble formation, detachment, and transport within porous structures are critical phenomena in various applications, including electrolyzers and chemical reactors. We numerically investigate the dynamics of bubble growth and detachment at a catalytic surface using the lattice Boltzmann method. The departure radius of a bubble, growing with either a pinned or moving contact line, shows good agreement with theoretical predictions. Beyond detachment, we examine the subsequent transport of bubbles through a porous transport layer, systematically evaluating transport efficiency by considering factors such as pressure gradients, reaction rates, and pore wettability. Our findings provide valuable insights for optimizing the design of porous structures, potentially resulting in enhanced performance in electrolyzers and other gas-evolving devices.

CPP 43.5 Fri 10:45 H47

Displacements in thin fluid and elastic films — •Andreas M. Menzel — Otto von Guericke University Magdeburg, Germany

We address the displacements of comparatively small objects in flat thin fluid films under low-Reynolds-number conditions or in flat thin elastic sheets under linear elasticity.

It is well-known that the fundamental solution of the corresponding continuum equations for forced in-plane displacements diverges logarithmically in strictly two-dimensional systems, the so-called Stokes paradox. We provide an illustrative way of interpretation and demonstrate how the divergence cancels under pairwise interactions and confinement [1,2]. Interestingly, logarithmic spatial dependencies prevail under rectangular clamping of elastic membranes [3]. Moreover, the divergence is still present in free-standing sheets of finite thickness, unless they are stabilized, for instance, by substrates [4,5].

We are confident that our analytical results will prove useful in corresponding quantitative experimental evaluations.

Magnetic dynamics in ferromagnetic liquid crystal emulsions — •Christoph Klopp[1], Hajnalka Nádasi[1], Darja Lisjak[2], and Alexey Eremin[1] — [1]Otto von Guericke University, Institute of Physics, 39106 Magdeburg, Germany — [2]Jozef Stefan Institute, Department for Materials Synthesis, 1000 Ljubljana, Slovenia

We explore magnetic liquid crystal (LC) emulsions for applications as manipulatable chemical sensors in giant cells of Characean algae. Such emulsions can be controlled by magnetic fields and provide targeted drug delivery or sensing [1]. The investigated emulsions consist of a ferromagnetic liquid crystal [2] dispersed in an aqueous solution. We investigate the dynamic magnetic response using AC-susceptometry [3] as a function of the carrier medium viscosity and the particle or droplet size distribution. The emulsions' magnetic spectra differ drastically from those in the bulk of the hybrid liquid crystal mixture. We demonstrate the influence of the liquid crystal director configuration at the water-droplet interface by analyzing the effect of different surfactants (mainly SDS and PVA) in the aqueous phase.

CPP 43.7 Fri 11:30 H47

Drying effects in soft colloidal monolayers — •Kai Luca Spanheimer[1], Matthias Karg[2], Nicolas Vogel[3], Liesbeth Janssen[4], and Hartmut Löwen[1] — [1]Institut für Theoretische Physik II: Weiche Materie Heinrich-Heine-Universität, 40225 Düsseldorf, Germany — [2]Physikalische Chemie I: Kolloide und Nanooptik Heinrich-Heine-Universität, 40225 Düsseldorf, Germany — [3]Lehrstuhl für Partikelsynthese Friedrich-Alexander-Universität,91058 Erlangen, Germany — [4]Soft Matter and Biological Physics Eindhoven University of Technology, 5600 MB Eindhoven, The Netherlands

Langmuir-Blodgett deposition is a staple of colloidal monolayer research. It is used in sample preparation for imaging techniques, that spatially resolve colloid patterns. Recent experimental observations have shown that drying can strongly rearrange micron sized microgel patterns after their deposition. The usual dictum that these drying effects do not play a role for colloidal deposition can thus not be held up as a general rule. While capillary effects are well known to be strong at microscopic length scales and play a significant role in drying processes they have been mostly neglected concerning Langmuir-Blodgett deposition. In order to better understand the mechanism of drying we propose a model based on capillary attraction as well as hard core and soft shell repulsion. This model reproduces colloid patterns observed at interfaces as well as ones that occur after drying in the corresponding parameter regimes. From here we are able to derive parameter ranges where drying can play a role in rearranging patterns of colloids and where it can't.

CPP 43.8 Fri 11:45 H47

Interplay of Elasticity and Capillarity in Droplets on Flexible Sheets — •Salik Sultan and Holger Stark — Technische Universität Berlin, Institute of Theoretical Physics, Hardenbergstr. 36, 10623 Berlin, Germany

Droplets resting on flexible sheets deform into lens-like shapes, offering promising applications in areas like tunable liquid lenses. We have extended and employ our fully three-dimensional Boundary Element Method (BEM) simulation framework [1] to investigate dynamic wetting on thin flexible sheets. Our study focuses on the intricate interplay between the mechanical properties of the sheet and droplet behavior, particularly emphasizing contact angle and droplet shape. By varying the tension and mechanical properties of the sheet, our model demonstrates how we can control and tune the shape of the droplet. Additionally, by introducing stiffness gradients, we aim to explore the potential to steer droplets along the sheet via durotaxis. The versatility of our model suggests potential extensions to other soft material and droplet interactions, such as capillary origami. This work sheds light on the complex interactions between soft substrates and liquid interfaces, leading the way for advancements in material science and interfacial biology.

Cluster quasicrystals composed of ultrasoft particles vs. soft quasicrystals built of colloids with hard cores — Robert F.B. Weigel and •Michael Schmiedeberg — Theoretical Physics: Lab for Emergent Phenomena, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

We study and compare two different approaches for the stabilization of quasicrystals:

First, we consider a Phase Field Crystal model of complex patterns that self-assemble in systems consisting of ultrasoft colloids. Quasicrystals can be either stabilized by interactions with multiple length scales [1,2] or by preferred binding angles as in patchy colloids [3].

Second, we study a system with patchy colloids with a hard core with a Density Functional Theory. The hard-core is implemented by using a variant of the Fundamental Meassure Theory [4] that probably is the best mean field approach to hard particles.

While the ultrasoft particles assemble in cluster quasicrystals where the particles can completely overlap, in case of hard cores we observe structures that are rather dominated by the tiles that occur on a local level. Our results explain the differences between quasicrystlas that occur in different systems.

Beyond rings and chains: exploring porous crystals and flexible networks with magnetic colloids — •Carina Karner — Technische Universität Wien

We report on the self-assembly of magnetic colloids engineered with two distinct magnetic patches positioned at their poles, an advancement from traditional Janus particles with a single magnetic dipole. While Janus particles are known to form a variety of superstructures including chains, rings, and close-packed arrangements [1], the two-patch design significantly expands the range of achievable structures. Our simulation study reveals the formation of porous networks with adjustable flexibility, variable pore sizes, and controllable crystalline order. Notably, we observe the formation of a porous Kagome lattice, reminiscent of the experimental Kagome lattice observed colloids with two hydrophobic patches, the well known Janus-triblock system [2]. This enhanced self-assembly behavior in two-patch magnetic particles opens up further possibilities for creating fully tunable, field-responsive ferrofluids. Such systems could useful for applications requiring externally modulated viscosity, such as adaptive damping systems in automotive and aerospace engineering. [1] Vega-Bellido, G. I., DeLaCruz-Araujo, R. A., Kretzschmar, I., & Córdova-Figueroa, U. M. (2019). Self-assembly of magnetic colloids with shifted dipoles. Soft Matter, 15(20), 4078-4086. [2] Chen, Q., Bae, S. CPP 43.11 Fri 12:30 H47

Effect of geometrical confinement on friction in soft solids — •Aashna Chawla and Deepak Kumar — Department of Physics, Indian Institute of Technology Delhi, New Delhi 110016, India

Soft and biological materials come in a variety of shapes and geometries. When two soft surfaces with mismatched Gaussian curvatures are forced to fit together, beautiful patterns emerge at the interface due to geometry-induced stress. In this study, we explore the effect of geometrically incompatible confinement of a thin sheet on a soft hydrogel substrate on friction. We use a novel experimental setup to measure the friction between a thin flat elastic sheet placed on a low-friction hydrogel substrate. We show that the frictional force at the interface strongly depends on the geometry and is significantly larger for the geometrically incompatible configuration of a flat sheet on a spherical substrate compared to the other two geometrically compatible configurations: flat sheet on a flat substrate and flat sheet on a cylindrical substrate. Furthermore, for the incompatible configuration of the flat sheet on a spherical substrate, we observe that the frictional force increases monotonically with the sheet radius, with a transition in the behavior at an intermediate radius. We show that these effects arise from the coupling of the stress developed in the sheet due to its geometrically incompatible confinement with the curvature of the interface, resulting in an increased normal force, thereby increasing friction. The insights gained from this study could have significant implications for our understanding of friction in various biological, nanoscale, and other soft systems.

CPP 44: 2D Materials

Time: Friday 11:30–12:30 Location: H34

CPP 44.1 Fri 11:30 H34

Sensors based on graphene field-effect transistors functionalized with molecularly imprinted polymers — •David Kaiser[1], Hamid Rasouli[1], Michael Ringleb[2,3], Ludwig Büttner[2], Martin Hager[2,4], Guobin Jia[5], Jonathan Plentz[5], Christian Beringer[4], Patrick Bräutigam[4], Uwe Hübner[5], Patrick Endres[2], Christof Neumann[1], Steffi Stumpf[2,3], Benjamin Dietzek-Ivanšić[1,4,5], Ulrich S. Schubert[2,3,4] und Andrey Turchanin[1,3,4] — [1]Institute of Physical Chemistry, Friedrich Schiller University Jena — [2]Laboratory of Organic and Macromolecular Chemistry, Friedrich Schiller University Jena — [3]Jena Center for Soft Matter, Friedrich Schiller University Jena — [4]Center for Energy and Environmental Chemistry Jena, Friedrich Schiller University Jena — [5]Leibniz Institute of Photonic Technology (Leibniz IPHT)

Monitoring of micropollutants has become a regulatory requirement due to their environmental and health impacts. However, their on-site detection remains challenging, as current methods require transporting samples to centralized laboratories. Here, we present a method for the direct identification of the pharmaceutical carbamazepine (CBZ) utilizing solution-gated graphene field-effect transistors (SG-GFETs) that is appropriate for on-site use. We integrate molecularly imprinted nanoparticles (MIPs) with a diameter of 20 nm onto graphene via their self-assembly, creating highly stable films that specifically bind CBZ, and demonstrate a detection sensitivity reaching as low as 1 pM in buffer solutions and 10 pM in samples of environmental water.

CPP 44.2 Fri 11:45 H34

Efficient DFT Band Gap Correction for 2D-Covalent Organic Frameworks Towards Hybrid Functional Level — •Laura Fuchs and Frank Ortmann — Technische Universität München, TUM School of Natural Sciences

Density functional theory (DFT) is the workhorse computational tool for predicting the structure and physical properties of inorganic and organic molecules as well as semiconductors. Unfortunately, the optical and fundamental band gaps are not well described by semi-local DFT approaches. In particular, common DFT methods like the local density approximation (LDA) and the generalized gradient approximation (GGA) severely underestimate the fundamental band gaps, which is commonly referred to as the "band gap problem". However, the correct band gap is of utmost importance for evaluating the suitability of materials such as organic semiconductors for applications like photocatalysis or green energy harvesting. Besides highly expensive many-body perturbation theory, hybrid functionals can address the band gap problem. However, these functionals still involve high computational costs and, for large two-dimensional covalent organic frameworks (2D-COFs), these efforts are not always feasible. Here, we study the relation between semi-local PBE and hybrid HSE06 functionals and present a simple and computationally cheap scheme to extrapolate the PBE band gaps in 2D-COFs to a more precise band gap at HSE06 level.

CPP 44.3 Fri 12:00 H34

Towards the Computational Design of Molecular Olfactory Receptors for Digital Odor Detection — •Li Chen[1], Leonardo Medrano Sandonas[1], Arezoo Dianat[1], Nina Tverdokhleb[1], Rafael Gutierrez[1], Alexander Croy[2], and Gianaurelio Cuniberti[1] — [1]Institute for Materials Science and Max Bergmann Center for Biomaterials, TUD Dresden University of Technology, 01062 Dresden, Germany — [2]Institute of Physical Chemistry, Friedrich Schiller University Jena

We present the MORE-Q dataset using quantum-mechanical (QM) simulations for dimer systems composed of body odor volatilome (BOV) and olfactory re-

ceptors. The dataset contains abundant QM properties of diverse BOV-receptor systems, both in the gas phase and when deposited on a graphene surface. After analyzing the property space spanned by MORE-Q, we observed flexibility when searching for a dimer configuration with a desired set of electronic binding features. To gain insights into the complex interplay between these sensing properties, an ensemble learning method (XGBoost) was constructed for the fast evaluation of BOV adsorption behavior using only the dimer configurations properties. The results show a significant increase in model performance by adding multiple conformers to the training procedure, and SHAP analysis identifies the most relevant descriptors for predicting the binding features. Our work provides valuable insights into the the sensing mechanism of BOV molecules and paves the way for the computational design of receptors with targeted sensitivity and selectivity.

CPP 44.4 Fri 12:15 H34

Effective EMI shielding solutions: the role of 2D materials and their performance across frequency ranges — •Reyhaneh Bahramian[1,2] and Mohammad Nezafati[2] — [1]Department of Cognitive Sciences, Faculty of Psychology and Education, University of Tehran, Tehran, Iran — [2]Condensed Matter National Laboratory, Institute for Research in Fundamental Sciences, Tehran 19395-5531, Iran

The rise in electronic device usage has led to increased electromagnetic interference (EMI), creating a pressing need for effective shielding materials that are flexible, lightweight, cost-efficient, and high-performing. Two-dimensional (2D) materials are emerging as strong candidates for next-generation EMI shielding solutions. This review examines the origins of electromagnetic responses and shielding mechanisms, focusing on photon-matter interactions, and evaluates the instruments and standards for measuring shielding effectiveness.

Recent advancements in 2D materials for EMI shielding are analyzed, comparing their performance across different frequency ranges with other composite materials. Although 2D material-based composites show significant promise, challenges remain in expanding their applications, particularly in the sub-gigahertz range.

CPP 45: Charged Soft Matter, Polyelectrolytes and Ionic Liquids II

Time: Friday 11:30–12:45 Location: H38

CPP 45.1 Fri 11:30 H38

Binding of small molecules to polyelectrolytes driven by electrostatics — •Ulrich Scheler — Leibniz-Institut für Polymerforschung Dresden e.V., Hohe Str. 6, 01069 Dresden

The interaction of small molecules or ligands to macromolecules (polyelectrolytes or proteins) in solution is plays an important role in biological and medical applications. Pulsed-field-gradient (PFG) nuclear magnetic resonance (NMR) has been applied to measure translational motion of molecules and complexes in aqueous solution, that may be diffusion orelectrophoretic motion. Two-dimensional NMR experiments correlating chemical shift that is used to assign different species with either the diffusion coefficient or the electrophoretic mobility enable determining the mobility of diffusion coefficient respectively in mixtures for the individual components. From the combination of diffusion and electrophoresis NMR the effective charge of the species under investigation is derived. Weak interaction of the ligand to the macromolecule means that the ligand binds for a fraction of time to the macromolecule and is free in the solution for another fraction. From the thus observed weighted average the bound fraction is calculated for every condition no titration experiment is required. The strong polyelectrolyte PDADMAC has been studied interacting with glutamic acid as a function of pH. The bound fraction of glutamic acid increases with increasing pH and thus increasing negative charge of glutamic acid showing that the interaction is driven by electrostatic interaction rather than other possible interactions. The bound fraction as a function of pH coincides with the charge.

CPP 45.2 Fri 11:45 H38

How charge regulation affects adsorption of proteins into polyelectrolyte brushes: A simulation study — •Keerthi Radhakrishnan and Christian Holm — Institute for Computational Physics, University of Stuttgart, D-70569 Stuttgart, Germany

In recent years, polyelectrolyte (PE) brushes have drawn significant attention for their industrial and biomedical applications, particularly their ability to immobilize proteins via electrostatic interactions, even beyond the isoelectric point where both brush and protein share a similar charge. This counterintuitive phenomenon is normally attributed to "charge patch" effects from protein surface heterogeneity or "charge regulation" involving reionization and charge reversal near charged entities.

Using coarse-grained simulations, we investigate weak PE brushes interacting with pH-responsive ampholytic nanoparticles exhibiting patchy and non-patchy charge distributions. Building on prior single-ion models, we incorporate realistic protein models with asymmetric charge group distributions to explore higher-order and charge patch-induced effects. Our findings reveal the critical role of charge regulation stemming from anisotropic nanoparticle surface charge, brush potential, and brush-induced pH modulation in driving protein adsorption beyond the isoelectric point.

[1] K. Radhakrishnan, D. Beyer, and C. Holm, How Charge Regulation Affects pH-Responsive Ampholyte Uptake in Weak Polyelectrolyte Brushes, https://doi.org/10.26434/chemrxiv-2024-b10lj-v2., Macromolecules, in print.

CPP 45.3 Fri 12:00 H38

Molecular Dynamics Simulations of Structural and Dynamical Properties of Polymerized Ionic Liquids — •Arshid Ahmad and Michael Vogel — Institute for Condensed Matter Physics, Technische Universität Darmstadt, Darmstadt, Germany

Ionic liquids consist of cations and anions and have melting points less than 100°C. Their key features include negligible vapor pressure, high thermal stability, and favorable solvation properties, rendering them valuable materials for applications, e.g., in green chemistry and electro-chemistry. In addition to these simple ionic liquids (SILs), polymerized ionic liquids (PILs) receive considerable attention because they add the favorable mechanical properties of polymers to these systems. We present MD simulations of a SIL and a corresponding PIL. The latter comprises BF4 anions and polymerized cations, which feature imidazolium rings connected by 6 methylene groups along the backbone. We use MD simulations to determine both structural and dynamical prop- erties of this PIL. In particular, we relate the temperature-dependent local and diffusive dynamics of the anions and polymerized cations and we analyze dynamical couplings of both components. For the anions, the analysis includes the mechanism and f the motion. For the polymerized cations, we investigate not only the segmental motion but we also tackle the question to which degree the Rouse model is capable of describing the dynamics of highly charged polymer chains, which strongly interact with counter-ions. A detailed comparison of the results for the SIL and PIL reveals the effects of cation polymerization on structural and dynamical properties.

CPP 45.4 Fri 12:15 H38

Condensate size control by charge asymmetry — •Chengjie Luo[1], Nathaniel Hess[2], Dilimulati Aierken[2], Yicheng Qiang[1], Jerelle A. Joseph[2], and David Zwicker[1] — [1]Max Planck Institute for Dynamics and Self-Organization — [2]Princeton University

Biomolecular condensates are complex droplets composed of various types of biomolecules, including nucleic acids and proteins. These condensates form mainly due to liquid-liquid phase separation, which is driven by short-range attraction between biomolecules. Typical biomolecules carry various net charges, so that long-ranged electrostatic interactions could affect phase separation. We study this situation using a simple model of two short-ranged attractive polymers with opposite charges and their counterions. We find that the charged polymers segregate from the solvent, and thus form two macrophases, when their charges are symmetric. In contrast, many droplets of equal size coexist when charge asymmetry is sufficiently strong. Such patterned phases form because the short-range attraction concentrates polymers within droplets, leading to net charges, which prevents droplet growth. Our molecular dynamics simulation and a continuous field theory demonstrate that droplet size decreases with charge asymmetry. Overall, we present a mechanism controlling droplet size via a trade-off between short-ranged attraction driving phase separation and long-ranged electrostatic repulsion if droplets accumulate net charges. Our results are relevant for understanding biomolecular condensates and creating synthetic patterns in chemical engineering.

CPP 45.5 Fri 12:30 H38

Structural transitions of a Semi-Flexible Polyampholyte — •Rakesh Palariya and Sunil P Singh — Indian Institute Of Science Education and Research, Bhopal , India

Polyampholytes (PA) are charged polymers composed of positively and negatively charged monomers. The sequence of the charged monomers and the bending of the chain significantly influence the conformation and dynamical behavior of the PA. Using coarse-grained molecular dynamics simulations, we comprehensively study the structural and dynamical properties of flexible and semi-flexible PA's. The simulation results demonstrate a flexible PA chain, displaying a transition from a coil to a globule in the parameter space of the charge sequence. Additionally, the behavior of the mean-square displacement (MSD), denoted as $< (\Delta r(t))^2 >$, reveals distinct dynamics, specifically for the alternat-

ing and charge-segregated sequences. The MSD follows a power-law behavior, where $< (\Delta r(t))^2 > \sim t^{\beta}$, with $\beta \approx 3/5$ and $\beta \approx 1/2$ for the alternating sequence and charge-segregated sequence in the absence of hydrodynamic interactions, respectively. However, when hydrodynamic interactions are incorporated, the exponent β shifts to approximately 3/5 for the charge-segregated sequence and 2/3 for the well-mixed alternating sequence. For a semi-flexible PA chain, varying the bending rigidity and electrostatic interaction strength (Γ_e) leads to distinct, fascinating conformational states, including globule, bundle, and torus-like conformations. The transition between various conformations is identified in terms of the shape factor estimated from the ratios of eigenvalues of the gyration tensor.

CPP 46: Closing Talk (joint session BP/CPP/DY)

Invited Talk CPP 46.1 Fri 13:15 H2

Active control of forces, movement and shape: from biological to non-living systems — •Ulrich S. Schwarz — Heidelberg University, Heidelberg, Germany

Animal cells are highly dynamic and continuously generate force, for example for division, migration and mechanosensing. Their main force generators are myosin II molecular motors, whose activity is precisely controlled by biochemical circuitry. We first discuss how this system can be hijacked by optogenetics, thus that cellular force generation can be controlled in time and space using light. Next, we use active gel theory combined with van der Waals theory for myosin II molecules to demonstrate that cell contractility is sufficient to explain cell migration and that optogenetics can be used to initiate and revert migration. For two myosin II species, we predict the possibility of oscillations. We then move up in scale and analyze force generation in intestinal organoids, which are epithelia with the topology of a sphere. Combining experimental data, image processing and the bubbly vertex model, we show how apico-basal asymmetries can lead to cell extrusion and budding. We finally discuss how force generation and shape changes can be achieved in non-living systems, in particular for nematic elastomers, in which the direction of contraction is imprinted during polymerization and actuation is achieved by temperature control.

DS 1: Thin Film Properties

Time: Monday 9:30–12:30 Location: H3

DS 1.1 Mon 9:30 H3

From ferromagnetic semiconductor to anti-ferromagnetic metal in epitaxial CrxTey monolayers — •Naina Kushwaha[1,2], Olivia Armitage[1], Brendan Edwards[1], Liam Trzaska[1], Jennifer Rigden[2], Peter Bencok[3], Deepnarayan Biswas[3], Tien-Lin Lee[3], Charlotte Sanders[2], Gerrit van der Laan[3], Peter Wahl[1,4], Phil D. C. King[1], and Akhil Rajan[1] — [1]University of St Andrews, UK — [2]Central Laser Facility, UK — [3]Diamond Light Source, UK — [4]Physikalisches Institut, University of Bonn , Germany

Two-dimensional (2D) materials can exhibit markedly distinct electronic and magnetic properties compared to their bulk counterparts [1]. Among these, the Cr-Te compounds are of particular interest. 1T-CrTe2, in particular, is a room-temperature ferromagnet in the bulk, but is only metastable, readily decomposing into self-intercalated compounds like Cr2Te3 [2]. Utilizing a nucleation-assisted molecular-beam epitaxy growth method [3], we achieve the growth of phase selective monolayer Cr2Te3 and 1T-CrTe2 with enhanced growth rates and uniformity. Characterization using X-ray magnetic circular dichroism, scanning tunneling microscopy, and angle-resolved photoemission spectroscopy reveals metallic antiferromagnetic behavior in 1T-CrTe2 and semiconducting ferromagnetic properties in Cr2Te3. These findings advance new understanding of the magnetic order in Cr-Te monolayers, and demonstrate routes to control this, of potential future interest for advancing 2D spintronics [1].

DS 1.2 Mon 9:45 H3

In-situ and operando characterization of atomic layer deposited SnO_2 and SnO_2/CeO_2 heterostructures for gas sensing applications — •Rudi Tschammer, Carlos Morales, Karsten Henkel, and Jan Ingo Flege — Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology, Cottbus, Germany

The amorphous and defective nature of atomic layer deposited (ALD) thin films results in material properties deviating from those of well-ordered and crystalline samples. For instance, we recently reported that ALD cerium oxide (CeO_2) ultrathin (<10nm) layers could be reduced under H_2/O_2 mixtures at room temperature without decoration with noble metals, thus opening the door to design miniaturized resistive sensors based on ALD-CeO_2 active layers. However, the remaining challenges include high electrical resistance (GΩ) and relatively long response and recovery times, which may be solved by combination with conductive oxides. In particular, tin oxide (SnO_2) has been shown to improve the sensing properties of CeO_2, tentatively explained by interface effects. Here, we present in-situ X-ray photoelectron spectroscopy (XPS) and operando spectroscopic ellipsometry measurements of ultra-thin ALD-SnO_2 layers, highlighting a linear growth rate, an evolution of the Sn Auger parameter related to distinct chemical envioroments rather than different oxidation states, and changes in C and N residues with the ALD number of cycles. Lastly, preliminary results from structural and chemical characterization, as well as sensing capabilities, of ALD-SnO_2/CeO_x heterostructures are discussed.

DS 1.3 Mon 10:00 H3

RF sputtered growth of β-Ga_2O_3 on Ru(0001) films — •Aman Baunthiyal, Marco Schowalter, Martin Williams, Jon-Olaf Krisponeit, Thorsten Mehrtens, Alexander Karg, Andreas Rosenauer, Martin Eickhoff, and Jens Falta — Institute of Solid State Physics, University of Bremen, Germany

Gallium oxide (Ga_2O_3) is a leading candidate for high-power, high-frequency electronics due to its wide bandgap and high breakdown voltage. While its growth on insulating substrates like AlN and Al_2O_3 has been well-studied, research on metal substrates remains limited. This study investigates RF-sputtered growth of Ga_2O_3 thin films on Ru(0001) surfaces with varying roughness at temperatures from room temperature (RT) up to 600°C [1].

AFM measurements showed that surface roughness peaks at intermediate growth temperatures, then decrease at 600°C, suggesting a shift toward two-dimensional growth or increased surface diffusion. XRD revealed the amorphous nature of RT-grown Ga_2O_3 films but polycrystallinity in higher-temperature grown films. Films grown at 600°C exhibited minimal change on annealing due to pre-existing polycrystallinity. TEM confirms polycrystalline β-Ga_2O_3, with crystallite sizes of ≈ 10 nm for RT samples and ≈ 80 nm for samples grown at 600°C after annealing. These results highlight the impact of substrate morphology, growth temperature, and annealing on optimizing Ga_2O_3 films, supporting developments in Ga_2O_3-based vertical devices.

[1] Baunthiyal *et al.*, Appl. Phys. Lett. **123**, 213504 (2023).

DS 1.4 Mon 10:15 H3

Molecule adsorption at Sc(x)Ga(1-x)N surfaces investigated by photo electron spectroscopy — •Fabian Ullmann[1,2] and Stefan Krischok[1,2] — [1]TU Ilmenau, Ehrenbergstraße 29, 98693 Ilmenau — [2]Zentrum für Mikro- und Nanotechnologien, Gustav-Kirchoff-Straße 7, 98693 Ilmenau

ScGaN can occur in various crystal orientations. The most important are wurtzite and rock salt formation. Depending on the scandium concentration, a phase transition between these orientations can be found. ScGaN surfaces with different scandium concentrations and orientations were grown by molecular beam epitaxy (MBE) to investigate the near-surface electronic structure. The interaction of gas molecules (oxygen and water) in vacuum were analyzed by X-ray (XPS) and ultraviolet photoelectron spectroscopy (UPS).

session break

DS 1.5 Mon 10:45 H3

Low temperature solid state dewetting of gold thin films on polystyrene nano structures — •Felix Lohmeyer and Jörg K.N. Lindner — Universität Paderborn, Department Physik, Warburgerstraße 100, 33098 Paderborn

Solid-state dewetting describes the breakup of a thin film into isolated objects due to surface energy minimization below the material's melting point. While well-studied for hard substrates, little research has been done on the dewetting of metal thin films on polymer substrates. This study shows that gold thin films can undergo dewetting at temperatures that preserve the underlying polymer substrate, with dewetting kinetics increasing with annealing temperature. Gold thin films (7 nm) were deposited on planar and nanostructured polystyrene (PS) substrates and thermally annealed at 100 to 120 °C, near the polymer's glass transition temperature ($T_{g,PS}$=100°C). Homogeneous spin coated PS films and nanostructured PS lamellae, created via block copolymer self-assembly, served as substrates. Dewetting was characterized using SEM, AFM, and TEM. On planar PS, dewetting was observed at any temperature and proceeded without incubation time, triggered by the initial non-uniformity of the gold film. On nanostructured PS, gold formed nanorods aligned with the polymer lamellae, breaking into particles while preserving the substrate pattern. These findings demonstrate the role of substrate morphology and temperature in dewetting and suggest a route to fabricating sub-10 nm gold structures for applications in sensing, catalysis, and nanoelectronics using BCP-based polymer templates.

DS 1.6 Mon 11:00 H3

Morphological characterization of Sub-10 nm surface patterns created by block-copolymer self-assembly — •Harikrishnan Venugopal, Janna X. Friebel, Julius Bürger, and Jörg K.N. Lindner — Universität Paderborn, Department Physik, Warburgerstraße 100

The microphase separation in block copolymers (BCPs) is a self-assembly process allowing to create ordered patterns on large substrate surfaces in short times and at low costs. Numerous applications of such patterns have been identified in the area of micro- and optoelectronics, data storage, catalysis, nanoporous membranes, and biomedical materials. If BCP self-assembly is used to create lithographic masks by removing one of the polymers selectively, for any targeted application it is important to characterise the morphology of polymer domains precisely at each processing step. In this work, we report on the morphology of silicon oxide nano structures fabricated by BCP self-assembly on Si substrates. A polystyrene-polydimethylsiloxane block copolymer (PS-b-PDMS) with a molar mass of 15 kg/mol and a PS volume fraction of 68.75 % was dissolved and spin coated onto silicon substrate. Microphase separation was initiated by solvent vapor annealing and results in the formation of fingerprint like surface patterns. A high-power oxygen plasma treatment is done to selectively remove the PS domains while converting the PDMS to silicon oxide. TEM, SEM and AFM analyses were performed to understand why after the plasma treatment half-cylinder patterns are observed.

DS 1.7 Mon 11:15 H3

Sub-10 nm Nanostructures in Thin Films of a Cylinder-Forming PS-b-PDMS Block Copolymer — •Janna X. Friebel, Harikrishnan Venugopal, Julius Bürger, and Jörg K. N. Lindner — Universität Paderborn, Germany

Block copolymers (BCPs) with a combined Flory-Huggins parameter $\chi N > 10$ form ordered domains even at low degrees of polymerization (N), enabling sub-10 nm nanostructures suitable for e.g. nanomasks in microelectronics. However, interfacial energy effects in thin films complicate the direct application of the bulk phase diagram by Bates et al. [1].

This study investigates the morphology of thin PS-b-PDMS high-χ BCP films with $N_B/N_A \approx 0.25$, spin-coated onto silicon, titanium, and chromium substrates (all with their native oxides). The films were top coated with PVA, solvent vapor annealed, PVA stripped, and the PS phase was selectively etched. Cross-sectional TEM reveals hemispherical structures instead of the expected hexagonal arrangement of cylinders, as suspected from SEM and AFM investigation. The energetic reasons for this geometry are discussed.

DS 1.8 Mon 11:45 H3

Ultrathin-Film Y6 at Air-Water Interface via the Langmuir-Blodgett Technique for Optoelectronic Application — •Yisak Tsegazab Gerase[1,2] and Martin Presselt[1,2] — [1]Institute of Physical Chemistry, Jena, Germany — [2]Leibniz Institute of Photonic Technology, Jena, Germany

Supramolecular structures are critical to the optoelectronic properties of films. The Langmuir-Blodgett (LB) technique provides precise molecular assembly, enabling control and homogenization of the morphology of Y6 Langmuir films, which is essential for scalable fabrication and commercial production. Y6, a non-fullerene acceptor, has significantly improved the power conversion efficiency of organic solar cells. We monitored the in-situ formation of Y6 Langmuir films using Brewster angle microscopy, surface pressure isotherms, and fluorescence spectroscopy. Isotherms revealed high packing densities, while compression-expansion cycles showed increased stiffness due to intermolecular rearrangements. BAM images confirmed smooth, well-defined quasi-2D films, and in-situ fluorescence spectroscopy identified the existence of Y6 fluorophore at the air-water interface and with lateral compression growth in supramolecular structure were observed. In agreement with in-situ observations, these well-ordered morphologies were further characterized after deposition on solid supports. Y6 films used in organic thin-film transistors showed a mobility of about 0.007 cm2 /Vs as cast film, comparable to other deposition techniques.

DS 1.9 Mon 12:00 H3

Femtosecond Laser Ablation (fs-LA) - A New Approach to XPS Depth Profiling — •samir mammadov — Thermo Fisher Scientific, 1 The Feldbridge Centre, Imberhorne Lane, East Grinstead, West Sussex, RH19 1XP, UK

XPS depth profiling is a widely employed analytical technique to determine the chemical composition of thin films, coatings and multi-layered structures, due to its ease of quantification, good sensitivity and chemical state information. Since the introduction of XPS as a surface analytical technique more than 50 years ago, depth profiles have been performed using ion beam sputtering. However, many organic and inorganic materials suffer from ion beam damage, resulting in incorrect chemical compositions to be recorded during the depth profile. This problem has been resolved for most polymers by using argon gas cluster ion beams (GCIBs), but the use of GCIBs does not solve the issue for inorganics. A prototype XPS depth profiling instrument has been constructed that employs a femtosecond laser rather than an ion beam for XPS depth profiling purposes. This novel technique has shown the capability of eradicating chemical damage during XPS depth profiling for all initial inorganic, compound semiconductor and organic materials examined. The technique is also capable of profiling to much greater depths (several 10s microns) and is much faster than traditional ion beam sputter depth profiling. fs-LA XPS depth profile results will be shown for selected thin films, coatings, multilayers and oxidised surfaces and the outlook for this new technique discussed.

DS 1.10 Mon 12:15 H3

Optimizing erbium luminescence for integrated photonics via ytterbium co-doping and thermal annealing — •Sören Lerner[1], Felix Mania[1], Jiale Sun[2], Zheru Qiu[2], Xinru Ji[2], Yang Liu[2], Tobias Kippenberg[2], and Carsten Ronning[1] — [1]Friedrich-Schiller Universität, Helmholtzweg 3, 07743 Jena, Germany — [2]École Polytechnique Fédérale de Lausanne, Switzerland

Erbium ions are promising candidates for enabling efficient optical amplification of signals in photonic integrated circuits, but their practicality is hindered by insufficient output power. To address this, we utilize ion implantation into ultralow-loss silicon nitride (Si_3N_4) thin films and investigate co-doping with ytterbium ions to enhance absorption and emission through resonant energy transfer. We systematically investigate the effects of doping concentration and subsequent thermal annealing parameters using photoluminescence measurements. These findings provide insights into optimizing erbium-based light emitters for integrated photonics.

DS 2: Layer Deposition

Time: Monday 9:30–10:45 Location: H14

DS 2.1 Mon 9:30 H14

Bidirectional Growth of Functional Oxides by Molecular Beam Epitaxy — •Nicolas Bonmassar[1], Georg Christiani[2], and Gennady Logvenov[2] — [1]University of Stuttgart, 70569 Stuttgart, Germany — [2]Max Planck Institute for Solid State Research, 70569 Stuttgart, Germany

Here I present some recent results on the use of offcut substrates by enabling atomic precision layer-by-layer growth in both in-plane and out-of-plane directions. This is achieved by in situ monitoring of the oscillations of the reflected high-energy electron diffraction (RHEED) patterns. The potential of this method is demonstrated using a bidirectionally grown superlattice of alternating $LaMnO_3$ and $SrMnO_3$ layers, showing interfacial ferromagnetism. This superlattice serves as a model system to showcase the method's versatility through detailed structural and functional characterization by using various scanning transmission electron microscopy techniques, sheet resistance measurements, and magnetometry. Next, the approach is applied to the growth of superconducting $La_{1.84}Sr_{0.16}CuO_4$ thin films grown in ozone atmosphere on various offcut substrates, where the anisotropic critical current is found to arise from two distinct mechanisms induced by the substrate geometry.

Furthermore, I will present the issues we faced when we first started this project and how we had overcome well-known problems like the loss over the in situ RHEED oscillations, terrace broadening, step bunching, 3D defect formation and the concomitant loss of functionalities like superconductivity.

DS 2.2 Mon 9:45 H14

Enabling vacuum process monitoring with time-of-flight spectroscopy — •Marco John, Kristian Kirsch, Andreas Trützschler, Christoph Bartlitz, Marcel Herrmann, and Klaus Bergner — VACOM Vakuum Komponenten & Messtechnik GmbH, Großlöbichau, Germany

A crucial aspect to manage industrial vacuum processes is the importance of fast in-situ monitoring and control of process parameters such as pressure and residual gas composition. Improving process control in this way minimizes production errors, avoids damage to process equipment and ensures longer operating times. The capabilities of hot cathodes and quadrupole mass spectrometers are limited for this complex task, as they can only measure either the total pressure or the gas composition. One answer to this challenge is our novel ion source NOVION*, which combines the well-known technology of time-of-flight spectroscopy with our patented ion trap to an industrially available gas analyzing application.

In this talk we present the fundamental physical principles of the novel ion source and explain the compact combination of time-of-flight spectroscopy with our own patented ion trap. We discuss the advantages and limits in different applications as well as best practices in the field and show the capability to push the principle to its limits at high pressures without compromising the performance or lifetime of the filaments.

DS 2.3 Mon 10:00 H14

Selective Area Atomic Layer Deposition via Photoexcitation — •Paul Butler[1,2], Stefan A. Maier[3], and Ian D. Sharp[1,2] — [1]Walter Schottky Institut, Technische Universität München, 85748, Garching, Germany — [2]Physics Department, TUM School of Natural Science, Technical Universität München, 85748, Garching, Germany — [3]School of Physics and Astronomy, Monash University, 3800, Melbourne, Australia

While atomic layer deposition (ALD) is a powerful technique for uniformly coating complex surfaces with thin films, achieving lateral control of ALD layers remains a primary challenge. In this work, we examine a selective-area ALD (S-ALD) process via photoexcitation of the growth surface. We demonstrate that optical laser excitation enhances ALD-growth of TiO_2 films on gold surfaces deposited onto Si and SiO_2. These surfaces were exposed to titanium isopropoxide (TTIP) and ozone as reactants for the ALD process, during which some of the samples were exposed to laser illumination. In-situ ellipsometry was used to monitor the growth rate of the TiO_2 films during ALD, and ex-situ ellipsometry was used to map the height profile of the resulting TiO_2 films deposited. The results show intensity-dependent enhanced growth on surfaces that were excited with laser illumination. We also show that a shadow mask can be used to make patterned depositions.

DS 2.4 Mon 10:15 H14

Enabling FAIR Data Practices in MBE Growth and Characterization — •Andrea Albino[1], Hampus Näsström[1], Sarthak Kapoor[1], Altuğ Yildirim[2], Oliver Bierwagen[2], Martin Albrecht[3], and Sebastian Brückner[1,3] — [1]Department of Physics, Humboldt-Universität zu Berlin, Berlin, Germany — [2]Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Berlin, Germany — [3]Leibniz-Institut für Kristallzüchtung, Berlin, Germany

Data-driven materials science is transforming materials design by moving beyond traditional trial-and-error methods. Molecular beam epitaxy (MBE) experiments highlight the challenge of navigating complex parameter spaces [1], often exceeding human cognitive limits, particularly when integrating diverse datasets. This complexity is compounded by the absence of standardized models for capturing detailed experimental workflows and instrument diversity. Addressing these issues requires metadata aligned with FAIR (Findable, Accessible, Interoperable, Reusable) principles [2].

Within the NOMAD ecosystem (nomad-lab.eu) [3], we digitize the data lifecycle for MBE growth, including in-situ and ex-situ characterization. Key tools, like Electronic Laboratory Notebooks (ELNs), systematically document growth procedures, enabling streamlined data management and AI-driven analytics to optimize MBE processes.

[1] O. Bierwagen et al., J. Phys. Condens. Matter 28, 22 (2016) [2] M. Wilkinson et al., Sci. Data 3, 160018 (2016) [3] M. Scheidgen et al., J. Open Source Software 8, 5388 (2023)

DS 2.5 Mon 10:30 H14

Role of point defects on the superconducting transition temperature in NbTIN thin films with positron annihilation spectroscopy — •Sebastian Klug[1], Maik Butterling[1], Maciej Oskar Liedke[1], Eric Hirschmann[1], Andreas Wagner[1], Bharath Reddy Lakki Reddy Venkata[2], Aleksandr Zubtsovskii[2], and Xin Jiang[2] — [1]Institute of Radiation Physics, HZDR, Germany — [2]Chair of Surface and Materials Technology, University of Siegen, Germany

Positron annihilation spectroscopy (PAS) is a non-destructive method for studying point defects in materials with high sensitivity. It can sense defect densities in the range of 10^{15} to $10^{19} cm^{-3}$. The time for positrons to annihilate with electrons depends on the local electron density. Therefore, positrons can be trapped in neutral and negatively charged open-volume defects. Positrons are implanted into the studied material with a defined implantation energy. Changing of this energy allows for depth-resolved characterization. The user facility ELBE of HZDR provides the two main PAS techniques Doppler broadening spectroscopy (DBS) and positron annihilation lifetime spectroscopy (PALS) which allows for evaluation of the atomic environment of defects as well as defect size and density.

In this contribution the most recent results of magnetron sputtered NbTiN thin films as promising candidate for improving the characteristics of superconducting radio-frequency cavities (SRF cavities) will be discussed. The correlation between defect size and their concentration and the superconducting transition temperature will be highlighted.

DS 3: 2D Materials and their Heterostructures I (joint session DS/HL)

Time: Monday 15:00–17:45 Location: H3

DS 3.1 Mon 15:00 H3

Nanoscale NMR of two-dimensional solids using NV centers in diamond — •Marcel Martin[1], Mokessh Kannah Ciwan[1], Yejin Lee[2], Jakob Nachtigal[1], Nicola Poccia[3,4], Uri Vool[2], Jürgen Haase[1], and Nabeel Aslam[1] — [1]Leipzig University, Leipzig, Germany — [2]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [3]Leibniz Institute for Solid State and Materials Research, Dresden, Germany — [4]Department of Physics, University of Naples Federico II, Naples, Italy

Nuclear magnetic resonance (NMR) is a powerful method to investigate electronic properties of condensed matter but is inherently limited by its low sensitivity. Nitrogen-vacancy (NV) centers in diamond are quantum sensors that allow extending NMR to thin films and μm-scale exfoliated flakes of 2D materials which exhibit electronic phases such as charge density waves (CDW) and superconductivity. For the latter, NMR is especially powerful as it can elucidate the pairing symmetry of the charge carriers.

In this talk, we first discuss solid-state nano-NMR with NV centers of CaF_2, a testbed material for this method. The ultimate goal, however, is to study the CDW and Ising superconductivity phases of few-layer NbSe2 with nano-NMR. In this context, we present initial optical studies of $NbSe_2$ flakes which have been exfoliated and transferred onto a diamond. In addition to this, we will present results of conventional NMR on bulk $NbSe_2$ which serve as a reference.

DS 3.2 Mon 15:15 H3

Twist-tunable spin control in twisted bilayer bismuthene — •Ludovica Zullo[1,2,3,4], Domenico Ninno[4,5], and Giovanni Cantele[5] — [1]Institut für Theoretische Physik und Astrophysik and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, 97074 Würzburg, Germany — [2]Department of Physics, University of Trento, Via Sommarive 14, 38123 Povo, Italy — [3]Sorbonne Université, CNRS, Institut des Nanosciences de Paris, UMR7588, F-75252 Paris, France — [4]Dipartimento di Fisica E. Pancini, Università degli Studi di Napoli *Federico II*, Complesso Universitario M. S. Angelo, via Cintia 21, 80126, Napoli, Italy — [5]CNR-SPIN, c/o Complesso Universitario M. S. Angelo, via Cintia 21, 80126, Napoli, Italy

The role of spin-orbit coupling (SOC) in twisted bilayers has gained increasing attention due to its potential for spintronics, opening a quest for new layers with substantial SOC. In this work [1], by means of first principles calculations, we investigate how the interplay between SOC and twist angle impacts the band structure and spin textures of twisted bilayer bismuthene. We find that the twist angle can be deemed a control knob to switch from a small-gap semiconductor to a metallic behavior. Most crucially, the accurate analysis of the energy bands close to Fermi energy reveals a twist-tunable splitting in the mexican-hat shape of the bands that can otherwise be obtained only by applying enormous electric fields, providing insight into innovative technologies for future spintronic devices. [1] Ludovica Zullo, Domenico Ninno, Giovanni Cantele, Phys. Rev. B, 110, 165411 (2024)

DS 3.3 Mon 15:30 H3

Iron Diffusion in Thermally Stable $Ti_3C_2Cl_2$ MXenes under UHV Conditions — •Moritz Vanselow[1], Maksim Riabov[2], Hanna Pazniak[2], Thierry Ouisse[2], and Ulf Wiedwald[1] — [1]University of Duisburg-Essen and Center for Nanointegration Duisburg-Essen, Germany — [2]Université Grenoble Alpes, CNRS, Grenoble INP, LMGP, France

MXenes are 2D materials derived from a MAX phase precursor. Molten salt etching of $Ti_3C_2Cl_2$ results in hydrophobic $Ti_3C_2T_X$ MXenes with T_X = -Cl as a termination species [1]. $Ti_3C_2Cl_2$ MXenes are deposited on Si(100)/SiO_2 and we in situ study its chemical stability by mass spectrometry and Auger electron spectroscopy in ultrahigh vacuum. Compared with standard hydrophilic $Ti_3C_2T_X$ MXenes, where T_X = -F, =O, and -OH, fluorine and hydroxyl groups can be removed by annealing at temperatures up to 1000 K, the thermal stability of $Ti_3C_2Cl_2$ MXenes is significantly enhanced. Moreover, intercalated water changing the MXene sheet separation, is not present in hydrophobic $Ti_3C_2Cl_2$ as proven by ex situ X-ray diffraction, wide-angle X-ray scattering (WAXS) and X-ray photoelectron spectroscopy (XPS). After optimizing the annealing procedure, we in situ intercalate Fe by e-beam assisted deposition on top of MXene thin films and subsequent Fe diffusion by soft annealing at 600 K. This work is funded by a joint ANR-DFG-Project under ANR-23-CE09-0031-01 and DFG ID 530103526. [1] T. Zhang et al., Chem. Mater. 36, 1998 (2024).

DS 3.4 Mon 15:45 H3

Interactions Between Two-Dimensional Crystals and Molecules via Density Functional Theory — •Stefan Wolff[1], Xin Chen[2], Tobias Dierke[1], and Janina Maultzsch[1] — [1]Department of Physics, Chair of Experimental Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg — [2]Institute of Chemistry and Biochemistry, Freie Universität Berlin

The unique properties of two-dimensional (2D) materials can be modified through chemical functionalization, driven by their interactions with functional groups or molecules. Density functional theory (DFT) calculations are employed to investigate non-covalent functionalization of bilayer graphene with 1,4,5,8,9,11-hexaazatriphenylenehexacarbonitrile (HATCN) molecules. The interactions between the graphene layers and the HATCN molecules play a significant role in determining the functionalization behavior, which depends on the stacking arrangement. Locally stacked regions within the moiré lattice of twisted bilayer graphene (tBLG) play a crucial role for functionalization. Consequently, the moiré pattern of tBLG can serve as a template to control the degree of functionalization. Furthermore, laser-triggered covalent functionalization of molybdenum disulfide (MoS_2) enables the fabrication of patterned 2D heterostructures with phenyl-based interface linkers. Through DFT calculations, various potential binding motifs and their associated optical properties are predicted. Calculations of reaction energies and Raman modes provide insights into the likelihood of different reaction pathways and the structures they yield.

DS 3.5 Mon 16:00 H3

Toward high-sensitivity and low-power consumption gas sensor devices based on 2D-transistors. — •Aurelio García Valenzuela[1], Zahra Fekri[1], Madhuri Chennur[1], Nikol Lambeva[1], Jens Zscharschuch[1], Victoria Constance Köst[2], Krysztof Nieweglowski[2], and Artur Erbe[1] — [1]Institute of Ion Beam Physics and Materials Research, HZDR, Dresden, Germany — [2]Institute of Electronic Packaging Technology, AVT, TU-Dresden, Germany

Two-dimensional (2D) materials exhibit excellent properties compared to their bulk counterparts and are promising for applications like gas sensors. Their high surface-to-volume ratio and surface-active sites enhance gas absorption and sensitivity, addressing challenges in detecting low concentrations and reducing power consumption.

This work presents the fabrication and testing of 2D materials-based field-effect transistor (FET) gas sensors. Mechanically exfoliated 2D materials are stacked into heterostructures to create back-gated FETs, with device patterning achieved via electron beam lithography.

The devices were exposed to NH3 and NO2 gases at various temperatures. Gas interactions caused systematic changes in p- and n-type currents and shifts in the transfer curve, depending on gas concentration and type (donor or acceptor). These results demonstrate the suitability of 2D materials-based FETs as efficient and sensitive gas sensors.

short break

DS 3.6 Mon 16:30 H3

Pressure-dependent Effective Hamiltonian and Topological Transitions for Twisted Bilayer Transition Metal Dichalcogenides — •Miftah Hadi Syahputra Anfa[1], Sabri Elatresh[1,2], Hocine Bahlouli[1,3], and Michael Vogl[1,2] — [1]Physics Department, King Fahd University of Petroleum & Minerals, Dhahran 31261, Saudi Arabia — [2]Interdisciplinary Research Center (IRC) for Intelligent Secure Systems, KFUPM, Dhahran, Saudi Arabia — [3]Interdisciplinary Research Center (IRC) for Advanced Materials, KFUPM, Dhahran, Saudi Arabia

Recent studies have shown the existence of nontrivial topological moire bands in twisted bilayer transition metal dichalcogenides (TMDs), which depend on the twist angle. Motivated by this, we present a study of such a system under applied vertical pressure. The study begins by first considering the untwisted bilayer case without pressure. We find that the system can be described by an effective low-energy Hamiltonian that behaves approximately quadratic and includes layer-shift dependent terms that we were able to determine by symmetry. The structure is then relaxed under pressure in the 0.0 - 3.5 GPa range using ab initio density functional theory (DFT). The DFT band structures for each corresponding pressure are fitted to the effective Hamiltonian to obtain the pressure-dependent parameters. Consecutively, the explicit expression for the twisted pressure-dependent Hamiltonian is obtained by treating the twist as a position-dependent shift between layers. We then present changes in Chern number results for the important energy bands due to pressure.

DS 3.7 Mon 16:45 H3

Effect of spin-dependent tunneling in a $MoSe_2/Cr_2Ge_2Te_6$ van der Waals heterostructure on exciton and trion emission — •Annika Bergmann[1], Swarup Deb[1,2], Veronika Schneidt[1], Mustafa Hemaid[1], Kenji Watanabe[3], Takashi Taniguchi[4], Rico Schwartz[1], and Tobias Korn[1] — [1]Institute of Physics, Rostock University, Rostock, Germany — [2]Saha Institute of Nuclear Physics, Kolkata, India — [3]Research Center for Electronic and Optical Materials, Tsukuba, Japan — [4]Research Center for Materials Nanoarchitectonics, Tsukuba, Japan

In recent years, thin films of magnetic van der Waals materials have gained increasing interest due to their potential applications in spintronics. For instance, heterostructures (HS) consisting of ferromagnetic CRI_3 and a WSe_2 monolayer have demonstrated the existence of magnetic proximity effects, manifesting in the lifting of WSe_2 valley degeneracy as well as helicity-dependent photoluminescence (PL) emission of the WSe_2 monolayer in proximity to the 2D ferromagnet [1,2]. Here, we study HS consisting of monolayer $MoSe_2$ and few-layer ferromagnetic $Cr_2Ge_2Te_6$ (CGT). Under circularly polarized excitation, PL measurements show that the $MoSe_2$ exciton-trion emission ratio depends on the relative orientation of excitation helicity and CGT magnetization, even though the PL emission itself is unpolarized. This hints at an ultrafast, spin-dependent interlayer charge transfer that competes with exciton and trion formation and recombination.

DS 3.8 Mon 17:00 H3

Magnetic and transport properties of all-epitaxial $Fe_{5-x}GeTe_2/WSe_2$ van der Waals heterostructures — •Hua Lv[1], Tauqir Shinwari[1], Kacho I. A. Khan[1], Jens Herfort[1], Michael Hanke[1], Chen Chen[2], Joan M. Redwing[2], Achim Trampert[1], Mehak Loyal[3], Gerhard Jakob[3], Mathias Kläui[3], Roman Engel-Herbert[1], and João Marcelo J. Lopes[1] — [1]Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Berlin, Germany — [2]2D Crystal Consortium Materials Innovation Platform, Materials Research Institute, The Pennsylvania State University, PA, United States — [3]Institute of Physics, Johannes Gutenberg University Mainz, Mainz, Germany

Van der Waals (vdW) heterostructures consisting of two-dimensional (2D) ferromagnetic and nonmagnetic materials hold great promises for tailoring their magnetic and transport properties. Here we report on the magnetic and transport properties of all-epitaxial $Fe_{5-x}GeTe_2$ (FGT, with $x \approx 0.2$)/WSe_2 heterostructures tailored via the FGT thickness. Magnetic characterizations and anomalous Hall effect measurements with both out-of-plane and in-plane magnetic fields reveal an enhanced perpendicular magnetic anisotropy (PMA) in thinner FGT and a ferromagnetic order up to room temperature. The pronounced unconventional Hall effect (UHE) suggests the possible formation of skyrmions. The thickness-dependent asymmetric magnetoresistance reveals a unique magnetization switching process. Our results demonstrate the high potential of all-epitaxial FGT/WSe_2 heterostructures for the advancement of future 2D spintronic applications.

DS 3.9 Mon 17:15 H3

Effect of Ni-doping on the structural/magnetic properties of large area epitaxial 2D-ferromganet Fe_3GeTe_2 — •Kacho Imtiyaz Ali Khan[1], Tauqir Shinwari[1], Hua Lv[1], Frans Munnik[2], Jens Herfort[1], Michael Hanke[1], and Joao Marcelo J. Lopes[1] — [1]Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Berlin, Germany — [2]Helmholtz-Zentrum Dresden- Rossendorf e.V. Dresden, Germany

2D ferromagnets with strong perpendicular magnetic anisotropy exhibit magnetic order down to the monolayer thickness and have the potential to overcome long-term challenges faced by 3D ferromagnets to build up advanced energy-efficient spintronic devices. In this work, we show the large-area epitaxial growth of Ni-doped Fe_3GeTe_2 films via molecular beam epitaxy. X-ray diffraction measurements demonstrate high-quality epitaxy of pure Fe_3GeTe_2 phase on graphene/SiC(0001) substrates. Magneto-transport measurement unveils the ferromagnetic nature of the film, with strong perpendicular magnetic anisotropy for pure Fe_3GeTe_2 and Ni-doped films. However, the Ni-doped Fe_3GeTe_2 shows a decrease in Curie temperature T_C with an increase in Ni-doping. We believe that the Ni doping modifies the lattice parameters and structure (e.g., Ni intercalation), which results in the dilution of magnetic properties of Fe_3GeTe_2 by reducing the T_C down to 50 K. Our findings show the role of Ni incorporation on the ferromagnetic behavior of Fe_3GeTe_2 films, which is crucial for the development of future spintronic devices.

DS 3.10 Mon 17:30 H3

The epitaxial growth of Gallium Selenide — Michele Bissolo, Marco Dembecki, Florian Rauscher, Jan Schabesberger, Abhilash Uhle, Jonathan J. Finley, Gregor Koblmüller, and •Eugenio Zallo — Walter Schottky Institut and TUM School of Natural Sciences, Technische Universität München, Garching, Germany

Group III-VI post-transition metal chalcogenides (PTMC, M={In,Ga} and C={S,Se,Te}) are van der Waals semiconductors with layer-dependent electronic, thermoelectric and optical properties, strong photoresponsivity, and a Caldera type valence band [1]. However, the limited scalability and risk of contamination of the standard mechanical exfoliation technique are detrimental to developing devices at an industrial scale. Here, we demonstrate the molecular beam epitaxy growth of PTMC [2] GaSe on 2-inch sapphire wafers. To study the pristine properties of this air-sensitive material in situ, we perform Raman spectroscopy in a UHV chamber directly connected to the growth chamber. Film composition and morphology are investigated by tuning the growth temperature and group VI/III flux ratio and by correlating them with the known spatial gradients across the whole substrate. The combination of these findings with ex-situ surface morphology characterization allows us to construct the phase diagram and identify the 2D layered region [3]. Perspectives on the growth of PTMC on 2D substrates and the epitaxial registry will be discussed. [1] H. Cai, et al., Appl. Phys. Rev. 6, 041312 (2019).[2] E. Zallo, et al., npj 2D Mater. & Appl. 7, 19 (2023).[3] M. Bissolo, et al., [to be submitted].

DS 4: 2D Materials and their Heterostructures II (joint session DS/HL)

Time: Tuesday 9:30–13:00 Location: H3

Invited Talk DS 4.1 Tue 9:30 H3

Graphene-based epitaxial 2D heterosystems: making graphene great again — •Christoph Tegenkamp — Institut für Physik, TU Chemnitz

2D materials and their heterostructures are at the forefront of research, anticipated to serve as fundamental building blocks for new quantum materials. Proximity coupling is a key concept in this domain, enabling diverse and novel functionalities. Epitaxial graphene (EG) grown on SiC(0001) resembles a truly 2D electron gas system, celebrated for its manifold and flexible functionalization schemes at both its vacuum and interface sites. These functionalization strategies enable extreme doping scenarios in graphene, tuning spin-orbit coupling, realizing interface states, or introducing mini-bands through zone folding. The controlled transition from linear to flat bands in EG, along with the coupling of functionalized epitaxial graphene to 2D electron gases (2DEGs), opens avenues for exploring electronic correlation effects and mesoscopic phenomena in epitaxial 2D heterostructures. In this presentation, I will showcase some recent findings achieved through the adsorption and intercalation of elements such as Pb and Sn, demonstrating their potential to further tune the properties of graphene.

DS 4.2 Tue 10:00 H3

Proximity-induced spin-orbit coupling in bilayer graphene quantum wires — •Michael Laumer and Angelika Knothe — Universität Regensburg, 93053 Regensburg, Germany

The gate-tuneable band gap and the possibility to tailor its band structure by proximitizing with other 2D materials [1] make bilayer graphene (BLG) an excellent platform for future quantum technologies. By applying spatially modulated displacement fields, one may confine BLG's charge carriers into electrostatically induced nanostructures [2, 3]. Proximitizing the BLG with a transition metal dichalcogenide (TMDC) strongly enhances the SOC of the adjoining graphene layer [1]. Fascinated by the concept of proximity-tailoring BLG nanostructures, we convey the idea of proximity-inducing SOC to a gate-confined BLG quantum wire. We theoretically study the resulting quantized subband structure for different SOC strengths and as a function of the wire geometry. Our results help us understand how proximity-induced SOC manifests in confined geometries and identify different regimes of the wires' electronic properties.

DS 4.3 Tue 10:15 H3

Above room temperature ferromagnetism in large-area Fe_3GaTe_2/graphene van der Waals heterostructures — •Tauqir Shinwari[1], Kacho Imtiyaz Ali Khan[1], Hua Lv[1], Atekelta Abebe Kassa[1], Frans Munnik[2], Achim Trampert[1], Michael Hanke[1], Jens Herfort[1], and Joao Marcelo Jordao Lopes[1] — [1]Paul-Drude-Institut für Festkörperelektronik, Berlin, Germany — [2]Helmholtz-Zentrum Dresden-Rossendorf e.V. Dresden, Germany

Two-dimensional (2D) magnetic materials and van der Waals (vdW) heterostructures offer new possibilities for the realization of advanced spintronic devices. Fe_3GaTe_2, a 2D ferromagnetic metal with a high Curie temperature (~ 360K) and strong perpendicular magnetic anisotropy, has emerged as a promising candidate for energy-efficient magnetic devices. However, all investigations conducted in Fe_3GaTe_2 so far have been performed using millimeter-sized bulk crystals and flakes exfoliated from them, both not suitable for integration in device processing. Hence, it is crucial to develop controlled large-scale growth of this material and investigate its properties. In this contribution, we present a breakthrough in the high-quality, large-area epitaxial growth of Fe_3GaTe_2 thin films on epitaxial graphene/SiC(0001) substrates using molecular beam epitaxy. These results are highly relevant for the future development of high-performance spintronic devices based on 2D heterostructures potentially revolutionizing data storage, processing, and quantum computing applications.

DS 4.4 Tue 10:30 H3

Modeling carbon nanomembranes through molecular dynamics simulations — •Levin Mihlan and Jürgen Schnack — University of Bielefeld

Carbon nanomembranes (CNMs) are nanometer-thin materials synthesized via electron-induced crosslinking of aromatic self-assembled monolayers. CNMs can be functionalized for various applications, initially serving as molecular filters. Due to their presumed irregular internal structure, these membranes pose challenges for standard spectroscopic efforts, often being insufficiently informative [1]. Ehrens et al. initially conducted molecular dynamics simulations to investigate CNM formation, replicating crosslinking and pore formation via momentum transfers in carbon-only systems [2]. Here, we extend the approach by incorporating hydrogen atoms, which may play a critical role in the crosslinking process, even though they largely disappear in the final CNM products. This additionally reduces the number of theoretical assumptions. We examine whether and in what way pores form and analyze properties such as aromaticity, sp content, and Young's modulus to compare with previous simulations and experiments.

DS 4.5 Tue 11:00 H3

Photo-electrochemical oxidation and thinning of transition metal dichalcogenides — •Simon Wörle[1], Lukas Wolz[1], Franz Gröbmeyer[2], Emiliano Cortes[2], Jeremy Robinson[3], and Ian Sharp[1] — [1]Walter Schottky Institute, Physics Department and TUM School of Natural Science, Technical University of Munich — [2]Nanoinstitute Munich and Faculty of Physics, Ludwig-Maximilians-Universität — [3]Naval Research Laboratory, Washington, D.C

Two-dimensional transition metal dichalcogenides (TMDs) exhibit unique optoelectronic and mechanical properties. For their integration in functional devices and for catalytic applications, it is crucial to understand and control their behavior in the reactive environments. Here, we investigate the stability of thin MoS_2, WS_2, $MoSe_2$ and WSe_2 films in acidic, neutral, and basic solutions using a three-electrode photoelectrochemical cell, which enables experiments under both illumination and in the dark. Under anodic conditions, sulfides and selenides undergo different protonic reactions, depending on the pH of the electrolyte, resulting in different resistances to oxidation. Additional exposure to light from a solar simulator creates photo-excited holes, which drive a self-limiting electrochemical thinning procedure that enables the top-down fabrication of large-area TMDs with a thickness of only a few layers. The degradation, initiated at the edges or defects, propagates through the flakes and can be monitored in-situ using an optical microscope. Under laser excitation, multilayer TMDs can be thinned in predefined patterns, paving a new route for processing and integration of 2D materials into functional devices.

DS 4.6 Tue 11:15 H3

Rapid MOCVD synthesis of stratified MoS2 and WS2 2D heterostructures — •Nikolas Dominik, Sebastian Klenk, Cormac Ó Coileáin, and Georg S. Duesberg — Institute of Physics, University of the Bundeswehr Munich & SENS Research Center, München, Deutschland

The two-dimensional (2D) structure of layered materials such as the transition metal dichalcogenides MoS2 and WS2, imparts exceptional electrical, mechanical and optical properties. This makes them particularly interesting for electronic, photovoltaic and sensing application. Van der Waals heterostacks, composed of assembled 2D materials, expand on the possible range of properties, and so have attracted extensive attention due to factors such as ultrafast carrier transport and high bandgap tunability.

Here we present metal-organic chemical vapour deposition (MOCVD) synthesis of MoS2/WS2 combination heterostructures using a highly controllable industrial-scale multi-precursor system, thus avoiding the laborious need for manual stacking. We show how this synthesis method allows the creation of clearly defined and highly ordered stacks by producing a 7-layer combination structure below 10 nm. We explore the characteristics of these films using Raman spectroscopy and XPS, EDX, TOF-SIMS and microscopy techniques.

DS 4.7 Tue 11:30 H3

Unveiling the mechanism of monolayer selective large-area exfoliation of 2D materials — •Jakob Ziewer[1], Abyay Ghosh[1], Michaela Hanušová[2], Luka Pirker[2], Otakar Frank[2], Matěj Velický[2], Myrta Grüning[1], and Fumin Huang[1] — [1]Queen's University Belfast, Belfast, U.K. — [2]J. Heyrovský Institute of Physical Chemistry

Metal assisted exfoliation has made it possible to selectively isolate single crystal monolayers of 2D materials at sizes up to a centimetre [1][2]. This represents a million fold increase compared to standard tape exfoliation.

In this presentation the mechanism of enhanced yield is discussed. Through spectroscopic measurements and observation of macroscopic bubbles it is discovered that the Au substrate decouples attached MoS_2 monolayers from the remaining crystal. The interfacial weakening is dependant on the thickness of the crystal and is maximised for thick crystals.

These findings are used to explain the mechanism behind metal assisted exfoliation and are expected to extend to other Au-2D heterostructures.

Probing the electronic band structure of the 2D magnetic materials MPS3 (M=Fe,Ni) across magnetic phase transitions — •Jeff Strasdas[1], Benjamin Pestka[1], Biplab Bhattacharyya[1], Adam K. Budniak[2], Marcus Liebmann[1], Niklas Leuth[1], Honey Boban[3], Lutz Waldecker[1], Bernd Beschoten[1], Christoph Stampfer[1], Lukasz Plucinski[3], Efrat Lifshitz[2], and Markus Morgenstern[1] — [1]II. Inst. Phys. B and JARA-FIT, RWTH, Aachen, Germany — [2]Schulich Chem. Fac., Solid State Inst., Russell Berrie Nanotech. Inst., Helen Diller Quantum Center, Technion - Israel Inst. of Technology, Haifa, Israel — [3]Forschungszentrum Jülich, Peter Grünberg Inst. (PGI-6), Jülich, Germany

We investigate the band structure of the van der Waals materials FePS3 [1] and NiPS3, both 2D antiferromagnetic insulators, using μm-scale Angular Resolved Photoelectron Spectroscopy (ARPES), above and below their Néel temperatures (TN). The data is compared with DFT+U calculations and simplified selection rules to deduce the orbital character of changing bands. In FePS3, we observe three distinct band structure changes across TN, involving bands with Fe 3d, S 3p, and pure P 3p character, reflecting the intricate competition of direct exchange between Fe atoms and superexchange via S and P atoms. In NiPS3, we identify one band shift near Γ across TN, containing a band of mixed Ni and S character. Here, pronounced deviations from the DFT+U calculations indicate more complex electronic correlations. Moreover, we refine the photoelectron selection rules using ARPES data from CrPS4. [1] B. Pestka et al. doi:10.1021/acsnano.4c12520

DS 4.9 Tue 12:15 H3

Investigation of 1T-TaS2 phase transition and charge transfer phenomena at interfaces with perovskites — •Georgios Chatzigiannakis[1,2], Anastasia Soultati[1], Spiros Gardelis[2], and Maria Vasilopoulou[1] — [1]Institute of Nanoscience and Nanotechnology, National Centre of Scientific Research Demokritos, 15341 Athens, Greece — [2]Department of Physics, National and Kapodistrian University of Athens, 15784 Athens, Greece

1T-TaS2 is a distinguished 2D-layered transition metal dichalcogenide with a rich phase diagram upon cooling including charge density wave (CDW) states and a Mott insulating phase. On the other hand, halide perovskites (HPs) are emerging as a unique class of materials in the field of photonics due to their intriguing optoelectronic properties. The combination of 1T-TaS2 with HPs is proposed as a viable solution to overcome the drawbacks of each category thanks to charge transfer phenomena.

In this work, we studied the phase transitions of 1T-TaS2 as a function of the cooling rate. In the case of nanothick crystals, CDW phase transitions were observed upon gradual cooling but they were totally absent afrer a vigorous cooling. On the contrary, for bulk crystals the CDW phase transitions were totally independent of the cooling rate. Furthermore, we developed 1T-TaS2/HPs heterostructures and we investigated charge transfer phenomena by XPS and UPS spectroscopy, both revealing electron transfer from 1T-TaS2 towards perovskite. Charge transfer could also enable the development of high-performance hybrid optoelectronic devices based on these materials.

DS 4.10 Tue 12:30 H3

The effect of a perpendicular electric field on charge-spin interconversion coefficients in proximitized graphene on 1T-TaS_2 monolayer — •Juraj Mnich[1], Marko Milivojević[2,3], and Martin Gmitra[1,4] — [1]Institute of Physics, P.J.Šafárik University in Košice, 04001 Košice, Slovakia — [2]Faculty of Physics, University of Belgrade, 11001 Belgrade, Serbia — [3]Institute of Informatics, SAS, 84507 Bratislava, Slovakia — [4]Institute of Experimental Physics, SAS, 04001 Košice, Slovakia

The proximity-induced spin-orbit coupling and exchange interactions in the graphene-based heterostructures provides an effective way to manipulate with charge-spin interconversion coefficients. In the talk we focused on charge-spin interconversion in bilayer and trilayer heterostructures of 1T-TaS_2 and graphene. By modulating the temperature, we can access the charge density wave phase and switch between the magnetic and non-magnetic phases of 1T-TaS_2 affecting consequently the graphene electrons. Using linear response theory we showed the dependence of charge-spin interconversion coefficients on a perpendicular applied electric field. For the specific configurations of the 1T-TaS_2 and graphene we observed a change in both the sign and the magnitude of the non-equilibrium spin density as a response to the perpendicular electric field. This result indicates a possibility of using electric fields as a tool to control the direction of spin density.

DS 4.11 Tue 12:45 H3

Self spin-orbit torque in proximitized graphene on 1T-TaS_2 monolayer — •Martin Gmitra[1,4], Maedeh Rassekh[1], Juraj Mnich[1], and Marko Milivojević[2,3] — [1]Institute of Physics, P.J.Šafárik University in Košice, 04001 Košice, Slovakia — [2]Faculty of Physics, University of Belgrade, 11001 Belgrade, Serbia — [3]Institute of Informatics, SAS, 84507 Bratislava, Slovakia — [4]Institute of Experimental Physics, SAS, 04001 Košice, Slovakia

We show that self spin-orbit torque induced in graphene-based van der Waals heterostructures represents a platform to extract the Rashba phase – a proximity-induced spin-orbit coupling parameter. Performing first-principles calculations, tight-binding modeling, and non-equilibrium Greens function transport calculations for graphene on 1T-TaS_2 monolayer we found that charge current in graphene generates non-equilibrium spin accumulation and self-torque in graphene due to the proximity-induced spin-orbit coupling and exchange interaction. The Rashba spin-orbit torque is a dominant contribution and weakly depends on the direction of magnetization in 1T-TaS_2. We propose that the magneto-optical Kerr effect can directly extract the Rashba spin-orbit coupling phase.

This work was supported by the APVV-SK-CZ-RD-21-0114, EU NextGenerationEU through the Recovery and Resilience Plan for Slovakia under the project No. 09I03-03-V05-00008, and IMPULZ IM-2021-42.

DS 5: Thin Oxides and Oxide Layers

How to functionalize 2D states at oxide interfaces by controlled redox reaction — •Pia Maria Düring, Andreas Fuhrberg, Timo Krieg, Verena Reva, and Martina Müller — FB Physik, Universität Konstanz, 78457 Konstanz

Oxide electronics provide the key concepts and materials for enhancing silicon-based semiconductor technologies with novel functionalities. In a recent paper, we provide evidence for individually emerging hole- and electron-type 2D band dispersions at Fe-$SrTiO_3$ heterostructures [1]. The emergence of p- or n-type bands is closely linked to the Fe oxidation state which enables the possibility to tune the interface properties to set or even switch between negatively (n) charged electrons or positively (p) charged holes. One of the main processes that controls the interface properties is the oxygen exchange between the film and the substrate. Using our UHV-MBE system, we grow high-quality ultra-thin TM (e.g. Fe, Co and Hf) oxide films on $SrTiO_3$ substrates by systematically varying the growth parameters, e.g. (i) growth temperature, (ii) substrate annealing, and (iii) metal film thickness. The present work discusses the effect of different growth parameters on the interfacial properties like oxygen vacancies, the oxidation state of the TM oxide as well as the concentration of defects in $SrTiO_3$, which strongly influences the valence band alignment between electron and hole band bending. In this way, we can effectively control the properties of the 2D interface to ultimately add ferroic functionalities to these confined electronic states.

DS 5.2 Tue 14:15 H3

Adsorption-controlled growth of α-(Al,Ga)2O3 and β-(Al,Ga)2O3 on Al2O3 by suboxide molecular-beam epitaxy (S-MBE) — •Sushma Raghuvansy[1], Marco Schowalter[1], Alexander Karg[1], Manuel Alonso-Orts[1,2], Martin Williams[1], Stephan Figge[1], Andreas Rosenauer[1,2], Martin Eickhoff[1,2], and Patrick Vogt[1,3] — [1]Institute of Solid-State Physics, University of Bremen, Otto-Hahn-Allee 1, 28359, Bremen, Germany — [2]MAPEX Center for Materials and Processes, University of Bremen, Bibliotheksstraße 1, 28359 Bremen, Germany — [3]Max Planck Institute for solid state research, Heisenbergstraße 1, 70569 Stuttgart, Germany

Gallium oxide (Ga2O3) is a promising ultra-wide band gap semiconductor with extremely high (predicted) breakdown field for high performance power electronics.

α-Ga2O3 is isostructural to α-Al2O3, and allows alloying over the entire composition range from Ga2O3 (x=0) and Al2O3 (x=1) in α-(AlxGa1-x)2O3 [1]. For β-(AlxGa1-x)2O3, range with which Al can be alloyed is $0 < x < 0.61$, which leads

to a bandgap range of 4.6-5.9 eV [2].

In this contribution, we demonstrate the growth of high quality α-(Al,Ga)2O3 on Al2O3 (10-10) and Al2O3 (11-20) and β-(Al,Ga)2O3 on Al2O3 (0001) by suboxide molecular beam epitaxy (S-MBE). We investigated the influence of Al flux and growth parameter space of (Al,Ga)2O3 alloys on differently oriented Al2O3 substrates.

Tuning the interlayer coupling in $La_{0.7}Sr_{0.3}MnO_3$ / $LaNiO_3$ multilayers with strong perpendicular-magnetic-anisotropy — •Jörg Schöpf[1], Valentina Piva[1], Paul H. M. van Loosdrecht[1], Padraic Shafer[2], Divine P. Kumah[3,4], Xuanyi Zhang[3,4], Lide Yao[5], Sebastiaan van Dijken[6], and Ionela Lindfors-Vrejoiu[1] — [1]Institute of Physics II, University of Cologne, Cologne, Germany — [2]Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, USA — [3]Department of Physics, Duke University, Durham, USA — [4]Department of Physics, North Carolina State University, Raleigh, USA — [5]OtaNano-Nanomicroscopy Center, Aalto University, Aalto, Finland — [6]Department of Applied Physics, Aalto University School of Science, Aalto, Finland

We report on the magnetic interlayer coupling between Ru-substituted $La_{0.7}Sr_{0.3}MnO_3$ thin films separated by few unit cell thin $LaNiO_3$ spacers, grown by pulsed-laser-deposition and investigated by SQUID-mangetometry, magnetotransport and the magneto-optive-Kerr effect. The magnetic anisotropy in Ru-substituted $La_{0.7}Sr_{0.3}MnO_3$ thin films, in combination with light compressive strain of a LSAT substrate, allows to tune the magnetic anisotropy from easy-plain to strong perpendicular-magnetic-anisotropy. $LaNiO_3$, allows for strong FM- or AFM-coupling between the manganite layers depending on spacer thickness. We propose a layer-by-layer type magnetization reversal in the case of strong PMA, introduced by substituting 10% of Mn by Ru, while films with lower substitution of 5% and weaker PMA instead show signs of collective, spin-flop-type transitions.

DS 5.4 Tue 14:45 H3

Multinary compositionally graded, spatially addressable materials libraries by pulsed laser deposition — •Jorrit Marius Bredow, Marius Grundmann, and Holger von Wenckstern — Felix Bloch Institute for Solid State Physics, Leipzig University

The discovery of novel, functional materials is increasingly based on the investigation of multinary materials with large composition spaces. Therefore, combinatorial synthesis and high-throughput characterization methods are preferable for the discovery of functional multi-component materials. Here, pulsed laser deposition (PLD) from segmented targets allows the synthesis of spatially addressable materials libraries (SA-ML) with continuous compositional gradients[1].

We demonstrate that PLD is a viable method for synthesizing multi-component SA-ML using n-fold azimuthally segmented targets. We present a roadmap for the fabrication of fivefold segmented targets using MgO, CoO, NiO, CuO, and ZnO, which can be readily applied to different material combinations. Moreover, we compare two approaches to target and deposition process design for PLD of SA-ML. The composition of the SA-ML is determined by high-throughput energy dispersive X-ray spectroscopy confirming the successful synthesis of a fivefold compositionally graded SA-ML by combinatorial PLD. Aditionally, the height distributions and elemental compositions are simulated with the thickness distribution parameters of the binary oxides and the simulation results are compared to the experimental data.

DS 5.5 Tue 15:00 H3

Tri-functionality in a Single Oxide Interface-Based Nanostructure with Reconfigurable Logic-in-Memory Applications — •Soumen Pradhan[1], Kirill Miller[1], Fabian Hartmann[1], Merit Spring[2], Silke Kuhn[1], Victor Lopez-Richard[3], Michael Sing[2], Ralph Claessen[2], and Sven Höfling[1] — [1]Julius-Maximilians-Universität Würzburg, Würzburg-Dresden Cluster of Excellence ct.qmat, Lehrstuhl für Technische Physik, Deutschland — [2]Julius-Maximilians-Universität Würzburg, Würzburg-Dresden Cluster of Excellence ct.qmat, Experimentelle Physik 4, Deutschland — [3]Department of Physics, Federal University of São Carlos, Brazil

We demonstrate transistor (T), memristive (M), and memcapacitive (MC) functionalities in nanowires, based on quasi-two-dimensional electron system in $LaAlO_3/SrTiO_3$ heterostructures depending on the biasing condition at lateral gates. Combining one T and one M, the device can be utilized for short term and long term synaptic plasticity. However, arranging two T in parallel and series with one M, the structures show logic OR and AND gates, respectively. In addition, the devices can memorize the logic output even after grounding the inputs taking advantage of its long term memory. Interestingly, the single structure can be reconfigured between OR and AND logic. Our findings on oxide nanostructures together with logic-in-memory and reconfigurability in logic as well as in functionality open a path towards oxide-based monolithic integrated circuits for brain inspired neuromorphic computing.

Fluorescent SiON-Doped Si Thin Films in Miniature Temperature Sensor Fabrication Using Machine and Deep Learning with Low Root Mean Square Error — Ali Karatutlu[1], Timuçin Emre Tabaru[2], •Zehra Gizem Mutlay[1], Esra Kendir Tekgül[1], Nurhan Güneş[2], and Bülend Ortaç[1] — [1]Institute of Materials Science Nanotechnology and National Nanotechnology Research Center (UNAM) Bilkent University, Ankara, Türkiye — [2]Department of Electrical Electronics Engineering, Sivas University of Science and Technology, Sivas, Turkey

SiON-doped Si, discovered by our project team last year (DOI: Advanced Optical Materials, 2023, DOI: 10.1002/adom.20230009), has a special molecular matrix with a refractive index that can be controlled depending on the amount of SiON. The counterpart structures, such as SixNy, SiOxNy, or Si-rich Si3N4, are conventional structures with general properties such as mechanical durability, thermal stability, chemical resistance, electrical insulation, and optical transparency. We report that SiON-doped Si can have a relatively even higher refractive index from 2.07 to 2.56 near the telecom wavelength of 1310 nm, depending on the SiON content. In terms of application, SiON-doped Si thin films were tested at room temperature to 200°C using different packaging materials such as borosilicate glass and aluminum, and their use as miniature temperature sensors will be demonstrated. The preliminary temperature-fluorescence spectrum correlation was investigated using machine learning and deep learning methods that yield the root mean square error of this system to be as low as 2°C.

DS 6.2 Wed 9:45 H3

Electron-transparent free-standing ultrathin membranes for studying gas-solid and liquid-solid interfaces at high pressures — •Max Gertig[1], Carlos Morales[1], Andreas Schubert[2], Carlos Alvarado[2], Christian Wenger[2], and Jan Ingo Flege[1] — [1]Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology Cottbus-Senftenberg, Germany — [2]IHP Leibniz-Insitut für innovative Mikroelektronik, Frankfurt (Oder), Germany

The chemical reactions of heterogenously catalyzed processes take place at the gas-solid and liquid-solid interfaces. Thus, significant efforts have been dedicated to developing new methods to study them under realistic conditions. In recent years, electron-transparent graphene windows have been used in ambient pressure X-ray photoelectron spectroscopy (AP-XPS) to separate liquids and gases at ambient pressure from a high vacuum. Following this design, we present free-standing ultrathin (up to 10 nm) Al_2O_3 membranes fabricated by atomic layer deposition (ALD) which are electron-transparent to tender and hard X-rays. Three different commercial supports are used: TEM SiN perforated membranes (1 μm), single-hole stainless steal apertures (20 μm), and TEM Cu-grids (80 μm). Their conformity has been examined by scanning electron microscopy (SEM) and atomic force microscopy (AFM), whereas their chemical composition and homogeneity by energy dispersive X-ray (EDX) mapping. Additionally, confocal μ-Raman microscopy complements the chemical and structural characterization. Conventional free-standing graphene membranes have also been fabricated for comparison purposes.

DS 6.3 Wed 10:00 H3

VO_2 Smart Windows for Applications: A Study of $Cu_xTi_{1-x}O_2$ Buffer Layers in Multilayer Thin Film Systems — •Hao Lu[1,2], Martin Becker[1,2], Jan Luka Dornseifer[1,2], and Peter J. Klar[1,2] — [1]Institute of Experimental Physics I, Justus-Liebig-University, Giessen, Germany — [2]Center of Materials Research (ZfM/LaMa), Justus Liebig University Giessen, Giessen, Germany

Alloying the TiO_2 with CuO_2 yielding $Cu_xTi_{1-x}O_2$ may provide a suitable buffer layer for optical smart windows based on VO_2. Preliminary work in the literature suggests that the phase transition temperature of the anatase to rutile structural phase transition of TiO_2 is lowered for by alloying Cu. However, that the band gap of $Cu_xTi_{1-x}O_2$ decreases with increasing x compared with the wide band gap of TiO_2. We successfully grew polycrystalline $Cu_xTi_{1-x}O_2$ alloys with x up to 31% on quartz substrates by conventional rf-sputtering employing a TiO_2 ceramic target and Cu wires as Cu source. We determined the crystal phase of the deposited thin films by XRD and Raman spectroscopy and established a 2D

phase map versus substrate temperature during growth and Cu content x. It shows that increasing Cu content considerably lowers the growth temperature where rutile $Cu_xTi_{1-x}O_2$ thin films can be obtained. Currently, we are assessing the trade-off between band gap, morphology, and growth temperature required for obtaining the most suitable rutile $Cu_xTi_{1-x}O_2$ buffer layer from the viewpoints of the best materials properties as well as a suitability for future commercialization in smart windows.

DS 6.4 Wed 10:15 H3

DS 6.5 Wed 10:45 H3

Achieving superconductivity in infinite-layer nickelate thin films by aluminum sputtering deposition — •dongxin zhang[1], A. Raji[2], L. M. Vicente-Arche[1], A. Gloter[2], M. Bibes[1], and L. Iglesias[1] — [1]Laboratoire Albert Fert, CNRS, Thales, Université Paris-Saclay, 91405, France — [2]Laboratoire de Physique des Solides, CNRS, Université Paris-Saclay, 91405, France

After decades of research, the recent discovery of superconductivity in hole doped infinite-layer nickelates (ABO2) has offered new perspectives to deepen the understanding of high-temperature superconductivity. infinite-layer (IL) nickelates are synthesized by topotactic reduction that selectively removes all apical oxygens of the precursor perovskite ABO3 phase. This is typically achieved by an ex-situ complex annealing using CaH2 as a reducing agent. However, the progress in this field is hampered by significant challenges in materials synthesis and the limited number of research groups capable of producing high-quality superconducting (SC) samples.Here, we present a new method to synthesize SC IL nickelates Pr0.8Sr0.2NiO2 thin films using an aluminum overlayer deposited by sputtering as a reducing agent. We optimized the aluminum deposition conditions and achieved SC samples reduced either in-situ or ex-situ. In-situ Al reduction enhances the quality of the SC Pr0.8Sr0.2NiO2 films, with a maximum transition temperature Tconset of 17 K. This simplified synthesis approach, more accessible than existing ones, enables more research groups to produce high-quality SC nickelate samples, Possibly advancing experimental understanding of superconductivity in IL nickelate.

DS 6.6 Wed 11:00 H3

Deposition and characterisation of NbTiN thin films for application in SRF cavities — •Bharath Reddy Lakki Reddy Venkata, Aleksandr Zubtsovskii, and Xin Jiang — Chair of Surface and Materials Technology, University of Siegen, Germany

Superconducting radio frequency (SRF) cavities are key components for modern particle accelerators. While bulk niobium (Nb), with the highest lower critical magnetic field, Hc1 (0.18 T), and transition temperature, Tc (9.23 K), among elemental superconductors, has dominated SRF applications, the performance of bulk Nb cavities has reached theoretical limits. Recent research focuses on the use of superconducting thin films of Nb or other alternative higher Tc materials, such as NbN, NbTiN, Nb3Sn, MgB2, etc, to enhance SRF cavity performance and cost efficiency. However, their lower Hc1 limits high accelerating gradients and quality factors. Gurevich's SIS multilayer theory offers a breakthrough to shield an underlying superconductor from the applied magnetic fields, thus increasing the maximum accelerating gradient beyond the bulk Nb limits. This study investigates NbTiN thin films deposited on Si substrates using reactive DC- and HiPIMS techniques. Deposition parameters were optimised to achieve improved microstructure and superconducting properties, enabling their integration into SIS structures. To understand the microstructural characteristics of NbTiN films, positron annihilation spectroscopy (PAS) was employed alongside SEM, XRD, AFM, and EDX, offering deeper insights into how deposition techniques and parameters affect material performance.

DS 6.7 Wed 11:15 H3

T-dependent switching of molecular spin-crossover (SCO) monolayers — •Fabian Streller[1], Kirill Gubanov[1], Stephen Goodner[2], Marat Khusniyarov[2], and Rainer Fink[1] — [1]Lehrstuhl für Physikalische Chemie II, Friedrich Alexander Universität Erlangen Nürnberg — [2]Lehrstuhl für Anorganische und Allgemeine Chemie, Friedrich Alexander Universität Erlangen Nürnberg

Spin-crossover (SCO) complexes are regarded as promising materials in spintronics, molecular electronics and ultra-high-density memory systems applications. Switching between diamagnetic low-spin (LS) and paramagnetic high-spin (HS) species is triggered by external stimuli, e.g., change of temperature, pressure, or illumination with light.[1] One major challenge is the transfer from solution or bulk towards thin films or even monolayers on well-defined surfaces without quenching of the switching behaviour. Six-coordinate iron(II) complexes have been used as SCO materials. This material is attached to the surface via a bidental phenanthroline ligand containing moieties suitable for bonding to the substrate. We report on a step-by-step formation of SCO-active single-layer films on Au(111) surfaces. Thus created specimens were characterized by atomic force microscopy (AFM), x-ray photoelectron spectroscopy (XPS) and temperature dependent near edge x-ray absorption fine structure (NEXAFS) to follow the molecular switching. Research is funded by the BMBF (contract 05K22WE2) [1] B. Rösner, M. Milek, A. Witt, B. Gobaut, P. Torelli, R. H. Fink, M. M. Khusniyarov Angewandte Chemie. 2015, 127, 13168-13172.

DS 6.8 Wed 11:30 H3

High Accuracy Reflection Prediction Model for Multi-Layer Anti-Reflection Coatings Using Deep Learning and Machine Learning — •Iremnur Duru, Semih Oktay, and Timuçin Emre Tabaru — Department of Electrical Electronics Engineering, Sivas University of Science and Technology, 58000 Sivas, Turkey

In order to optimize the thickness parameters, this work employs Machine Learning (ML) and Deep Learning (DL) approaches to develop an accurate reflection prediction model that will direct the design of filters with multilayer Anti-Reflection Coating (ARC). A dataset of information derived from 3000 (1500 Ge- Al2O3, 1500 Ge- SiO2) computer simulations based on the thicknesses of multilayer structural materials has been used to create this model. Al2O3 and SiO2 served as the second layers in both coatings, with Ge serving as the substrate. Reflectance values for wavelengths ranging between the 3-5 *m and 8-12 *m bands characteristic of the mid-wave infrared (MWIR) and long-wave infrared (LWIR) bands are included in the data set. The average reflectance in the given 2-layer data set was at least 0.36 at thicknesses of 515 nm Ge and 910 nm SiO2. In terms of predicting reflectance values, the results demonstrate that machine learning (ML) models*specifically, decision tree, random forest and bagging methods perform better than the DL model and offer a useful guide for conceptualizing and manufacturing optical thin-film filters.

DS 7: Spins in Molecular Systems: Strategies and Effects of Hyperpolarization

Time: Wednesday 9:30–11:45 Location: H14

Invited Talk DS 7.1 Wed 9:30 H14

Enhancing Organic Spin Valves Through Spinterface Engineering — •Shuaishuai Ding and Wenping Hu — Institute of Molecular Aggregation Science, School of Science, Tianjin University, Tianjin, China

Organic spin valves hold immense promise for efficient spintronic devices, driving advancements in information processing and storage technologies. The spinterface, the interface between an organic semiconductor and a ferromagnetic electrode, plays a crucial role in the performance of these devices. However, the inherent instability of the spinterface poses challenges that must be addressed to fully realize this potential. To tackle these issues, we have developed a comprehensive approach that combines innovative fabrication techniques and material engineering. Electrode transfer technology enhances interfacial properties by enabling the precise deposition of high-quality ferromagnetic electrodes onto organic semiconductors, while doping with F4-TCNQ effectively improves spin injection efficiency through modulation of electronic and magnetic characteristics. Moreover, the engineering of controllable bottom spinterfaces allows for precise regulation of spin injection, resulting in highly tunable device performance. By leveraging the spinterface, we have achieved in-situ control of device

tunability, significantly expanding the multilevel resistance modulation of organic spin valves. These advancements not only address key challenges of unstable spinterface but also establish novel methods for device modulation, marking an important leap forward in organic spintronics.

DS 7.2 Wed 10:00 H14

Hyperpolarised electron spins as a sensitive probe for investigating structure–function relationship in organic energy materials — •Till Biskup — Universität Rostock, Rostock, Germany

Energy conversion and storage is of paramount importance, and organic functional materials are increasingly being used for this purpose. Hyperpolarised electron spins as created, e.g., by light excitation act as sensitive probe of their environment. This allows to investigate the structure–function relationship of these materials by using time-resolved electron paramagnetic resonance (TREPR) spectroscopy. Insights range from morphology and details of the aggregation behaviour in both, film and solution to triplet routes to the electronic structure of these materials far beyond exciton delocalisation. Here, we focus particularly on the effects of conjugation break and systematic backbone variation on exciton delocalisation as well as solvent and cooling rate on aggregate formation. TREPR spectroscopy provides insight into these effects with molecular resolution that is not available by and complementary to other methods.

DS 7.3 Wed 10:15 H14

The CISS magnetoresistance effect for polyalanine and polyproline molecules studied by ambient STM — •Thi Ngoc Ha Nguyen[1], Lech Tomasz Baczewski[2], Tobias Theiss[3], Tanja Gulder[3], and Christoph Tegenkamp[1] — [1]Solid Surface Analysis, Institute of Physics, Chemnitz University of Technology, Chemnitz, Ger- many — [2]Reichenhainerstr., 70 — [3]Institute of Organic Chemistry, Faculty of Chemistry and Mineralogy, Leipzig University, Leipzig, Germany

The chirality induced spin selectivity (CISS) effect has been up to now measured in a wide variety of systems but its exact mechanism is still under debate. Whether the spin polarization occurs at an interface layer or builds up in the helical molecule is yet not clear. We investigated the current transmission through helical polyalanine molecules, revealing a strong and length dependent dipole moment, as a part of a tunnel junction realized with a scanning tunneling microscope. Depending on whether the molecules were chemisorbed directly on the magnetic Au/Co/Au substrate or at the STM Au-tip, the magnetizations of the Co layer had been oriented in the opposite direction in order to preserve the symmetry of the IV-curves. These results show that besides the helicity also the electric dipole play a crucial role. Latest experiments with polyproline with a small electric dipole moment showed that the CISS effect is almost vanishing. Our results can be explained by a spin-polarized or spin-selective interface effect, induced and defined by the helicity and electric dipole orientation of the molecule at the interface.

session break

DS 7.4 Wed 10:45 H14

Analysis of polaron pair lifetime dynamics and secondary processes in exciplex driven TADF OLEDs using organic magnetic field effects (MFE) — •Annika Morgenstern[1], Dominik Weber[2], Lukas Hertling[1,3], Konstantin Gabel[1], Ulrich T. Schwarz[1], Daniel Schondelmaier[2], Dietrich R.T. Zahn[1,3], and Georgeta Salvan[1,3] — [1]Institute of Physics, TU Chemnitz — [2]Physical Engineering and Computer Science, WH Zwickau — [3]MAIN, TU Chemnitz, Chemnitz

MFE in TADF materials have been shown to influence the reverse intersystem crossing and to impact on electroluminescence and conductivity. Here, we present a novel model combining Cole-Cole and Lorentzian functions to describe low and high MFE originating from hyperfine coupling, the Δg mechanism, and triplet processes. We applied this approach to organic light-emitting devices of third generation based on TCTA and TPBi, exhibiting blue emission, to unravel their loss mechanisms. The quality of the regression function was evaluated using k-fold cross-validation. The scoring was compared to various alternative fitting functions, which were previously proposed in literature. Density functional theory calculations, photoluminescence, and electroluminescence studies validated the formation of a TADF exciplex system. Furthermore, we propose successful encapsulation using a semi-permeable polymer, showing promising results for magnetic field sensing applications. This study provides insights into the origin of MFE in exciplex-TADF materials, with potential applications in optoelectronic devices and sensing technologies.

DS 7.5 Wed 11:00 H14

Employing CISS for Modification of Skyrmion Diffusion and Size — •Fabian Kammerbauer[1], Yael Kapon[2], Theo Balland[1], Shira Yochelis[2], Yossi Paltiel[2], and Mathias Kläui[1] — [1]Institut für Physik, Johannes-Gutenberg-Universität Mainz, 55099 Mainz, Germany — [2]Institute of Applied Physics, Faculty of Sciences, The Hebrew University of Jerusalem, Jerusalem 9190401, Israel

Chirality-induced spin selectivity (CISS) is a phenomenon that has garnered significant attention due to its ability to generate large spin polarizations in organic molecules and its associated effects, such as the magnetic switching of ferromagnets induced by chiral molecules [1]. In hybrid systems, these chiral molecules have been found to influence magnetic properties, including changes in the magnetization [2]. This study explores the interaction between chiral molecules, specifically alpha-helix polyalanine, and chiral spin structures such as magnetic skyrmions. The skyrmions are stabilized in ferromagnetic/heavy metal multilayers via the Dzyaloshinskii-Moriya interaction [3]. Through magneto-optic Kerr effect imaging, we demonstrate that chiral polypeptides can alter the stability of skyrmions by shifting the temperature and magnetic field ranges where they remain stable. Furthermore, we reveal the impact of chiral molecules on skyrmion size and thermal skyrmion diffusion.

DS 7.6 Wed 11:15 H14

Microscopic and Macroscopic CISS Effect Characterization: Moving from MBE to Sputter-Deposited Au/Co/Au Substrates — •Lokesh Rasabathina[1], Thi Ngoc Ha Nguyen[1], Julia Krone[1], Annika Morgenstern[1], Franziska Schölzel[1,2], Markus Gössler[1], Karin Leistner[1], Aleksandr Kazimir[4], Jannik Knoche[4], Christina Lamers[4], Irene Coin[4], Lech Thomasz Baczewski[5], Christoph Tegenkamp[1], Georgeta Salvan[1,2], and Olav Hellwig[1,2,3] — [1]Chemnitz University of Technology, Chemnitz, Germany — [2]Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Chemnitz University of Technology,Chemnitz, Germany — [3]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [4]Leipzig University, Leipzig, Germany — [5]Polish Academy of Sciences, Warszawa, Poland.

Adsorption of alpha-helical polyalanine molecules on metallic substrates enables interfacial selective electron transport with a defined spin direction, a phenomenon known as Chirality Induced Spin Selectivity (CISS). We combine microscopic STM/STS of hybrid spin-valve structures with macroscopic MOKE magnetometry for CISS effect characterization on Au/Co/Au substrates. Microscopically we observe magneto resistance changes across the hybrid spin-valve structure and macroscopically we find a coercivity enhancement of the Co layer after exposure to molecules. To use more complex systems, we moved from MBE to sputterd substrates and discuss the challenges related to this transition.

DS 7.7 Wed 11:30 H14

Towards a quantum sensing approach to single-cell chemical and mechanical analysis using nanoscale NMR — •Baha Sakar[1], Sirswa Kuldeep Shree Ram[1], Maximilian Püllmann[1], Frank Sauer[2], Rustem Valiullin[1], Josef A. Käs[2], and Nabeel Aslam[1] — [1]Felix-Bloch-Institut für Festkörperphysik - Universität Leipzig, Leipzig, Deutschland — [2]Peter-Debye-Institut für Physik der weichen Materie - Universität Leipzig, Leipzig, Deutschland

Understanding single-cell mechanical and chemical properties is key to exploring cellular behavior and dysfunction, influencing processes like development, immune response, and disease progression, including cancer metastasis. While fluorescence microscopy enables structural insights and tracking, it lacks the chemical specificity of conventional NMR. The latter is however limited to ensemble measurements and cannot resolve single-cells. In this study, we utilize a quantum sensing platform based on NV centers in diamond, which are atomic-scale spin defects capable of detecting nuclear spins with sensitivities up to fifteen orders of magnitude higher than conventional NMR, enabling single-cell resolution. By applying resonant microwave pulse sequences and specially designed magnetic fields, we probe the NMR signal of the cells' nuclear spins. In this talk, we will discuss the steps towards studying the micromechanical and chemical properties of single cells, distinguishing between intracellular and extracellular molecular diffusion processes. Furthermore, we will present initial results of correlating fluorescence microscopy and NMR spectroscopy with the goal to investigate the link between cell mechanics and tumor aggressiveness.

DS 8: Optical Analysis of Thin Films I

Time: Wednesday 12:00–13:00 Location: H3

DS 8.1 Wed 12:00 H3

Initial stages of Palladium growth on vicinal Si(001)-(2*1) surfaces — •Sandhya Chandola[1], Norbert H. Nickel[1], Julian Plaickner[2], Jörg Rappich[1], Karsten Hinrichs[1], and Norbert Esser[2] — [1]Nanoscale Solid-Liquid Interfaces, Helmholtz-Zentrum Berlin für Materialien und Energie,Schwarzschildstr. 8, 12489 Berlin, Germany — [2]Institut für Festkörperphysik, TU Berlin, Hardenbergstr. 36, 10623 Berlin, Germany

Although palladium-based silicides are of great interest in many microelectronic applications, their formation mechanisms are still not fully understood, especially for thin films where the silicidation reaction may be controlled from the initial Pd-Si interactions at the interface.

The early stages of palladium silicide formation have been investigated in ultra-high vacuum (UHV), using Reflectance Anisotropy Spectroscopy (RAS) and Raman spectroscopy on vicinal Si(001) surfaces with different degrees of ordering. Raman spectroscopy has identified silicide-like reacted phases at the Si-Pd interface upon annealing, with the appearance of several phonon modes which are in very good agreement with vibrational modes obtained from ab initio calculations for Pd incorporation into Si surface layers.

The growth morphology of the Pd-Si structures was shown to be dependent on the initial surface reconstruction with in-situ RAS and ex-situ AFM (atomic force microscopy) clearly distinguishing between two types of structures depending on the substrate template.

DS 8.2 Wed 12:15 H3

Ultrafast Charge Carrier Dynamics in Niobium Probed in the Visible Spectral Range — •Noah Stiehm[1], Shirly Espinoza[2], Mateusz Rebarz[2], Saul Vazquez Miranda[2], Erik Müller[3], Hannes Töpfer[3], Stefan Krischok[1], and Rüdiger Schmidt-Grund[1] — [1]Technische Universität Ilmenau, Fachgebiet Technische Physik I, Weimarer Straße 32, 98693 Ilmenau, Germany — [2]ELI Beamlines Facility, The Extreme Light Infrastructure ERIC, Za Radnicí 835, 25241 Dolní Břežany, Czech-Republic — [3]Technische Universität Ilmenau, Fachgebiet Theoretische Elektrotechnik, Helmholtzplatz 2, 98693 Ilmenau, Germany

With the recently developed experimental method of femtosecond time-resolved spectroscopic ellipsometry (trSE) [1], it is possible to obtain the transient dielectric function of a sample after excitation in a pump-probe scheme. We present results of applying the technique to study the ultrafast charge carrier dynamics in the transition metal Niobium. We show that it is possible to observe bleaching in the dielectric function for several 100 picoseconds and up to 1 nanosecond, depending on the pump wavelength, resulting from exciting charge carriers into higher conduction bands, where they relax into band minima and remain stable for some time until recombination.

The initial results from this study at room temperature provide valuable insight into the ultrafast charge carrier dynamics and good motivation to conduct further investigations under cryogenic conditions in the superconducting phase.

[1] S. Richter *et al.*, Rev. Sci. Instrum. 92, 033104 (2021).

DS 8.3 Wed 12:30 H3

Investigation of metal surfaces using Surface Resonant Raman Scattering — •Sarang Bhasme, Mariella Denk, Simon Kalteis, and Peter Zeppenfeld — Johannes Kepler University, Linz, Austria

We have recently demonstrated the possibility to investigate surface phonons on metals by surface resonant Raman spectroscopy (SRRS), in which the Raman cross section is significantly enhanced by resonant excitation of optical transitions involving surface electronic states [1]. Here we report new investigations regarding the phonon and electron scattering mechanism on clean and adsorbate-modified Cu(110) surfaces using SRRS and reflectance difference spectroscopy (RDS) under ultra-high vacuum (UHV) conditions and variable temperatures. We have modified the Cu(110) surface electronic states via ion bombardment and by adsorption of small molecules such as oxygen or CO to explore its effect on the Raman signals. We find that both the phonon and the electron related scattering strongly depend on the details of the surface cleanliness and structural properties, underscoring the influence of the surface electronic structure and adsorbate interactions on the Raman signatures.

DS 8.4 Wed 12:45 H3

Watching hydrogen diffusion into Lutetium and Yttrium thin films with Pd cap layers — •Zahra Hojjati, Philipp Flad, and Harald Giessen — 4. Physikalisches Institut, Universität Stuttgart

Hydrogenated Lutetium is one of the materials that may have a potential to be used as high-temperature superconductor under high pressure. Recently, reports have indicated that the Lu-H-N system undergoes a phase transition to blue when hydrogenated, with unconfirmed reports suggesting superconductivity. Therefore, we investigate hydrogen-lutetium interactions and the dynamics of hydrogen diffusion within lutetium, which is influenced by the ambient temperature, crystal structure and the hydrogen concentration. Hydrogen diffusion in metals involves interstitial diffusion through the lattice and surface absorption. We find that lutetium is a good hydrogen storage material due to its diffusion properties.

We analyzed the progression of the blue hydrogenation front in Lutetium and subsequently measured the drift velocity for each sample. We calculated the activation energy required for protons to overcome the potential barrier using the Arrhenius equation. Following this, we determined the diffusion constant based on the diffusion equation. We also carry out the same experiments with Yttrium.

DS 9: Optical Analysis of Thin Films II

Time: Thursday 9:30–12:45 Location: H3

Invited Talk DS 9.1 Thu 9:30 H3

Inverse Problems and Uncertainty Quantification for the analysis of thin films and nanostructured surfaces — •Sebastian Heidenreich[1], Nando Hegemann[1], Victor Soltwisch[2], and Markus Bär[1] — [1]Mathematical Modelling and Data Analysis, PTB, Abbestr. 2-12, 10587 Berlin — [2]Radiometry with Synchrotron Radiation, PTB, Abbestr. 2-12, 10587 Berlin

For the analysis of thin films and nanostructured surfaces, indirect optical measurement techniques are often used to determine the optical and geometrical properties by solving an inverse problem. Due to measurement errors and model errors, the results are subjected to uncertainties. In the talk we give an overview about statistical inverse problems with applications in the metrology of thin films and nanostructured surfaces. We start with a discussion of the advantages and disadvantages of frequently used Least-Squares, then consider the Maximum-Likelihood method and introduce the Bayesian approach as a statistical method [1]. We apply the Bayesian approach to thin film examples as well as to line grating structures and show how to deal with measurement uncertainties and model errors. Furthermore, we discuss some drawbacks of the Bayesian method and present recent developments like polynomial chaos, transport maps or neural networks to tackle these drawbacks [2]. –[1] Soltwisch, Fernandez Herrero, Pflüger, Haase, Probst, Laubis, Krumrey, Scholze, J. Appl. Cryst. 50, 2017; Heidenreich, Gross, Bär, Metrologia 55(6), 2018. [2] Hegemann, Heidenreich, J. Open Software 8 (89), 2023; Hagemann, Hertrich, Casfor, Heidenreich, Steidl, Mach. Learn:Sci. Technol. 5, 2024.

Invited Talk DS 9.2 Thu 10:00 H3

Metrological spectroscopic and imaging Mueller matrix ellipsometry for the analysis of thin films and nanostructured surfaces — •Bernd Bodermann[1], Matthias Wurm[1], Manuela Schiek[2], Jana Grundmann[1], and Tim Käseberg[1] — [1]Optical Nanometrology, PTB, Bundesallee 100, 38116 Braunschweig — [2]Center for Surface and Nano-Analytics (ZONA) Johannes Kepler University Linz, Austria

Spectroscopic Mueller ellipsometry is a widely used method for analysing thin films and nanostructured surfaces. The extension to imaging ellipsometry enables measurements on small measurement objects << 1 mm2 and investigations of local parameter variations. However, as an integral and indirect measurement method, the determination of the corresponding measurement uncertainties is challenging and requires complex analysis methods. Imaging ellipsometry, involves an even higher level of complexity both in terms of data analysis and the necessary metrological system characterisation. We give an overview of various experimental sources of uncertainty including structure-induced contributions and how these can be characterised. Both deterministic and stochastic contributions of the measurement system as well as the samples under test will be discussed. Additionally, we present investigations of sensitivity-enhanced ellipsometry, by e.g. exploiting local plasmonic or dielectric resonances in the sample structure, and advanced methods that use additional structures to amplify and/or guide resonances for the detection and characterisation of periodic and non-periodic structures.

session break

DS 9.3 Thu 10:45 H3

Structured Light Microscopy for Optical and Topological Characterization — •Denis Ukolov, Polina Gromova, and Peter Lemmens — IPKM, TU-BS, Braunschweig, Germany

Structured light beams with orbital angular momentum (OAM) are applied to study topological properties of thin films and metasurfaces. Using a laser confocal microscope with integrated interferometry, we investigate phase distributions and topological features of chiral structures.

Experimental data are compared with simulations to understand the interaction of OAM with surface geometry and its topological effects. This method offers a novel approach to characterizing surface properties in complex systems.

Work supported by DFG EXC-2123 QuantumFrontiers - Light and Matter 390837967.

DS 9.4 Thu 11:00 H3

Synchrotron-based VUV ellipsometry on passivated Si samples for optical thin film metrology — •Julian Plaickner[1], Alexander Gottwald[2], Mattia Mulazzi[2], Jörg Rappich[3], Karsten Hinrichs[3], Christoph Cobet[4], Johanna Reck[5], and Norbert Esser[1] — [1]Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin — [2]Physikalisch-Technische Bundesanstalt, Abbestr. 2-12, 10587 Berlin — [3]Nanoscale Solid-Liquid Interfaces, Helmholtz Zentrum Berlin für Materialien und Energie GmbH, Albert Einstein Str. 15, 12489 Berlin — [4]Center for Surface and Nanoanalytics, Johannes Kepler Universität, Altenbergerstr. 69, 4040 Linz — [5]SENTECH Instruments GmbH, Schwarzschildstr. 2, 12489 Berlin

The vacuum ultraviolet (VUV) spectral range spectral range is characterized by a lack of reliable data on optical properties due to the extreme surface sensitivity and the requirements of a high brightness light source. A method for determining traceble optical data with well-defined uncertainty budget is tested on novel reference materials. For this purpose, chemically passivated vicinal silicon surfaces were measured between 2 and 30 eV with the synchrotron-based VUV ellipsometer[1] at the Metrology Light Source (MLS) of the PTB. X-ray photoelectron spectroscopy (XPS) and IR ellipsometry measurements serve as quality cross checks for the prepared surfaces. In the spectral range between 2 and 6 eV, results are compared to reference measurements made with commercial SENTECH ellipsometers.

DS 9.5 Thu 11:15 H3

Tailoring Properties of Epitaxially Grown Bismuth Telluride Thin Films through Stoichiometric Control — •Felix Hoff, Christoph Ringkamp, Alexander Kiehn, Thomas Schmidt, Dasol Kim, Jonathan Frank, Timo Veslin, and Matthias Wuttig — I. Institute of Physics (IA), RWTH Aachen University, Germany

The Earth's crust contains a significant number of minerals formed by elements such as Bi and Te, which is surprising given their scarcity. This rich mineral diversity can be attributed to strong interlayer interactions within layered chalcogenides, leading to complex phase diagrams. Bismuth tellurides, in particular, exhibit various stacking sequences that influence their properties as thermoelectrics and topological insulators. While their structural and thermoelectric properties are well-studied in bulk forms, high-quality thin films and their optical and vibrational properties remain underexplored. We address this gap by examining the vibrational and dielectric properties of epitaxially grown thin films of nine distinct BiTe compositions grown on Si (111). Using Raman and fs pump-probe spectroscopy, we characterized the lattice dynamics while optical spectroscopy was employed to determine the dielectric properties. The variation in phonon frequencies with respect to the Bi share can be attributed to the differing strengths of the interlayer bonds. The height of the dielectric absorption peak increases with increasing Bi share, accompanied by a shift in the absorption maximum to lower photon energies. Our results demonstrate the potential of the BiTe system as a versatile and tunable platform for thin film applications.

DS 9.6 Thu 11:30 H3

VUV ellipsometry for the determination of thin film optical constants — •Mattia Mulazzi[1], Julian Plaickner[2], Jörg Rappich[3], Alexander Gottwald[1], and Norbert Esser[2] — [1]Physikalisch-Technische Bundesanstalt, Abbestr. 2-12, 10587, Berlin, Germany — [2]Technische Universität Berlin, Hardenbergstr. 36, 10623, Berlin, Germany — [3]Helmholtz-Zentrum-Berlin für Materialien und Energie, Hahn-Meitner Platz 1, 14109 Berlin, Germany

Motivated by the purpose of determining the optical constants of thin films materials, we present our investigation method based on spectroscopic ellipsometry in the vacuum-ultraviolet spectral range using monochromatised synchrotron radiation. The measurements are characterised by low noise and high accuracy, both quantified according to state-of-the-art metrological procedures, and are well-suited to be fit by numerical methods to obtain the refractive index and the absorption coefficient in a non-parametric way, i.e., independent of the underlying physics of the material under investigation. We show exemplary measurements on surfaces of hydrogen-passivated Si, native SiO2 on Si, graphene on Si and the evaluation steps necessary to determine the optical constants from the measured data.

session break

DS 9.7 Thu 12:00 H3

Optical absorption by two-dimensional excitons (with and without screening) — •Stefan Zollner and Carlos Armenta — New Mexico State University, Las Cruces, NM

Two-dimensional excitons form not only in 2D layered materials (such as transition metal dichalcogenides) or in quantum wells. They also dominate the visible absorption by 2D van Hove singularities in 3D semiconductors. As an example, we measured and calculated the optical absorption of germanium near the E_1 and $E_1 + \Delta_1$ transitions. The 2D character of these transitions stems from the large optical mass along the (111) direction, where the highest valence bands and the lowest conduction band are nearly parallel. Elliot's formalism for the Sommerfeld enhancement of optical absorption (as modified by Tanguy for 2D excitons) provides an excellent description of these absorption peaks, if the momentum matrix element from $\vec{k} \cdot \vec{p}$-theory is used as the optical dipole matrix element. We also discuss how band filling with Fermi-Dirac statistics after intense laser excitation reduces the absorption. We are not aware of a (Banyai-Koch) theory that can be applied to the screening of 2D excitons. This work was supported by the US Air Force (FA-9550-24-1-0061).

DS 9.8 Thu 12:15 H3

All-optical quality-control of indenene intercalation into graphene/SiC — •Cedric Schmitt[1,2], Simone Sotgiu[3], Stefan Enzner[2,4], Jonas Erhardt[1,2], Elena Stellino[3], Domenico Di Sante[5], Giorgio Sangiovanni[2,3], Ralph Claessen[1,2], Simon Moser[1,2], and Leonetta Baldassarre[3] — [1]Physikalisches Institut, Universität Würzburg — [2]Würzburg-Dresden Cluster of Excellence ct.qmat — [3]Department of Physics, Sapienza University of Rome — [4]Institut für Theoretische Physik und Astrophysik, Universität Würzburg — [5]Department of Physics and Astronomy, University of Bologna

Intercalating two-dimensional quantum materials beneath a sheet of graphene provides effective environmental protection and facilitates ex situ device fabrication. However, developing a functional device requires rapid, large-scale screening methods to evaluate the quality of the intercalant, which to date can be monitored only by slow, UHV-based surface science techniques. In this study, we utilize ex situ Raman micro-spectroscopy to optically and non-destructively identify the quantum spin Hall insulator indenene, a monolayer of indium sandwiched between a SiC(0001) substrate and a single sheet of graphene. Color modulation combined with indenene's distinctive low-frequency Raman fingerprint enables rapid assessment of its homogeneity and crystalline quality. Density functional perturbation theory indicates that this Raman signature originates mainly from indenene's shear and breathing modes, while additional higher-order modes are tentatively attributed to defect-assisted and two-phonon Raman processes.

DS 9.9 Thu 12:30 H3

Moiré lattice of twisted bilayer graphene as template for non-covalent functionalization — •Tobias Dierke[1], Stefan Wolff[1], Roland Gillen[1], Tamara Nagel[2], Jasmin Eisenkolb[2], Sabine Maier[1], Milan Kivala[3], Frank Hauke[2], Andreas Hirsch[2], and Janina Maultzsch[1] — [1]Chair of Experimental Physics, FAU Erlangen-Nürnberg, Erlangen — [2]Department of Chemistry and Pharmacy, FAU Erlangen-Nürnberg — [3]Organisch-Chemisches Institut, Centre for Advanced Materials, Universität Heidelberg

We present an innovative approach to achieve spatial variations in the degree of non-covalent functionalization of twisted bilayer graphene (tBLG). The tBLG with local twist angle variations between * 5° and 7° was non-covalently functionalized with 1,4,5,8,9,11- hexaazatriphenylenehexacarbonitrile (HATCN) molecules. We observe a correlation between the twist angle of tBLG and the degree of functionalization, determined through Raman spectroscopy. We propose that the adsorption of HATCN molecules follows the moiré pattern of twisted bilayer graphene, preferentially avoiding AA-stacked regions and primarily attaching to regions with local AB-stacking order, resulting in an overall ABA-stacking arrangement. This hypothesis, is further supported by density functional theory (DFT) calculations [1]. [1] Dierke et al., Angew. Chemie Int. Ed., accepted (2024), DOI: 10.1002/anie.202414593

DS 10: Transport Properties

Time: Thursday 11:30–12:30 Location: H14

DS 10.1 Thu 11:30 H14

A tunable room temperature nonlinear Hall effect in elemental bismuth thin films — •Pavlo Makushko[1], Sergey Kovalev[1], Yevhen Zabila[1], Igor Ilyakov[1], Alexey Ponomaryov[1], Atiqa Arshad[1], Gulloo Lal Prajapati[1], Thales V. A. G. de Oliveira[1], Jan-Christoph Deinert[1], Paul Chekhonin[1], Igor Veremchuk[1], Tobias Kosub[1], Yurii Skourski[1], Fabian Ganss[1], Denys Makarov[1], and Carmine Ortix[2] — [1]Helmholtz-Zentrum Dresden-Rossendorf e.V. — [2]Università di Salerno, Fisciano (SA), Italy

The nonlinear Hall effect with time-reversal symmetry is a second-order electronic transport phenomenon that induces frequency doubling and occurs in non-centrosymmetric crystals with Berry curvature dipole. This effect was typically reported in complex compounds characterized by Dirac or Weyl electrons at low temperatures. Here, we report a room temperature nonlinear Hall effect in polycrystalline thin films of the centrosymmetric elemental bismuth. The nonlinear transversal currents are induced by electrons at the (111) free surface, which possesses a Berry curvature triple. The nonlinear transverse voltage can be boosted by the geometric nonlinear Hall effect in arc-shaped bismuth stripes. The geometric curvature induced frequency doubling is extended to the second-harmonic generation in the terahertz spectral range. We also demonstrate efficient high-harmonic generation in polycrystalline bismuth films and bismuth-based heterostructures across a broad range of terahertz frequencies.

DS 10.2 Thu 11:45 H14

Electrochemical characterization of CeO_2/YSZ multilayer systems with well-defined interfaces — •Julius K. Dinter[1], Anja Henss[1,2], and Matthias T. Elm[1,2] — [1]ZfM, JLU Gießen — [2]Institute of Experimental Physics, JLU Gießen

Mixed ionic and electronic conductors (MIECs) are key components for a variety of electrochemical devices. Their functionality depends on their ability to store or transport both electrons and ions. However, most materials with high ionic conductivity exhibit poor electronic conductivity and vice versa. A common approach to overcome this challenge is the preparation of artificial mixed conductors by mechanically mixing a good electronic conductor with an ionic conductor. Consequently, these artificial MIECs are characterized by a high number of interfaces, which can significantly affect charge storage and charge transport in the composites. A detailed understanding of the impact of these interfaces on the electrochemical properties is essential for the design and improvement of electrochemical devices with enhanced functionality. We present the preparation and characterization of multilayer heterostructures of ceria (CeO_2) and yttria-stabilized zirconia (YSZ). The multilayers with constant thickness but varying number of interfaces were prepared by pulsed laser deposition to obtain thin film structures with well-defined interfaces. Structural characterization was performed using Raman microscopy and time-of-flight secondary ion mass spectrometry. The electrochemical properties were characterized by electrochemical impedance spectroscopy at different temperatures and under varying atmospheric conditions.

DS 10.3 Thu 12:00 H14

Magneto transport in bilayer graphene cavities — •Florian Schöppl[1], Michael Barth[1], Ming-Hao Liu[2], Klaus Richter[1], and Angelika Knothe[1] — [1]Institut für Theoretische Physik, 93053 Regensburg, Germany — [2]Department of Physics, National Cheng Kung University, Tainan City 701, Taiwan

The remarkable sample quality of bilayer graphene in combination with the unprecedented electronic control of the band-structure makes bilayer-graphene an excellent platform for electron optics. While the purity of the system allows for ballistic transport on the micrometer scales [1,2], the trigonal warping of the band structure close to each K points induces a valley dependent selection of momenta leading to unique transport and scattering properties [3,4]. Interested in the interplay of symmetry breaking induced by a variety of all-electronic gate confinements and the trigonal warping, we implement various quantum mechanical tight binding models as well as semiclassical simulations and deploy them to investigate magneto transport through bilayer graphene cavities.

DS 10.4 Thu 12:15 H14

Electrical transport across thin catalyst/defect-engineered titania corrosion protection layer interfaces for photoelectrochemical applications — •Julius Kühne[1,2], Tim Rieth[1,2], and Ian D. Sharp[1,2] — [1]Walter Schottky Institute, Technichal University of Munich, Am Coulombwall 4, 85748 Garching, Germany — [2]Physics Department, TUM School of Natural Sciences, Technical University of Munich, Am Coulombwall 4, 85748 Garching, Germany

Producing value-added products via light-driven photoreduction represents a promising approach to sustainably address increasing CO2 emissions and meet the growing global energy demand. However, such solar fuels systems require passivating layers to chemically protect semiconductor light absorbers from harsh reaction environments. Despite great progress in the development of atomic layer deposited (ALD) protection layers, the factors governing efficient charge injection into the catalytic component remain not well understood. The nanoscale thickness of these ultrathin layers presents unique challenges, particularly for in-plane electrical measurements, complicating the reliable characterization of their transport properties compared to bulk materials. Here, the charge transport characteristics between various defect-engineered TiO2 protection layers grown with ALD and metal catalyst layers are investigated. By analyzing contact resistivity, carrier transport, and interface kinetics, this work seeks to deepen understanding of the interface between catalyst and protection layer.

DS 11: Thermoelectric and Phase Change Materials

Time: Thursday 15:00–16:00 Location: H3

DS 11.1 Thu 15:00 H3

Bond strength and force constants in RESbS — •Franziska Zahn[1], Christopher Benndorf[2], Hans H. Falk[1], Konrad Ritter[1], Sergiu Levcenko[1], Edmund Welter[3], Oliver Oeckler[2], and Claudia S. Schnohr[1] — [1]Felix Bloch Institute for Solid State Physics, Leipzig University, Germany — [2]Institute of Inorganic Chemistry and Crystallography, Leipzig University, Germany — [3]Deutsches Elektron Synchrotron DESY, Hamburg, Germany

Our recent study on bond strength in different materials has shown that elemental Sb exhibits characterics of regular covalent and multicenter bonding based on the behavior of force constants with increasing interatomic distance. *RE*SbS are Sb-containing rare-earth (*RE*) pnictide chalcigenides that show special electronic and magnetic properties. They consist of different layeres, including Sb monolayers that alternate with *RE*-S double layers. To study the structural and vibrational properties of *RE*SbS with *RE* = La, Ce, Pr, and Nd in more detail, extended X-ray absorption fine structure spectroscopy (EXAFS) was performed at the Sb K-edge at ten different temperatures ranging from 20 to 295 K. The temperature dependence of the bond length variation σ^2 (mean square relative displacement) was evaluated using a correlated Einstein model, providing static disorder and force constants. The behavior of the force constants with incrasing interatomic distance is compared to other materials and to elemental Sb in particular. This contributes to the fundamental understanding of physical properties of *RE*SbS and their potential origin.

DS 11.2 Thu 15:15 H3

Enhancing mechanical flexibility and thermoelectric efficiency of amorphous TiNiSn — •Denis Music — Department of Materials Science and Applied Mathematics, Malmö University, SE-205 06 Malmö, Sweden

Thermoelectrics can convert heat to electricity without greenhouse gas emissions and hold significant potential as energy sources for wearable devices. Current research focuses on designing compounds that combine high conversion efficiency with mechanical flexibility. Half-Heusler phases, such as TiNiSn, demonstrate promising chemical stability and thermoelectric efficiency, but their inherent brittleness limits their application in flexible devices. To address this shortcoming, amorphous TiNiSn thin films were synthesized by sputtering on various substrates, such as Kapton, silk, and paper, to evaluate their bending response. These thin films show good adhesion to the substrates, as predicted by density functional theory, and do not delaminate under mechanical loading. Bending tests up to 154 degrees reveal minimal crack formation, indicating a high degree of flexibility. Consequently, amorphous TiNiSn is a promising candidate for flexible thermoelectric devices. To further enhance the thermoelectric efficiency of these devices, density functional theory and Boltzmann transport theory were employed to tune the electronic structure and identify suitable doping elements among 3d and 4d transition metals. Experiments were carried out to validate these predictions, yielding an order of magnitude increase in performance at room temperature.

DS 11.3 Thu 15:30 H3

Atomic arrangement in MBE grown chalcogenide thin films: structural investigation based on LEED-IV — •Maximilian Buchta[1], Christoph Ringkamp[1], Lucas Bothe[1], and Matthias Wuttig[2] — [1]Peter Grünberg Institute - JARA-Institute Energy Efficient Information Technology (PGI-10), Jülich, Germany — [2]I. Institute of Physics (IA), RWTH Aachen University, Germany

If chalcogenides such as GeTe or Sb2Te3 are confined to reduced dimensions, for instance by reducing the film thickness, distortions in the atomic arrangement of the crystal emerge, which have been investigated by techniques such as X-ray diffraction (XRD). However, for the chalcogenides SnTe and SnSe, density functional theory (DFT) predicts pronounced distortions not only for thin films but also at the vicinity of the surface, which cannot be resolved by XRD. Further, as the distortions occur in both out-of-plane and in-plane directions, advanced structural characterization techniques are necessary to determine the atomic arrangement. In this work, Low Energy Electron Diffraction (LEED) Intensity vs. Electron Energy (LEED-IV) curves will be utilized to determine the surface atomic arrangement of tin-based chalcogenide thin films (SnTe and SnSe), grown by Molecular Beam Epitaxy (MBE), providing direct experimental evidence for structural predictions based on DFT.

DS 11.4 Thu 15:45 H3

Characterization of Nucleation and Growth Processes in the Phase Change Material GeTe upon Laser-Induced Switching — •Ramon Pfeiffer, Pascal Schröder, Elias Hildebrand, and Matthias Wuttig — I. Institute of Physics (IA), RWTH Aachen University, Germany

We have investigated how germanium telluride (GeTe) phase change material behaves during laser-induced switching at a wavelength of 658 nm. Starting with an amorphous GeTe matrix, which we have crystallized using laser pulses, GeTe has been reverted back to an amorphous state before recrystallizing it again. To analyze concomitant changes, we have examined individual crystal grains using electron backscatter diffraction (EBSD) and topographic changes by atomic force microscopy (AFM). Additionally, we have explored larger spot sizes during the second crystallization phase to assess the influence of a crystalline matrix on nucleation and growth dynamics within the material. These experiments revealed distinct nucleation and growth mechanisms that depend on the parameters used for crystallization.

DS 12: Gaede-Jubiläumssitzung

The Gaede Prize was founded 40 years ago by Dr Manfred Dunkel and is awarded annually for outstanding scientific work in basic research and application, for which the use of vacuum is relevant. To mark this anniversary, Selina Olthof (2019 prizewinner), Philip Willke (2022), Philip Hofmann (2011), and Andreas Waag (1998) from the illustrious list of prizewinners will give presentations in this session, covering a broad spectrum from the prize-relevant fields of thin films, surface science, semiconductor physics, and nanotechnology.

Time: Thursday 16:15–18:30 Location: H3

Invited Talk DS 12.1 Thu 16:15 H3

Probing the Electronic Structure of Halide Perovskites — •Selina Olthof — Department of Chemistry, University of Cologne — Chair of Material and Surface Analysis, University of Wuppertal

Halide perovskites are a novel class of thin film semiconductors that have revolutionized the field of photovoltaics, nowadays even surpassing in record efficiency the conventional silicon-based cells. Their remarkable defect tolerance, solution-based processability and tunable band gap make them highly promising for next-generation optoelectronic technologies.

This talk will provide a brief introduction to halide perovskites, highlighting the origins of their exceptional material properties. Next, I will introduce UV photoelectron spectroscopy (UPS) as well as reflection electron energy loss spectroscopy (REELS) as powerful tools to gain deeper insight into device relevant material properties. Specifically, I will discuss our investigations into the valence and conduction band density of states in tin and lead-based 3D perovskites. By combining photoelectron spectroscopy results with density functional theory, we identified the roles of atomic positions, bond hybridization, and lattice distortions in shaping the electronic properties.

Additionally, I will introduce our recent work on reduced-dimensionality perovskites (2D layers), which are gaining attention for their potential to optimize interfaces and enhance solar cell efficiencies. Here, I will present a systematic study using alkyl-based organic cations with varying chain length, which we used to track effects of interlayer spacing on the electronic and optical properties.

Invited Talk DS 12.2 Thu 16:45 H3

Quantum Science with Single Atoms and Molecules on Surfaces — •Philip Willke — Physikalisches Institut, Karlsruhe Institute of Technology, Karlsruhe, Germany

The quantum nature of a physical system often emerges from its fundamental building blocks and demands a deep understanding to leverage its benefits for future quantum devices. In this talk, I introduce the combination of electron spin resonance (ESR) and scanning tunneling microscopy (STM) as a new platform for coherent control of spins on surfaces (1). This technique enables for instance the addressing of individual atoms on surfaces with exceptional energy resolution. It allowed for high-resolution magnetic sensing, for instance by resolving their hyperfine interaction between the electron and nuclear spins. Recently, we have extended this technique to achieve spin resonance on individual molecules (2), which is particularly exciting as it extends ESR-STM into the realm of molecular quantum technologies: Promising new avenues involve organizing spins through molecular self-assembly into larger structures, alongside the application of on-surface chemistry techniques. As an example, we demonstrate how constructing new complexes through tip-assisted on-surface assembly can lead to spin systems with improved dynamic spin properties (3), that can be coherently controlled. session break

Invited Talk DS 12.3 Thu 17:30 H3

Gallium Nitride Technology - the second pillar of microelectronics — •Andreas Waag — Nitride Technology Center NTC, TU Braunschweig

The highly efficient radiative recombination makes GaN ideally suited for microLEDs with dimensions as small as 1 μm and even below. Besides display applications, their capability to produce optical patterns with high resolution, which can be modulated at extremely high frequencies, makes them suitable for numerous other applications.

Besides chip-based microscopy and highly efficient sensing, we explore these exciting properties for a new highly significant application: utilizing microLEDs in optical processing units for artificial intelligence workloads.

The talk will focus on technological challenges of chip processing and hybrid integration with silicon CMOS microelectronics. For all these applications, nitride technology and the exciting properties of GaN semiconductor devices are a key.

Invited Talk DS 12.4 Thu 18:00 H3

Ultrafast X-ray photoelectron spectroscopy and photoelectron diffraction — •Philip Hofmann — Department of Physics and Astronomy, Aarhus University, Denmark

X-ray photoelectron spectroscopy (XPS) is an experimental tool capable of accurately determining the core level binding energies of atoms. This energy is not only element-specific but also provides detailed information on the atoms' oxidation state and chemical environment, making XPS an essential tool for studying catalytic processes. XPS line shapes have also attracted considerable interest, leading to the development of many-body theories to study the solid's electronic and vibrational properties. Finally, the core level photoemission intensity can be interpreted as a diffraction pattern that gives access to the emitting atom's local geometrical environment in an experimental approach called X-ray photoelectron diffraction (XPD).

The increasing availability of ultrafast X-ray sources at free electron lasers now opens the opportunity to take XPS and XPD into the ultrafast time domain and this talks will give two recent examples. For graphene, it is shown that a study of the time-dependent XPS line shape can reveal detailed insight into the excitation of the system, directly giving access to parameters such as the electronic temperature. A demonstration of XPD is given in which the motion of surface atoms of the topological insulator Bi_2Se_3 is tracked after the excitation of a coherent optical phonon.

DS 13: Poster

Time: Thursday 18:00–20:00 Location: P1

DS 13.1 Thu 18:00 P1

Establishing Circular Dichroism Spectroscopy as predictor for CISS in molecular thin films — •Franziska Schölzel[1,3], Dominik Hornig[2,3], Lokesh Rasabathina[1], Olav Hellwig[1,3], Michael Mehring[2,3], and Georgeta Salvan[1,3] — [1]TU Chemnitz, Institute of Physics, 09126 Chemnitz, Germany — [2]TU Chemnitz, Institute for Chemistry, 09111 Chemnitz, Germany — [3]TU Chemnitz, Research Center for Materials, Architectures and Integration of Nanomembranes, 09126 Chemnitz, Germany

Circular Dichroism Spectroscopy which utilizes the differential absorption of left and right circularly polarized light to distinguish between the enantiomers of a chiral molecule. Previously it has been shown that the method is able to predict the strength of the chirality induced spin selectivity (CISS) effect [1]. Although many studies show that CISS relies on the interface between a chiral molecule and a magnetic substrate, CD spectroscopy is mainly used for the analysis of molecules in solution [1]. Therefore, it is crucial to develop a method for the interpretation of CD exhibited by molecular thin films.

In this study we present a homebuilt setup to implement the analysis of thin films systems into the Jasco J-1500 CD spectrophotometer. Furthermore, we propose a way to overcome artefacts that may be caused by optical anisotropy of the film and the substrate [2].

[1] Chem. Rev. 124, 4, 1950-1991 (2024) [2] J. Am. Chem. Soc. 143, 21519-21531 (2021)

DS 13.2 Thu 18:00 P1

Wannier description using CP2K — •Nisarg Trivedi, Maximilian F. X. Dorfner, and Frank Ortmann — School of Natural Sciences, Technische Universität München

Wannier functions provide an ideal basis for simulating quantum transport using Model Hamiltonians (i.e., tight binding models). Most Wannier generation tools use a plane-wave basis to expand the Wannier functions. However, using a gaussian basis to expand such functions can make simulations more efficient by using the sparsity of the matrices. Here, we present a procedure to obtain moderately localized Wannier functions on an atom-centered gaussian basis. Interfaced with the CP2K software, the method uses the Kohn-Sham Hamiltonian and Overlap matrices obtained from DFT simulation in the same atom-centered gaussian basis to obtain the Bloch states and then transform them into Wannier functions. We present the results of the application of this method on different polymers, which show excellent reproduction of band structure using a simple tight binding model based on the respective Wannier functions for all studied polymers.

DS 13.3 Thu 18:00 P1

Geometry and electronics of helical nanostructures — •Faezeh Shabani[1], Sibylle Gemming[1], Florian Günther[2], Jeffrey Kelling[1], Hadis Ghodrati Saeini[1], Christoph Tegenkamp[1], Thi Ngoc Ha Nguyen[1], and Georg Kuenze[3] — [1]Technische Universität Chemnitz, Chemnitz, Germany — [2]Instituto de Geociências e Ciências Exatas, Universidade Estadual Paulista, Rio Claro, Brazil — [3]Universität Leipzig, Leipzig, Germany

Helical nanostructures are intriguing systems where geometry and chirality drive unique electronic phenomena, including the chiral-induced spin selectivity (CISS) effect. This interplay enables efficient spin polarization in electron transport, offering exciting prospects for spintronic applications. In this study, the electronic band structure of helical nanostructures is explored, highlighting how their geometry influences transport as well as spin-dependent properties. These insights will inspire further investigations into biological helices, such as peptides and proteins, which share similar structural motifs and could broaden our understanding of spin polarization in natural systems. This work is part of TRR 386 HYPMOL, funded by DFG. (www.hypmol.net)

DS 13.4 Thu 18:00 P1

local charge transport properties of n-type organic semiconductor films based on T2-(NDI-T2)2 — •Zihao Liu[1], Hajar Komekoz[1], Nisarg Trivedi[2], Dietrich R. T. Zahn[1], Michael Sommer[1], Frank Ortmann[2], and Georgeta Salvan[1] — [1]Fakultät für Naturwissenschaften, Semiconductor Physics group, Technische Universität Chemnitz — [2]TUM School of Natural Sciences,Technische Universität München

Due to the advantages of organic semiconductor thin films, such as weak spin-orbit coupling and low spin scattering, organic materials have emerged as a strong alternative to traditional metallic spacer layers in the field of spin valve devices with vast potential for future spintronic applications. This study investigates conjugated organic semiconductor materials, specifically T2-(NDI-T2)2, and its related compounds with different side chain lengths focusing on their electrical properties on the micrometer and nanometer scales. High-quality organic semiconductor thin films were fabricated on gold substrates by spin coating. The dielectric function ϵ and the film thicknesses were determined by spectroscopic ellipsometry. Kelvin Probe Force Microscopy (KPFM) and conductive atomic force microscopy (c-AFM) were employed to analyze the local charge transport properties of the films systematically. The findings provide crucial insights into the influence of molecular orientation on conductivity and charge carrier mobility providing a solid foundation for further understanding and application of organic semiconductor materials

DS 13.5 Thu 18:00 P1

A graph-theoretical approach to spin-polarised quantum walks in chiral environment — •Saba Arshad[1], Sibylle Gemming[1], and Shahid Iqbal[2] — [1]TU Chemnitz, Chemnitz, Germany — [2]NUST, Islamabad, Pakistan

Exploring the model where a particle or system of particles moves between neighboring nodes couple with autonomous spins on the edges, leading to the propagation of entanglement. The work highlights how entanglement, along with spin oscillations and relaxation dynamics, offers significant advantages while transmitting directed quantum information through the quantum walks, providing faster quantum computations. This approach establishes a connection between spin dynamics and quantum computation, with potential applications in cryptography, quantum key distribution, super-dense coding, teleportation, and quantum computing, leveraging entangled states for secure and efficient information processing.

DS 13.6 Thu 18:00 P1

Self-Assembly Kinetics of Polyalanine α-helix Monolayers: Insights from Coarse-Grained Molecular Dynamics Simulations — •Hadis Ghodrati Saeini[1], Thi Ngoc Ha Nguyen[1], Faezeh Shabani[1], Olav Hellwig[1,2], Christoph Tegenkamp[1], Sibylle Gemming[1], Florian Günther[3], and Jeffrey Kelling[1,4] — [1]Institute of Physics, Technische Universität Chemnitz, Chemnitz, Germany — [2]Institute for Ion Beam Physics, Helmholtz-Zentrum Dresden - Rossendorf, Dresden, Germany — [3]Instituto de Física de São Carlos, Universidade de São Paulo (USP), São Carlos, Brazil — [4]Institute for Radiation Physics, Helmholtz-Zentrum Dresden - Rossendorf, Dresden, Germany

Helical molecules, such as polyalanine α-helices, are promising candidates for spintronic applications due to their strong spin-filtering ability via the Chiral-Induced Spin Selectivity (CISS) effect. Understanding their intermolecular interactions and collective behavior is essential for harnessing their properties in practical applications. This study employs molecular dynamics simulations with coarse-grained molecular potentials to explore the kinetics of monolayer self-assembly by deposition from solution onto a smooth van der Waals substrate.

Simulations conducted at room temperature reveal key aspects of molecular relaxation, structural organization, and dynamical time-scales. These insights enhance our understanding of the self-assembly mechanisms and stability of polyalanine monolayers, supporting their development for advanced spintronic technologies.

DS 13.7 Thu 18:00 P1

Simulation of self-assembled polyalanine α-helices films: Development and application of an empirical potential — Kevin Preis[1], Hadis Ghodrati Saeini[1], Christoph Tegenkamp[1], Sibylle Gemming[1], Jeffrey Kelling[2], and •Florian Günther[3] — [1]Technische Universität Chemnitz, Chemnitz, Germany — [2]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [3]São Paulo State University, Rio Claro, Brazil

Polypeptide molecules have been discussed as potential candidates for electronic spin-filters because of the so-called chiral-induced spin selectivity. For this reason, tremendous effort is invested to characterize the structural and electrical properties of self-assembled monolayers (SAMs) of peptide helices, e.g. polyalanine (PA) α-helices. In our work, we aim at characterizing the intermolecular interactions that govern the formation of PA-SAM films. For this, we elaborated an empirical potential that models the interaction of two isolated helices using the density functional based tight-binding method. With these potentials, energetically most favored arrangements in SAM films were simulated via a Monte-Carlo approach using the simulated annealing and the Metropolis algorithm. Statistically analyzing the relative positioning of adjacent molecules, we are able to classify the degree of frustration in SAM films. For enantiopure systems, we found that a frustration-free arrangement is possible yielding a perfect hexagonal lattice. For mixtures of different chiralities, parallel aligned domains of differently handed helices were obtained. Both of these observations are in great agreement to experimental works.

DS 13.8 Thu 18:00 P1

Thin films of atomically precise chiral bismuth oxido nanoclusters — •Dominik Hornig[1], Rico Thomas[1], Annika Morgenstern[2], Franziska Schölzel[2], Thi Ngoc Ha Nguyen[2], Christoph Tegenkamp[2], Georgeta Salvan[2], and Michael Mehring[1] — [1]TU Chemnitz, Institute of Chemistry, Germany — [2]TU Chemnitz, Institute of Physics, Germany

The adsorption of chiral molecules on metallic surfaces induces electron spin polarization at the interface, enabling novel applications in chiral opto-spintronics. This effect, known as chiral-induced spin selectivity (CISS), strongly depends on the binding and ordering of the species on surfaces.[1] In our studies, we investigate the adsorption behavior of chiral bismuth oxido nanoclusters (BiO-NCs) on gold (Au) surfaces. The chiral BiO-NCs represent monodisperse nanoclusters which can be modulated by an exchangeable ligand shell. This has been demonstrated for the stable $[Bi_{38}O_{45}]$ cluster architecture and enables targeted modification of the BiO-NC with regard to optical properties.[2,3] By functionalizing BiO-NCs with amino acids such as Boc-L-methionine and Boc-L-phenylalanine, the chiral nanoclusters $[Bi_{38}O_{45}(Boc\text{-}L\text{-}Met\text{-}O)_{24}]$ or $[Bi_{38}O_{45}(Boc\text{-}L\text{-}Phe\text{-}O)_{24}]$ were synthesized. Furthermore, tuning of physical properties is possible by doping these atomically precise nanoclusters with other metals. Here we present the preparation of thin films of atomically precise chiral BiO-NCs and results of ellipsometry, UV-Vis, STM and STS measurements. [1] Nat. Rev. Chem. 2019, 3, 250-260. [2] Langmuir 2024, 40, 16320-16329.[3] Nanomaterials 2022, 12, 1815.

DS 13.9 Thu 18:00 P1

Twist angle dependent proximity induced spin-orbit-coupling in graphene/NbSe2 heterostructures — •Thomas Naimer[1], Martin Gmitra[2], and Jaroslav Fabian[1] — [1]Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany — [2]Pavol Jozef Safarik University in Kosice, 04001 Kosice, Slovakia

We investigate the effect of the twist angle on the proximity spin-orbit coupling (SOC) in graphene/niobium diselenide (Gr/NbSe2) heterostructures from first principles. The low energy Dirac cones of several different commensurate twisted supercells are fitted to a model Hamiltonian, allowing us to analyze the twist-angle dependency of the SOC in detail. This reveals the possibility to triple the Rashba SOC, when going from 0° to 30° twist angle. Furthermore, at a critical twist angle of 23° the in-plane spin structure acquires a significant radial component, enabling collinear charge-to-spin conversion. Analyzing the Dirac cone with respect to allowed Umklapp processes and orbital decomposition shines light on the observed twist angle dependencies. In addition we evaluate the potential for (collinear and perpendicular) charge-to-spin conversion in such heterostructures within linear response theory. All authors acknowledge support by the FLAG ERA JTC 2021 project 2DSOTECH. T. N. and J. F. were also supported by the European Union Horizon 2020 Research and Innovation Program 881603 (Graphene Flagship). M.G. acknowledges additional financial support provided by the Slovak Research and Development Agency provided under Contract No. APVV-SK-CZ-RD-21-0114 and Slovak Academy of Sciences project IMPULZ IM-2021-42.

DS 13.10 Thu 18:00 P1

Wet-Chemical Transfer and Post Characterization of Hexagonal Boron Nitride Grown on Ge(001)/Si Substrates — •Monika Choudhary[1], Max Franck[1], Daniele Capista[1], Rasuole Lukose[1], Christian Wenger[1,2], and Mindaugas Lukosius[1] — [1]IHP-Leibniz-Institut für Innovative Mikroelektronik, Frankfurt Oder, Germany — [2]Semiconductor Materials, BTU Cottbus-Senftenberg, Cottbus, Germany

This study presents a poly (methyl methacrylate) (PMMA) assisted transfer process for hexagonal boron nitride (hBN) epitaxially grown on Ge(001)/Si substrates via chemical vapor deposition using borazine at 900-980°C. The transfer involves sequential etching of Si at 95°C in KOH solution [1] and of Ge in NH4OH, H2O2, and H2O solution (1/1/5) at 75°C [2]. The PMMA/hBN is then transferred onto SiO2/Si and TiN/Si substrates, confirmed by optical microscopy, Raman and X-ray photoelectron spectroscopy analyses. Furthermore, metal-insulator-metal devices are fabricated by gold deposition on hBN/TiN, yielding a resistivity of 5.1e-10 ohm*cm and a dielectric constant of 2.4, as determined by current-voltage and capacitance-voltage measurements. Additionally, hBN/graphene/hBN heterostructures are fabricated and characterized using optical microscopy and Raman analyses. Hall bar devices are then created by defining structures on the hBN/graphene/hBN stack using photolithography and reactive ion etching.

DS 13.11 Thu 18:00 P1

Tuning the electronic structure of MoSe2 through molecular adsorbates — •Carolin Sabrina Schüle, Joschua Büble, and Heiko Peisert — Institut für Physikalische und Theoretische Chemie Universität Tübingen, Deutschland

Layered transition metal dichalcogenides have emerged as a promising alternative to conventional semiconductor materials. The electronic properties of TMDCs can be tuned by the adsorption of molecules, including weakly interacting, physisorbed carbon molecules. As example, a quenching of the low-temperature defect photoluminescence of MoS2 was observed after adsorption of metal-phthalocyanines, depending strongly on the central metal atom of the phthalocyanine.1 We studied interface properties of phthalocyanines (CoPc and CoPcF16) on MoSe2 and p-doped MoSe2 as example for comparably weakly interacting molecules, and compare them to HATCN - a strong electron acceptor. For the cobalt phthalocyanines, the exchange of the metal centre has only a small effect on the position of the highest occupied molecular orbital (HOMO), whereas fluorination of the molecular backbone lowers the HOMO considerably. The formation of dipols, interface states, as well as a band bending in the MoSe2 bulk substrates was observed, depending on the molecule under consideration. (1) DOI: 10.1021/jacs.1c07795.

DS 13.12 Thu 18:00 P1

Synthesis of MoS_2 films for electronic and optoelectronic device applications — •Axel Printschler, Md Tarik Hossain, Julian Picker, Christof Neumann, and Andrey Turchanin — Friedrich-Schiller-Universität Jena, Institute of Physical Chemistry, Jena, Deutschland

Transition metal dichalcogenides (TMDs) are a class of 2D materials that have exceptional promise for a wide range of electronic and optoelectronic applications. In particular, TMD-based field-effect transistors (FETs) are continually in the focus of research because of their potential to overcome the limitations of traditional silicon-based devices. To efficiently fabricate FETs based on TMD monolayers, it is crucial to synthesize continues mono- or few layers of these materials on wafer scale and/or enable their growth at a predefined position on the wafer. In this study, we compare different methods for bottom-up synthesis of MoS_2 monolayers and thin films and characterize their properties for device applications. To this end, we employ CVD growth from solid and liquid state precursors as well as MOCVD growth using gaseous precursors. The synthesized films are characterized using complementary spectroscopy and microscopy techniques including optical and atomic force microscopy (AFM), X-ray photoelectron, Raman and photoluminescence (PL) spectroscopy, which is further complemented by electrical and optoelectrical measurements of the microfabricated FET devices.

DS 13.13 Thu 18:00 P1

Conventional and nanoscale NMR investigation of NbSe2 for various temperatures, magnetic field strengths and orientations — •Mokessh Kannah Ciwan[1], Marcel Martin[1], Jakob Nachtigal[1], Yejin Lee[4], Nicola Poccia[2,3], Uri Vool[4], Jürgen Haase[1], and Nabeel Aslam[1] — [1]Leipzig University, Leipzig, Germany — [2]Leibniz Institute for Solid State and Materials Research, Dresden, Germany — [3]Department of Physics, University of Naples Federico II, Naples, Italy — [4]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany

Niobium diselenide (NbSe2) is a transition metal dichalcogenide (TMD) that has attracted particular interest for decades due to the coexistence/competition of charge density waves (CDW) and the superconducting state in the bulk crystal. To this end, nuclear magnetic resonance (NMR) can be used to measure relaxation times and shifts in the resonance frequency, which reveal how the charge carriers in these phases interact with the nuclei of the host material.

Using conventional NMR, we investigate the electronic behaviour of bulk NbSe2 over a wide range of magnetic field amplitudes and orientations as well as temperatures down to the CDW phase. Additionally, we are working towards nanoscale NMR using nitrogen vacancy (NV) centers in diamond as quantum sensors. This method allows NMR measurements on um-scale exfoliated flake down to the monolayer. In this direction we have already achieved first promising results. Findings from both bulk and flake measurements will be presented.

DS 13.14 Thu 18:00 P1

A Hybrid Organic-hBN Platform for Quantum Sensing — •Xuan-Kai Zhou, Yan-Tung Kong, Ruo-Ming Peng, and Jörg Wrachtrup — Universität Stuttgart, 3. Physikalisches Institut, Allmandring 13, Stuttgart, Deutschland

Optically activated molecular spin qubits are promising candidates for quantum sensing applications due to their customizable molecular design, enabling biocompatibility and close proximity to target environments. However, organic molecules under ambient conditions often suffer from weak emission signals, instability, and degradation caused by solvent evaporation, air exposure, and low resistance to photobleaching during measurements. In this work, we address these challenges by encapsulating organic molecules within two-dimensional hexagonal boron nitride (2D-hBN) rather than diluting them in conventional host organic polymers such as p-terphenyl. This hybrid organic-2D material heterostructure stabilizes the fluorescence of organic molecules, potentially enhancing the performance of optically detected magnetic resonance (ODMR) measurements. Furthermore, this innovative encapsulation method integrates physical chemistry into 2D materials approaching the monolayer limit, significantly advancing sensing capabilities, including surface-sensitive techniques and biocompatible detection strategies.

DS 13.15 Thu 18:00 P1

Towards infrared photodetection with an ultra-low carrier density moiré superconductor — Giorgio Di Battista[1], •Leon G. Schubert[1], Kin Chung Fong[2,3], Andrés Díez-Carlón[1], Kenji Watanabe[4], Takashi Taniguchi[5], and Dmitri K. Efetov[1,6] — [1]Fakultät für Physik, LMU — [2]Department of Physics, Harvard University — [3]Quantum Engineering and Computing Group,

Raytheon BBN Technologies — [4]Research Center for Functional Materials, NIMS, Tsukuba — [5]International Center for Materials Nanoarchitectonics, NIMS, Tsukuba — [6]Munich Center for Quantum Science and Technology (MCQST)

Single-photon detectors (SPDs) offer remarkable capabilities for highly-sensitive detection of electromagnetic radiation. To achieve high performance, state-of-the-art SPDs rely on the photon-induced breaking of Cooper pairs in superconductors (SCs). However, extending SPD capabilities to lower photon energies requires novel SC materials with significantly lower charge carrier densities which offer a larger relative perturbation of the SC state. The moiré superconductor magic-angle twisted bilayer graphene (MATBG) holds great promise with its unprecedentedly low carrier density of $\sim 10^{11}\mathrm{cm}^{-2}$ which is ~ 5 orders of magnitude lower than conventional SCs. We demonstrate a proof-of-principle experiment to detect single near-infrared photons by voltage biasing a MATBG device near its SC phase transition. Our work offers insights on the MATBG-photon interaction and opens new opportunities for developing novel quantum sensors with the potential for single photon detection in the terahertz spectrum.

DS 13.16 Thu 18:00 P1

Qauntum anomalous Hall effect in Cr-doped BST — •Edoardo Tosi[1,2], Gertjan Lippertz[1], Anjana Uday[1], Bibek Bhujel[1], Alexey Taskin[1], Marco Moretti[2], and Yoichi Ando[1] — [1]University of Cologne — [2]Polytechnic University of Milan

The quantum anomalous Hall (QAH) effect in a magnetic topological insulator (TI) represents a new state of matter originating from the interplay between topology and magnetism. The defining characteristics of the QAH ground state are the quantized Hall resistivity and vanishing longitudinal resistivity in the absence of an external magnetic field. Manipulating the QAH state is of great importance in both the understanding of topological quantum physics and the implementation of dissipationless electronics.

To observe the QAH effect, fabrications of thin-film devices are required which allows for tuning the Fermi level across the Dirac point. It is necessary to improve growth conditions for the ternary compound (Bi1-xSbx)2Te3 such that the composition between n-type Bi2Te3 and p-type Sb2Te3 can be almost perfectly compensated. Decreasing the thickness of the MBE grown films, reduces the bulk-to-surface ratio and leads to TI samples where the surface transport is dominating. Doping ultrathin films with Cr allows to obtain the ferromagnetic state, which opens a gap in the surface states, leading to the QAH effect at low temperatures.

In this contribution we report our efforts to realize the QAH effect in the magnetic topological insulator Cr-doped (Bi,Sb)2Te3 (CBST) grown by molecular beam epitaxy (MBE) on an InP substrate.

DS 13.17 Thu 18:00 P1

VO2 oscillator with advanced neuron-like feature originating from blinking filament — •Zhong Wang, Kajal Tiwari, Yishen Xie, Jae-Chun Jeon, Ke Xiao, and Stuart Parkin — Max Planck Institute of Microstructure Physics, Weinberg 2, 06120 Halle(Saale), Germany

The insulator-metal-transition of VO2 gives rise to the electric oscillation that has extensive applications in neuromorphic computing[1]. Although the oscillation feature is typically stable and deterministic, advanced neuromorphic applications require more complex and adaptive device properties[2]. Here we discover the neuron-like bursting with the non-deterministic separation time in the VO2 thin film-based device, which is only detectable in a narrow temperature range below transition. This feature of VO2 indicates the dynamical process beyond ordinary insulator-metal-transition and capacitive charging. By scanning near-field optical microscopy and modelling, we identify the flipping filament formation in multiple positions as the physical origin of the complex feature observed. Our work unveils the mechanism underlying VO2 oscillator that could assist future device design for neuromorphic computing.

DS 13.18 Thu 18:00 P1

Advanced modeling of X-ray reflectivity for metallic multilayer systems with GenX 3 — •Rico Ehrler[1,2] and Olav Hellwig[1,2,3] — [1]Chemnitz University of Technology, D-09107 Chemnitz, Germany — [2]Research Center MAIN, D-09126 Chemnitz, Germany — [3]Helmholtz-Zentrum Dresden-Rossendorf, D-01328 Dresden, Germany

X-ray reflectivity (XRR) is a versatile, nondestructive technique for probing thin film systems at grazing incidence, offering insights into layer thickness, roughness, and density. However, due to the inherent phase problem in X-ray techniques, extracting these parameters from the XRR data requires careful sample modeling. Especially for metallic multilayers with a complex microstructure, creating a well parametrized model may be challenging. We explore different modeling approaches using the open-source software "GenX 3"[1] on the example of sputter deposited, magnetic Co/Pt multilayer systems. A simplified model without the complex multilayer structure is found to fit the data surprisingly well, when limiting the XRR to a reasonable range. We then add the actual multilayer, modeled with a damped, periodic function following a graded-interface approach to account for the complex microstructure.[2] Finally, real space transmission electron microscopy (TEM) images are used to motivate and validate the models.

DS 13.19 Thu 18:00 P1

In-Situ XAS study of ZnO and Mn-ZnO thin films — •Sulaiman Al Salem[1,2], Sreeju Sreekantan Nair Lalithambika1[2], Shagun Thakur[3], Simone Techert[1,2,3], and Christian Jooss[3] — [1]Institute of X-ray Physics, University of Göttingen, 37077 Germany — [2]Structural Dynamics in Chemical Systems, Deutsches Elektronen-Synchrotron, DESY, Notkestrasse 85, D-22607, Hamburg, Germany — [3]Institute of Materials Physics, University of Göttingen, 37077 Germany

High-performance catalysts with low overpotential for oxygen evolution reaction (OER) are critical for green energy transition. Transition metal-doped ZnO thin films make it a promising catalyst for efficient OER. Understanding the electronic properties of such materials in a catalytically relevant environment is crucial for tailoring and tuning these materials for OER applications. X-ray Absorption Spectroscopy (XAS) is a powerful spectroscopic technique that is element-selective and environment-sensitive. We present an investigation into the electronic structure of Zinc Oxide (ZnO) and Mn-doped thin films using XAS at the Oxygen K-edge as well as the Zn and Mn L-edges. The XAS spectra, which serve as the basis for further investigation upon Mn-doping, show the characteristic peaks of the elements present in the films. Besides, soft x-ray XAS spectra at in-situ ZnO and Mn-doped ZnO - water interface conditions were measured further to study the electronic structure at catalytically relevant conditions.

DS 13.20 Thu 18:00 P1

Martensitic Transformation in Ultrathin Layered Stacks of $Fe_{85}Ni_{15}$ and $Fe_{71}Ni_{29}$ — •Nancy Töws, Pascal Strathkötter, Roland Schubert, Inga Ennen, Judith Bünte, Laila Bondzio, Dario Stierl, and Andreas Hütten — Universität Bielefeld, Dünne Schichten und Physik der Nanostrukturen, Universitätsstr. 25, 33615 Bielefeld, Germany

Magnetic shape memory alloys, such as various Heusler alloys, have been extensively studied over the past decade for their potential in magnetocaloric applications. In the realm of thin-film technology, stacking different Heusler alloys in layered systems offers a microstructural design framework initiated through the interaction of strain fields during the martensitic transformation of the stack*s individual components*.

Here, we present results on the stacking of two well-known FeNi alloys, $Fe_{85}Ni_{15}$ and $Fe_{71}Ni_{29}$, and the resulting physical properties. We report on investigations conducted using structural, magnetic, and thermal methods, alongside findings on the progression of martensitic and austenitic transformations within these distinct layered systems.

DS 13.21 Thu 18:00 P1

Structural and electronical investigation of the Electrode/MoS2 interface by electron microscopy and photoemission — •Eric Juriatti, Christoph Späth, Heiko Peisert, and Marcus Scheele — Universität Tübingen, Institut für Physikalische und Theoretische Chemie, Tübingen, Germany

In search for new semiconducting devices the group of transition-metal dichalcogenides (TMDCs) like molybdenum disulfide (MoS2) is of increasing scientific interest. The exceptionally unique electronic properties, including the tunability of the band gap by exfoliation, of these layered semiconductors allow further miniaturization of devices like photodetectors, which are promising candidates to fulfill Moore*s law in future applications.

The successful manufacturing of astonishingly fast and responsive TMDC photodetectors contacted by gold electrodes was recently demonstrated. However, the influence of the electrodes on the TMDC/metal interface properties, which would supposedly also affect charge carrier transport in devices, has not been studied in detail so far.

In this study, different metals which are typical electrode materials were deposited as thin films on clean MoS2 bulk crystals to mimic the resulting TMDC/Metal interface. The resulting heterostructure was investigated by X-ray and ultraviolet photoelectron spectroscopy (XPS, UPS). In addition, scanning electron microscopy (SEM) was performed to study the growth of the metals on the TMDC surface.

DS 13.22 Thu 18:00 P1

Transition metal oxide doped ZnO films for electro-synthesis — •Shagun Thakur, Pia Henning, and Jasnamol Palakkal — Institute of Materials Physics, Georg-August-University of Göttingen, Germany

Understanding the crystal structure and morphology is crucial for investigating the electrocatalytic activity of inorganic materials. Zinc oxide doped with transition metal oxides are interesting candidates for electro-conversions owing to their unique reactivity. The ZnO crystal exhibits different polarity and surface stability in different crystallographic directions [1][2]. With this aim of producing well-defined ZnO films, we utilized the advancements of thin film technology.

Sputtering is used for growing epitaxial undoped and Mn-doped ZnO thin films with temperature and oxygen control. We will also use pulsed laser deposition which is modified by attaching molecular beam sources to prepare such surfaces with precise fine-doped elements and stoichiometry control. These films will be later compared.

This work presents our ongoing studies on transition metal-doped ZnO thin films, focusing on magnetic dopants and their impact on catalytic activity via sputtering and hybrid PLD systems.

DS 13.23 Thu 18:00 P1

Tuning high-T_C ferromagnetism and perpendicular magnetic anisotropy in van der Waals magnet $Cr_{1+\delta}Te_2$ — •Laura Pflügl, Pia Henning, Anna Tschesche, and Jasnamol Palakkal — Institute of Materials Physics, Georg-August-University of Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

In recent years, chromium tellurides ($Cr_{1+\delta}Te_2$) have gained significant interest due to their promising characteristics, such as ferromagnetic ground states with tunable transition temperatures and perpendicular magnetic anisotropy (PMA) which open up various possible applications in spintronics [1]. However, the fabrication of high-quality stochiometric and epitaxial $Cr_{1+\delta}Te_2$ thin films is difficult and calls for advanced synthesis techniques. Using a hybrid setup combining pulsed laser deposition for Cr and a molecular beam source for Te, we deposited $Cr_{1+\delta}Te_2$ thin films with precise stoichiometry control [2]. Changes of the magnetism were previously reported in $Cr_{1+\delta}Te_2$ due to extreme air-sensitivity and nonself-limited oxidation [3]. Since our films are epitaxially stabilized on a substrate, they are free from defect introduction and offer air stability by forming a passive surface oxide layer. We will address the ongoing challenges during the growth of this material and put forward effective tuning by varying deposition control parameters.

DS 13.24 Thu 18:00 P1

Investigating interfacial mechanisms and switching behavior in GST-124/Sb_2Te_3 superlattices using Atom Probe Tomography — •Athanasia Piperidou[1], Jan Köttgen[1], Lucas Bothe[2], Lukas Conrads[1], Yuan Yu[1], and Matthias Wuttig[1,2] — [1]I. Institute of Physics (IA), RWTH Aachen University, Germany — [2]Peter Grünberg Institute - JARA-Institute Energy Efficient Information Technology (PGI-10), Jülich, Germany

Chalcogenide-based phase-change materials like $GeSb_2Te_4$ (GST) are crucial for non-volatile storage technologies due to their rapid and reliable switching. Reducing the energy required for transitions between amorphous and crystalline states can improve device performance significantly, as demonstrated in phase-change memories using superlattices (SLs). Here we investigate the switching behavior of MBE-grown 60nm GST-124/Sb_2Te_3 SLs. Using a pulsed laser, we induce amorphization and recrystallization processes. Atom Probe Tomography (APT) is used to compare the structural and chemical characteristics of interfaces in recrystallized and as-deposited regions. APT's three-dimensional, near-atomic resolution reveals changes in morphology and element distribution, shedding light on the mechanisms driving switching. Our results show that the SL structure enhances switching efficiency through unique interfacial mechanisms, offering insights for the design of next-generation memory devices.

DS 13.25 Thu 18:00 P1

Deposition of Medium-Entropy Telluride Thin Films via Hybrid Pulsed Laser Deposition — •Niklas Kohlrautz, Pia Henning, and Jasnamol Palakkal — Institute of Materials Physics, Georg-August-University of Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

High- and medium-entropy materials (HEMs and MEMs) are known for their great multifunctional properties, such as ordered magnetism and promising catalytic behavior [1]. Moreover, tellurides are recognized for their novel magnetic properties, including room-temperature ferromagnetism and large magnetic anisotropy, as well as catalytic potential [2][3]. Designing novel high-entropy tellurides opens new possibilities for discovering multifunctional materials. Toward the goal of synthesis of novel HEMs, we fabricated MEM tellurides (FeCrNiTe) via hybrid pulsed laser deposition (PLD). In this presentation, we will address the challenges in growing $(FeCrNi)_xTe$ and the detailed structural and physical characterization. FeCrNiTe films were synthesized on $SrTiO_3(001)$ substrates providing FeCrNi via the standard PLD process and Te through a molecular beam source, allowing easy Te stoichiometry control. Systematic studies of growth parameters yielded high-quality epitaxial thin films with elemental surface homogeneity. We are investigating the magnetic, electric and electrocatalytic properties of the films, comparing the results with the crystal structure.

DS 13.26 Thu 18:00 P1

Thin Film Effects in Ultra-thin, MBE-grown In_2Te_3-Films — •Lucas Bothe[1], Maximilian Buchta[1], Felix Hoff[2], Timo Veslin[2], Christoph Ringkamp[2], Ka Lai Mak[1], and Matthias Wuttig[1,2] — [1]Peter Grünberg Institute - JARA-Institute Energy Efficient Information Technology (PGI-10), Jülich, Germany — [2]I. Institute of Physics (IA), RWTH Aachen University, Germany

InSbTe (IST) as an unconventional Phase Change Material is of significant interest in recent years. However, the related binary compound In_2Te_3 is less studied. With its small direct band gap and high absorption coefficient, it is an interesting candidate for e.g. photodetectors.

Here, a thin film series of In_2Te_3 was fabricated employing Molecular Beam Epitaxy (MBE) to achieve highly textured thin films. These films are characterized via XRD, RHEED and Raman spectroscopy. Next to the structural bulk values measured for the thickest In_2Te_3 sample, a decrease in the out-of-plane lattice constant by up to 0.4 A with decreasing film thickness is reported. The in-plane lattice constants however increase for thinner films. This trend with reduced film thickness contrasts known thin-film effects in metavalently bonded materials like Sb_2Te_3 or Bi, as In_2Te_3 is not expected to exhibit metavalency. Furthermore, the structural changes in the thin films are unlikely to arise from strain, given the Te-terminated Si surface promotes van der Waals growth, preventing alignment of the Si and In_2Te_3 in-plane lattice constants.

In addition, thickness-dependent vibrational properties were determined by Raman spectroscopy.

DS 13.27 Thu 18:00 P1

The interface wz-GaN/rs-ScN studied by depth profiling photoelectron spectroscopy — Fabian Ullmann[1,2] and •Stefan Krischok[1,2] — [1]TU Ilmenau, Ehrenbergstraße 29, 98693 Ilmenau — [2]Zentrum für Mikro- und Nanotechnologien, Gustav-Kirchoff-Straße 7, 98693 Ilmenau

Theoretical predictions show extreme high polarization gradients and polarization-induced surface charge densities at interfaces of rock salt ScN and wurtzite GaN.

Experimental investigation were made by depth profiling X-ray photoelectron spectroscopy (XPS) along the interface of rs-ScN and wz-GaN grown by molecular beam epitaxy (MBE).

DS 13.28 Thu 18:00 P1

Deposition of Cr self-intercalated $Cr_{1+\delta}Te_2$ thin films by Hybrid Pulsed Laser Deposition — •Pia Henning, Laura Pflügl, Anna Tschesche, Tobias Meyer, and Jasnamol Palakkal — Institute of Material Physics, Georg-August-Universität Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

$Cr_{1+\delta}Te_2$ thin films exhibited an increased interest over the last few years, due to their tunable magnetic anisotropy and ferromagnetism with T_C ranging from 150 K to 350 K [1]. This tunability of magnetic properties is sensitively linked to the stoichiometry, governed by the self-intercalation of Cr species between $CrTe_2$ layers [1]. Therefore, the sensitive control of δ in addition with the insurance of high crystalline quality, with epitaxial and low defect growth, is crucial for a profound discussion and comparison of thin film properties. In this work, we used a hybrid pulsed laser deposition (PLD) unit attached with Te molecular beam source for growing high quality $Cr_{1+\delta}Te_2$ thin films [1]. We studied the influences of different growth parameter settings on the thin film quality and properties. We were able to carefully modify the δ and thickness of the films and investigated their correlation with the magnetic and electronic properties. This material system is a promising candidate for spintronics application due to room temperature ferromagnetism, anisotropic magnetoresistance and huge perpendicular magnetic anisotropy. Our findings manifest the advantages of this technique for depositing further novel transition metal chalcogenides. [1] A. Tschesche, P. Henning, et al., Preprint on Research Square, https://doi.org/10.21203/rs.3.rs-4861088/v1

DS 13.29 Thu 18:00 P1

Investigating Lateral Molecular Heterogeneity with Phase-Resolved Vibrational SFG Microscopy — •Ben John, Alexander P. Fellows, Tuhin Khan, Martin Wolf, and Martin Thämer — Fritz Haber Institute of the Max Planck Society, Berlin, Germany

Understanding molecular heterogeneity at interfaces is crucial for applications in fields such as biophysics and materials science. Systems like lipid rafts in biological membranes or functionalized surfaces in microfluidics require techniques capable of resolving molecular structures, orientations, and compositions with high sensitivity and spatial resolution. Phase-resolved vibrational sum-frequency generation (vSFG) microscopy has emerged as a powerful tool to meet these needs, offering vibrational specificity, orientational sensitivity via second-order selection rules, and sub-micron spatial resolution through frequency up-conversion. Despite its potential, traditional vSFG microscopy has faced significant technical challenges in detecting weak signals from monolayers and spatially mapping them. We address these limitations with an advanced phase-resolved vSFG microscope, which achieves improved signal-to-noise ratios and spatial resolution. Using this system, we successfully image phase-separated monolayers of mixed chiral lipids, revealing spatial heterogeneity in molecular orientations and packing structures. This breakthrough positions phase-resolved vSFG microscopy as a transformative approach for characterizing interfacial molecular systems, enabling deeper insights into the complex behaviors of molecular assemblies in both natural and engineered environments.

DS 13.30 Thu 18:00 P1

Structural and optical properties of β-Ga_2O_3 thin films obtained by spray pyrolysis — •Polina Shamrovska[1,2], Oleksandr Selyshchev[1], Narmina Balayeva[1], Volodymyr Kudin[2], and Dietrich Zahn[1] — [1]Technische Universität Chemnitz, Chemnitz, Germany — [2]Taras Shevchenko National University of Kyiv, Kyiv, Ukraine

β-Ga_2O_3 thin films have gained significant research interest due to their wide bandgap, high thermal stability and breakdown voltage, making them suitable *e.g.* for UV photodetectors. Here, β-Ga_2O_3 thin films were deposited on c-plane sapphire substrates via spray pyrolysis, a cost-effective technique suitable for large-scale production. For deposition, we used $Ga(NO_3)_3$ dissolved in a 1 : 1 water-ethanol mixture or water with 1% polyethyleneimine, followed by annealing at 800 °C or 1000 °C. The films were characterized by SEM, AFM, Raman, XRD, spectroscopic ellipsometry, UV-vis spectroscopy, and electrical resistance measurements by the four-point probe.

The stoichiometric β-phase Ga_2O_3 films revealed a preferred $(\bar{2}01)$ orientation in agreement with previous results [1]. The samples showed transparency of up to 99% in the visible range and a sharp absorption edge in the UV range with bandgaps of 4.9 to 5.3 eV. The resistivity of the films was in the GΩ range. The results obtained reveal that spray pyrolysis allows the fabrication of highly crystalline, transparent, and high-resistive β-Ga_2O_3 films suitable for further studies as UV photodetectors.

DS 13.31 Thu 18:00 P1

"Green" Aqueous Synthesis and Characterization of Cu_2NiSnS_4 and Cu_2ZnSnS_4 Nanocrystal Thin Films — •Oleksandra Ivakhno-Tsehelnyk[1], Oleksandr Selyshchev[1], Serhiy Kondratenko[2], Volodymyr Dzhagan[3], Lukas Hertling[1], and Dietrich R.T. Zahn[1] — [1]Semiconductor Physics & Research Center for Materials, Architectures and Integration of Nanomembranes, Chemnitz University of Technology, 09107 Chemnitz, Germany. — [2]Taras Shevchenko National University of Kyiv, 01601 Kyiv, Ukraine. — [3]Lashkaryov Institute of Semiconductor Physics, NAS of Ukraine, 03038 Kyiv, Ukraine.

We investigated thin films of Cu_2NiSnS_4 (CNTS) and Cu_2ZnSnS_4 (CZTS) nanocrystals (NCs) obtained by "green" colloidal synthesis [1,2]. This synthesis approach provides a way to non-toxic and scalable production for sustainable and low-cost light-absorbing nanomaterials. To assess the potential of thin films of these NCs for photovoltaic and other possible applications, electrical studies are necessary. Colloidal NCs were deposited on glass substrates by spin coating and annealed at temperatures starting from 180 °C to obtain conductive thin films. Analytical techniques such as Raman spectroscopy, AFM, XRD, spectroscopic ellipsometry, and 4-point probe measurements were used to characterize their structural, optical, and electrical properties. We discuss the optical and electrical differences related to Zn-to-Ni substitution in the NC structure and establish the correlation between electrical properties of the films and elemental composition in both colloidal NCs and annealed films.

DS 13.32 Thu 18:00 P1

An in-situ μGISAXS growth study of CoFeB thin film on ion beam sculptured Si template — •Vishnu Narayan Manoj Kumar[1], Praveen Kumar Dubey[2], Prasanta Karmakar[3], Kristian A Reck[4], Benedikt Sochor[1], Yusuf Bulut[1], Thomas Strunskus[4,5], Franz Faupel[4,5], Stephan V Roth[1,6], Peter Müller Buschbaum[7], Ajay Gupta[2], and Sarathlal Koyiloth Vayalil[1,2] — [1]DESY, Notkestr. 85, 22607 Hamburg, Germany — [2]UPES, Bidholi, Dehradun, India-248007 — [3]VECC, 1/AF, Bidhannagar, Kolkata -700064, India — [4]Chair for Multicomponent Materials, Department of Materials Science, Kiel University Kaiserstr. 2, 24143 Kiel, Germany — [5]Kiel Nano, Surface, and Interface Science, KiNSIS, Kiel University, Christian-Albrechts Platz 4, 24118 Kiel, Germany — [6]Division of Coating Technology, KTH Royal Institute of Technology, Teknikringen 48, 100 44 Stockholm, Sweden — [7]Technical University of Munich, TUM School of Natural Sciences, Department of Physics, Chair for Functional Materials, James-Franck-Str. 1, Garching 85748, Germany

In this work, the growth and structural evolution of CoFeB thin films deposited on nanopatterned Si templates prepared by N_2^+ ion beam irradiation has been done using in-situ micro GISAXS. Different growth regimes have been identified using appropriate growth models. Thin film is found to replicate the sawtooth ripple geometry of the templates up to a large extent of film thickness near 15nm. Strong uniaxial magnetic anisotropy has been observed in this system. Direction of magnetic easy axis is found to be changing with annealing.

DS 13.33 Thu 18:00 P1

Structure evolution of multi-component Ti-Nb-Zr-based thin films with Ag addition during heat treatment — •Anna Benediktová, Lucie Nedvědová, Zdeněk Jansa, Palaniappan Subramanian, Michal Procházka, and Ján Minár — University of West Bohemia, Pilsen, Czech Republic

Multicomponent and high-entropy alloys represent an intensively studied group of materials. Due to their potential to be chemically and structurally very stable, wear resistant and hard, they have also become the subject of study as biomaterials. Conventional metallic biomaterials usually have many disadvantages, including inadequate antibacterial properties leading to infections and possible implant loss. To improve the surface properties, thin films with different amounts of silver as an antibacterial agent were prepared by magnetron sputtering. Their structure in the as-deposited state and the evolution of the structure during heat treatment were analyzed in detail by diffraction techniques (XRD, SAED) and by scanning and transmission electron microscopy (SEM, TEM). The chemical states of the surface were investigated by X-ray photoelectron spectroscopy (XPS). The chemical stability of the films in phosphate buffered solution (pH ~ 7.4) was evaluated by electrochemical methods such as potentiodynamic polarization and electrochemical impedance spectroscopy.

DS 13.34 Thu 18:00 P1

Microscale Domain Structures in AlScN Thin Films — •Ella Dieball[1], Nicolas Hayen[1], Otto Lippmann[1,3], Philipp Jordt[1], Niklas Wolff[2], Lorenz Kienle[2], Fabian Westermeier[4], Michael Sprung[4], and Bridget Murphy[1,4,5] — [1]Institute of Experimental and Applied Physics, Kiel University, Germany — [2]Institute of Material Sciences, Kiel University, Germany — [3]Helmholtz-Zentrum Hereon, Geesthacht, Germany — [4]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [5]Ruprecht Haensel Laboratory, Hamburg, Germany

Thin films of Aluminium-Scandium Nitride (AlScN) are used as central components in magnetoelectric surface-acoustic wave sensors utilized extensively within the Collaborative Research Center 1261 "Biomagnetic Sensing".

High resolution XRD experiments were conducted at microfocus beamline P10 at PETRA III. Bragg diffraction on AlScN thin films grown on GaN was investigated at the [0 0 0 2], [0 0 0 4] and [0 1 -1 5] reflections. The material exhibits an unexpected domain structure on the μm scale, which is associated with Scandium-rich and Scandium-depleted regions.

Additional synchrotron experiments are in planning to further investigate AlScN, e.g. grazing incidence diffraction or absorption measurements around the Scandium K-edge.

DS 13.35 Thu 18:00 P1

In Operando Grazing Incidence Diffraction in AlScN Surface Acoustic Wave Sensors — •Otto Carlos Lippmann[1,2], Nicolas Hayen[1], Philipp Jordt[1], Jana Meyer[5], Fabian Lofink[5], Henrik Wolframm[4], Didier Wermeille[7], Laurence Bouchenoire[7], Florian Bertram[3], and Bridget Murphy[1,3,6] — [1]Institute of Experimental and Applied Physics, Kiel, Germany — [2]Helmholtz-Zentrum Hereon, Geesthacht, Germany — [3]Deutches Elektronen Synchrotron, DESY, Hamburg, Germany — [4]Faculty of Engineering, Kiel, Germay — [5]Fraunhofer Institute for Silicon Technology ISIT, Itzehoe, Germany — [6]Ruprecht-Haensel Laboratory, Hamburg, Germany — [7]European Synchrotron Radiation Facility, Grenoble, France

Magnetic field sensors based on thin-film surface acoustic wave (SAW) technology are widely utilized in Collaborative Research Center 1261 "Biomagnetic Sensing". The use of Aluminium-Scandium-Nitride (AlScN) as the piezoelectric material allows for significant improvements in device sensitivity.

To investigate the microstructure of AlScN during the excitation of acoustic modes, an *in operando* setup was developed for high-resolution X-ray diffraction (XRD). This setup induces standing waves and allows the observation of diffraction patterns. A comparison of grazing-incidence diffraction (GID) of the [0 1 3] Bragg reflection between the stationary and operating state shows a shift in the signal peak position. Additional experiments are planned, along with the development of a new setup for time-resolved experiments. These efforts aim to enhance the understanding of SAW propagation in these materials.

DS 13.36 Thu 18:00 P1

Deterministic single ion-implantation of Er into thin film lithium niobate — •Maranatha Andalis, Reiner Schneider, and Klaus D. Jöns — Institute for Photonic Quantum Systems (PhoQS), Center for Optoelectronics and Photonics Paderborn (CeOPP) and Department of Physics, Paderborn University, 33098 Paderborn, Germany

Incorporating rare earth ions (REIs) into lithium niobate-on insulators (LNOI) is of great interest in scalable photonic integrated circuits (PIC), enhancing the potential of LNOI with added functionalities enabled by the REIs. Erbium ions can be incorporated into LNOI using ion implantation and implemented at telecom wavelengths. Together with Ionoptika Ltd., we have customized a single ion implantation system called Q-One with up to 40 kV acceleration voltage. For most quantum applications, the site-selective implantation of a single REI is required. Our results show single Er ion implantation into LNOI with 85% efficiency using secondary electron emission detection. The Q-One single ion implanter, with its high-resolution mass-filtered focused ion beam, nanometer-precision stage, and choice of ion source, holds significant potential in deterministic ion implantation, crucial for scalable quantum technologies with REIs.

DS 13.37 Thu 18:00 P1

Impact of ITO electrodes on the electrical and optical properties of a smart window — •Rebecca Cizek[1], Florian Sutter[1], Stephan Heise[1], Kai Gehrke[2], Eckhard Lüpfert[1], and Robert Pitz-Paal[1] — [1]German Aerospace Center, Institute of Solar Research, Oldenburg, Almería, Köln, Germany — [2]German Aerospace Center, Institute of Networked Energy Systems, Oldenburg, Germany

This study investigates the impact of indium tin oxide (ITO) electrodes on the performance of smart windows utilizing reversible metal electrodeposition (RME). RME is a promising technique for fabricating electrochromic devices, offering dynamic control over light transmission. ITO electrodes, known for their high conductivity and transparency, play a critical role in facilitating the electrochemical processes that govern the reversible metal deposition and dissolution on the window surface. The effects of ITO electrode characteristics, such as conductivity, surface morphology, and transparency, are explored in relation to the electric and optical performance of the smart window. Long-term measurements are conducted with voltage applied over several hours to assess the durability and performance of the electrodes under operation.

DS 13.38 Thu 18:00 P1

Antibacterial activity of ZnO and Al doped ZnO nanocoatings — •Maria Stefanova[1], Dimitrina Petrova[1,2], Vladimira Videva[1], Dimitre Dimitrov[1,3], Nadia Todorova[4], and Vera Marinova[1] — [1]Institute of Optical Materials and Technologies, Bulgarian Academy of Sciences, Sofia, Bulgaria — [2]South-West University Neofit Rilski, Blagoevgrad, Bulgaria — [3]Institute of Solid State Physics, Bulgarian Academy of Sciences, Sofia, Bulgaria — [4]Institute of Nanoscience and Nanotechnology, National Centre for Scientific Research Demokritos, Athens, Greece

Here we report on thin coatings of metal oxides (ZnO and ZnO doped with Al (AZO)) deposited by ALD technology. Their structural, surface-morphological and optical properties were investigated by AFM analysis, UV-Vis and fluorescence spectroscopy, as well as surface contact angle measurements. The antibacterial activity against Escherichia coli bacteria was evaluated in the dark and under ultraviolet light illumination. AZO nanocoatings were found to demonstrate more effective antibacterial action, mostly due to the improved sensitivity at UV spectral range as well as hydrophilicity in comparison with ZnO. The studied nanocoatings can serve as effective antimicrobial agents in a variety of applications.

Chiral Induced Spin Selectivity Cooling — •Ohad Golan[1], Yossi Paltiel[1], and Ron Naaman[2] — [1]Hebrew University of Jerusalem, Jerusalem, Israel — [2]Weizmann Institute of Science, Rehovot, Israel

Chiral Induced Spin Selectivity (CISS) is a quantum phenomenon in which electron spins become selectively polarized as they pass through chiral materials. This effect enhances spin-dependent interactions without the need for external magnetic fields, playing a crucial role in various spintronic and chemical processes. Building on this principle, the Chiral Induced Spin Selectivity Cooling (CISSCO) effect exploits CISS to generate a temperature gradient across chiral materials. When current flows through a chiral system from a source to a drain, spin alignment at the source increases local entropy, leading to heating, while spin randomization at the drain reduces entropy, resulting in cooling. Unlike conventional thermoelectric and magnetocaloric effects, CISSCO requires no magnetic materials, enabling efficient and highly localized cooling. This groundbreaking mechanism has the potential to transform nanoscale heat management, offering an innovative solution for cooling micro- and submicron electronic devices.

DS 13.40 Thu 18:00 P1

NaCl-assisted TAC synthesis of MoSe2 films for optical humidity sensor applications — •Blagovest Napoleonov[1], Katerina Lazarova[1], Dimitrina Petrova[1,2], Vladimira Videva[1,3], Dimitre Dimitrov[1,4], and Vera Marinova[1] — [1]Institute of Optical Materials and Technologies, Bulgarian Academy of Sciences, Sofia, Bulgaria — [2]South-West University Neofit Rilski, Blagoevgrad, Bulgaria — [3]Faculty of Chemistry and Pharmacy, Sofia University, Sofia, Bulgaria — [4]Institute of Solid State Physics, Bulgarian Academy of Sciences, Sofia, Bulgaria

We present the synthesis of MoSe2 through the Thermal Assisted Conversion (TAC) method with Mo liquid precursor solution composed of MoO3 dissolved in a 1:1 mixture of H2O and H2O2, with NaCl as an additive. The precursor solution enables controlled delivery of Mo during the TAC growth. The presence of NaCl influences the growth kinetics and crystallization during the annealing step. Raman spectroscopy, TEM, AFM and XPS measurements were employed for comprehensive material characterization, revealing the effectiveness of this precursor combination in synthesizing high-quality MoSe2 films. Based on optical reflectance measurements, the MoSe2 films demonstrate sensitivity to relative humidity changes by reflectance variation. These results led to the development of an optical humidity sensor, showcasing the material's potential in sensor applications. Acknowledgements: This work is supported by the Bulgarian Science Fund under the grant number KP-06-COST/15 under the COST Action CA20116 OPERA European Network for Innovative and Advanced Epitaxy.

DS 13.41 Thu 18:00 P1

Functionalization of Al-doped ZnO nanolayers for display applications — •Stefani Bogoeva[1], Vladimira Videva[1], Dimitrina Petrova[1,2], Vera Marinova[1], and Dimitre Dimitrov[1,3] — [1]Institute of Optical Materials and Technologies, Bulgarian Academy of Sciences, Sofia, Bulgaria — [2]Faculty of Engineering, South-West University, 2700 Blagoevgrad, BG — [3]Institute of Solid State Physics, BAS, 1784 Sofia, BG

The integration of highly transparent and conductive thin films into functional structures and devices plays an important role in the advancement of next-generation technologies. Here we report about Aluminum doped ZnO (AZO) thin films synthesized on different substrates using the atomic layer deposition (ALD) technique, which allows excellent conformality. The effect of post-deposition treatments on the optical and electrical properties of the films was studied using variety of characterization techniques.

Based on the above characteristics, integration of AZO layers in liquid crystal (LC) devices and Polymer Dispersed Liquid crystals (PDLC) structures are demonstrated, with measured electro-optical characteristics and response time. Implementation of AZO layers opens prospective applications for future ITO-free optoelectronics.

Acknowledgments The research was supported by the Scientific Research Fund project No. KP-06-*-58/12, as well as the distributed scientific infrastructure INFRAMAT, part of the National Roadmap of Bulgaria for scientific infrastructure, financially supported by the Ministry of Education and Science.

DS 13.42 Thu 18:00 P1

A high-field, high power instrument for (nonlinear) Terahertz Emission Spectroscopy — •Jonas Woeste[1,2], Nikola Stojanovic[2], Sergey Pavlov[2], Sergey Kovalev[3], and Michael Gensch[1,2] — [1]Institut für Optik und Atomare Physik, Technische Universität Berlin, Berlin, Germany — [2]DLR - Institute of Optical Sensor Systems, Berlin, Germany — [3]Fakultät Physik, Technische Universität Dortmund, Dortmund, Germany

The quest to understand nonlinear terahertz phenomena has driven the development of advanced instruments towards the capability to detect faint terahertz transients with sub-cycle time resolution. The instrument presented here is optimized for a mJ-level laser amplifier operating at kHz repetition rates. It generates high-field THz pulses with peak fields of a few 100 kV/cm spanning frequencies from 0.3-1 THz. Using ultrashort NIR pulses for tilted-pulse-front pumping of a lithium-niobate crystal, pulse energies of up to 5 μJ are achieved. Demonstration experiments include studies on various doped semiconductors, graphene, and chip-integrated Dirac materials giving insights into different nonlinear and non-perturbative quantum phenomena.

DS 13.43 Thu 18:00 P1

Techno-Enviro-Economic Evaluation for Thin-film Solar Cells Integrated with Hybrid Renewable Energy System — •Tawfik Hussein — Mechanical Engineering Dep., National Research Centre (NRC), El Buhouth st.,Dokki, Cairo, Egypt

Thin-film solar cells (TFSC) have surfaced as a potentially viable substitute in recent years. TFSC have emerged as a transformative technology in the renewable energy sector, offering unique advantages such as lightweight construction, flexibility, and cost-effectiveness compared to conventional crystalline silicon photovoltaics.

The main objective of this study is to design an optimal hybrid renewable energy system (HRES) integrating TFSC in order to achieve efficient use of the available renewable energy sources (RES). Therefore, a HRES consisting of different RES integrated with TFSC is proposed to cover reliable electricity to a scientific farm in Egypt with technical, environmental, and economic evaluation. The research highlights the performance of TFSC under varying environmental conditions, emphasizing their superior efficiency in low-light and high-temperature scenarios. All the parameters, such as system performance, net present cost, and carbon emissions, are considered.

The results showed that the proposed TFSC delivers highly efficient energy generation at significantly lower costs compared to traditional configurations. From an environmental perspective, it achieves a significant reduction in carbon emissions and demonstrates improved sustainability.

DS 13.44 Thu 18:00 P1

Molecular packing and alignment of prototypical acenes in organic 2D-material heterostructures — •Jan Vincent Schreiber and Gregor Witte — Philipps-Universität Marburg, Molekulare Festkörperphysik, 35032 Marburg, Germany

Heterostructures comprised of thin films of organic molecules and two-dimensional materials, notably monolayers of transition metal dichalcogenides, are emerging as a promising class of systems for applications in organic electronics. Unlike metallic surfaces, two-dimensional materials interact with adsorbates primarily through van der Waals forces, resulting in substrate-adsorbate interactions comparable in strength to intermolecular forces. This delicate balance means that even minor variations in surface characteristics or growth conditions can significantly affect the relative molecular alignment. A systematic investigation of the molecular model systems pentacene and 5,7,12,14-pentacenetetrone allows comparison of the influence of electrostatic forces on the film alignment. Techniques ranging from scanning tunnelling microscopy to optical polarisation microscopy highlight the necessity of understanding these interactions across multiple length scales. We demonstrate that for most substrates, specific molecular orientations optimize the system's structural energy, a phenomenon known as van der Waals epitaxy. Our findings emphasize the need for rigorous structural studies to unravel the interplay between molecular structure and substrate properties.

DS 13.45 Thu 18:00 P1

Spectroscopy of organic dye/TMDC heterostructures — •Christoph von der Oelsnitz[1,2], Julian Schröer[1,2], Tim Völzer[1,2], Tobias Korn[1,2], and Stefan Lochbrunner[1,2] — [1]Institut für Physik, Universität Rostock, Albert-Einstein-Straße 23, 18059 Rostock, Deutschland — [2]Department LL&M, Albert-Einstein-Straße 25, 18059 Rostock, Deutschland

Heterostructures composed of organic molecules adsorbed onto transition metal dichalcogenide (TMDC) monolayers can exhibit charge separation after optical excitation, making these systems promising candidates for optoelectronic applications. In this study, we investigate heterostructures consisting of the organic dyes copper phthalocyanine (CuPc) and 3,4,9,10-perylenetetracarboxylic diimide (PTCDI) deposited onto TMDC monolayers and hexagonal boron nitride (hBN), with the latter serving as a non-interacting reference system. First, the preparation of the dye layers via thermal vapor deposition was calibrated and performed. Subsequently, we investigated the dye/TMDC and dye/hBN heterostructures using various spectroscopic methods. In the event of charge separation in the dye/TMDC system, photoluminescence quenching of the dye is expected.

DS 13.46 Thu 18:00 P1

Substrate-driven Molecular Orientation of BQQDI-based Organic Thin Films — •Jeya Vishva Jeyaraj Pandian and Gregor Witte — Philipps-Universität Marburg, FB Physik

Thin films of PhC_2-BQQDI, a high-performance n-type organic semiconductor, exhibit preferential molecular orientations depending on the substrate. On weakly-interacting amorphous SiO_2 substrates, the molecules adopt an upright orientation. Furthermore, a co-existence of thin-film phase was observed depending on the growth parameters, which is characterised by the increased molecular tilt angle with respect to the surface of the substrate. Notably, a domination of thin-film phase was observed at elevated temperatures. This phenomenon contradicts a commonly observed growth behaviour in organic thin films, whereby bulk phase prevails under such growth conditions. However, post-deposition annealing results in a transition from thin-film phase into bulk phase with significant dewetting. In contrast to SiO_2, on surfaces of alkali halides such as KCl, the molecules exhibit a recumbent orientation. Furthermore, an epitaxial growth was observed, driven by the templating effect of the underlying substrate. These findings pave the way for a phase-selective preparation of thin films of PhC_2-BQQDI which can be used to deepen the understanding of electronic transport in devices based on PhC_2-BQQDI.

DS 13.47 Thu 18:00 P1

The influence of stoichiometry on molybdenum oxide-based memristors — •Katerina Maskanaki[1], Gion Kalemai[2,3], Evangelos K. Evangelou[1], and Anastasia Soultati[2] — [1]Department of Physics, University of Ioannina, 45110 Ioannina, Greece — [2]Institute of Nanoscience and Nanotechnology (INN), National Center for Scientific Research Demokritos, 15341 Agia Paraskevi, Athens, Greece — [3]Department of Physics, University of Patras, 26504 Patra, Rio, Greece

Transition metal oxides (TMOs) are a promising class of materials for neuromorphic computing and processing systems demonstrating a variety of resistive switching (RS) mechanisms. However, little is known about the correlation between its stoichiometry and RS. This study is focused on the development and characterization of molybdenum oxide memristors with different stoichiometry. Both, fully-stoichiometric (MoO_3) and sub-stoichiometric (MoO_{3-x}) molybdenum oxide devices showed good resistive switching behavior. However, the stoichiometric memristor exhibited better RS properties with endurance of 250 cycles, ON/OFF ratio > 10^2 and high retention of 2×10^4 s, compared to the poor RS behavior of the device based on the MoO_{3-x} film. This impressive memristive behavior could be attributed to the excess of oxygen vacancies in the case of fully-stoichiometric memristor in respect to the sub-stoichiometric MoO_{3-x} which play crucial role in the conductive behavior of the device. The high reproducibility observed in MoO_3-based memristor highlights their potential for practical applications and scalability.

DS 13.48 Thu 18:00 P1

In and ex situ detection of oxygen vacancies in HfO2 - advanced by PLD growth control and (HAX)PES spectroscopy — •Berk Yildirim[1], Seema Seema[1], Oliver Rehm[1], Pia Düring[1], Andreas Fuhrberg[1], Andrei Gloskovskii[2], Christoph Schlueter[2], and Martina Müller[1] — [1]Fachbereich Physik, Universität Konstanz, 78457 Konstanz, Germany — [2]DESY, Hamburg, Germany

Hafnium dioxide (HfO2) has emerged as a promising ferroelectric material, particularly suitable for non-volatile memory devices. Ferroelectricity in HfO2 is closely linked to oxygen vacancies (OV), but their direct experimental observation is challenging. This study uses tailored growth conditions to systematically control the OV concentration in HfO2 thin films as an essential prerequisite for their in and ex situ detection. In our pulsed laser deposition (PLD) system, parameters such as temperature, laser fluence, and oxygen partial pressure were varied to prepare HfO2 thin films with defined OV concentrations. In situ X-ray photoelectron spectroscopy (XPS) and ex situ hard X-ray photoelectron spectroscopy (HAXPES) provided detailed insight into OV distribution with different depths sensitivity, while structural properties were examined by in situ RHEED and ex situ X-ray diffraction (XRD) as well as atomic force microscopy (AFM). In and ex situ (HAX)PES analysis indicates a direct relationship between oxygen supply and the OV content via analysis of the Hf3+/Hf4+ spectral weight. In addition, the structural analysis points towards a systematic dependence between the onset of epitaxy and oxygen supply.

DS 13.49 Thu 18:00 P1

Oxygen vacancy mediated epitaxial superstructure thin film in tungsten sub-oxides — •Kyeong Jun Lee[1], Hyowon Seo[2], Yeong Gwang Kim[2], Yong-Jun Kwon[3], Bongju Kim[1], Minu Kim[1], Chan Ho Yang[3], Hyun Hwi Lee[4], Sangyoun Park[4], Gyungtae Kim[5], Jung-ho Kim[6], Young Jun Chang[2], and Seo Hyoung Chang[1] — [1]Department of Physics, Chung-Ang University, Seoul 06974, South Korea — [2]Department of Physics, University of Seoul, Seoul 02504, South Korea — [3]Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon 34141, South Korea — [4]Pohang Accelerator Laboratory, POSTECH, Pohang 37673, South Korea — [5]National NanoFab Center, Daejeon 34141, South Korea — [6]Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439, USA

In metal oxides, oxygen vacancies are key to enhancing energy conversion and unconventional properties. Crystallographic shear (CS) planes in these structures are vital for electrochemical electrodes. While powders and polycrystals are well studied, research on single crystals or epitaxial films is essential to link oxygen vacancies with electronic and crystal structures. We fabricated epitaxial {103} CS superstructures in tungsten sub-oxides (Magnéli phases) on NdGaO3 (110)o substrates. X-ray scattering, AFM, and TEM confirmed epitaxial growth. W L3 RIXS revealed W6+ 5d0 and W6+ 5d1 states, showing oxygen vacancies' role in mediating superstructures and electronic properties.

DS 13.50 Thu 18:00 P1

Electronic structure of the TiO2/AlInP heterointerface studied by photoemission spectroscopy — •Mohammad Amin Zare Pour[1,2], Sahar Shekarabi[1], Jonathan Diederich[3], Negin Mogharehabed[2], Christian Höhn[3], Wolfram Jaegermann[4], Dennis Friedrich[3], Roel van de Krol[3], Agnieszka Paszuk[2], and Thomas Hannappel[1] — [1]Grundlagen von Energiematerialien, Technische Universität Ilmenau — [2]Paszuk group, Technische Universität Ilmenau — [3]Institut für solare Brennstoffe, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH — [4]Fachgebiet Oberflächenforschung, Technische Universität Darmstadt

Many world-record photoelectrochemical cells use AlInP as a window layer for selective electron transport passivated with TiO2, which is stable in electrolytes. The electronic and atomic properties of the TiO2/AlInP heterointerface in dependence to AlInP surface terminations to were examined. TiO2 was deposited by atomic layer deposition on various AlInP surface reconstructions and the TiO2/AlInP interface band diagram was experimentally examined. XPS/UPS studies reveal that TiO2 deposition reduces AlInP band bending, while remaining surface states pin the fermi level and still induce band bending towards the interface. Based on AlInP surface reconstruction, the valence band offset ranges from 1.7 to 1.9 eV. The presence of an oxide layer hinders the growth of TiO2 relative to clean surfaces. AlInP window layers are prevalent in III-V heterostructures, therefore mapping the TiO2/AlInP interface's electrical properties can optimize photoelectrochemical interfaces and more.

DS 13.51 Thu 18:00 P1

Resonance Raman and DFT analysis of structural and point defects in transparent conductive oxide SnO2:X (X=Ta, F) — •Lukas Prager[1], Carlos Romero Muñiz[2], Frans Munnik[1], Justus Haag[1], Ramon Escobar Galindo[3], and Matthias Krause[1] — [1]Helmholtz-Zentrum Dresden - Rossendorf, Bautzner Landstraße 400, 01328 Dresden, Germany — [2]Departamento de Física de la Materia Condensada, Universidad de Sevilla, Avda. Reina Mercedes s/n, 41012-Sevilla, Spain — [3]Departamento de Física Aplicada I, Escuela Politécnica Superior, Universidad de Sevilla, Virgen de África 7, 41011-Sevilla, Spain

Structural and point defects have a crucial influence on the electronic and optical properties of transparent conductive oxides. In this contribution we characterize different types of defects in SnO2:X (X = Ta, F) by the combination of laser-wavelength dependent Raman spectroscopy and state-of-the-art density functional theory (DFT) calculations using hybrid functionals.

Sn-vacancy- and O-interstitial-type point defects are found in transparent conductive SnO2:Ta thin films grown at 575 °C. These defects are responsible for strong, fingerprint-like Raman lines out of the phonon range of SnO2 [1], which are resonance-enhanced in the visible spectral range. The defects induce strong distortions of the electronic structure in the upper range of the valence band of Ta-doped SnO2. Moreover, the DFT calculation reveal a localized, molecular nature of the O interstitial and a delocalized nature of the Sn vacancy defect.

DS 13.52 Thu 18:00 P1

Ion Beam Sputter Deposition of Aluminium oxide Thin Films for electronic applications — •Prakrthi Alankaru Narayana[1,2], Aurelio García-Valenzuela[1], Jens Zscharschuch[1], Charlotte Kielar[1], Holger Lange[1], Claudia Neisser[1], Thomas Seyller[2], and Artur Erbe[1] — [1]Institute of Ion Beam Physics and Materials Research, HZDR, Dresden, Germany — [2]Institute of Physics, Technische Universität Chemnitz, Germany

Aluminium oxide (Al2O3) has drawn considerable interest from the research community due to its versatility in microelectronics particularly as a high-k dielectric in Complementary Metal Oxide Semiconductor (CMOS) devices. Ion Beam Sputter Deposition (IBSD), a physical vapor deposition method, facilitates the formation of Al2O3 thin films with fewer defects, improved composition, and better adhesion than compared to other physical deposition methods.

This work focuses on optimizing ion beam parameters to improve film properties such as stoichiometry, surface roughness, crystallinity, optical transmittance, and dielectric constant. Furthermore, the influences of oxygen flux and annealing on film properties have been investigated. To demonstrate the applicability of the deposited Al2O3 films, they have been utilized as a high-k dielectric material in metal-insulator-metal capacitors.

DS 13.53 Thu 18:00 P1

Band gap engineering of $SrNbO_3$ using anions — •Abhishek Sharma, Jasnamol Palakkal, and Christian Jooss — Institute of Materials Physics, Georg-August-University of Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

Green energy is the demand of this generation for a better, eco-friendly future. Solar energy, being a renewable source can fulfill our demand through solar energy harvesting, which converts available sunlight to electrical energy. Transparent conducting oxide $SrNbO_3$ is a promising material for use in silicon tandem solar cells due to its wide bandgap (1.99 eV) and flexibility of the transparency window to be varied across different wavelengths using defects concentration [1]. Cationic and anionic defect engineering also varies this material's electrical conductivity from a metallic conductor to a ferroelectric insulator [2]. Upon introducing Sr vacancies, we changed the plasma frequency of $SrNbO_3$ from the visible light region (1.99 eV) to the near-infrared region (1.37 eV) [1]. In our ongoing work, we further vary the electrical and optical properties using anion modification in the form of oxygen defects and nitrogen anion introduction. A hybrid pulsed laser deposition unit with plasma sources for gases is being used carefully to control the anions in this materials system.

DS 13.54 Thu 18:00 P1

Thickness dependence of transport in thin crystalline FeTe films — •Paul Zhuromskyy, Christian Stenz, and Matthias Wuttig — I. Institute of Physics (IA), RWTH Aachen University, Germany

Iron chalcogenides present an intriguing material class for solid state physics; they have been shown to display antiferromagnetism, tunable superconductivity, inverted phase change behaviour, and unique interface effects when brought into contact with topological insulators. The layered compound FeTe has been predicted to be a topological semimetal. Although it has been the subject of numerous investigations, so far little attention has been given to the effects of nanoscale confinement below a thickness of 100 nm. Besides electrical transport, we have also analyzed optical and vibrational properties with regards to topological effects and phase transitions of FeTe for decreasing film thicknesses, from 80nm down to a few monolayers, and identified inflection points at which the phase transitions and conduction behaviour change due to confinement effects. Due to the importance of interfaces for topologically nontrivial materials, this presents a step towards the understanding of electronic phenomena in iron chalcogenides, as well as finding practical applications for FeTe in nanoelectronics. Our findings reveal that the complexity of solid-state systems makes them challenging to model but offers tunable parameters like quantum confinement to create novel phenomena and materials. Characterizing these dependencies helps uncover new connections and property design opportunities.

DS 13.55 Thu 18:00 P1

Charge Density Waves and resulting properties of polycrystalline CuTe Films — Johannes Holters, •Christian Stenz, and Matthias Wuttig — I. Institute of Physics (IA), RWTH Aachen University, Germany

Charge density waves (CDWs) are periodic modulations of charge density in materials, often coupled with structural distortions and electronic property changes. The layered transition metal monochalcogenide CuTe exhibits a CDW phase below 335 K in single crystals, accompanied by a Peierls distortion along its Te-chains, which confines electron transport to a quasi-1D channel. While this phenomenon has been extensively studied in bulk single crystals, its manifestation in polycrystalline thin films is less well characterized. Here, we investigate the CDW phase and topological properties of sputter-deposited CuTe thin films with varying thickness. We observe that the CDW transition persists in these films, and its characteristics are influenced by thickness and microstructure. By modeling the resistivity curves, we extract key physical parameters, like the CDW transition temperature and its broadening due to the grain size distribution. Further, we explore the topological semimetal (TSM) characteristics in the non-CDW state (T>335K), examining features such as magnetoresistance and the planar Hall effect. Our results highlight the robustness of the CDW in polycrystalline CuTe and its sensitivity to film structure, extending the understanding of CDW behavior beyond bulk crystals. These findings reveal the interplay between CDWs, TSMs and microstructure, offering potential for novel device applications.

DS 13.56 Thu 18:00 P1

Mechanical stress of Ge films upon ion irradiation — •Karla Paz Corrales[1], Aaron Reupert[2], Berit Marx-Glowna[3], Martin Hafermann[1], Elke Wendler[1], and Carsten Ronning[1] — [1]Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 3, 07743 Jena, Germany — [2]Otto Schott Institute of Materials Research, Friedrich Schiller University Jena, Lessingstraße 12-14, D-07743 Jena, Germany — [3]Helmholtz Institute Jena, Fröbelstieg 3, D-07743 Jena, Germany

Mechanical stress in thin films significantly affects the performance, reliability, and durability of optoelectronic components. Polycrystalline films are considered to be in a "stressed state" due the mismatch of the thermal expansion coefficients between the film and substrate. Amorphous Ge films (~600nm) were deposited on fused silica substrates by magnetron sputtering. Subsequent annealing was performed at 600°C for 1h and 7h in vacuum to achieve crystallization. GIXRD patterns show peaks related to the polycrystalline Ge with preferred orientation along the [111] direction. Laser curvature measurements showed compressive stress for amorphous Ge-films, while the polycrystalline Ge samples became tensile stressed after annealing. In situ curvature measurements during ion-irradiation, using Au ions with 1.8 MeV on the polycrystalline Ge, show a decrease in stress with increasing irradiation fluence. Furthermore, optical measurements were performed after irradiation, and a reduction in the reflectance region of 450 to 650 nm and a shift of the absorption region up to ~1000 nm were observed due to ion beam-induced defect formation.

DS 13.57 Thu 18:00 P1

Single-Phase Crystallization and Optimization for Optical and Electrical Properties of Sputtered In_3SbTe_2-SnTe Thin Films — •Zhengchao Zhu, Thomas Schmidt, Christian Stenz, and Matthias Wuttig — I. Institute of Physics (IA), RWTH Aachen University, Germany

Chalcogenide phase-change materials (PCMs) are known for their distinct differences in dielectric property i.e. $\epsilon(\omega)$ and electrical conductivity between their amorphous and crystalline states. This ability to rapidly switch between phases under light or electrical pulses makes them promising for applications in data storage and solar energy systems. One of the next-generation PCMs, In_3SbTe_2 (IST), exhibits a transition from dielectric to metallic behaviour when crystallized, a characteristic that spans the entire infrared spectrum and offers gigantic potential for advancing nanophotonic technologies. However, IST faces a limitation at high temperatures, where it decomposes into InSb and InTe, leading to reduced phase contrast and diminished performance. SnTe, with its similar lattice structure to IST, shows excellent miscibility with IST and can prevent phase separation. Never the leer, mixtures containing 30%-60% IST still exhibit tendencies of phase separation. This study aims to synthesize single-phase alloys using magnetron sputtering, evaluating phase separation across different stoichiometries. Subsequent investigations will focus on determining crystallization temperatures, electrical conductivity, and optical constants of the samples.

DS 13.58 Thu 18:00 P1

Bond Confinement Induced Tayloring of Optical Properties — •Thomas Schmidt, Peter Kerres, Felix Hoff, Julian Mertens, Yiming Zhou, Maria Häser, and Matthias Wuttig — I. Institute of Physics (IA), RWTH Aachen University, Germany

Chalcogenide materials, such as GeTe and Sb_2Te_3, exhibit a broad range of properties that enable applications in thermoelectrics and phase change material (PCM) memory storage, where rapid and reversible switching between amorphous and crystalline states alters optical and electrical characteristics. Recent studies on textured chalcogenide thin films have focused on understanding structure-property relationships, particularly how properties evolve with film thickness. It is also explored how confinement influences atomic arrangement and bonding. Changes in bonding, particularly the transition from metavalent to covalent-like bonding, are linked to significant variations in material properties with decreasing thickness. In this work, we investigate the optical contrast of chalcogenide films by analyzing the thickness-dependent changes in the dielectric function. These findings are compared with the dielectric function of a mono-elemental system molecular beam epitaxy (MBE)-grown Bi films with thicknesses ranging from 2 to 30 nm to establish a link between bonding and optical properties.

DS 13.59 Thu 18:00 P1

Coherent Control of Optical Phonon Modes in Bi Thin Films Using Polarization and Double-Pulse Excitation — •Timo Veslin[1], Felix Hoff[1], Jonathan Frank[1], Felix Nöhl[1], Abdur Rehman Jalil[3], and Matthias Wuttig[1,2,3] — [1]I. Institute of Physics (IA), RWTH Aachen University, Germany — [2]Jülich-Aachen Research Alliance (JARA FIT and JARA HPC) — [3]Peter Grünberg Institute - JARA-Institute Energy Efficient Information Technology (PGI-10), Jülich, Germany

A new approach in the coherent control of optical phonon modes has been explored, enabling advances in material manipulation. By integrating polarization control with temporal modulation of double-pulse excitation, we show the selective and independent modulation of A1g and Eg phonon modes in a 12.5 nm bismuth thin film using a femtosecond pump-probe setup. This method takes advantage of the unique polarization dependencies of each phonon mode and quantum interference effects resulting from varying time delays between two pump pulses. The proposed approach is widely applicable to various materials and offers an unique level of active control over optical phonon excitation. This advancement could be relevant for emerging phononic technologies, such as nanoscale heat management, phononic data processing, and telecommunications. These applications are particularly vital for addressing the "THz gap" in the 1-10 THz spectral range, marking a crucial progress for the next generation of high-speed information transfer.

DS 13.60 Thu 18:00 P1

Ultra-fast exciton and charge carrier dynamics in monolayer MoS_2 seen in the transient spatial dielectric function — •Jakob Seyfarth[1], Andy Engel[2], Noah Stiehm[1], Younes Slimi[1], Lucas Krätschmer[1], Markus Olbrich[2], Theo Pflug[2], Alexander Horn[2], Stefan Krischok[1], and Rüdiger Schmidt-Grund[1] — [1]Fachgebiet Technische Physik I, Technische Universität Ilmenau, Weimarer Straße 32, 98693 Ilmenau, Germany — [2]Laserinstitut Hochschule Mittweida, Schillerstraße 10, 09648 Mittweida, Germany

We present the charge carrier dynamics of monolayer MoS_2 on c-cut sapphire measured using pump-probe imaging reflectometry and interferometry with a spatial resolution of 0.65 micrometers and temporal resolution of 40 femtoseconds [1]. The time-resolved spatial dielectric function shows a diffusion which can be related to the dynamics of charge carriers. The dynamics can be attributed to specific events in the band structure of MoS_2 by comparing the results of a specific probe photon energy with previous time-resolved spectroscopic ellipsometry results [2]. DS 13.61 Thu 18:00 P1

Anomalous Nernst effect in Fe-Ge-N thin films for power generation applications — •Robin Kidangan Paul[1], Imants Dirba[1], Oliver Gutfleisch[1], Jakub Vít[2], Petr Levinský[2], Kyo-Hoon Ahn[2], Karel Knížek[2], Markéta Jarošová[2], Jaroslav Kohout[2], Stanislav Mráz[3], Marcus Hans[3], and Jochen Schneider4[3] — [1]Functional Materials, Technical University of Darmstadt, Germany — [2]Institute of Physics of the CAS, Praha, Czech Republic — [3]Materials Chemistry, RWTH Aachen University, Aachen, Germany

With the growing demand for sustainable energy solutions, thermoelectric devices that convert heat directly into electricity have gained significant interest. While conventional thermoelectric devices based on the Seebeck effect are well-established, their complex designs and geometric limitations have hindered large-scale adoption. Anomalous Nernst Effect (ANE)-based devices have recently emerged as a promising alternative, offering simpler geometries and device flexibility. However, their adoption is constrained by lower efficiencies and output voltages compared to Seebeck-based counterparts. This study focuses on addressing these challenges by exploring materials with high ANE coefficients. Among the candidates, Fe4N has attracted attention due to its cost-effectiveness, nontoxicity, and tunability through elemental doping. DFT calculations of the Berry curvature indicate that doping Fe4N with Ge can enhance its ANE coefficient. In this work, thin films of doped Fe4-xGexN were fabricated onto MgO substrates using magnetron sputtering. Crystal structure, microstructure and transport properties are systematically characterized.

DS 13.62 Thu 18:00 P1

Resolving crystalline domains in an amorphous matrix via APT — •Elias Hildebrand[1], Jan Köttgen[1], Ramon Pfeiffer[1], Yuan Yu[1], and Matthias Wuttig[1,2] — [1]I. Institute of Physics (IA), RWTH Aachen University, Germany — [2]Peter Grünberg Institute - JARA-Institute Energy Efficient Information Technology (PGI-10), Jülich, Germany

Controlling crystallization from the amorphous state is critical for the development of new energy-efficient, non-volatile data storage technologies. The direct observation of crystalline nuclei is a challenging task because they are undetectable using classical X-ray diffraction.

In recent years, atom probe tomography (APT) has been established as an analytical technique for studying the microscopic structure of materials. Furthermore, it has been shown that for some chalcogenide materials (i.e., metavalently bonding materials), the difference between their amorphous and crystalline phases can be observed directly in APT data by utilizing the Probability of Multiple Events (PME).

In this project, APT is used to characterize amorphous and crystalline domains on a microscopic scale. The samples are produced using an in-house switching setup (the Phase Change Optical Tester) to reliably create crystalline regions within an amorphous matrix.

With this combination of techniques, we aim to achieve a better understanding of the crystallization mechanisms in chalcogenide glasses. This novel approach may help bridge the gap left by XRD measurements for small nuclei and thus improve control over crystallization and understanding of nucleation and growth on a nanometer scale.

DS 13.63 Thu 18:00 P1

Electrical switching dynamics of Ge-Sb-Te alloys for phase-change memories — •Alexander Kiehn[1], Ramon Pfeiffer[2], and Matthias Wuttig[1,2] — [1]Peter Grünberg Institute - JARA-Institute Energy Efficient Information Technology (PGI-10), Jülich, Germany — [2]I. Institute of Physics (IA), RWTH Aachen University, Germany

Phase-change materials composed of Ge-rich Ge-Sb-Te alloys are promising candidates for next-generation phase-change memory (PCM) due to their non-volatile nature, temperature stability, and fast switching speeds. These properties make them ideal for in-memory computing or applications in sensor systems, where fast, energy-efficient and reliable memory is crucial. However, in order to integrate PCMs into the usual semiconductor devices, it is necessary to reduce the switching voltage and current. This is influenced by the stoichiometry of the sputtered Ge-Sb-Te layer, which was varied in this study. Using industry-standard CMOS fabrication processes, chips were manufactured based on a confined cell PCM design. Based on the electrical switching results, trends in thermal stability and the resulting voltage requirements are clearly shown for increasing Ge content. These trends are supported by further investigating the crystallization behavior in optically-switched thin films.

DS 13.64 Thu 18:00 P1

Tailoring Metavalent Materials: Exploring the Structural and Functional Properties of $(GeTe)_x(SnTe)_{1-x}$ Alloys — •Jari Klinkmann[1], Lucas Bothe[1], Felix Hoff[2], and Matthias Wuttig[1,2] — [1]Peter Grünberg Institute - JARA-Institute Energy Efficient Information Technology (PGI-10), Jülich, Germany — [2]I. Institute of Physics (IA), RWTH Aachen University, Germany

Metavalent materials have attracted significant interest due to their unique property portfolio, including medium electrical conductivities, high optical dielectric constants, large Born effective charges, and high Grüneisen parameters. GeTe and SnTe in particular are highly relevant for applications in thermoelectrics and phase-change memories. Here, we provide a comprehensive study of $(GeTe)_x(SnTe)_{1-x}$ alloys fabricated using molecular beam epitaxy (MBE). Structural characterization using x-ray diffraction alongside polarization-resolved Raman spectroscopy reveal the stoichiometry dependence of the rhombohedral-to-cubic phase transition, characterized by the loss of Raman-active modes in the cubic phase. Furthermore, coherent phonon investigations captured via femtosecond pump-probe spectroscopy detail the phase transition temperature evolution. Electrical and optical characterizations demonstrate the impact of stoichiometry on material properties, highlighting opportunities for tailoring these alloys for advanced technological applications.

DS 14: Members' Assembly

Time: Thursday 18:30–20:00 Location: H3

All members of the Thin Films Division are invited to participate.

DS 15: Organic Thin Films, Organic-Inorganic Interfaces

Time: Friday 9:30–11:45 Location: H3

Invited Talk DS 15.1 Fri 9:30 H3

Structure formation and growth at the metal-organic interface — •Peter Zeppenfeld — Institute of Experimental Physics, Johannes Kepler University Linz, Austria

The evolution of the structural, electronic and optical properties of organic thin films strongly depend on the ordering, aggregation and orientation of the molecules within the very first or a few deposited monolayers. The chosen substrate and its intentional modification (e.g. by pre-adsorption of inorganic or organic species) may thus have a strong influence on the structural, electronic and optical properties of the growing organic thin film. Using complementary experimental methods, namely, surface optical spectroscopy (RDS, DRS), diffraction (LEED) and microscopy (STM, PEEM), supported by empirical models and ab-initio calculations we aim to identify (and eventually quantify) the underlying driving forces. We will present examples on the 2D condensation of organic molecules on metal surfaces, the structural and orientational ordering in 2D (and quasi 1D) monolayer phases and its influence on the further growth of the organic thin film. Finally, we will illustrate the effects of modification / templating of the substrate on the structure and properties of the organic layers.

DS 15.2 Fri 10:00 H3

Thin film heterostructures based on Co/Ni synthetic antiferromagnets on polymer tapes: towards a sustainable flexible spintronics — •Mariam Hassan[1], Sara Laureti[2], Christian Rinaldi[3], Federico Fagiani[3], Gianni Barucca[4], Manfred Albrecht[5], and Gaspare Varvaro[2] — [1]Institute of Physics, TU Chemnitz, Germany — [2]CNR-ISM, nM2-Lab, Italy — [3]Department of Physics, Politecnico di Milano, Italy — [4]Università Politecnica delle Marche, Dipartimento SIMAU, Italy — [5]Institute of Physics, University of Augsburg, Germany

The PGMs-free Co/Ni-system offers several advantages for spin-based devices such as low damping and high spin polarization, and they contribute to a more sustainable future. Moreover, these films could be good substrates for the investigation of the chiral-induced spin selectivity "CISS" effect. In this work, flexible synthetic-antiferromagnets with perpendicular-magnetic-anisotropy (PMA-SAFs) and GMR-spin-valves (SVs) containing a SAF-reference electrode and a Co/Ni-free layer were deposited on flexible polyethylene naphthalate tapes with different combinations of buffer and capping layers (Pt, Pd, Cu/Ta). High-quality SAFs with a fully compensated antiferromagnetic region and SVs with a sizeable GMR ratio were obtained. The best performances are achieved with PGMs used as buffer layer and Cu as capping layer[1]. The results indicate that complex Co/Ni-based heterostructures with reduced content of PGMs deposited on flexible tapes allow for the development of novel shapeable and sustainable spintronic devices.

[1]ACS Appl. Mater. Interfaces. 14 (2022) 51496-51509.

DS 15.3 Fri 10:15 H3

highly crystalline, cleavable, and transferable semi-conducting 2D imine COF film — •diksha srivastava[1], vipin mishra[2], showkat h. mir[3], jyotirban dey[1], jayant k. singh[1], manabendra chandra[1], and thiruvancheril g. gopakumar[1] — [1]Indian Institute of Technology Kanpur, Kanpur 208016, India — [2]KU Leuven, Celestijnenlaan 200F, Leuven B-3001, Belgium — [3]University of Kashmir, Hazratbal, Srinagar 190006, Jammu and Kashmir, India

Two-dimensional (2D) imine-based covalent organic frameworks (COFs) are emerging crystalline organic polymers with potential applications in thin-film electronics, sensing, and catalysis, driven by their stability, tunable electronic properties, and versatile functionality. We present a scalable method for synthesizing 2D imine-COF films on dielectric glass substrates via a Schiff base reaction between p-phenylenediamine (PDA) and benzene-1,3,5-tricarboxaldehyde (TCA) over 15 hours. This yields highly crystalline 2D networks with film thicknesses ranging from 100 nm to a few monolayers and lateral dimensions up to 2 cm. Sonication exfoliation is employed for producing free-standing films. Structural characterization via SEM, TEM, and AFM confirms highly crystalline 2D structures. XPS analysis validates the chemical composition, while optical measurements indicate a semi-conducting band gap. DFT calculations show a semiconductor-like band structure with strong band dispersion near the conduction and valence band edges, signifying efficient charge transport and potential for future electronic applications.

session break

DS 15.4 Fri 10:45 H3

Excited state dynamics in thin films of planar and twisted azaperopyrene derivatives — •Jakob Steidel[1], Robert Eichelmann[2], Jakob Sawatzki[1], Lutz Gade[2], and Petra Tegeder[1] — [1]Physikalisch-Chemisches Institut — [2]Anorganisch-Chemisches Institut, Universität Heidelberg, Germany

Azaperopyrene derivatives are a class of organic semiconductors with a high potential for applications in optoelectronic devices. The molecular π-system of planar octaazaperopyrenedioxide (OAPPDO-H) is substituted with chlorine yielding OAPPDO-Cl, a molecule with a twisted structure.

In this contribution we utilised transient absorption spectroscopy to elucidate excited state dynamics of OAPPDO derivatives with planar and twisted molecular π-systems in thin films. On a short time scale of several hundred femtoseconds we observed fast population of excited states and fluorescence in both materials. The lifetimes of these processes show a similar dependency on the intensity of the excitation pulse. On a long time scale of several nanoseconds striking differences were observed. While the lifetimes of the excited state in OAPPDO-Cl increased and saturated with increasing excitation intensity, the lifetimes in OAPPDO-H showed a maximum at a medium excitation intensity of 400 nJ per pulse. We assign this behaviour to the opening of an additional decay pathway due to triplet-triplet-annihilation that requires cofacial arrangement of two molecules. Only planar OAPPDO-H can arrange in such a way, while the increased steric hindrance in OAPPDO-Cl suppresses this intermolecular interaction.

DS 15.5 Fri 11:00 H3

Thermally Tuning the Optical Properties of Discrete NDI-T2 Oligomer Thin Films — •Alexander Ehm[1], Fabian Eller[2], Meike Kuhn[2], Rukiya Matsidik[1], Michael Sommer[1], Eva M. Herzig[2], and Dietrich R. T. Zahn[1] — [1]Faculty of Natural Sciences, Technische Universität Chemnitz, D-09107 Chemnitz, Germany — [2]Dynamik und Strukturbildung - Herzig Group, Universität Bayreuth, Universitätsstr. 30, D-95447 Bayreuth, Germany

In the pursuit of developing and optimizing n-type organic semiconductors for the use in organic electronics, materials derived from naphthalene diimide (NDI) and bithiophene (T2), such as P(NDI2OD-T2), are highly interesting [1]. Changing the average molecular orientation via thermal annealing, and thereby their opto-electronic properties, allows finetuning for specific applications [2].

Recently, we showed that the optical anisotropy of the discrete oligomers NDI-(T2-NDI)2 and T2-(NDI-T2)2 can be influenced by thermal annealing [3]. Here, we extend this study and reveal that the photoluminescence and optical anisotropy, as found by variable-angle spectroscopic ellipsometry of T2-(NDI-T2)2 can be continuously tuned by the choice of the annealing temperature. The

correlation with molecular alignment is investigated using grazing-incidence wide-angle X-ray scattering.

DS 15.6 Fri 11:15 H3

Highly-Robust Double Neuromorphic Device Based on Perovskite/Molybdenum Oxide-Sulfide Compound Heterojunction — •Gion Kalemai[1,2], Michael-Alexandros Kourtis[3], Anastasia Soultati[1], Apostolos Verykios[1], Dimitris Davazoglou[1], and Maria Vasilopoulou[1] — [1]Institute of Nanoscience and Nanotechnology (INN) National Center for Scientific Research Demokritos, Agia Paraskevi, Athens, Greece — [2]Department of Physics, University of Patras, Patra Rio, Greece — [3]Institute of Informatics & Telecommunications, National Center for Scientific Research Demokritos, Agia Paraskevi, Athens, Greece

This study addresses the fundamental perovskite memristor limitations by integrating a robust molybdenum oxide-sulfide (MoO3-MoS2) mixed layer beneath a RbCsMAFA quadruple cation perovskite, precisely engineered through sulfurization of sub-stoichiometric MoO3-x. The resulting neuromorphic device exhibits impressive RS, with an ON-OFF ratio of 100, high retention & endurance, and a 0.5sec switching speed. Analysis confirm the successful control in the MoO3-MoS2 structure, which introduces trap states within the bandgap, facilitating SCLC and enabling robust memory function.

The composite, demonstrates enhanced synaptic emulation capabilities, such as PPF-PPD, and STP-LTP, replicating key synaptic functions for neuromorphic computing. Notably, this device offers excellent stability under 85°C, an enhanced ON-OFF ratio under illumination. Thus, the potential of sub-stoichiometrically engineered architectures is underlined.

DS 15.7 Fri 11:30 H3

Spatially resolved work-function manipulation of azobenzene-functionalized self-assembled monolayers by optical stimulation — Jan Böhnke[1], Beatrice Andres[1], Larissa Boie[1,2], Angela Richter[1], Cornelius Gahl[1], Martin Weinelt[1], and •Wibke Bronsch[1,3] — [1]Freie Universität Berlin, Fachbereich Physik, Arnimallee 14, 14195 Berlin, Germany — [2]Paul Scherrer Institut, Forschungsstrasse 111, 5232 Villigen, Switzerland — [3]Elettra-Sincrotrone Trieste S.C.p.A., Strada Statale 14-km 163.5 in AREA Science Park, 34149 Basovizza, Trieste, Italy

Strongly differing static dipole moments of the trans and cis isomers of photochromic azobenzene allow for optical work-function switching of azobenzene-functionalized self-assembled monolayers (SAMs) [1,2]. We apply these properties in a fundamental experiment to manipulate the area size of the switched SAM [3]. In our experiments we spatially resolve the transient isomerization profile of the SAM after UV illumination by means of photoemission electron microscopy imaging. We demonstrate the capability of spatial tuning of the SAM's work function and discuss the role of the laser spot profile in generating sharp edges or gradual changes of the work function across the sample.

Sessions

– Invited Talks, Tutorials, Contributed Talks, and Posters –

DY 1: Hands-on Tutorial: AI Fundamentals for Research (joint session BP/TUT/DY/AKPIK)

Artificial intelligence (AI) has become an essential tool in modern physics, enabling new approaches to data analysis, modeling, and prediction. This hands-on tutorial provides an accessible introduction to key AI concepts, emphasizing their practical applications in physics research.

Please bring your laptop. There will be limited power outlets in the room, so come with a fully charged battery.

Materials will be made available from 10.03.2025, accessible via the following options:

GitHub repository:

https://github.com/RedMechanism/DPG-SKM-2025-Tutorial-AI-Fundamentals-for-Research

ZIP file download:

https://jlubox.uni-giessen.de/getlink/fiAGRzcGTiCL3GZxk8WAjom4/

Participants are encouraged to download them ahead of time.

Organized by Jan Bürger (Aachen), Janine Graser (Duisburg), Robin Msiska (Duisburg/Ghent), and Arash Rahimi-Iman (Gießen), with support from Stefan Klumpp (Göttingen) and Tim Ruhe (Dortmund).

Time: Sunday 16:00–18:15 Location: H2

See BP 1 for details of this session.

DY 2: Nonequilibrium Quantum Systems (joint session TT/DY)

Time: Monday 9:30–12:30 Location: H31

See TT 2 for details of this session.

DY 3: Active Matter I (joint session DY/BP/CPP)

Time: Monday 9:30–12:45 Location: H37

DY 3.1 Mon 9:30 H37

Odd dynamics and pattern formation in mixtures of magnetic spinners and passive colloids — •Dennis Schorn[1], Stijn van der Ham[2], Hanumantha Rao Vutukuri[2], and Benno Liebchen[1] — [1]Technische Universität Darmstadt, 64289 Darmstadt, Germany — [2]MESA+ Institute, University of Twente, 7500 AE Enschede, The Netherlands

Starfish embryos aggregate into chiral crystals exhibiting odd elasticity (Tan *et al.* Nature **607**, 287 (2022)). Similar structures have been recently observed in externally driven magnetic colloids. In this talk, I present experiments and simulations of binary mixtures of magnetic spinners and passive colloids. We develop a model to predict the phase diagram of the system, which comprises four distinct phases that can be systematically reproduced in experiments. In particular, our simulations and experiments show a phase where the passive particles form a gel-like network featuring significant holes filled with self-organized rotating chiral clusters made of spinners. This phase can be reversed by changing the system's composition and magnetic field strength, featuring a system spanning spinner phase with embedded counter-rotating chiral clusters made of passive colloids. Our system may open the route towards a new type of viscoelastic active chiral matter involving nonreciprocal interactions between both species.

DY 3.2 Mon 9:45 H37

Symmetry breaking in active non-reciprocal systems — •Kim L. Kreienkamp and Sabine H. L. Klapp — TU Berlin, Germany

Non-reciprocity significantly impacts the dynamical behavior in mixtures. One of its particularly striking consequences is the spontaneous emergence of time-dependent phases that break parity-time symmetry [1-3]. Here, we study a paradigmatic model of a non-reciprocal polar active mixture with completely symmetric repulsion [4,5]. Using a combination of field theory and particle-based simulations, we identify two qualitatively distinct regimes of non-reciprocity-induced dynamics. In the regime of weak intra-species alignment, non-reciprocity leads to asymmetric clustering in which only one of the two species forms clusters. Notably, the asymmetric density dynamics is driven alone by non-reciprocal orientational couplings [4,5]. In contrast, in the strongly coupled regime, the corresponding field theory exhibits exceptional points that have been associated with the emergence of chiral phases where the polarization direction rotates over time [2]. Our simulations confirm that spontaneous chirality arises at the particle level. In particular, we observe chimera-like states with coexisting locally synchronized and disordered regions. At the coupling strengths associated with exceptional points, the spontaneous chirality peaks.

DY 3.3 Mon 10:00 H37

Emergent phases in a discrete flocking model with non-reciprocal interaction — •Swarnajit Chatterjee, Matthieu Mangeat, and Heiko Rieger — Center for Biophysics & Department for Theoretical Physics, Saarland University, 66123 Saarbrücken, Germany

Non-reciprocal interactions arise in systems that seemingly violate Newton's third law "actio=reactio". They are ubiquitous in active and living systems that break detailed balance at the microscale, from social forces to antagonistic inter-species interactions in bacteria. Non-reciprocity affects non-equilibrium phase transitions and pattern formation in active matter and represents a rapidly growing research focus in the field. In this work, we have undertaken a comprehensive study of the non-reciprocal two-species active Ising model (NRTSAIM), a non-reciprocal discrete-symmetry flocking model. Our study uncovers a distinctive *run-and-chase* dynamical state that emerges under significant non-reciprocal frustration. In this state, A-particles chase B-particles to align with them, while B-particles avoid A-particles, resulting in B-particle accumulation at the opposite end of the advancing A-band. This run-and-chase state represents a non-reciprocal discrete-symmetry analog of the chiral phase seen in the non-reciprocal Vicsek model. Additionally, we find that self-propulsion destroys the oscillatory state obtained for the non-motile case, and all the NRTSAIM steady-states are metastable due to spontaneous droplet excitation and exhibit motility-induced interface pinning. A hydrodynamic theory supports our simulations and confirms the reported phase diagrams.

DY 3.4 Mon 10:15 H37

Emergent phases in a discrete flocking model with reciprocal interaction — •Matthieu Mangeat[1], Swarnajit Chatterjee[1], Jae Dong Noh[2], and Heiko Rieger[1] — [1]Saarland University, Saarbrücken, Germany — [2]University of Seoul, Seoul, Korea

We have undertaken a comprehensive study of the two-species active Ising model (TSAIM), a discrete-symmetry counterpart of the continuous-symmetry two-species Vicsek model, motivated by recent interest in the impact of complex and heterogeneous interactions on active matter systems. In the TSAIM, two species

of self-propelled particles undergo biased diffusion in two dimensions, interacting via local intraspecies alignment and reciprocal interspecies anti-alignment, along with the possibility of species interconversion. We observe a liquid-gas phase transition, exhibiting macrophase-separated bands, and the emergence of a high-density parallel flocking state, a feature not seen in previous flocking models. With species interconversion (species-flip dynamics), the TSAIM corresponds to an active extension of the Ashkin-Teller model and exhibits a broader range of steady-state phases, including microphase-separated bands that further enrich the coexistence region. We also find that the system is metastable due to droplet excitation and exhibits spontaneous motility-induced interface pinning, preventing the system from reaching long-range order at sufficiently low noise. A hydrodynamic theory complements our computer simulations of the microscopic model and confirms the reported phase diagrams.

DY 3.5 Mon 10:30 H37

Emergent collective behavior from cohesion and alignment — •Jeanine Shea and Holger Stark — Technische Universität Berlin, Institut für Theoretische Physik, Hardenbergstr. 36, 10623 Berlin, Germany.

Collective behavior is all around us, from flocks of birds to schools of fish. These systems are immensely complex. To explore their basic characteristics, we introduce a minimal model for cohesive and aligning self-propelled particles in which group cohesion is established through additive, non-reciprocal torques [1]. These torques cause constituents to effectively turn towards one another, while an additional alignment torque competes in the same spatial range. By changing the strength and range of these torque interactions, we uncover six states which we distinguish via their static and dynamic properties. These states range from disperse particles to closely packed worm-like formations. A number of the states generated by this model exhibit collective dynamics which are reminiscent of those seen in nature.

Invited Talk DY 3.6 Mon 10:45 H37

Collective behavior of photoactive macroscopic particles — •Iker Zuriguel — University of Navarra, Pamplona, Spain

Active matter refers to systems of interacting, self-propelled agents that convert energy into mechanical motion, representing a nice example of out-of-equilibrium systems. In this work, a novel type of active particles is introduced. These are active granular (i.e. they interact solely through physical contacts) and photoactive, meaning that they self-propel using energy from light. Therefore, by means of a programmable LED panel, we are able to change the illumination pattern and, consequently, the particle activity in space and time, allowing a precise exploration of a variety of scenarios related to collective behavior. This possibility has been exploited in microscopic systems but is genuinely new in macroscopic ones.

First, we will present the clustering behavior of these agents under homogeneous illumination. By varying the illumination intensities and changing the population size, we observed a power-law-like distribution for both the cluster sizes and durations. We identified a transition from unstable to stable clusters, as indicated by the divergence of average cluster durations. Higher particle activities and smaller populations led to the creation of small unstable clusters, while lower particle activities and larger populations result in big, stable clusters that persist over time. This transition is explained with the help of a simple model capturing the most important processes involved in cluster dynamics. In the last part of the talk, the collective behavior under inhomogeneous illumination patterns will be introduced.

15 min. break

DY 3.7 Mon 11:30 H37

Swarming model with minority interaction exhibits temporal and spatial scale-free correlations — •Simon Syga[1], Chandraniva Guha Ray[2,3,4], Josué Manik Nava Sedeño[5], Fernando Peruani[6,7], and Andreas Deutsch[1] — [1]Technische Universität Dresden — [2]Max Planck Institute for the Physics of Complex Systems — [3]Max Planck Institute of Molecular Cell Biology and Genetics — [4]Center for Systems Biology Dresden — [5]Universidad Nacional Autónoma de México — [6]Université Côte d'Azur, Nice — [7]CY Cergy Paris Université

Collective motion is a widespread phenomenon in social organisms, from bird flocks and fish schools to human crowds and cell groups. Swarms of birds and fish are particularly fascinating for their coordinated behavior and rapid escape maneuvers during predator attacks. Critical motion is hypothesized as an optimal trade-off between cohesive group behavior and responsiveness to well-informed individuals. However, traditional models only show criticality at the phase transition between ordered and unordered motion. Here, we extend the Vicsek model with a minority interaction, where individuals primarily follow neighbors but can switch to follow a defector moving against a well-aligned group. This triggers cascades of defections, leading to rich dynamics, including large-scale fluctuations, scale-free velocity distributions, and a scale-free return time distribution of the order parameter. Our model underscores the biological importance of minority interactions in swarming and their role in critical behavior.

DY 3.8 Mon 11:45 H37

'Predator-prey' driven swarmalator systems — •Ginger E. Lau, Mario U. Gaimann, and Miriam Klopotek — Stuttgart Center for Simulation Science (SimTech), Cluster of Excellence EXC 2075, University of Stuttgart, Germany

Swarmalators are an active matter system of oscillators which exhibit swarming and collective motion in physical space, as well as synchronization behavior in an additional phase variable space, originally introduced by O'Keeffe *et al.* (*Nat. Commun.* 8(1), 1504, 2017). Such systems with bidirectional couplings in space and phase can be observed in nature, such as in the chorusing behavior of Japanese tree frogs characterized by Aihara *et al.* (*Sci. Rep.* 4(1), 3891, 2014). The interplay between attraction, repulsion, and phase synchronization provides several distinct regimes of self-organizational behavior. Akin to biological swarm systems responding to predator interactions, swarmalators can respond collectively to external perturbations by a repulsive driver. In previous work, driving was realized with a mobile 'pacemaker' by Xu *et al.* (*Chaos* 34(11), 113103, 2024). The present study introduces a new 'predator-prey' driven swarmalator model showing rich adaptive behavior. This could have a wide variety of potential future applications, from biological physics to swarm robotics to nature-inspired learning algorithms and methods of inference.

DY 3.9 Mon 12:00 H37

Inertial active matter governed by Coulomb friction — •Alexander Antonov[1], Lorenzo Caprini[2], and Hartmut Löwen[1] — [1]Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany — [2]University of Rome La Sapenzia, Rome, Italy

Coulomb, or dry friction, is a common phenomenon that can be encountered in various systems, such as granular matter or Brownian motors. The Coulomb friction force resists the motion and, unlike the friction in wet systems, is almost independent of the relative velocity. We show that this characteristic feature of Coulomb friction leads to emergence of dynamical states when subjected to active, or self-propelled motion [1]. At low activity levels, the dynamics resembles Brownian motion, while at greater activity, a dynamic Stop & Go regime emerges, marked by continuous switching between diffusion and accelerated motion. At even higher activity levels, a super-mobile regime arises, characterized by fully accelerated motion and an anomalous scaling of the diffusion coefficient with activity. Near the transition between the Stop & Go and super-mobile regimes, we reveal a novel activity-induced phase separation in collective behavior [2]. Our theoretical findings have been also demonstrated in experiments, where vibrobots on a horizontal surface are activated by vertical oscillations generated using an electromagnetic shaker.

DY 3.10 Mon 12:15 H37

Active nematic turbulence with substrate friction — •Peter A. E. Hampshire[1,2] and Ricard Alert[1,2,3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Center for Systems Biology Dresden, Dresden, Germany — [3]Cluster of Excellence Physics of Life, Dresden, Germany

Active nematics with high activity exhibit turbulent-like flows, characterized by vortices, spatio-temporal chaos and power laws in the energy spectra [1-3]. Continuum models have been successfully used to predict the scaling of the energy spectra with the wavevector. Most theoretical work has focused on free-standing, active nematic films. However, in several experimental realisations, such as bacterial colonies and epithelial monolayers, the active nematic is in contact with a solid substrate. We generalised a 2D, incompressible active nematic model to include substrate friction, and studied its impact on the transition to turbulence and the energy spectra of the turbulent-like flows. We find a variety of dynamic states including flow in lanes, stable vortices and both isotropic and anisotropic turbulence. At high activity and moderate friction, we found a power-law scaling in the kinetic energy spectrum $E(q) \sim q^3$, where q is the wavevector, at low wavevectors. The exponent of 3 can be justified with a power-counting argument. Overall, we have developed a model for active nematic turbulence on a substrate that can be compared to biological systems. [1] L. Giomi, *Phys. Rev. X* **5**, 031003 (2015). [2] R. Alert, J.-F. Joanny, J. Casademunt, *Nat. Phys.* **16**, 682-688 (2020). [3] B. Martínez-Prat*, R. Alert*, et al., *Phys. Rev. X* **11**, 031065 (2021).

DY 3.11 Mon 12:30 H37

Self-sustained patchy turbulence in shear-thinning active fluids — •Henning Reinken and Andreas M. Menzel — Otto-von-Guericke-Universität Magdeburg

Bacterial suspensions and other active fluids are known to develop highly dynamical vortex states, denoted as active or mesoscale turbulence. We reveal the pronounced effect of non-Newtonian rheology of the carrier fluid on these

turbulent states, concentrating on shear thinning. As a consequence, a self-sustained heterogeneous state of coexisting turbulent and quiescent areas develops, which results in anomalous velocity statistics. The heterogeneous state emerges in a hysteretic transition under varying activity. We provide an extensive numerical analysis and find indirect evidence for a directed percolation transition. Our results are important, for instance, when addressing active objects in biological media with complex rheological properties.

DY 4: Focus Session: Nonlinear Dynamics and Stochastic Processes – Advances in Theory and Applications I

Deterministic chaos and stochastic processes are often seen as opposites. However, not only do they share the aspect of being mechanisms for irregular temporal fluctuations, but more importantly, the theory of stochastic processes has helped to understand and quantify many aspects of chaos. Deterministic diffusion, intermittency, long-range temporal correlations can be generated by simple deterministic systems, but are conveniently characterized by concepts of stochastic processes. In both classes of systems, the inclusion of time delays in feedbacks through memory kernels has introduced additional phenomena, and more recently non-normalizable distributions have been found as causes of ageing. While a unified approach to chaos and stochastics is fascinating and satisfying from a theoretical point of view, it also has surprisingly strong application relevance. Examples include the study of turbulence, the nonlinear dynamics of wind turbines, industrial processes for metal milling and turning, laser dynamics, cardiac dynamics, and neuronal systems.

Welcome and Remarks — •Robert Magerle[1], Holger Kantz[2], and Theo Geisel[3] — [1]Technische Universität Chemnitz, Institut für Physik, 09126 Chemnitz, Germany — [2]Max Planck Institute for the Physics of Complex Systems, 01187 Dresden, Germany — [3]Max Planck Institute for Dynamics and Self-Organization, 37077 Göttingen, Germany

Welcome and introductory remarks.

Invited Talk DY 4.2 Mon 9:45 H43

Physical application of infinite ergodic theory — •Eli Barkai — Phys. Dept. Bar-Ilan University, Ramat-Gan, Israel

Norm conserving dynamical mappings, for example the Pomeau Manneville scenario for intermittency, exhibit either a normalized invariant density or an infinite (non-normalized) state, depending on the non-linearity of the map. In the latter case infinite ergodic theory plays a key role in the description of time averages. We will present physical applications of infinite ergodic theory in the context of stochastic Langevin dynamics [1] where the normalizing partition function diverges, and for a gas of laser cooled atoms [2]. This allows for the construction of thermodynamical relations in a non-equilibrium setting, provided that the dynamics is recurrent.

DY 4.3 Mon 10:15 H43

Towards a model-free inference of hidden states and transition pathways — •Xizhu Zhao[1], Dmitrii E. Makarov[2], and Aljaž Godec[1] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]University of Texas at Austin, Austin, Texas, USA

Experiments on biophysical systems typically probe lower-dimensional observables, which are projections of high-dimensional dynamics. In order to infer a consistent model capturing the relevant dynamics of the system, it is important to detect and account for the memory in the dynamics. We develop a method to infer the presence of hidden states and transition pathways based on transition probabilities between observable states conditioned on history sequences for projected (i.e. observed) dynamics of Markov chains. The histograms conditioned on histories reveal information on the transition probabilities of hidden paths locally between any specific pair of states, including the duration of memory. The method can be used to test the local Markov property of observables. The information extracted is also helpful in inferring relevant hidden transitions which are not captured by a Markov-state model.

DY 4.4 Mon 10:30 H43

Interaction statistics in persistent Lotka-Volterra communities — •Joseph Baron[1], Thomas Jun Jewell[3], Christopher Ryder[4], and Tobias Galla[2] — [1]University of Bath, UK — [2]IFISC, Palma de Mallorca, Spain — [3]University of Oxford, UK — [4]University of Manchester, UK

One criticism that was levelled at Robert May's seminal ecological work, which posited random interactions to describe the stability of many-species ecological communities, was that such interactions may not arise naturally in any reasonable model of the ecosystem dynamics. In this talk, I discuss the kinds of interactions that arise between species in communities modelled by generalised Lotka-Volterra dynamics. Far from being iid random variables, there is an intricate structure of correlations between different species' interactions. These arise due to constraints on the species abundances that are imposed by the dynamics. I show that in order to correctly predict stability, one can no longer think of species as being statistically equivalent – a hierarchy amongst the species naturally emerges, even when the initial pool of species are statistically interchangeable. In a similar vein, I also show how the initial interaction network between species is warped by the Lotka-Volterra dynamics, changing the degree distribution, and introducing correlations between a species' connectivity and its interaction statistics. In the end, we see that the interactions in coexisting communities have non-trivial statistical interdependencies, and understanding this statistical structure can help us to understand which species are able to persist in a particular community.

DY 4.5 Mon 10:45 H43

Reduced order stochastic modeling of turbulent passive scalar mixing — Abhishek Joshi, Tommy Starick, •Marten Klein, and Heiko Schmidt — BTU Cottbus-Senftenberg, Cottbus, Germany

Turbulent mixing is composed of chaotic stirring (macromixing) and molecular diffusion (micromixing). The detailed numerical modeling of turbulent mixing has remained a challenge since all relevant flow scales have to be represented in a computationally feasible manner. Map-based stochastic modeling approaches address this challenge by a radical abstraction, which is accomplished by dimensional reduction and utilization of generalized baker's maps to model turbulent fluid motions. Dimensional reduction introduces limitations, but the modeling approach offers interpretability of the emerging complexity and, hence, further physical insight into turbulent mixing. In this contribution, the Hierarchical Parcel Swapping (HiPS) [Kerstein, J. Stat. Phys. 153, 142–161 (2013)] and the One-Dimensional Turbulence (ODT) [Kerstein, J. Fluid Mech. 392, 277–334 (1999)] models are used to study turbulent mixing of passive scalars. Both models aim to represent the state space of 3-D turbulent mixing by a 1-D computational domain. HiPS is a fully event-based mixing model with prescribed sampling from a turbulent cascade, whereas ODT employs an energy-based rejection sampling only for macromixing such that a turbulent cascade is the result of a prescribed physical forcing mechanism. Capabilities of both models are demonstrated for canonical single and multiple passive scalar mixing cases using standalone model formulations across diffusivities.

DY 4.6 Mon 11:00 H43

Which methods are best suited for predicting chaotic time series? — •Ulrich Parlitz — Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany

Since the pioneering work in the 1980s on approximating the time evolution of dynamical systems using delay embedding, many methods for predicting univariate and multivariate chaotic time series have been proposed and published. Recently, the prediction of chaotic time evolution has also been used to demonstrate the performance of novel machine learning algorithms, but in many cases only low-dimensional chaos is considered, as generated by the classical Lorenz-63 system. In this talk, different prediction methods will be contrasted and compared in terms of their prediction power and complexity when applied to low- and high-dimensional chaotic time series.

Invited Talk DY 4.7 Mon 11:30 H43

Modelling the movements of organisms: Movement ecology meets active particles and anomalous diffusion — •Rainer Klages — Centre for Complex Systems, School of Mathematical Sciences, Queen Mary University of London

Organisms living at very different spatio-temporal scales, from migrating in the microworld to foraging at the surface of the earth, typically all display random-looking movement patterns. Understanding these complex patterns by constructing mathematical models from data provides a fundamental challenge. In this talk I first review fundamental stochastic models for understanding movement data, like random walks, Langevin equations and active Brownian particles. On this basis experimental data for the movement paths of foraging sea turtles, migrating cells and bumblee flights is analysed. For all three examples generalised overdamped Langevin equations are constructed from data revealing active and anomalous diffusive properties. I then put forward a generalised underdamped Langevin equation for modelling organismic movements, which blends key ingredients of the three fields of movement ecology, active particles and anomalous diffusion. I illustrate the application of this equation for constructing a stochastic model of bumblebee flights from experimental data and outline its theoretical foundation.

DY 4.8 Mon 12:00 H43

Self-diffusion anomalies of an odd tracer in soft-core media — Pietro Luigi Muzzeddu[1], •Erik Kalz[2], Andrea Gambassi[3,4], Abhinav Sharma[5,6], and Ralf Metzler[2] — [1]University of Geneva — [2]University of Potsdam — [3]SISSA, Trieste — [4]INFN, Trieste — [5]University of Augsburg — [6]IPF, Dresden

Odd-diffusive systems, characterised by broken time-reversal and/or parity symmetry, have recently displayed counterintuitive features such as interaction-enhanced dynamics in the dilute limit. Here we extend the investigation to the high-density limit of an odd tracer embedded in a soft Gaussian core medium (GCM) using a field-theoretic approach based on the Dean-Kawasaki equation. Our theory reveals that interactions can enhance the dynamics of an odd tracer even in dense systems. We demonstrate that oddness results in a complete reversal of the well-known self-diffusion (Ds) anomaly of the GCM. Ordinarily, Ds exhibits a non-monotonic trend with increasing density, approaching but remaining below the interaction-free diffusion, D0, (Ds < D0) so that Ds approaches D0 at high densities from below. In contrast, for an odd tracer, self-diffusion is enhanced (Ds > D0) and the GCM anomaly is inverted, such that Ds approaches D0 at high densities from above. The transition between the standard and reversed GCM anomaly is governed by the tracer's oddness, with a critical oddness value at which the tracer diffuses as a free particle (Ds = D0) across all densities. — arXiv:2411.15552

DY 4.9 Mon 12:15 H43

Memory effects and non-linear responses in colloidal depinning — Arthur V. Straube[1,2] and •Felix Höfling[2,1] — [1]Zuse-Institut Berlin — [2]Institut für Mathematik, Freie Universität Berlin

Particle transport in inhomogeneous environments is complex and typically exhibits non-Markovian responses. The latter can be quantified by a memory function within the framework of the linear generalised Langevin equation (GLE). Here, we exemplify the implications of steady driving on the memory of a colloidal model system for Brownian motion in a corrugated potential landscape, a prototypical set-up to study depinning and non-linear responses far from equilibrium [1,2]. Relying on exact solutions of the model, we show that the random force entering the GLE displays a bias far from equilibrium, which corroborates a recent more general prediction. Based on Brownian dynamics simulations, we show that already moderate driving accelerates the decay of the memory function by several orders of magnitude in time. Moreover in equilibrium, the memory persists much longer than suggested by the timescales of the mean-square displacement. Furthermore, the memory function changes from a monotonic decay to non-monotonic, damped oscillations, which can be understood from a competition of confined motion and depinning. The simulated transport process also is pronouncedly non-Gaussian, which questions the usual Gaussian approximation of the random force in the GLE.

Non-Gaussian random forces in the generalized Langevin equation — •Hélène A. Colinet and Roland R. Netz — Freie Universität Berlin

The generalized Langevin equation (GLE), derived by projection from a general many-body Hamiltonian, exactly describes the dynamics of an arbitrary coarse-grained variable in a complex environment. The complementary force term (typically called a random force) describes the interaction with the environment, and is characterized by its second moment, linking it to the time-dependent friction memory kernel. For practical applications, this complementary force is commonly modeled as a Gaussian stochastic process, thus neglecting higher-order moments, which can become a bad approximation for non-linear systems. Leveraging advanced GLE extraction and simulation techniques, we explore the limitations of the Gaussian assumption and examine the role of non-Gaussian random forces in protein folding and conformational changes.

Chemo-mechanical motility modes of partially wetting liquid droplets — •Florian Voss[1] and Uwe Thiele[1,2] — [1]Institute for Theoretical Physics, University of Münster, Germany — [2]Center for Nonlinear Science, University of Münster, Germany

We consider a simple thermodynamically consistent model that captures the interplay between an autocatalytic reaction of chemical species on the free surface of a droplet, the solutal Marangoni effect and the physics of wetting in the presence of chemical fuel [1]. We find that a positive feedback loop between the local reactions and the Marangoni effect induces surface tension gradients, allowing for self-propelled droplets. Besides simple directional motion, we find crawling, shuttling and randomly moving droplets. We study the occurring dynamics and show how the observed states generically emerge from (global) bifurcations. We speculate that our results may also be relevant to the study of cell crawling [2] and self-propelled biomolecular condensates [3].

The scaling behaviour of localised and extended states in one-dimensional tight-binding models with disorder — •Luca Schaefer and Barbara Drossel — Technische Universität Darmstadt, Hochschulstraße 6, 64289 Darmstadt

We investigate two one-dimensional tight-binding models with disorder that have extended states at zero energy. We use the eigenmodes of the Hamiltonian and the associated participation ratios, and the transfer-matrix method to determine the localisation length. The first model has no on-site disorder, but random couplings. While the participation ratio remains finite at zero energy, the localisation length diverges logarithmically as the energy goes to zero. We provide an intuitive derivation of this logarithmic divergence based on the weak coupling of the two sublattices. The second model has a conserved quantity as the row sums of the Hamiltonian are zero. This model can be represented as a harmonic chain with random couplings, or as a diffusion model on a lattice with random links. We find, in agreement with existing analytical calculations, that the number of system-spanning eigenmodes increases proportionally to the square root of the system size, and we related this power law to other power laws that characterise the scaling behaviour of the eigenmodes, the participation ratio, the localisation length, and their dependence on energy and system size. When disorder is so strong that the smallest hopping terms can be arbitrarily close to zero, all these power laws change, and we show a crossover between the two scaling regimes. All these results are explained by intuitive arguments based on scaling.

DY 5.2 Mon 9:45 H47

How hidden free energy landscapes imprint on the time-ordering of observed states — •Francesco Malcangi and Aljaz Godec — Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany

Single molecule experiments, such as FRET, Plasmon Ruler, or optical tweezers, probe low (often one-) dimensional projections of high dimensional dynamics. Unless the unobserved, hidden degrees of freedom relax much faster than the observable, the projection induces memory effects. By accessing the information encoded in the time-ordering of projected states, we show in our work that opportunely chosen functionals of observed paths, in particular their fluctuations and correlations, may be used to infer the presence of hidden free-energy barriers, multiple pathways, and even irreversible drifts. These hidden features are found to display common manifestations upon projection, which together with the comparison with manifestly Markovian dynamics in the free energy landscape may be used as a diagnostic tool. We demonstrate our findings with illustrative examples.

DY 5.3 Mon 10:00 H47

Long-term behavior of master equations on a countable system — •Bernd Michael Fernengel[1], Thilo Gross[1], and Wolfram Just[2] — [1]HIFMB, Oldenburg, Germany — [2]University of Rostock, Rostock, Germany

Master equations play a crucial role in natural science, as they describe the time evolution of probability distributions of all systems that can be modeled as directed, weighted graphs. Despite their essential role, computing a solution is often avoided and authors refer to numerical methods or approximation techniques instead.

We present both a mathematically sound framework for master equations on a discrete, countable configuration space as well as sufficient conditions the generator of the master equation must have for the time limit t -> infinity to converge, which is not guaranteed on an infinite dimensional space.

We discuss the assumptions for the possibility of interchanging the thermodynamic limit and the time limit. This makes it possible to obtain the long-term behavior of an infinite system from a thermodynamic limit of stationary solutions of corresponding finite subnetworks.

Our method is demonstrated by a few examples of master equations on linear, infinitely long chains, with one- and two open ends.

DY 5.4 Mon 10:15 H47

Density Fluctuations, Solvation Thermodynamics and Coexistence Curves in Grand Canonical Molecular Dynamics Simulations — •Mauricio Sevilla, Luis A. Baptista, Kurt Kremer, and Robinson Cortes-Huerto — Max Planck Institute for Polymer Research

The physics of externally driven systems is a challenge as the complexity of the amount of effects involved, yet crucial to be understood as it is present in many biological systems. Aiming to build a computational method to deal with such situations, it is first needed to reproduce correctly the equilibrium statistics of open systems. However, open-boundary computational methods are scarce and often do not satisfy all the conditions imposed by reality. The system of interest (SoI) must be at thermodynamic and chemical equilibrium with an infinite reservoir of particles. The fluctuations of the SoI in equilibrium should sample the grand canonical ensemble. The local solvation thermodynamics, extremely sensitive to finite-size effects due to particle depletion, should be correctly described. The method should be robust enough to deal with phase transitions and coexistence conditions that might occur in the SoI. In this context, the adaptive resolution method (AdResS), where the system's atomistic and ideal gas representations coexist at constant thermodynamic and chemical equilibrium, emerges as a promising alternative. Indeed, in this talk, we demonstrate with prototypical liquid systems that AdResS, coupled with particle insertion/deletion steps, satisfies all these requirements, and it is thus a suitable method to perform simulations of open systems.

DY 5.5 Mon 10:30 H47

Optimal control of fluid transitions in a Lennard-Jones like system — •William D. Pineros and Etienne Fodor — Department of Physics and Material Science, University of Luxembourg, 162a, avenue de la Faïencerie, L1511, Luxembourg

We study optimal control transitions in a system of Lennard-jones like fluid via a linear-response framework whose solutions correspond to minimum dissipation protocols in a thermodynamic space. In particular, we investigate fluid-fluid transitions via changes in particle size and attraction strength both in the homogenous and phase separated state. We compute the underlying friction tensor, representing the ease of parameter change in this space, directly from simulations and compare against an analytical approximation for low density fluids at the continuum level.

DY 5.6 Mon 10:45 H47

Noether-constrained correlations and hyperforces in equilibrium liquids — •Sophie Hermann[1,2], Silas Robitschko[1], Florian Sammüller[1], and Matthias Schmidt[1] — [1]Universität Bayreuth, Bayreuth, Germany — [2]Sorbonne Université/CNRS, Paris, France

Noether's calculus of invariant variations in statistical mechanics yields exact identities ("sum rules") from functional symmetries. The invariance of spatial transformation of the underlying classical many-body Hamiltonian at first order in the transformation field Noether's theorem yields the local force balance. At second order three distinct two-body correlation functions emerge, namely the standard two-body density, the localized force-force correlation function, and the localized force gradient. An exact Noether sum rule interrelates these correlators. More generally exploiting invariance of a thermally averaged classical phase space functions results in hyperforce sum rules. These relate the mean gradient of a phase-space function to its negative mean product with the total force. As applications we investigate via computer simulations (including Lennard-Jones liquids, monatomic water and a colloidal gel former) the emerging one-body force fluctuation profiles in bulk and confined liquids. These local correlators quantify spatially inhomogeneous self-organization, demonstrate their fundamental role in the characterization of spatial structure and their measurement allows for the development of stringent convergence tests and enhanced sampling schemes in complex systems.

DY 5.7 Mon 11:00 H47

Hybrid particle-phase field model and renormalized surface tension in dilute suspensions of nanoparticles — •Alexandra Hardy, Abdallah Daddi-Moussa-Ider, and Elsen Tjhung — The Open University, Milton Keynes, UK

We present a two-phase field model and a hybrid particle-phase field model to simulate dilute colloidal sedimentation and flotation near a liquid-gas interface (or fluid-fluid interface in general). Both models are coupled to the incompressible Stokes equation, which is solved numerically using a combination of sine and regular Fourier transforms to account for the no-slip boundary conditions at the boundaries. The continuum two-phase field model allows us to analytically solve the equilibrium interfacial profile using a perturbative approach, demonstrating excellent agreement with numerical simulations. Notably, we show that strong coupling to particle dynamics can significantly alter the liquid-gas interface, thereby modifying the liquid-gas interfacial tension. In particular, we show that the renormalized surface tension is monotonically decreasing with increasing colloidal particle concentration and decreasing buoyant mass.

The square lattice Ising model with quenched surface disorder — Luca Cervellera, Oliver Oing, Jan Büddefeld, and •Fred Hucht — Fakultät für Physik, Universität Duisburg-Essen

Using exact enumeration, the Casimir amplitude and the Casimir force are calculated for the square lattice Ising model with quenched surface disorder on one surface in cylinder geometry at criticality. The system shape is characterized by the aspect ratio $\rho = L/M$, where the cylinder length L can take arbitrary values, while the circumference M is varied from $M = 4$ to $M = 54$, resulting in up to 2^{54} numerically exact free energy calculations. A careful $M \to \infty$ extrapolation shows that quenched surface disorder is irrelevant in two dimensions, but gives rise to logarithmic corrections.

DY 6.2 Mon 11:45 H47

Partition Function Zeros of the Frustrated J_1-J_2 Ising Model on the Honeycomb Lattice — •Denis Gessert[1,2], Martin Weigel[3], and Wolfhard Janke[1] — [1]Institut für Theoretische Physik, Leipzig University, 04081 Leipzig, Germany — [2]Centre for Fluid and Complex Systems, Coventry University, Coventry CV1 5FB, United Kingdom — [3]Institut für Physik, Technische Universität Chemnitz, 09107 Chemnitz, Germany

We study the partition function zeros in the complex temperature plane (Fisher zeros) and in the complex external field plane (Lee-Yang zeros) of a frustrated Ising model with competing nearest-neighbor ($J_1 > 0$) and next-nearest-neighbor ($J_2 < 0$) interactions on the honeycomb lattice. We consider the finite-size scaling (FSS) of the leading Fisher and Lee-Yang zeros as determined from a cumulant method and compare it to a traditional scaling analysis based on the logarithmic derivative of the magnetization $\partial \ln\langle|M|\rangle/\partial\beta$ and the magnetic susceptibility χ. While for this model both FSS approaches are subject to strong corrections to scaling induced by the frustration, their behavior is rather different, in particular as the ratio $\mathscr{R} = J_2/J_1$ is varied. As a consequence, an analysis of the scaling of partition function zeros turns out to be a useful complement to a more traditional FSS analysis. The scaling of the zeros convincingly shows that the system remains in the Ising universality class for $\mathscr{R}$ as low as -0.22, where results from traditional FSS using the same simulation data are less conclusive. The approach hence provides a valuable additional tool for mapping out the phase diagram of models afflicted by strong corrections to scaling.

DY 6.3 Mon 12:00 H47

Cluster percolation in the three-dimensional $\pm J$ random-bond Ising model — •Lambert Muenster and Martin Weigel — Institut für Physik, TU Chemnitz, 09107 Chemnitz, Germany

We study the relation between cluster percolation and ordering phenomena in the three-dimensional $\pm J$ random-bond Ising model with different fraction of ferromagnetic bonds by performing Monte Carlos simulations. In particular a certain type of two-replica clusters is studied [1,2]. The density of these clusters can be linked to the overlap. We start the analysis with the pure ferromagnet

and demonstrate that the percolation transition maps onto the ferromagnetic phase transition. Then, we continue our analysis with the frustrated disordered ferromagnet and finally consider the spin-glass system where half of all bonds are anti-ferromagnetic and point out differences as well as similarities between the cases.

Analysis of the Mpemba effect in magnetic systems — •Janett Prehl and Martin Weigel — Technische Universität Chemnitz, Chemnitz, Deutschland

The Mpemba effect, first discovered by Mpemba and Osborne for water [1], is observed when a hot sample cools faster than an initially colder one, when both are refrigerated in the same thermal reservoir. During the last years this effect has also been found to take place in the general context of magnetic phase transitions of different orders [2–4]. Here, we investigate and discuss the occurrence of this non-equilibrium process for different ferromagnetic models exhibiting a phase transition at a critical temperature T_c. We aim to analyze how different initial temperatures, structural properties or updating dynamics influence the time behavior of quantities such as energy per spin $\langle e \rangle$ or the average domain length ℓ for different system sizes L to get a deeper insight in the occurring mechanism of the Mpemba effect for the systems under consideration.

Relating phase transitions of confined materials and topology of pore network — Georgiy Baroncha[1], Rustem Valiullin[1], and •Eustathios Kikkinides[2] — [1]Leipzig University, Leipzig, Deutschland — [2]Aristotle University of Thessaloniki, Thessaloniki, Griechenland

Measuring adsorption/desorption and melting/freezing transitions in porous materials is a common route to obtain information about pore structure. To describe phase transition behavior we exploit statistical network models including cooperative effects. In this way, important properties such as pore size distribution can be deduced. By constructing statistically-disordered random-brunching Bethe lattices we show that the average pore connectivity can be assessed. However, phase transitions remain insensitive to fine details of pore network, namely its topology. Further we discuss the experimental approaches to probe pore network topology.

DY 6.6 Mon 12:45 H47

Study of the de Almeida-Thouless (AT) line in the one-dimensional diluted power-law XY spin glass — •Ramana Bharadwaj Vedula — IISER Bhopal, Bhopal, India

The behavior of finite-dimensional spin glasses at low temperatures has been debated for decades, with the replica symmetry breaking (RSB) and droplet pictures offering competing explanations. This work investigates the Almeida-Thouless (AT) line in the one-dimensional power-law diluted XY spin glass model, where interactions decay as $1/r^{2\sigma}$. Tuning σ emulates dimensional changes, bridging mean-field and non-mean-field regimes.

A novel heatbath algorithm was developed to efficiently equilibrate XY spins at low temperatures. Using this, we studied phase transitions for $\sigma = 0.6\ (< 2/3)$, where clear evidence for an AT line exists, and for $\sigma = 0.75,\ 0.85\ (> 2/3)$, where the evidence weakens. Interestingly, data for $\sigma = 0.75$ and $\sigma = 0.85$ suggest finite-size effects mimic RSB-like behavior, but analysis aligns with the droplet picture.

Unlike traditional approaches, we also varied the magnetic field at fixed temperature, providing unique insights into spin glass properties. Our results show that the AT line disappears as σ increases, favoring the droplet model for low-dimensional spin glasses.

Emerging cellular dynamics from turbulent flows steered by active filaments — Mehrana Nejad[1,4], Julia Yeomans[2], and •Sumesh Thampi[2,3] — [1]Department of Physics, Harvard University, Cambridge, MA 02138 — [2]The Rudolf Peierls Centre for Theoretical Physics, Parks Road, Oxford OX1 3PU, UK — [3]Department of Chemical Engineering, Indian Institute of Technology, Madras, Chennai, India 600036 — [4]School of Engineering and Applied Sciences, Harvard University, Cambridge, MA 02138, USA

Describing the mechanics of cell collectives and tissues within the framework of active matter, without resorting to the details of biology is an exciting area. We develop a continuum theory to describe the dynamics of cellular collectives, discerning the cellular force-generating active filaments from cells shape. The theory shows that active flows and straining part of the active turbulence can elongate isotropic cells, which form nematic domains. This is important as cell morphology is not only an indicator of diseases but it can affect the nucleus morphology, gene expression and other biochemical processes inside the cells. Our theory highlights the importance of distinguishing the roles of active filaments from cell shape and explains outstanding experimental observations such as the origin of cell-filament alignment patches. Further, we reconcile how the contractile forces generated by the cytoskeletal network makes the cells to exhibit flow behaviours similar to that of extensile active systems. Revealing the crucial role of activity and rheology to describe the dynamics of cellular layers, our study is in consonance with a number of experimental observations.

DY 7.2 Mon 15:15 H37

Defects in active solids: self-propulsion without flow — •Fridtjof Brauns[1], Myles O'Leary[2], Arthur Hernandez[3], Mark Bowick[1], and Cristina Marchetti[4] — [1]Kavli Institute for Theoretical Physics, Santa Barbara, USA — [2]Princeton University, Princeton, USA — [3]Leiden University, Leiden, the Netherlands — [4]University of California Santa Barbara, Santa Barbara, California 93106, USA

Topological defects are a key feature of orientational order and act as organizing centers of orientation fields. Self-propulsion of +1/2 defects has been extensively studied in active nematic fluids, where the defects are advected with the fluid through the flow field they generate. Here, we propose a minimal model for defect self-propulsion in a nematic active solid: a linear elastic medium with an embedded nematic texture that generates active stress and in turn is coupled to elastic strain. We show that such coupling gives rise to self-propelled +1/2 defects that move relative to the elastic medium by local remodeling of the nematic texture. This mechanism is fundamentally different from the fluid case. We show that this mechanism can lead to unbinding of defect pairs and stabilize +1 defects. Our findings might help explain how orientational order, e.g. of muscle fibers, is reconfigured during morphogenesis in solid-like tissues. For instance, motility and merging of +1/2 defects play a crucial role in setting up the body axis during Hydra regeneration.

DY 7.3 Mon 15:30 H37

Isovolumetric dividing active matter — Samantha R. Lish[1], Lukas Hupe[1], Ramin Golestanian[1,2], and •Philip Bittihn[1] — [1]Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — [2]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, Oxford OX1 3PU, United Kingdom

We introduce and theoretically investigate a minimal particle-based model for a new class of active matter where particles exhibit directional, volume-conserving division in confinement while interacting sterically, mimicking cells in early embryogenesis. We find that complex motion, synchronized within division cycles, displays strong collective effects and becomes self-similar in the long-time limit. Introducing the method of normalized retraced trajectories, we show that the transgenerational motion caused by cell division can be mapped to a time-inhomogenous random walk with an exponentially decreasing length scale. Analytical predictions for this stochastic process allow us to extract effective parameters, indicating unusual effects of crowding and absence of jamming. Robustness of our findings against desynchronized divisions, cell size dispersity, and variations in confinement hints at universal behavior. Our results establish an understanding of the complex dynamics exhibited by isovolumetric division over long timescales, paving the way for new bioengineering strategies and perspectives on living matter.

DY 7.4 Mon 15:45 H37

Tracking plankton-to-biofilm transition in phototrophic bacteria — •Anupam Sengupta — Physics of Living Matter Group, Department of Physics and Materials Science, University of Luxembourg, Luxembourg — Institute for Advanced Studies, University of Luxembourg, Luxembourg

Phototrophic bacteria commonly inhabit natural aquatic and marine ecosystems, exhibiting both motile and sessile lifestyles [1]. Yet, how and when they switch between the two states has remained unknown. Using quantitative imaging, AFM and mathematical modeling, we track the conditions and phenotypic changes across multiple generations in Chromatium okenii, a motile pho-

totrophic purple sulfur bacterium [2]. Enhanced cell-surface adhesion together with changes in the cell shape and cellular mass distribution facilitate the motile-to-sessile shift. Our results, supported by cell mechanics model, establish a synergistic link between motility, mass distribution and surface attachment in promoting biofilm lifestyle. [1] T. Sommer et al., Geophys. Res. Lett. 44, 2017. [2] F. Di Nezio,.., & A. Sengupta, Plos one 19, e0310265, 2024.

DY 7.5 Mon 16:15 H37

How localized active noises influence the conformations and dynamics of semiflexible filaments — •Shashank Ravichandir[1], Jens-Uwe Sommer[1,2], and Abhinav Sharma[1,3] — [1]Leibniz-Institut für Polymerforschung, 01069 Dresden, Germany — [2]Technische Universität Dresden, 01069 Dresden, Germany — [3]Universität Augsburg, 86159 Augsburg, Germany

The structure and dynamics of active polymers have been recently studied in some detail. In these works all the monomers are considered to be active. However, in most biological systems non-equilibrium fluctuations manifest as activity only at isolated locations within the polymer. There have been only few studies of such polymers, in which the active monomers occur periodically along the polymer contour. We consider arbitrary active-passive copolymers and isolate the effects of the number and locations of active monomers on the conformational and dynamical properties of polymers. We use Langevin dynamics simulations to calculate the end-to-end distance, radius of gyration, and mean-squared displacement of such semiflexible filaments and classify the various states of these polymers based on their conformational properties. We also present preliminary results of polymers in which the location of active monomer moves dynamically along the chain contour. This is an idealized model of biopolymers such as DNA, during DNA transcription, and microtubules, which are driven by kinetic motors that traverse along its length.

DY 7.6 Mon 16:30 H37

Sequence-specific folding of partially active polymers — •Shibananda Das — Department of Physics, Indian Institute of Science, Bengaluru, India

Biological polymers like actin filaments and microtubules exhibit important physical properties due to their out-of-equilibrium behavior induced by ATP or GTP. In contrast, synthetic polymers rely on energy from their surrounding environment, often using local chemical, electrical, or thermal gradients to remain far from equilibrium. Theoretically, active polymers serve as minimal models for these systems, enabling systematic study of the competition between thermodynamic and active forces while they undergo conformational changes.

Using a combined analytical and numerical approach, we investigate an active polymeric chain composed of multiple self-avoiding units, representing good solvent condition in the absence of active forces. For partially active polymers without orientational constraints, we find that distribution of the active units in distinct sequences along the backbone can induce a significant collapse into folded, globular structures. Detailed analysis shows that this activity-dependent collapse is driven by a reduction in swim pressure of the monomers, linking the distribution of active forces along the polymer contour to its folded conformations.

DY 7.7 Mon 16:45 H37

Effect of interactions on the chemotactic response of active-passive chains — •Hossein Vahid[1], Jens-Uwe Sommer[1,2], and Abhinav Sharma[3] — [1]Leibniz-Institut für Polymerforschung, Dresden, Germany — [2]Technische Universität Dresden, Germany — [3]University of Augsburg, Augsburg, Germany

Living organisms, from single cells to populations, exhibit complex behaviors driven by the need to navigate toward favorable environments. These behaviors are often shaped by interactions within clusters or mixed populations, where collective dynamics play a crucial role in the characteristic properties of multicellular systems.

Chemotactic bacteria, found in diverse environments such as the gastrointestinal tract, plant surfaces, and aquatic ecosystems, demonstrate the significance of chemotaxis at the population level. While extensive research has focused on the properties of active polymers in spatially homogeneous activity fields, their behaviors in inhomogeneous fields remain less explored.

This study investigates the behavior of self-propelled polymers in activity gradients, emphasizing the effects of inter- and intra-chain interactions, such as steric and excluded volume effects, on chemotactic responses. These interactions give rise to distinct phases or collective behaviors that influence the stability and persistence of chemotaxis. Additionally, polymer density emerges as a critical factor impacting diffusion and the overall efficiency of chemotaxis. This work aims to study the dynamics of the active polymer populations in non-uniform environments systematically.

DY 8: Focus Session: Nonlinear Dynamics and Stochastic Processes – Advances in Theory and Applications II

Deterministic chaos and stochastic processes are often seen as opposites. However, not only do they share the aspect of being mechanisms for irregular temporal fluctuations, but more importantly, the theory of stochastic processes has helped to understand and quantify many aspects of chaos. Deterministic diffusion, intermittency, long-range temporal correlations can be generated by simple deterministic systems, but are conveniently characterized by concepts of stochastic processes. In both classes of systems, the inclusion of time delays in feedbacks through memory kernels has introduced additional phenomena, and more recently non-normalizable distributions have been found as causes of ageing. While a unified approach to chaos and stochastics is fascinating and satisfying from a theoretical point of view, it also has surprisingly strong application relevance. Examples include the study of turbulence, the nonlinear dynamics of wind turbines, industrial processes for metal milling and turning, laser dynamics, cardiac dynamics, and neuronal systems.

Spatio-temporal pattern formation in time-delayed optical systems — •Svetlana Gurevich — Institute for Theoretical Physics, University of Münster, Germany

Control and engineering of complex spatio-temporal patterns in high-dimensional non-equilibrium systems has evolved as one of the central issues in applied nonlinear science. However, real-world complex systems can be strongly influenced by time delays due to unavoidable finite signal propagation speeds and time-delayed dynamical systems have proven to be a fertile framework for the modeling of nonlinear phenomena. Nonlinear laser dynamics is one of the fields where time-delayed system are frequently employed to model the arising complex dynamics. In this talk, we will explore time-delayed models to describe the behavior of ultrashort pulses in optical micro-cavities, highlighting their potential for the formation of spatio-temporal structures.

DY 8.2 Mon 15:30 H43

Thermo-optical excitations and mixed-mode oscillations in an injected Kerr microcavity — •Elias Koch[1], Julien Javaloyes[2], and Svetlana Gurevich[1,3] — [1]Institute for Theoretical Physics, University of Münster, Wilhelm-Klemm-Str. 9, 48149 Münster, Germany — [2]Departament de Fisica, Universitat de les Illes Balears & IAC-3, Cra. de Valldemossa, km 7.5, E-07122 Palma de Mallorca, Spain — [3]Center for Nonlinear Science (CeNoS), University of Münster, Corrensstraße 2, 48149 Münster, Germany

We study the dynamics of a vertically emitting micro-cavity containing a Kerr nonlinearity that is subjected to detuned optical injection. To this end, we present an extended model that allows investigation of the influence of cavity heating, which shifts the microcavity resonance and thus the detuning on a slow time scale. As a consequence of this scale separation, we uncover a canard scenario featuring dark and bright excitations, as well as mixed-mode oscillations that can be manipulated by tuning the injection amplitude and frequency. When the microcavity is coupled to a long external feedback loop, subjecting it to strong time-delayed optical feedback, we can examine the additional influence of the time delay on excitability dynamics, as well as the impact of thermal effects on preliminary studies.

DY 8.3 Mon 15:45 H43

Back to the future: Fermi–Pasta–Ulam–Tsingou recurrence in a time-delayed system — •Jonas Mayer Martins[1], Elias Koch[1], Julien Javaloyes[2], and Svetlana V. Gurevich[1] — [1]Institute for Theoretical Physics, University of Münster, Wilhelm-Klemm-Str. 9 and Center for Nonlinear Science (CeNoS), University of Münster, Corrensstrasse 2, 48149 Münster, Germany — [2]Departament de Física and IAC-3, Universitat de les Illes Balears, C/ Valldemossa km 7.5, 07122 Palma de Mallorca, Spain

We demonstrate Fermi–Pasta–Ulam–Tsingou (FPUT) recurrence, a surprising quasi-periodicity of certain spatially extended systems, in a time-delayed system. Although the bi-Riccati system that we study is not integrable, we find in the long-delay limit that its normal form is a partial differential equation approximating the integrable Korteweg–de Vries (KdV) equation, prominently known to exhibit FPUT recurrence. Our results underscore the analogy between spatially extended and time-delayed systems.

DY 8.4 Mon 16:00 H43

Momentum space induced complex billiard dynamics — •Lukas Seemann, Jana Lukin, and Martina Hentschel — Institut für Physik, TU Chemnitz, Deutschland

While billiard models have always been a paradigm to study nonlinear dynamics, their class has been enriched by realistic models such as optical cavities, ballistic quantum dots, or graphene systems over the past decades. The originally hard billiard walls are replaced by confinement through total internal reflection of light or potential wells trapping electrons. They are well-known model systems in the field of mesoscopic physics, quantum chaos, and wave-ray correspondence exhibiting a broad range of dynamical behavior, ranging from regular and mixed to purely chaotic dynamics depending on their geometric shape. However, employing their material-specific properties allows one to influence and even control their complex dynamics in more ways. Using an anisotropy (as for electrons in bilayer graphene systems), one can induce chaotic motion even in a circularly shaped cavity [1]. We develop a ray tracing algorithm for anisotropic media and illustrate how anisotropy affects the billiards dynamics in real and phase space. In particular we show how deformation away from the circular shape in real and momentum space, changes the phase space structure and can be optimized to the formation of large stable island [2] that we quantify using Lyapunov exponents.

Stochastic Properties of Musical Time Series: Measuring Musical Variability — Corentin Nelias and •Theo Geisel — Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany

Music philosophers and psychologists have argued that emotions and meaning in music depend on an interplay of expectation and surprise. We aimed to quantify the variability of musical pieces empirically by considering them as correlated dynamical processes. Using a multitaper method we determined power spectral density (PSD) estimates for more than 550 classical compositions and jazz improvisations down to the smallest possible frequencies [1]. The PSDs typically follow inverse power laws ($1/f^{\beta}$-noise) with exponents near β=1 for classical compositions, yet only down to a cutoff frequency, where they end in a plateau. Correspondingly the pitch autocorrelation function exhibits slow power law decays only up to a cutoff time, beyond which the correlations vanish abruptly. We determined cutoff times between 4 and 100 quarter note units serving as a measure for the degree of persistence and predictability in music. They tend to be larger in Mozart's compositions than in Bach's, which implies that the anticipation and expectation of the musical progression tends to last longer in Mozart's than in Bach's compositions

Nonlinear dynamics and time delays in metal cutting — •Andreas Otto — Fraunhofer Institute for Machine Tools and Forming Technology IWU, Reichenhainer Str. 88, 09126 Chemnitz, Germany

Since products and consequently production processes in manufacturing industry becomes more and more individual, an agile and robust process design is important for minimizing costs while guaranteeing high product quality. A fundamental understanding of the underlying physics of the manufacturing processes is essential for finding sweet spots of high productivity with optimal quality of the produced part.

In this talk, we present some examples from metal cutting, where especially the complex behavior of mechanical vibrations also known as chatter lead to undesired noise, tool wear and scraped parts. We show that mechanical vibrations at machine tools can be described by nonlinear delay differential equations and in many situations the time delay is, in addition, distributed, time-varying or state-dependent. Some recent developments for the prediction of the stability of metal cutting processes with respect to chatter vibrations and applications for online chatter detection are presented.

DY 8.7 Mon 17:15 H43

Stability of power grids concerning strong perturbations - tropical cyclones and increasing resilience — •Jürgen Kurths — Potsdam Institute for Climate Impact Research, Telegraphenberg, 14473 Potsdam

The infrastructure of our modern society is efficient but also sensitive concerning strong perturbations, as terrorist attacks on the cybersystem or extreme climate events. An important part of modern infrastructure are power grids, which are characterized by multistability. For them, the strongly ongoing transition to distributed renewable energy sources leads to a proliferation of dynamical actors. The desynchronization of a few or even one of those would likely result in a substantial blackout. We discuss the concept of basin stability covering strong perturbations and identify most vulnerable motifs in power grids. To consider the vulnerability of power grids against extreme wind loads, we combine a detailed model of of extreme events, and a cascadable model of the transmission network to provide a holistic co-evolution model to consider wind-induced failures of transmission lines in the Texan electrical network.

DY 8.8 Mon 17:30 H43

Critical demand in a stochastic model of flows in supply networks — •Yannick Feld[1] and Marc Barthelemy[1,2] — [1]Université Paris-Saclay, CNRS, CEA, Institut de Physique Théorique, 91191 Gif-sur-Yvette, France — [2]Centre d'Analyse et de Mathématique Sociales (CNRS/EHESS) 54 Avenue de Raspail, 75006 Paris, France

Supply networks are essential to modern production, yet their critical properties remain understudied. This talk presents a stochastic model with random production capacities that allows us to investigate material flow to a root node, focusing on the network topology and buffer stocks. We examine the critical demand at the root, where unsatisfied demand diverges. Without stocks, minimal production governs behavior, and topology is mostly irrelevant. Buffer stocks introduce memory, significantly altering the dynamics. Now the topology is crucial, with local connectivity proving beneficial.

DY 8.9 Mon 17:45 H43

Generalizations of laminar chaos — •David Müller-Bender — Institute of Physics, Chemnitz University of Technology, 09107 Chemnitz, Germany

Laminar chaos was originally discovered in scalar dynamical systems with a large periodically time-varying delay [Phys. Rev. Lett. 120, 084102 (2018)]. This demonstrated how drastically a temporal modulation of the delay can change the dynamics of a system as laminar chaos is an extremely low-dimensional dynamics compared to turbulent chaos, which is observed in such systems with constant delay. In this talk, I give an overview of recent generalizations of laminar chaos to systems with quasiperiodic [Phys. Rev. E 107, 014205 (2023)], random and chaotic delay time modulation. Using a connection to spatially disordered circle maps [Phys. Rev. E 106, L012202 (2022)], it is found that short-time correlated random and chaotic delays lead to low-dimensional generalized laminar chaos in almost the whole delay parameter space spanned by the mean delay and the delay amplitude. This is in stark contrast to the case of a constant delay, where only high-dimensional turbulent chaos is found. Finally, an outlook on laminar chaos in systems with state-dependent delay is given. I acknowledge the contributions of the late Günter Radons to these results.

DY 8.10 Mon 18:00 H43

Chaotic Diffusion in Systems with Delay — •Tony Albers, David Müller-Bender, and Lukas Hille — Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany

Chaotic Diffusion is a purely deterministic phenomenon occurring in nonlinear systems. While much is known about chaotic diffusion in low-dimensional dynamical systems such as iterated maps or Hamiltonian systems, there are only a few works dealing with chaotic diffusion in higher-dimensional systems. In this talk, we show that chaotic diffusion is also possible in dynamical systems with time delay, which raises the dimension of the problem formally to infinity. Moreover, we demonstrate that introducing a periodic modulation of the delay can increase the strength of the diffusion, as measured by the diffusion coefficient, by several orders of magnitude [1]. This phenomenon is counterintuitively related to a significant decrease of the Kaplan-Yorke dimension of the chaotic attractor due to the appearance of so-called laminar chaos [2], which is a recently discovered type of chaos that is not observed in systems with constant delay. We acknowledge the contributions of the late Günter Radons who initiated this work.

DY 8.11 Mon 18:15 H43

Weak generalized synchronization in random neural networks and its impact on time series forecasting — •Hiromichi Suetani[1,2] and Ulrich Parlitz[3,4] — [1]Faculty of Science and Technology, Oita University, Oita, Japan — [2]International Research Center for Neurointelligence , The University of Tokyo, Tokyo, Japan — [3]Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — [4]Institute for the Dynamics of Complex Systems, Universität Göttingen, Göttingen, Germany

Time series forecasting is one of the important issues in data science, and approaches based on reservoir computing (RC), have been attracting attention. Previous studies have often suggested that the hyperparameter region at the so-called "edge of chaos," provides optimal performance in time series forecasting. But this concept is problematic because generally a reservoir is a non-autonomous dynamical system driven by external inputs, it should be referred to as the "edge of conditional stability" rather than the edge of chaos.

In this study, we argue that this is not just a matter of terminology, and that the edge of conditional stability does not provide optimal performance. For this purpose, we clarify the relevance of the concept of "weak generalized synchronization (W-GS)." This study demonstrates that random neural networks driven by chaotic inputs exhibit W-GS and shows that the fractal nature of the GS function affects forecasting ability. We quantitatively compare the relationship between the characteristics of GS and those of RC, such as the information processing capacity, to elucidate the role of GS in RC.

Shear-driven diffusion with stochastic resetting — •Iman Abdoli, Kristian Stølevik Olsen, and Hartmut Löwen — Institut für Theoretische Physik II - Weiche Materie, Heinrich-Heine-Universität Düsseldorf, D-40225 Düsseldorf, Germany

Here, we explore the non-equilibrium dynamics that emerge from the interplay between linear shear flow and stochastic resetting. The particle diffuses with a constant diffusion coefficient while simultaneously experiencing linear shear and being stochastically returned to its initial position at a constant rate. We perturbatively derive the steady-state probability distribution that captures the effects of shear-induced anisotropy on the spatial structure of the distribution. We show that the dynamics, which initially spread diffusively, will at late times reach a steady state due to resetting. At intermediate timescales, the system approaches this steady state either by passing through a superdiffusive regime (in the shear-dominated case) or by exhibiting purely sub-diffusive behavior (in the resetting-dominated case). The steady state also gains cross correlations, a feature absent in simpler resetting systems. We also show that the skewness has a non-monotonic behavior when one passes from the shear-dominated to the resetting-dominated regime. We demonstrate that at small resetting rates, the energetic cost of maintaining the steady state becomes significantly higher due to the displacement caused by shear, a unique scaling not seen without shear. Surprisingly, if only the x-position is reset, the system can maintain a Brownian yet non-Gaussian diffusion pattern with non-trivial tails in the distribution.

DY 9.2 Mon 15:15 H47

Propulsion force and heat exchange for nonreciprocal nanoparticles — •Laila Henkes[1], Kiryl Asheichyk[2], and Matthias Krüger[1] — [1]Institute for Theoretical Physics, Georg-August-Universität — [2]Department of Theoretical Physics and Astrophysics, Belarusian State University

Nonreciprocity allows for interesting new phenomena in Casimir physics, such as propulsion forces pointing in translationally invariant directions, and persistent heat currents between objects of the same temperatures. To study these quantities, we derive general formulas for heat transfer and Casimir force involving a non-reciprocal point particle. These display how nonreciprocity of the particle couples to the nonreciprocity of the surrounding and also yield conditions for persistent heat current or propulsion force. Furthermore, we find a bound for the propulsion force acting on a point particle in terms of its heat exchange. This is, e.g., relevant for the efficiency of this arrangement when used as a heat engine.

DY 9.3 Mon 15:30 H47

Exponential change of relaxation rate by quenched disorder — •Jan Meibohm and Sabine H. L. Klapp — Technische Universität Berlin, Institut für Theoretische Physik, Hardenbergstraße 36, 10623 Berlin, Germany

We determine the asymptotic relaxation rate of a Brownian particle in a harmonic potential perturbed by quenched Gaussian disorder, a simplified model for rugged energy landscapes in complex systems. Depending on the properties of the disorder, we show that the mean and variance of the asymptotic relaxation rate are non-monotonous functions of the parameters for a broad class of disorders. In particular, the rate of relaxation may either increase or decrease exponentially compared to the unperturbed case, implying that the effect of disorder is stronger than that associated with other, well-studied anomalous-relaxation effects. In the limit of weak disorder, we derive the probability distribution of the asymptotic relaxation rate and show that it is Gaussian, with analytic expressions for the mean and variance that feature universal limits. Our findings indicate that controlled disorder may serve to tune the relaxation speed in complex systems.

DY 9.4 Mon 15:45 H47

Mean back relaxation for position, densities and others — •Gabriel Knotz and Matthias Krüger — Institute for theoretical physics, Göttingen, Germany

Recently, a so-called mean back relaxation (MBR) has been introduced, which correlates a scalar observable at three time points. The deviation of its long-time value from 1/2 has been shown to be a marker for breakage of time-reversal symmetry for observables with finite mean. We have extended the discussion by introducing a cut off length when evaluating the MBR from trajectories. For Gaussian systems we can derive a relation between MBR and the mean squared displacement and demonstrate that the MBR can be easily applied to stochastic observables like positions and densities. We discuss the application of the density MBR to multi-particle systems.

Invited Talk DY 9.5 Mon 16:00 H47

Large-deviation simulations of non-equilibrium stochastic processes — •Alexander K. Hartmann — University of Oldenburg, Germany

Stochastic processes are investigated by obtaining the probability distributions $P(S)$ of relevant quantities S of interest. A full description is obtained, if $P(S)$ is known over its full range of support. Also the structure of the entities contributing to the different parts of $P(S)$ are of interest. Usually analytical calculations are not feasible, so most of the time one has to use numerical simulations. Unfortunately, most of the support, in particular in the tails, is not accessible by standard algorithms.

By applying special large-deviation algorithms, also the tails can be accessed, down to probabilities such as 10^{-200}, or even much smaller. Here, a very general *black-box* algorithm [1] is explained, which allows one to study rather arbitrary stochastic processes. Some application examples are shown, such as force-induced RNA unfolding [2], S being the physical work W; interface growth [3], S being the height H; fractional Brownian motion [4], S being the area A under the curve; or the spread of diseases [5], S being the number of infected.

Dissipation bounds precision of current response to kinetic perturbations — •Krzysztof Ptaszyński[1,2], Timur Aslyamov[1], and Massimiliano Esposito[1] — [1]Department of Physics and Materials Science, University of Luxembourg, L-1511 Luxembourg City, Luxembourg — [2]Institute of Molecular Physics, Polish Academy of Sciences, Mariana Smoluchowskiego 17, 60-179 Poznań, Poland

The precision of currents in Markov networks is bounded by dissipation via the so-called thermodynamic uncertainty relation (TUR). We conjecture [1] and prove [2] a similar inequality that bounds the precision of the static current response to perturbations of kinetic barriers. Perturbations of such type, which affect only the system kinetics but not the thermodynamic forces, are highly important in biochemistry and nanoelectronics. Our inequality cannot be derived from the standard TUR, but rather implies it and provides an even tighter bound for dissipation. We also provide a procedure for obtaining the optimal response precision for a given model.

Theory of Nonequilibrium Responses for Markov Jump Processes — •Timur Aslyamov[1] and Massimiliano Esposito[2] — [1]University of Luxembourg, Luxembourg — [2]University of Luxembourg, Luxembourg

The theory of nonequilibrium responses in complex systems to parameter perturbations is fundamental, spanning disciplines from ecology to metabolic control and the design of low-noise devices. The framework of Markov jump processes is one of the most popular approaches for studying a broad range of nonequilibrium phenomena across various fields.

In recent papers [1, 2], we formulated a theory of static response for Markov jump processes under arbitrary parameterizations. Leveraging stochastic thermodynamics, we developed a novel approach based on simple linear algebra, enabling us to extend beyond previously known results. Through our analysis, we uncovered a novel fundamental property of Markov processes: the responses are constrained by specific linear combinations, which we term the Summation and Cycles Response Relations.

How topologically distinct non-equilibrium currents imprint on projected observables — •Felix Tippner and Aljaz Godec — Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany

Almost all measurements track only a limited subset of degrees of freedom simultaneously. Mathematically, the higher-dimensional stochastic process governing a physical system (e.g., the dynamics of protein conformation) is accessible only through observables of projected dynamics, which, in practice, are constrained by strict experimental limitations. These projections not only introduce or amplify non-Markovian effects but also obscure features such as irreversible currents (e.g., driven versus non-driven systems) or barriers in the underlying energy landscape. In our work we investigate how topological and geometric properties imprint on projected dynamics that appear similar (i.e., those exhibiting the same observed steady state), both in and out of equilibrium. This is achieved by examining path-wise observables, such as empirical densities and currents inferred from projected trajectories, through a detailed analysis of their fluctuations and (cross-)correlations.

DY 9.9 Mon 17:30 H47

Slow relaxation in a facilitated trap model — •Gregor Diezemann — Department Chemie, JGU Mainz

Trap models have successfully been applied to understand a number of relaxation features of simulated and real-world supercooled liquids. A common choice for the transition rates is that the system leaves a trap and chooses the destination trap at random. Depending on the form of the prior distribution of trap energies, a broad the relaxation spectrum results. Recently, a facilitated trap model (FTM) in which each transition is accomponied by a small change in the energies of all traps equivalent to a diffusion of trap energies has been implemented. It has been shown that a strong asymmetry of susceptibilities can be obtained with reasonable assumptions regarding the model parameters(1).

In the present contribution, we present the numerical solution of the master equation for the FTM and discuss the relaxation behavior of various one-time and two-time quantities, both in equilibrium and in the particular non-equilibrium situation encountered after temperature jumps, such as in typical aging experiments. Using a model of random rotational jumps for the reorientational motion, the linear dielectic susceptibility in thermal equlibrium is found to be given as a convolution of a Debye-like response originating from the energy drift inherent in the FTM and the response of the original trap model.

DY 9.10 Mon 17:45 H47

Nonequilibrium shortcuts and anomalous thermal relaxations: the Mpemba effect — •Gianluca Teza[1], John Bechhoefer[2], Antonio Lasanta[3], Oren Raz[4], and Marija Vucelja[5] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Simon Fraser University, Burnaby, Canada — [3]Universidad de Granada, Ceuta, Spain — [4]Weizmann Institute of Science, Rehovot, Israel — [5]University of Virginia, Charlottesville, USA

Most of our intuition about the behavior of physical systems is shaped by observations at or near thermal equilibrium. However, even a phenomenon as basic as a thermal quench leads to states far from any thermal equilibrium, where counterintuitive effects can occur. A prime example of anomalous thermal relaxation is the Mpemba effect, a phenomenon in which a hot system cools down faster than an equivalent colder one. Although originally witnessed in water, perspectives towards the design of optimal heating/cooling protocols and observations in a variety of systems pushed the development of a high-level characterization in the framework of nonequilibrium statistical mechanics. In this talk, I will review the phenomenology of this and related anomalous relaxation effects, in which nonmonotonic relaxation times act as the common denominator. With a focus on Ising systems, I will provide insight on the physical mechanisms that enable their emergence. I will show how they can survive arbitrarily weak couplings, highlighting the role played by equilibrium and dynamical features, as well as experimental observation of these effects in quantum simulators.

DY 9.11 Mon 18:00 H47

Power-Efficiency Trade-offs in Finite-Time Thermodynamics: From Minimal Model to General Principle — •Shiling Liang[1,2,3,4], Yu-Han Ma[5,6], Daniel Maria Busiello[4], and Paolo De Los Rios[1] — [1]EPFL, Lausanne, Switzerland — [2]Okinawa Institute of Science and Technology, Okinawa, Japan — [3]Center for Systems Biology Dresden, Dresden, Germany — [4]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [5]Beijing Normal University, Beijing, China — [6]Graduate School of China Academy of Engineering Physics, Beijing, China

Thermodynamic systems operating in finite time face fundamental trade-offs between power output and efficiency. While conventional wisdom dictates that Carnot efficiency is only attainable in the quasi-static limit with vanishing power, we demonstrate theoretically that this constraint can be circumvented in finite-time operations. We present a minimal heat engine model incorporating intrinsic energy level degeneracy that achieves Carnot efficiency at maximum power in the thermodynamic limit. The enhanced performance originates from first-order phase transitions far from the linear response regime, enabled by collective effects in many-body systems. Our results reveal how collective advantages can fundamentally alter power-efficiency trade-offs and suggest new strategies for designing efficient heat engines operating at finite times far from equilibrium.

Fluctuating diffusivity in living cells: Analog of Carnot engine — •Yuichi Itto — Aichi Institute of Technology, Japan — ICP, Universität Stuttgart, Germany

The diffusivity fluctuating over local areas of living cells is experimentally known to obey the exponential law for normal/anomalous diffusion. In Ref. [1], a formal analogy of the fluctuating diffusivity to thermodynamics has been studied. Remarkably, the exponential law is formally equivalent to the "canonical distribution": the diffusivity, which is proportional to local temperature of the cell in nonequilibrium stationary states [2], is identified with the analog of the system energy. Consequently, the analogs of the internal energy, the quantity of heat, work, and the Clausius inequality have been established.

Here, the analog of the heat engine is constructed for the fluctuating diffusivity [3]. This heat-like engine consists of processes realized by compression/expansion of the cell and the change of temperature, along which the average value of the diffusivity or local temperature is kept fixed. The efficiency of the engine in a cycle, which characterizes how much the diffusivity change as the analog of work is extracted, is found to formally take that of Carnot's. The result is expected to be useful, for example, for tuning the rates of biochemical reactions in cells, see, e.g., Ref. [4].

Controlling Many-Body Quantum Chaos — •Lukas Beringer[1], Mathias Steinhuber[1], Juan Diego Urbina[1], Klaus Richter[1], and Steven Tomsovic[1,2] — [1]Institut für Theoretische Physik, Universität Regensburg, D-93040 Regensburg, Germany — [2]Department of Physics and Astronomy, Washington State University, Pullman, WA USA

Controlling chaos is a well-established technique that leverages the exponential sensitivity of classical chaotic systems for efficient control. This concept has been generalized to single-particle quantum systems [1] and, more recently, extended to bosonic many-body quantum systems described by the Bose-Hubbard model [2]. In direct analogy to the classical paradigm, a localized quantum state can be transported along a specific trajectory to a desired target state. In the latter context, this approach reduces to time-dependent control of the chemical potentials, making it suitable for implementation in optical lattice experiments. Highlighted potential applications are rapid, customizable state preparation and stabilization of quantum many-body scars in one-, two-, and three-dimensional lattices. Recent progress includes potential applications to large time-crystal platforms and preparation protocols for entangled states, such as cat-like states.

DY 13.2 Tue 9:45 H37

Exact spectral function and nonequilibrium dynamics of the strongly interacting Hubbard model — Ovidiu I. Pâțu[1], •Andreas Klümper[2], and Angela Foerster[3] — [1]Institute for Space Sciences, Bucharest-Măgurele, R 077125, Romania — [2]Fakultät für Mathematik und Naturwissenschaften, Bergische Universität Wuppertal, 42097 Wuppertal, Germany — [3]Instituto de Física da UFRGS, Av. Bento Gonçalves 9500, Porto Alegre, RS, Brazil

Analytical results on the correlation functions of strongly correlated many-body systems are rare in the literature and their importance cannot be overstated. We present determinant representations for the space-, time-, and temperature-dependent correlation functions of the strongly interacting one-dimensional Hubbard model in the presence of an external trapping potential. These representations are exact and valid in both equilibrium and nonequilibrium scenarios like the ones initiated by a sudden change of the confinement potential. In addition, they can be implemented numerically very easily significantly outperforming other numerical approaches. As applications of our results we investigate the single particle spectral functions of systems with harmonic trapping and show that dynamical quasicondensation occurs for both fermionic and bosonic spin-1/2 systems released from a Mott insulator state.

DY 13.3 Tue 10:00 H37

Quantum many-body scars beyond the PXP model in Rydberg simulators — Aron Kerschbaumer[1], Marko Ljubotina[1,2,3], Maksym Serbyn[1], and •Jean-Yves Desaules[1] — [1]Institute of Science and Technology Austria, Klosterneuburg, Austria — [2]Technical University of Munich, Garching, Germany — [3]Munich Center for Quantum Science and Technology, Munich, Germany

Persistent revivals recently observed in Rydberg atom simulators have challenged our understanding of thermalization and attracted much interest to the concept of quantum many-body scars (QMBSs). QMBSs are non-thermal highly excited eigenstates that coexist with typical eigenstates in the spectrum of many-body Hamiltonians, and have since been reported in multiple theoretical models, including the so-called PXP model, approximately realized by Rydberg simulators. At the same time, questions of how common QMBSs are and in what models they are physically realized remain open.

In our work, we demonstrate that QMBSs exist in a broader family of models that includes and generalizes PXP to longer-range constraints and states with different periodicity. We show that in each model, multiple QMBS families can be found. Each of them relies on a different approximate su(2) algebra, leading to oscillatory dynamics in all cases. However, in contrast to the PXP model, their observation requires launching dynamics from weakly entangled initial states rather than from a product state. The new QMBSs we unveil may be experimentally probed using Rydberg atom simulator in the regime of longer-range Rydberg blockades.

DY 13.4 Tue 10:15 H37

Roughening dynamics of quantum interfaces — Wladislaw Krinitsin[1,2], •Niklas Tausendpfund[1,3], Matteo Rizzi[1,3], Markus Heyl[4], and Markus Schmitt[1,2] — [1]Institute of Quantum Control (PGI-8), Forschungszentrum Jülich, Jülich, Germany — [2]Faculty of Informatics and Data Science, University of Regensburg, Regensburg, Germany — [3]Institute for Theoretical Physics, University of Cologne, Köln, Germany — [4]Center for Electronic Correlations and Magnetism, University of Augsburg, Augsburg, Germany

The roughening transition, known from three-dimensional classical spin systems, describes how fluctuations of interfaces transition from being bounded to being extensive when crossing the characteristic roughening temperature. We explore signatures of such phenomena in the dynamics of domain walls in the two dimensional quantum Ising model, where we observe pre-thermal steady states in their evolution well beyond the perturbative limit using Tree Tensor Networks. We formulate an effective model of the interface, which captures qualitative features of a roughening transition. Most notably, it exhibits a Berezinskii Kosterlitz Thouless quantum phase transition from smooth to rough interfaces, whose signatures extend to finite temperatures. These findings can be related to the observed slow thermalization in the full model, opening the way to a better understanding of pre-thermalization effects in interface dynamics, which can be easily implemented and tested in experimental setups such as Rydberg atom experiments.

DY 13.5 Tue 10:30 H37

Semigroup Influence Functionals for the Dynamics of Quantum Impurity Models — •Michael Sonner[1], Valentin Link[2], and Dmitry Abanin[3,4] — [1]Max-Planck-Institut für Physik komplexer Systeme, Nöthnitzer Straße 38, D-01187 Dresden, Germany — [2]Institut für Theoretische Physik, Technische Universität Dresden, D-01062 Dresden, Germany — [3]Department of Physics, Princeton University, Princeton, New Jersey 08544, USA — [4]Google Research, Brandschenkestrasse 150, 8002 Zürich, Switzerland

Quantum impurity models~(QIM) consist of a local interacting impurity which is coupled to baths of free fermions. These models exhibit a range of non-trivial phenomena such as the Kondo effect. and play a central role in the dynamic mean field theory (DMFT) approach to correlated matter. However, despite their importance, computing the real time dynamics of QIM remains a challenge. Recently, approaches based on matrix product states (MPS) representation of influence functionals (IF) have been proven effective approaches to this problem. These method work by capturing the, generically non-markovian dynamical effects of the quantum environments on the local impurity in a multi time object, which then is compressed as MPS. Taking explicit advantage of time-translation invariance of the model, we find an infinite MPS or semigroup representation of the IF. I will demonstrate how these ideas can be used to predict QIM dynamics for very long times as well as give direct access to stationary non-equilibrium states.

DY 13.6 Tue 10:45 H37

Quantum Fisher information of monitored random circuits — •Arnau Lira Solanilla, Xhek Turkeshi, and Silvia Pappalardi — Universität zu Köln

We characterize the multipartite entanglement structure of monitored random quantum circuits using the quantum Fisher information. We show that, despite the known phase transition in bipartite correlations, the multipartiteness is bounded. On the other hand, we generate a phase with extensive multipartite

entanglement under symmetry preserving random operations by introducing two-qubit measurements. We focus on the limit where no unitary operations are applied, but there is a competition between two noncommuting projective measurements. We exploit a map to bond percolation to precisely calculate the universal scaling of multipartite entanglement.

DY 13.7 Tue 11:00 H37

Entanglement in quantum circuits with SU(2) symmetry — •Tobias Dörstel and Michael Buchhold — Institute for Theoretical Physics, Cologne

Quantum circuits offer a robust framework for studying the out-of-equilibrium dynamics of quantum many-body systems. We investigate one-dimensional monitored quantum circuits with global SU(2) symmetry, serving as digital counterparts to the Heisenberg chain. These circuits consist of unitary qubit SWAPs and non-unitary SWAP-measurements. Entanglement in the chain is governed by the configuration of qubit singlet states, whose count is fixed by the symmetry sector. Varying the measurement rate, unitary operations, and singlet number reveals diverse entanglement behaviors, ranging from volume law to $\log^2(L)$ and $\log(L)$ scaling of half-chain entanglement. We explain these scaling regimes analytically using an SU(2)-symmetric "Page law" and a mapping to loop models with crossings.

Generalized dual-unitary circuits from biunitarity — •Michael A. Rampp, Suhail A. Rather, and Pieter W. Claeys — Max-Planck-Institut für Physik komplexer Systeme, Dresden

We present a general framework for constructing solvable lattice models of chaotic many-body quantum dynamics with multiple unitary directions using biunitary connections. We show that a network of biunitary connections on the Kagome lattice naturally defines a multi-unitary circuit, where three 'arrows of time' directly reflect the lattice symmetry. These models unify various constructions of hierarchical dual-unitary and triunitary gates and present new families of models with solvable correlations and entanglement dynamics. Using multilayer constructions of biunitary connections, we additionally introduce multilayer circuits with monoclinic symmetry and higher level hierarchical dual-unitary solvability and discuss their (non-)ergodicity. Our work demonstrates how different classes of solvable models can be understood as arising from different geometric structures in spacetime.

Magic spreading in doped Clifford circuits — •Jiangtian Yao and Pieter W. Claeys — Max Planck Institute for the Physics of Complex Systems

We study the spreading of magic, or nonstabilizerness, in Clifford circuits with doping by non-Clifford gates. We characterize the spatial extent of magic in classes of Clifford circuits where the growth behavior of entanglement entropy and operator strings are known. The dynamics of magic spreading in such circuits is compared to that of entanglement entropy, and quantitative measures for longer-ranged magic are also explored.

DY 13.10 Tue 12:00 H37

One magnon magnetization dynamics for the kagome lattice antiferromagnet — Henrik Schlüter, •Jannis Eckseler, and Jürgen Schnack — Faculty of Physics, Bielefeld University, Bielefeld, Germany

We present aspects of the one-magnon dynamics of the antiferromagnetic kagome lattice as an example of flat-band dynamics extending the work of [1] to two dimensional systems. We illustrate how localized eigenstates also called localized magnons [2] influence the dynamics of excitations and possibly prevent the system from thermalization. To this end we introduce a $J_1 - J_2$-model for the kagome lattice which guarantees the stability of one out of three localized magnons and lets us distinguish the different flat bands.

DY 13.11 Tue 12:15 H37

Towards a Many-Body Generalization of the Wigner-Smith Time Delay — •Georg Maier[1], Carolyn Echter[2], Juan Diego Urbina[1], Caio Lewenkopf[3], and Klaus Richter[1] — [1]Institut für Theoretische Physik Universität Regensburg, Regensburg, Germany — [2]Mathematische Fakultät Universität Regensburg, Regensburg, Germany — [3]Instituto de Física Universidade Federal Fluminense, Niterói RJ, Brazil

Many body systems with a large number of degrees of freedom are usually described by statistical physics on the theoretical side while experiments usually relay on scattering (e.g. particle physics). Is it possible to relate scattering and statistical physics, or to measure scattering-related observables which directly relate to quantities of statistical physics? At least for single particle systems a close relation exists between the well known Wigner-Smith delay time in scattering theory and the density of states of the scattering system.

I will present a novel ansatz relating a many-body version of dwell-/Wigner-Smith delay time and many body density of states based on the famous Birman-Krein-Friedel-Loyd formula connecting scattering theory and statistical observables in the many-body context. Due to the flexibility of this ansatz it can be used to investigate a wide variety of MB systems. I will discuss interesting scaling behaviors for different systems, like the harmonic trap[1] or the free particle together with the different behavior of bosons, fermions and indistinguishable particles.

DY 13.12 Tue 12:30 H37

Subleading logarithmic behavior in the parquet formalism — •Marcel Gievers[1,2], Richard Schmidt[3], Jan von Delft[1], and Fabian B. Kugler[4] — [1]Ludwig-Maximilians-Universität, München — [2]Max-Planck-Institut für Quantenoptik, Garching — [3]Universität Heidelberg — [4]CCQ, Flatiron Institute, New York

The Fermi-edge singularity in x-ray absorption spectra of metals is a paradigmatic case of a logarithmically divergent perturbation series. Prior work has thoroughly analyzed the leading logarithmic terms. Here, we investigate the perturbation theory beyond leading logarithms and formulate self-consistent equations to incorporate all leading and next-to-leading logarithmic terms. This parquet solution of the Fermi-edge singularity goes beyond the previous first-order parquet solution and sheds new light on the parquet formalism regarding logarithmic behavior. We present numerical results in the Matsubara formalism and discuss the characteristic power laws. We also show that, within the single-boson exchange framework, multi-boson exchange diagrams are needed already at the leading logarithmic level.

DY 13.13 Tue 12:45 H37

Ballistic transport in a disordered, boundary-driven XXZ spin chain. — •Johannes S Hofmann[1], Adam McRoberts[2], and Roderich Moessner[1] — [1]Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Str. 38, 01187 Dresden, Germany — [2]International Centre for Theoretical Physics, Strada Costiera 11, 34151, Trieste, Italy

Recent experiments on Google's sycamore NISQ device on spin transport realised ballistic transport in a edge-driven XXZ chain without disorder; and theoretical works on the classical variant demonstrated the survival of ballistic regime in the easy-plane upon the introduction of bond disorder. Here, we consider various generalisations of this set-up.

DY 14: Focus Session: Nonlinear Dynamics in Biological Systems I (joint session DY/BP)

Nonlinear dynamics play a central role for biological systems to achieve remarkable complexity and adaptability. They underlie processes where small changes cascade into large effects, critical thresholds drive transitions, and feedback mechanisms maintain intricate balances. Biological systems are often far from equilibrium, exhibiting behaviors shaped by competing forces, stochastic fluctuations and emergent behavior. From the amplification of sensory signals near bifurcation points to the development of turbulence, concepts from nonlinear dynamics provide a unifying framework for studying patterns, stability, and collective behavior in living systems. This focus session explores the richness of nonlinear dynamics across biological scales, from molecular circuits to population-level phenomena, spanning vastly different fields from cardiac dynamics, embryogenesis and cell motility to active fluids, condensates and origin of life. Through theoretical models, experimental insights, and computational approaches, the talks illustrate how nonlinear-dynamics principles unravel the mechanisms driving function and complexity in biology, offering new perspectives across disciplines.

Organized by Philip Bittihn (Göttingen), Stefan Klumpp (Göttingen), and Carsten Beta (Potsdam)

Time: Tuesday 9:30–12:30 Location: H43

Invited Talk DY 14.1 Tue 9:30 H43

Robust signal amplification and information integration via self-tuned proximity to bifurcation points — •Isabella Graf — Developmental Biology Unit & Theory Transversal Theme, EMBL Heidelberg, Germany

Many living systems demonstrate exquisite sensitivity to small input signals. A tempting hypothesis is that these systems operate close to bifurcation or critical points, where the system's response exhibits a diverging susceptibility to the control parameter and small signals are amplified into a large collective response. A common concern, however, is that proximity to such points requires fine-tuning of parameters, which seems impossible for noisy biological systems. Based on several distinct sensory systems, we have investigated a feedback motif that robustly maintains these systems close to their respective bifurcation point. The key ingredient is that the collective response feeds back onto the control parameter. To illustrate this idea, I will mention several examples ranging from snake thermosensing to mammalian hearing and discuss the functional benefits associated with being near-critical.

DY 14.2 Tue 10:00 H43

Exceptional Points and Stability in Nonlinear Models of Population Dynamics having PT symmetry — •Alexander Felski — Max Planck Institute for the Science of Light, Erlangen, Germany

Nonlinearity and non-Hermiticity, for example due to environmental gain-loss processes, are a common occurrence throughout numerous areas of science. For the latter, parity-time-reflection (PT) symmetry has played an eminent role in understanding exceptional-point structures and phase transitions in these systems. Yet their interplay has remained by-and-large unexplored. We analyze models governed by the replicator equation of evolutionary game theory and related Lotka-Volterra systems of population dynamics. These foundational nonlinear models offer a broad platform for non-Hermitian theory beyond physics. In this context we study the emergence of exceptional points in two cases: (a) when the governing symmetry properties are tied to global properties of the models, and, in contrast, (b) when these symmetries emerge locally around stationary states–in which case the connection between the linear non-Hermitian model and an underlying nonlinear system becomes tenuous. We outline further that when the relevant symmetries are related to global properties, the location of exceptional points in the linearization around coexistence equilibria coincides with abrupt global changes in the stability of the nonlinear dynamics. Exceptional points may thus offer a new local characteristic for the understanding of these systems.

DY 14.3 Tue 10:15 H43

Pattern selection and the route to turbulence in polar active fluids — Henning Reinken[1], Sebastian Heidenreich[2], •Markus Bär[2,3], and Sabine Klapp[3] — [1]OVGU Magdeburg, Germany — [2]Physikalisch-Technische Bundesanstalt, Germany — [3]TU Berlin, Germany

Active fluids, such as suspensions of microswimmers, are well known to self-organize into complex spatio-temporal flow patterns. An intriguing example is mesoscale turbulence, a state of dynamic vortex structures exhibiting a characteristic length scale. Here, we employ a minimal model for the effective microswimmer velocity field to explore how the turbulent state develops from regular, stationary vortex patterns when activity is increased. First, we demonstrate analytically that the system develops a stationary square vortex lattice in the absence of nonlinear advection. Subsequently, we perform an extended stability analysis and uncover a linear instability, above which the square vortex lattice becomes unstable. In numerical simulations, we confirm that this instability is predictive for the unset of turbulence. In addition, an extended region of hysteresis where turbulence and a stable vortex lattice coexist, is found Reference: H. Reinken, S. Heidenreich, M. Bär, S. Klapp, New J. Phys. 26 063026 (2024).

DY 14.4 Tue 10:30 H43

Likelihood-based inference for heterogeneous motile particle ensembles — •Jan Albrecht[1], Cristina M. Torres[1], Carsten Beta[1], Manfred Opper[2,3,4], and Robert Grossmann[1] — [1]Institute of Physics and Astronomy, University of Potsdam, 14476 Potsdam, Germany — [2]Faculty of Electrical Engineering and Computer Science, Technische Universität Berlin, 10587 Berlin, Germany — [3]Centre for Systems Modelling and Quantitative Biomedicine, University of Birmingham, B15 2TT, United Kingdom — [4]Institute of Mathematics, University of Potsdam, 14476 Potsdam, Germany

The inherent complexity of biological agents often leads to motility behavior that appears to have random components. Robust stochastic inference methods are therefore required to understand and predict the motion patterns from time discrete trajectory data provided by experiments. In many cases second-order Langevin models are needed to adequately capture the motility. Additionally, population heterogeneity needs to be taken into account when analyzing data from multiple individual organisms. We present a maximum likelihood approach to infer stochastic models and, simultaneously, estimate the heterogeneity in a population of motile active particles from discretely sampled trajectories. To this end we propose a new method to approximate the likelihood for nonlinear second order Langevin models. We demonstrate that our approach outperforms alternative methods for heterogeneity estimation, especially for short trajectories, while also providing a measure of uncertainty for the estimates. We use the approach to investigate population heterogeneity in systems of ameboid cells.

DY 14.5 Tue 10:45 H43

Surviving the first "winter": Protocells with polymerization reactions protects against environmental fluctuations — •Xi Chen, Jens-Uwe Sommer, and Tyler Harmon — Leibniz Institute of Polymer Research, Dresden, Germany

The origin of life has been a long standing question with various hypotheses describing the emergence of the first protocells. Phase separated condensates are promising candidates for protocells because they are compartments that enrich specific polymers and host nonequilibrium reactions that leads to growth and division. However, the ability of protocells to survive in an environment that has large fluctuations, such as temperature and composition, is poorly understood. We show with a mean-field model that condensates formed by polymers which undergo nonequilibrium polymerization/depolymerization reactions exhibit significant robustness to large environmental fluctuations.

This robustness occurs when the nonequilibrium polymerization reactions are faster inside condensate phases than outside. The first condensate does not form until environmental factors lead to strong enough reactions that polymers long enough to phase separate form. The effects of nonequilibrium polymerization is then fully realized because a condensate exists. From here, the condensate does not dissolve until the nonequilibrium reactions are diminished to significantly below when the condensate formed. Altogether, this forms a hysteretic loop with respect to the environmental factors that drive nonequilibrium reactions. We show this hysteretic loop prevents protocells from dying from environmental fluctuations.

DY 14.6 Tue 11:00 H43

How inter-particle interaction affects two species transport in nano-channels — •Wolfgang Bauer — Dept. of Internal Medicine I, UKW, Würzburg, Germany

Channel transport mechanisms of multiple species is essential for cell physiology and nanotechnology. Here, we present a model maintaining spatial correlations of two species, moving away from mean field approaches. The spatial occupations of the channel give the state space, where local flux and entropy production

determine channel transport and its thermodynamic efficiency. Optimal transport coupling between species occurs in an attractive empty channel and strong repulsive forces between particles of the same species. This confines state space to a circular topology with concentration gradients of the two species acting as thermodynamic driving forces in series. For opposing gradients, the species with the stronger gradient produces positive entropy, while the other negative entropy. Attenuating the repulsive force within one species and maintaining that of the other adds a bypass path on the circular topology in state space. This enables a leak flow of the less repulsive species parallel to its gradient, generating local positive entropy on the bypass. For a certain range of opposing gradients, both species can produce positive overall entropy simultaneously. However, the rectifying potential of the concentration gradient of the species with bypass option is diminished, i.e. it cannot rectify flow of the other species above a threshold of the latter's opposing gradient. Vice versa the flow of the species with bypass option may always be rectified parallel to the concentration gradient of the other.

Beyond the connectionist view: (De-)synchronizing neural networks via cell-intrinsic dynamics — •Susanne Schreiber — Humboldt-Universität zu Berlin, Institute for Theoretical Biology, Berlin, Germany

Neural computation is thought to arise from the connectivity among neurons. Accordingly, we are often more than happy to ignore seemingly unimportant and potentially overwhelming biological detail, for example, related to the properties of the neurons themselves. In this talk, however, I will highlight how cell-intrinsic dynamics, namely the biophysics of action-potential generation, can have a decisive impact on network behaviour. Recent work of my lab shows that, among regularly firing neurons, the somewhat unattended homoclinic type (characterized by a spike onset via a saddle homoclinic orbit bifurcation) particularly stands out: First, spikes of this type foster specific network states - synchronisation in inhibitory and splayed-out/frustrated states in excitatory networks. Second, homoclinic spikes can be easily induced in by changes in a variety of physiological parameters (like temperature, extracellular potassium, or dendritic morphology). As a consequence, small changes in these parameters can suffice to induce drastic switches in network states. I will discuss functional consequences of homoclinic spikes for the design of pattern-generating motor circuits in Drosophila as well as for mammalian pathologies like febrile seizures. Our work predicts an interesting role for homoclinic action potentials as an integral part of brain dynamics in both health and disease.

DY 14.8 Tue 12:00 H43

Transient spatiotemporal chaos in cardiac excitable media — •Melvin Dix[1,2], Thomas Lilienkamp[1,3], Stefan Luther[1,4,5], and Ulrich Parlitz[1,2,5] — [1]Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — [2]Institute for the Dynamics of Complex Systems, Georg-August-Universität Göttingen, Göttingen, Germany — [3]Faculty for Applied Mathematics, Physics, and General Science, Computational Physics for Life Science, Nuremberg Institute of Technology Georg Simon Ohm, Nürnberg, Germany — [4]Institute of Pharmacology and Toxicology, University Medical Center Göttingen, Göttingen, Germany — [5]German Center for Cardiovascular Research (DZHK), Partner Site Göttingen, Göttingen, Germany

Life-threatening cardiac arrythmia such as ventricular fibrillation have been linked to spatiotemporal chaotic dynamics governed by scroll or spiral waves. It has been observed in vivo and in vitro that these dynamics can be transient, e.g. abruptly stop. Using simulations with different numerical models we investigate the effects of factors such as heterogeneities, motivated by the complexity of the heart. We show that these perturbations can (significantly) prolong the duration of chaotic transients and may also lead to persistent chaos or stable periodic wave patterns [1].

DY 14.9 Tue 12:15 H43

Nonlinear dynamics of heart and brain — •Irene Pellini[1,2], Simon Bauer[1], Johannes Zierenberg[1,3], Philip Bittihn[1,3], and Viola Priesemann[1,3] — [1]Max Planck Institute for Dynamics and Self Organisation, Göttingen, Germany — [2]Max Planck School Matter to Life, Heidelberg, Germany — [3]Institute for the Dynamics of Complex Systems, University of Göttingen, Germany

The core function of the heart and brain arises from the coordinated interaction of their cells. Both organs rely on excitable units – cardiomyocytes and neurons – that propagate electrical signals when a specific threshold is exceeded. Despite this similarity, the two organs exhibit opposed collective behavior due to marked differences in intercellular dynamics and network topology. In the heart, localized electrical connectivity through reciprocal gap junctions generates local synchronization and traveling waves, ensuring efficient pumping function with low entropy. In the brain, long-range connectivity via delayed, non-reciprocal chemical synapses promotes asynchronous dynamics with high entropy, supporting information processing.

Using coupled FitzHugh-Nagumo oscillators, we showcase that characteristic non-linear dynamics for the heart and brain can be related to the network structure, which places both systems on opposite sides of a synchronization phase transition. Crossing this phase transition would lead to pathological conditions, e.g., heart arrhythmia or brain seizures, quantifiable via entropy measures. Our joint view on heart and brain dynamics may foster new perspectives on the function and pathology of both organs.

DY 15: Active Matter III (joint session DY/BP/CPP)

Time: Tuesday 9:30–13:00 Location: H47

DY 15.1 Tue 9:30 H47

From micro to macro: systematic coarse-graining of active particle models and implications on phase separation — •Sumeja Burekovic[1], Filippo De Luca[2], Cesare Nardini[1,3], Ananyo Maitra[4,5], and Michael E. Cates[2] — [1]CEA, Paris-Saclay, France — [2]DAMTP, University of Cambridge, UK — [3]LPTMC, Sorbonne Université, France — [4]LPTM, CY Cergy Paris Université, France — [5]LJP, Sorbonne Université, France

Significant insights into collective phenomena of active systems, such as phase separation, have been obtained through minimal field theories developed in a top-down manner. In contrast, the bottom-up approach seeks to link these continuum models to the microscopic dynamics of active particles, often formulated as Langevin equations for their position and orientation. This connection is typically achieved via explicit coarse-graining and allows active field theories to be expressed in terms of physically meaningful parameters. A major challenge in coarse-graining is the consistent elimination of irrelevant fast degrees of freedom to derive closed equations for the hydrodynamic variables or order parameters, such as the density field. We propose a systematic extension of standard homogenization/projection-operator techniques. As we show in minimal examples with few degrees of freedoms, our technique allows to go beyond the state of the art of homogenization in the mathematical literature. We then discuss the predictions of our coarse-graining methods for the large-scale phenomenology of non-aligning active particles, including cases in which microphase separation - rather than full phase separation - emerges due to activity.

DY 15.2 Tue 9:45 H47

Active Quadrupolar Dumbbells — •Margaret Rosenberg[1], Marco Musacchio[1], Lorenzo Caprini[2], and Hartmut Löwen[1] — [1]Heinrich-Heine University Düsseldorf, Universitätsstraße 1, 40225 Düsseldorf — [2]Università di Roma Sapienza, P.le Aldo Moro 2, 00185 Rome, Italy

The field of Active Matter has thrived in recent years, driven both by the insight that it underlies fundamental processes in nature, and by its vast potential for applications. Although the self-propulsion mechanisms of Active Matter allow us to consider and control a wide range of motions, there is - by default - no obvious control over the orientation and rotation of the particles. One approach to resolve this is the use of anisotropic particles and interactions. This contribution presents a computational study of a novel system composed of active, quadrupolar dumbbells, the phase behavior of which is determined by the competition between active motion and the orthogonal alignment favored by quadrupolar attraction. We explore the novel phase behavior unlocked by these anisotropic interactions, and discuss options for experimental realizations and applications.

DY 15.3 Tue 10:00 H47

Order by disorder in a swarm with obstacles — Pradeep Kumar[1], Sanjay Puri[1], and •Martin Weigel[2] — [1]School of Physical Sciences, Jawaharlal Nehru University, New Delhi – 110067, India — [2]Institut für Physik, Technische Universität Chemnitz, 09107 Chemnitz, Germany

Simple models of swarming and active matter such as the Vicsek model [1] have been studied in detail, and the phase diagram as a function of noise strength and particle density is by now well understood. Real active systems are usually affected by impurities and random disorder, however. The presence of a quenched distribution of disc-like obstacles in the domain of the Vicsek model

is observed to have a dramatic effect on the ordering behavior [2]: in contrast to the model without obstacles, where the strongest alignment is observed for the lowest noise, as soon as obstacles are added only the presence of a certain amount of noise leads to a global alignment of particles. This order by disorder phenomenon for active systems is traced back to the interplay of multiple length scales in the system: the typical inter-obstacle distance, the typical cluster size, and the resulting mean-free-paths of cluster-obstacle and cluster-cluster collisions. We present scaling arguments explaining these connections and provide an outlook towards similar phenomena in related systems.

DY 15.4 Tue 10:15 H47

Autonomous navigation in synthetic microswimmers: solving mazes with chemical echolocation — •Aritra K. Mukhopadhyay[1], Linhui Fu[2], Kai Feng[2], Ran Niu[2], and Benno Liebchen[1] — [1]Technische Universität Darmstadt, Darmstadt, Germany. — [2]Huazhong University of Science and Technology, Wuhan, China.

Motile microorganisms like bacteria and algae combine self-propulsion, cooperation, and decision-making at the micron scale. Inspired by these biological systems, synthetic microswimmers are emerging as human-made counterparts capable of self-propulsion. Recent breakthroughs provide a platform to integrate additional functionalities, bridging the gap between biology and synthetic systems.

We propose and experimentally demonstrate a mechanism enabling synthetic microswimmers, such as autophoretic colloids, droplet swimmers, and ion-exchange-driven modular swimmers, to make autonomous navigational decisions. These swimmers generate chemo-hydrodynamic signals that interact with boundaries, creating echoes that carry structural information about the environment. Remarkably, these echoes invoke automatic responses, such as synthetic chemotaxis, enabling the swimmers to avoid dead ends and autonomously find paths through complex mazes.

Our findings illustrate how simple physical principles can endow synthetic systems with advanced navigation functionalities, which could be useful for developing self-navigating micromachines with potential applications in targeted drug delivery and environmental sensing.

DY 15.5 Tue 10:30 H47

Active Particles in Tunable Colloidal Environments — •Abhimanyu Nowbagh[1], Venkata M.S.G. Tanuku[2], Thomas Palberg[2], and Ivo Buttinoni[1] — [1]Institute of Experimental Colloidal Physics, Heinrich-Heine University, 40225 Düsseldorf — [2]Institute of Physics, Johannes-Gutenberg University, 55128 Mainz

Active colloids are microscopic particles which propel through aqueous media by converting the externally available energy into directed motion. Using non equilibrium thermodynamics to understand biological systems: interactions of active colloids with crowded systems, and emergent phenomena of ensembles of active particles, remain an important and open question.

In this work, we investigate the dynamics of active particles in crowded environments subjected to alternating-current (AC) electric fields. The AC electric field is used to control: i) the velocity of active particles and ii) the inter-particle interaction between passive colloids. As we increase electric field strength, the velocity of active particles increases and the inter-particle interaction between passive colloids becomes stronger. We study the behaviour of active particles as a function of: i) the frequency of the applied AC electric field, ii) the area fraction of the passive crowd, iii) the active to passive particle number ratio, and iv) the velocity of the active particles.

Our experimental findings show that the active particles reorient faster with an increasing electric field strength. With an increase in the active to passive particle ratio, we show that cluster formation is non-monotonically sensitive to the passive crowd density.

Invited Talk DY 15.6 Tue 10:45 H47

Beyond spheres - active matter in new shapes — •Juliane Simmchen — University of Strathclyde, Cathedral street 295, Glasgow UK

Surface minimisation for a given volume is energetically favourable on the small scale - this is why most colloidal particles are spherical. In active matter they have the added advantage of facilitating comparison between experiment and theory, one of the reasons why spherical Janus particles dominate the field.

However, broadening the range of materials has led to interesting discoveries - behaviour that would not have been observable in the spherical regime. This talk will give an overview of the intriguing behaviour of non-spherical active materials at the microscale - from plates to truncated bipyramids and rods.

DY 15.7 Tue 11:30 H47

Modeling Filamentous Cyanobacteria — •Elias Fischer and Holger Stark — Institute Of Theoretical Physics, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin, Germany

Filamentous cyanobacteria play an important role in many ecosystems and the carbon cycle of our planet, both in the present and the past. They triggered the great oxygenation event about 2.5 billion years ago, generating the atmospheric oxygen of our planet while contributing large parts of our fossil fuel record.

Filamentous cyanobacteria exhibit gliding motility when in contact with solid surfaces or each other. Despite their ecological relevance and increased use in biotech applications, the exact nature of the force-generating process remains not fully understood. Furthermore, the gliding of cyanobacteria is strongly affected by external cues, most importantly light. They aggregate in regions with the highest light intensity, which means best environmental conditions for photosynthesis.

Following recent advances in understanding the self-organization of cyanobacteria, we present a novel approach for modeling the mechanical and behavioral aspects of individual cyanobacteria filaments, including force synchronization and response to light. Each filament is modeled as a bead-spring chain in 3D with bending and torsional elasticity, as well as a hard-core repulsion between the filaments. Notably, the propulsion forces that drive the individual parts of the filament forward are only considered locally where the filament comes into contact with another surface. First results on the 3D bending and twisting motion of a filament and its reaction to light are presented.

DY 15.8 Tue 11:45 H47

Self-assembly and control of active and passive triblock Janus colloids — •Juri Franz Schubert, Salman Fariz Navas, and Sabine H. L. Klapp — Institut für Theoretische Physik, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin

Triblock Janus colloids belong to the family of patchy particles, interacting with hydrophobic attraction at opposite poles and electrostatic repulsion in the equatorial region. They are known to self-assemble into a colloidal kagome crystal from experiments [1] and theory [2,3,4]. However, investigating the self-assembly of such systems via Brownian Dynamics can result in timescales inaccessible to brute force simulations, often requiring complex sampling techniques [3]. Recently, it has been shown that introducing self-propulsion can significantly accelerate self-assembly and enhance the Kagome yield [4]. Here, we study the model introduced in [4] and further investigate the self-assembled structures in active and passive systems. Using simple time-dependent activity protocols, we are able to sample a temperature-density state diagram of the passive system. Our results closely match with earlier studies [2,3], where different triblock models and sampling techniques were used.

DY 15.9 Tue 12:00 H47

Enhanced Diffusion and Universal Rouse-like Scaling of an Active Polymer in Poor Solvent — Suman Majumder[1], Subhajit Paul[2], and •Wolfhard Janke[3] — [1]Amity Institute of Applied Sciences, Amity University Uttar Pradesh, Noida 201313, India — [2]Department of Physics and Astrophysics, University of Delhi, Delhi 110007, India — [3]Institut für Theoretische Physik, Universität Leipzig, IPF 231101, 04081 Leipzig, Germany

By means of Brownian dynamics simulations we study the steady-state dynamic properties of a flexible active polymer in a poor solvent condition. Our results show that the effective diffusion constant of the polymer D_{eff} gets significantly enhanced as activity increases, much like in active particles. The simulation data are in agreement with a theoretically constructed Rouse model of active polymer, demonstrating that irrespective of the strength of activity, the long-time dynamics of the polymer chain is characterized by a universal Rouse-like scaling $D_{\text{eff}} \sim N^{-1}$, where N is the chain length. We argue that the presence of hydrodynamic interactions will only have an insignificant effect on the observed scaling behavior.

DY 15.10 Tue 12:15 H47

A Pulsating Active Solid — •Umang A Dattani[1], Francesco Serafin[1], Jonas Ranft[2], and Etienne Fodor[1] — [1]Department of Physics and Materials Science, University of Luxembourg, L-1511 Luxembourg City, Luxembourg — [2]Institut de Biologie de l ENS, Ecole Normale Superieure, CNRS

Active matter has garnered significant attention in recent decades due to its numerous parallels with biological systems. Inspired by recent studies of biological tissues, such as cardiac cells, where constituent cell sizes periodically vary, a new form of activity termed "pulsating active matter" has been introduced recently. We propose a model of a pulsating active solid, consisting of size-changing particles linked by a triangular spring network. Despite the fixed connectivity, our model exhibits a variety of patterns and topological phase defects, akin to previous studies. Additionally, we explore the elastic continuum limit, which success-

fully predicts several essential features of the microscopic model. We conclude by highlighting intriguing properties of this system and its different potential parallels.

Invited Talk DY 15.11 Tue 12:30 H47

Emergent correlations and boundary fluctuations in epithelial cell sheets — •Silke Henkes — Lorentz Institute, Leiden University, Leiden, The Netherlands

In soft active materials, the driving motion of individual constituents competes with their mechanical interactions, giving rise to active liquids, solids or glasses. An especially important example of this are epithelial cell sheets, which form a barrier function in the body and where the active crawling motion of cells over the substrate acts against cell-cell adhesion and repulsion.

I will show that a minimal model of cell sheets with uncorrelated activity, based on active Brownian dynamics and a vertex model, is a good quantitative match to data from two experiments on corneal and MDCK cell sheets. Its core feature is an emergent correlation length, arising from the diffusive spread of active forces through an elastic solid. This is a very general result that emerges in many active solids.

The boundary of such cell sheets exhibits a 'fingering instability' where the initially straight boundary develops large, spatiotemporally correlated fluctuations. Despite previous interpretations within many frameworks as an instability, I will show that it can be fully explained as arising from the active correlations of the cell sheets driving the boundary.

DY 16: Many-body Systems: Equilibration, Chaos, and Localization (joint session DY/TT)

Time: Tuesday 14:00–15:30 Location: H37

DY 16.1 Tue 14:00 H37

Power-law banded random matrices as models for quantum many-body Hamiltonians — •Wouter Buijsman[1], Masudul Haque[2,1], and Ivan M. Khaymovich[3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]TU Dresden, Institute of Theoretical Physics, Dresden, Germany — [3]Nordita, Stockholm, Sweden

Hamiltonians of one-dimensional, disordered single-particle sytems with long-range hoppings can naturally be modeled by power-law banded random matrices. In this picture, the phase diagram of power-law banded random matrices show an ergodic, weakly ergodic, and localized phase. Motivated by modern developments on ergodicity breaking and localization in interacting quantum many-body systems, we study many-body interpretations of such random matrices. We discuss a number of ways to label the basis states with many-body configurations, and compare the physical properties of the resulting Hamiltonians. Specifically, we study the scaling of the many-body entanglement entropy with system size for eigenstates at both the bulk and the edge of the spectra. Using a scaling analysis on the full sets of eigenstates, we subsequently provide a quantitative picture of the phase diagram. We elaborate on the physical relevance of this interpretation of random matrix models for quantum many-body systems.

DY 16.2 Tue 14:15 H37

Escaping the Krylov space during reorthogonalization — •Max Pieper, Jannis Eckseler, and Jürgen Schnack — Universität Bielefeld

Krylov complexity [1] is often used as a measure of complexity in quantum many-body-systems. During its calculation, the Lanzcos algorithm is used to construct an operator basis. Due to the poor orthogonality of the resulting basis reorthogonalization is often employed [2]. We investigate how using reorthogonalization causes the Lanczos algorithm to accumulate non-Krylov basis elements. We suspect this to negatively affect the Krylov algorithm.

DY 16.3 Tue 14:30 H37

An estimate of the equilibration time based on the operator growth hypothesis — •Merlin Füllgraf, Jiaozi Wang, and Jochen Gemmer — Universität Osnabrück

We study the equilibration times T_{eq} of local observables in quantum chaotic systems by considering their auto-correlation functions. Based on the recursion method, we suggest a scheme to estimate T_{eq} from the corresponding Lanczos coefficients. We numerically find that, if an observable follows the *operator growth hypothesis*, a finite number of Lanczos coefficients is sufficient for a reasonable estimate of the equilibration time. This implies that equilibration occurs on a realistic time scale much shorter than the life of the universe. The numerical findings are further supported by analytical arguments.

DY 16.4 Tue 14:45 H37

Effects of chaos in Bose-Hubbard systems with few degrees of freedom. The smallest possible heat engine? — •Viviane Bauer, Nico Fink, and James Anglin — Physics Department and Research Center OSCAR, RPTU Kaiserslautern-Landau

Microscopic engines are a research focus in both biochemistry and nanotechnology. While other forms of engines besides heat engines are also being considered, the fully microscopic limit of a heat engine is a fundamentally important problem in physics. What happens to thermodynamics when not only the working fluid and mechanism of a heat engine, but even the hot and cold reservoirs are microscopic?

To realize such microscopic heat baths, we turn to the process of chaotic ergodization, studied in Bose-Hubbard dimers and trimers.

One realization we currently study is based on two Bose-Hubbard trimers, which allow energy and particle transport between them. The particle transport is furthermore coupled to a mass, so our engine works against a force to lift it. Moreover, we have identified a dynamic mechanism which can stabilize this lifting process. The result is a system which operates just like a heat engine, except for being fully microscopic. The structure of coupled chaotic subsystems both supports and requires an understanding of the fully microscopic heat engine in terms of open-system control.

DY 16.5 Tue 15:00 H37

Impurity coupled to the SYK bath — •Anastasia Enckell and Stefan Kehrein — Institute for Theoretical Physics, Georg-August-Universität Göttingen, Germany

System-plus-bath models play an important role in addressing fundamental questions in condensed matter physics. One challenging aspect is modelling the bath, which is often approached using free-particle or open quantum system frameworks. Here, we explore the Sachdev-Ye-Kitaev (SYK) model as a new kind of quantum bath with unique properties, including the absence of quasiparticles, maximal chaos, and non-integrability, which make it a valuable framework for studying system-plus-bath interactions. We study the time evolution of the occupation of an impurity coupled to the SYK bath following a quench. From the Kadanoff-Baym equations for a noninteracting impurity, we see that the only relevant property for the impurity occupation is a combination of hybridisation and density of states of the bath. These parameters can be adjusted in order to model the impurity coupled to any bath of interest. Using this approach, we can study the impurity dynamics coupled to the SYK bath by making suitable changes to the hybridisation in impurity plus Fermi bath setting, which significantly simplifies the task. We observe oscillatory dynamics of the impurity at zero temperature, with the oscillations decreasing as the temperature increases. This behaviour contrasts with that of a free-particle bath and suggests interesting underlying physics.

DY 16.6 Tue 15:15 H37

Thermal-relaxation asymmetry in fluctuating hydrodynamics — •Felipe Pereira-Alves and Aljaž Godec — Mathematical bioPhysics Group, Max Planck Institute for Multidisciplinary Sciences, 37077 Göttingen, Germany

It was theoretically predicted and recently experimentally confirmed that small systems, such as trapped colloidal particles quenched far from equilibrium, heat up faster than they cool down. The phenomenon was coined thermal-relaxation asymmetry. The proposed physical explanation of the asymmetry instigated intriguing questions about its existence in the thermodynamic limit. Here we investigate thermal relaxation dynamics in far-from-equilibrium temperature quenches on the level of fluctuating hydrodynamics of short- and long-range (logarithmically) interacting many-body systems. We prove the existence of a strict asymmetry for any temperature quench for both, short- and long-range interactions. Remarkably, in contrast to small systems, there is no "close-to-equilibrium" regime of quenches for which heating and cooling are symmetric. Notably, we find that relaxation is self-similar up to the relaxation time, and uncover intricate differences between short- and long-range interactions.

DY 17: Focus Session: Nonlinear Dynamics in Biological Systems II (joint session DY/BP)

Nonlinear dynamics play a central role for biological systems to achieve remarkable complexity and adaptability. They underlie processes where small changes cascade into large effects, critical thresholds drive transitions, and feedback mechanisms maintain intricate balances. Biological systems are often far from equilibrium, exhibiting behaviors shaped by competing forces, stochastic fluctuations and emergent behavior. From the amplification of sensory signals near bifurcation points to the development of turbulence, concepts from nonlinear dynamics provide a unifying framework for studying patterns, stability, and collective behavior in living systems. This focus session explores the richness of nonlinear dynamics across biological scales, from molecular circuits to population-level phenomena, spanning vastly different fields from cardiac dynamics, embryogenesis and cell motility to active fluids, condensates and origin of life. Through theoretical models, experimental insights, and computational approaches, the talks illustrate how nonlinear-dynamics principles unravel the mechanisms driving function and complexity in biology, offering new perspectives across disciplines.

Organized by Philip Bittihn (Göttingen), Stefan Klumpp (Göttingen), and Carsten Beta (Potsdam)

Time: Tuesday 14:00–15:15 Location: H43

Invited Talk DY 17.1 Tue 14:00 H43

Mechanistic origins of temperature scaling in the early embryonic cell cycle — •Lendert Gelens — Laboratory of Dynamics in Biological Systems, Department of Cellular and Molecular Medicine, KU Leuven, Herestraat, 49, Leuven, Belgium

Temperature profoundly impacts organismal physiology and ecological dynamics, particularly affecting ectothermic species and making them especially vulnerable to climate shifts. Even though complex physiological processes usually involve dozens of enzymes, empirically it is found that the rates of these processes often obey the Arrhenius equation, which was originally derived for single enzyme-catalyzed reactions. Here we have examined the temperature scaling of the early embryonic cell cycle, with the goal of understanding why the Arrhenius equation approximately holds, and why it breaks down at temperature extremes.

Using experimental data from different frog, fish, fly, and worm species, we find that the apparent activation energies for the early embryonic cell cycle for diverse ectotherms are all similar. Computational modeling and experiments with frog egg extracts show that the non-Arrhenius scaling can be accounted for by biphasic temperature scaling in critical individual components of the cell cycle oscillator circuit, in combination with imbalances in the activation energies for different partially rate-determining enzymes. These findings provide mechanistic insights into the dynamic interplay between temperature and complex biochemical processes, and into why biological systems fail at extreme temperatures.

DY 17.2 Tue 14:30 H43

Reshaping morphogen gradients through porous tissue architecture — •Diana Khoromskaia[1,2] and Zena Hadjivasiliou[1,2,3] — [1]Francis Crick Institute, London, United Kingdom — [2]University College London, London, United Kingdom — [3]London Centre for Nanotechnology, London, United Kingdom

The morphogenesis of tissues during embryonic development is controlled by concentration gradients of morphogens – signalling molecules whose readout determines cell fate decisions. How the spread of morphogens is affected in tissues with complex geometry and spatially heterogeneous architecture is not well understood. To address this question, we introduce a porous vertex model, by explicitly considering the network of extracellular spaces between the cells. Morphogens produced by source cells disperse through the tissue via three modes of transport: extracellular diffusion, membrane-bound diffusion, and cell-based transport through recycling. With this model we investigate numerically and analytically how cell-scale geometry, such as cell size, cell shape anisotropy, and cell distance, influences effective diffusion and degradation of morphogens at tissue-scale. We further show that a non-linear coupling between cell packing and morphogen concentration renders the morphogen gradient robust to perturbations, for instance by locally buffering fluctuations in the production. Our characterisation of tissues as active porous materials provides new insights into how morphogenesis and cell fate determination may interact during embryonic development.

DY 17.3 Tue 14:45 H43

Active viscoelastic condensates provide controllable mechanical anchor points — •Oliver Paulin[1], Luise Zieger[2,3], Júlia Garcia-Baucells[5], Alexander Dammermann[5], Sebastian Aland[2,3,4], and David Zwicker[1] — [1]Max Planck Institute for Dynamics and Self-Organization, Göttingen — [2]TU Bergakademie Freiberg — [3]HTW Dresden — [4]Center for Systems Biology, Dresden — [5]Max Perutz Labs, University of Vienna

Many biological materials must couple mechanical strength with the ability to rapidly self-assemble at a specific location. In particular, biomolecular condensates readily self-assemble via phase separation, but may also need to anchor external forces to fulfil their function. Spatial localisation of condensate formation can be controlled by active cores that preferentially drive the production of condensate material at a particular point, while resistance to external forces can be facilitated by viscoelastic material properties. Here, we develop a continuum model of viscoelastic growth around an active core, and investigate the results in a spherically symmetric geometry. We find that viscoelastic stresses restrict condensate growth, but also impart resistance to deformation. We investigate the effect of varying different mechanical properties on condensate growth and strength, and also study how strain-dependent material incorporation may limit the maximum rate of growth. Finally, we compare the predictions of our model to experimental data from centrosomes in C. elegans embryos, identifying a parameter regime in which rapid growth can be combined with appropriate mechanical strength.

DY 17.4 Tue 15:00 H43

Modelling cell crawling on different substrate stiffness — Sohei Nakamura and •Mitsusuke Tarama — Kyushu University, Fukuoka, Japan

Crawling cells sense the mechanical properties of the underlying substrate and change their dynamics accordingly. This ability called durotaxis is of great importance in various biological processes including development and homeostasis. In order to understand how intracellular chemical reactions and cellular mechanics give rise to durotaxis, we constructed a simple model from reaction diffusion equations for intracellular chemical compounds and force balance equations for the intracellular mechanics including the effect of the substrate stiffness. We found that within the model, the cell speed and diffusion coefficient change non-monotonically with the substrate stiffness, indicating the existence of an optimal substrate stiffness for migration. This non-monotonic behavior of the cell speed is consistent with experimental observations and can be understood to be caused by the competition between substrate adhesion and cell shape deformation. We further discuss cell migration on a patterned substrate.

DY 18: Pattern Formation

DY 18.1 Tue 14:00 H47

Amplitude and envelope equation for the conserved-Hopf bifurcation — •Daniel Greve[1] and Uwe Thiele[1,2] — [1]Institut für Theoretische Physik, Universität Münster, Münster, Germany — [2]Center for Nonlinear Science (CeNoS), Münster, Germany

Nonreciprocal interactions and conservation laws both play an important role in out-of-equilibrium pattern formation processes, e.g., in biochemical systems.[1,2] The generic large-scale oscillatory instability in such systems – the conserved-Hopf instability – is a central organizing element for such processes.[3,4] After classifying this instability within an extension of the Cross-Hohenberg[5] scheme, we use weakly nonlinear multi-scale analysis to obtain aclosed form (but nonlocal) slow time evolution equation for the spatiotemporal dynamics of the amplitude of fast time oscillations for thee example of two-species nonreciprocal Cahn-Hilliard models. Analytical results then reveal

a universal coarsening suppression in oscillatory phase separation. Finally, we demonstrate the agreement of the two levels of description in a comparison of numerical results for the reduced and full model.

DY 18.2 Tue 14:15 H47

Wavelength selection mechanism for turbulent superstructures in Rayleigh Bénard convection — •Fabián Alvarez-Garrido and Michael Wilczek — University of Bayreuth, Bayreuth, Germany

Large-scale flow patterns coexist with small-scale turbulence in high-aspect-ratio Rayleigh-Bénard cells. These flow patterns, known as turbulent superstructures, are significantly larger than convection rolls that emerge at the onset of convection. Direct numerical simulations of the Oberbeck-Boussinesq equations reveal that the size of these structures increases with the Rayleigh number. However, the mechanism behind this increase has not been elucidated.

Small-scale turbulence plays an important role in the redistribution of heat across the system. Motivated by how the background temperature gradient profile varies between the boundary layers and the bulk, we formulate effective equations for the large scales introducing a height-dependent turbulent thermal diffusivity. A sharp increase in the diffusivity renders the boundary layers effectively thermally insulating boundaries, fundamentally modifying how the fluid exchanges heat with its surroundings. A linear stability analysis of our model shows that this change in boundary conditions goes along with a change of the type of instability, which then leads to an increased wavelength of the flow patterns. These findings provide a mechanism to understand the increasing size of turbulent superstructures.

DY 18.3 Tue 14:30 H47

Turbulence-like behavior of spot patterns mediated by defects in the context of the liquid crystal light valve experiment — •Simon Navia[1], Marcel Clerc[2], and Pedro Aguilera[2] — [1]University of Münster, Münster Germany — [2]University of Chile, Santiago, Chile

The liquid crystal light valve experiment (LCLV) with optical feedback consists of a liquid crystal cell stimulated by a voltage and a photodiode that is coupled to the intensity of the light reaching the cell, thereby creating the optical feedback loop. This experiment exhibits a variety of complex spatiotemporal phenomena. This talk presents the experimental results of the observed formation of aperiodic spatiotemporal patterns in a quasi-one-dimensional channel, characterized by power-law scaling in the temporal and spatial-spectral density of the measured light intensity, as well as in the pseudo-envelope and pseudo-phase. Moreover, theoretically, the system is locally described as being near nascent bistability and spatial instability, from which a simplified model could be derived. We performed numerical simulations of this simplified model which show chaotic spatiotemporal patterns and spectral densities with exponents similar to those observed in the experiment.

DY 18.4 Tue 14:45 H47

Efficient formation of Turing patterns using physical interactions — •Cathelijne ter Burg, Chengjie Luo, and David Zwicker — Max Planck Institute for Dynamics and Self-Organisation, Am Fassberg 17, Gottingen 37077, Germany

Turing patterns arise when an activating and an inhibitory component drive local activation and global inhibition of their production. Physical interactions between the components can facilitate such patterns. Using a thermodynamically-consistent version of such a model, we show that physical interactions lower the energetic requirements for forming patterns of a given length scale. Stronger physical interactions thus permit pattern formation for systems that are less active. However, we also found a dynamic regime where structures of well-defined length scales evolve chaotically for very strong physical interactions. This regime emerges from an interplay of coarsening and spinodal decomposition of bulk phases. We conclude that physical interactions of intermediate strength are energetically optimal for forming stationary patterns of a well-defined length scale.

DY 18.5 Tue 15:00 H47

Numerical and Experimental Analysis of Multi-Soliton Interactions in Ultrafast Lasers — •Julia Lang and Georg Herink — Universität Bayreuth

Ultrafast lasers are excellent platforms for experimentally observing multi-soliton solutions of the nonlinear Schrödinger equation in real-time. Interactions between solitons are often neglected in common pulse propagation models. However, they generate a variety of nonlinear dynamics, which manifest in distinct soliton trajectories observed via real-time spectral interferometry. Here, we report on soliton interactions in two different classes of widely established laser systems, namely Kerr-lens mode-locked Ti:sapphire [1] and SESAM mode-locked Er:fiber [2] lasers. Laser system-specific components result in virtually opposite behaviour, i.e., in soliton attraction, repulsion and/or binding. We discuss their representations in the generalized Schrödinger equation and present one-to-one correspondences between experiment and theory.

DY 18.6 Tue 15:15 H47

Self-similarity in 1 and 2-dimensional cellular automata — •Jens Christian Claussen — University of Birmingham, UK

Cellular automata with a localized single seed initial condition can exhibit deterministic time series with power-law scaling, which led us numerically to the identification of two universality (sub)classes within the Wolfram class IV cellular automata [1], where rule 90 (Sierpinski) and rule 150 are representatives of these classes. The generated time series can be analytically described by a tensorial Fibonacci iteration [2]. An exploration of 2-dimensional outer-totalistic cellular automata showed that fractals with more general one- or two-step self-similarity may exist, including a rule providing a triple replication, and generating a 2-dim spatial Sierpinski pattern. Here we also consider the more general question what variety of universality classes can be found, eventually extending the dynamics to more general algebraic structures. We show that in the 1-dimensional ECA case of a mod 2 dynamics indeed only the two self-similarity cases represented by rule 90 and rule 150 exist.

DY 19: Focus Session: Quantum Emission from Chaotic Microcavities (joint session HL/DY)

In this joint focused session of the divisions DY, HL, and TT, we bring together two dynamic areas of research: semiconductor quantum emitters and chaotic cavities. While quantum emitters in cavities represent an established building block for quantum information technologies, chaotic microcavities may promise novel design routes towards optimized cavity performance parameters. Experts from both fields will provide an overview of the current state of research, exploring the potential of chaotic and unconventional microcavities to enhance the emission of quantum states.

Organized by Sonja Barkhofen (University of Paderborn) and Christian Schneider (University of Oldenburg).

From complex internal dynamics to emission characteristics control in quantum billiards — •Martina Hentschel — 1 Institute of Physics, Technische Universität Chemnitz, D-09107 Chemnitz, Germany

The field of mesoscopic physics has given access to new classes of fascinating model systems ranging from ballistic quantum dots via microcavity lasers to graphene billiards over the past decades. Their rich internal dynamics, subject to quantum chaos and often successfully accessed employing wave-particle correspondence in real and phase space, is directly related to their emission properties. Here, we illustrate this close connection for various examples and system classes. For optical microcavities, we vary the internal dynamics by changing the geometric shape of the resonator and explain how the far-field emission charac-

teristics is determined by the underlying steady probability distribution and a possibility to achieve directional emission required for microlasing devices with the Limaçon geometry. Placing sources into the cavity will affect the internal dynamics of the cavity by, taking the particle point-of-view, effectively changing the set of initial conditions, as observed for optical cavities as well as for graphene billiards in the form of Dirac fermion optics. A further way to change the dynamics of a system is the existence of anisotropies that can either be intrinsically present such as in bilayer graphene in the form of trigonal warping [1], or can be induced to a given system by, for example, applying a mechanical strain. [1] L. Seemann, A. Knothe, and M. Hentschel, New J. Phys. 26, 103045 (2024).

Invited Talk DY 19.2 Wed 10:00 H17

Positioning of microcavities around single emitters — •Tobias Huber-Loyola — Technische Physik, Physikalisches Institut, Julius-Maximilians-Universität Würzburg, 97074 Würzburg, Germany

Single emitters in solids are great sources of single and entangled photons for usage in quantum information technologies. Many emitters possess high internal quantum efficiency, majority of the emission into the zero-phonon line and controllable single charge spins that can be used as quantum memories or as resource to generate chains of entangled photons. However, due to their solid-state host, which usually comes with a high refractive index, the outcoupling of photons requires the use of nanophotonic structures such as waveguides or microcavities. In this talk, I will show how we place microcavities around pre-registered quantum dots using hyperspectral imaging and e-beam lithography and I will give an overview of how placement accuracy has different effects on the emitted photons' properties based on the type of cavity.

Invited Talk DY 19.3 Wed 10:30 H17

Exploring Wave Chaos and Non-Hermitian Physics: Future Prospects for Quantum Emission from Chaotic Microcavities — •Jan Wiersig — Otto-von-Guericke-Universität Magdeburg, Germany

Optical microcavities play a fundamental role in many fields of basic and applied research in physics. A chaotic microcavity is a type of cavity where the light ray dynamics is (partially) chaotic [1]. This can occur in a microdisk cavity with a deformed boundary shape. Chaotic microcavities are ideal for studying ray-wave correspondence, or wave chaos, in open systems, allowing direct comparisons with experiments [2]. These cavities can also exhibit non-Hermitian phenomena such as reflectionless scattering modes [3] and exceptional points [4].

The light emission from chaotic microcavities has been studied exclusively within the classical domain. The effects of electromagnetic field quantization, including phenomena like entanglement, single-photon states, and squeezed light, remain unexplored in this context. In this talk, I will review my group's recent efforts to investigate classical emission from chaotic microcavities and quantum emission from semiconductor quantum dots embedded in conventional microcavities. Additionally, I will discuss the prospects for achieving genuine quantum emission from chaotic microcavities.

Invited Talk DY 19.4 Wed 11:15 H17

Correlations and statistics in cavity embedded quantum dot sources of quantum light — •Ana Predojevic — Stockholm University, Stockholm, Sweden

Single quantum dots coupled to photonic cavities are established emitters of single photons and entangled photon pairs. The cascaded generation of photon pairs intrinsically contains temporal correlations that negatively affect the ability of such sources to perform two-photon interference, hindering applications. I will show how such correlation interacts with decoherence and temporal postselection, and under what conditions temporal postselection could improve two-photon interference visibility. Our study identifies crucial parameters of the source and shows the way to achieve optimal performance. The single photons emitted by a quantum dot exhibit quantum statistics, which is usually verified in an autocorrelation measurement. Single photons can be subjected to more extensive tests of quantum nature, such as non-Gaussianity. However, there is little evidence that such a measurement can be made on pairs of photons. I will show that pairs of photons exhibit strongly non-classical properties that can be quantified. Our result is applicable to a wide range of quantum light sources and measurement methods.

Invited Talk DY 19.5 Wed 11:45 H17

Nonlinear Phenomena in Exciton-Polaritons from Bound States in the Continuum — •Dario Ballarini — CNR-NANOTEC, Lecce, Italy

Exciton-polaritons in semiconductor microcavities have demonstrated remarkable collective behaviors and nonlinear interactions. In this work, we introduce an alternative platform to study strong light-matter interactions within a waveguide configuration. Among other interesting phenomena and applications, such as dispersion engineering of waveguide exciton-polaritons or exciton tuning through the Stark effect [1,2], we highlight the demonstration of parametric nonlinearities, polariton lasing from bound-in-the-continuum (BIC) states, and the recent realization of polariton BICs operating at room temperature in 2D materials [3-5].

DY 20.1 Wed 9:30 H37

The Sound of Entanglement — •Benjamin Orthner[1], Clemens Wenger[5], Johannes Kofler[2], Richard Küng[2], Enar de Dios Rodríguez[3], Martin Ringbauer[4], Alexander Ploier[2], and Philipp Haslinger[1] — [1]Vienna Center for Quantum Science and Technology, Atominstitut, TU Wien, Vienna, Austria — [2]Johannes Kepler University Linz, Austria — [3]Internationale Forschungszentrum Kulturwissenschaften, Kunstuniversität Linz, Austria — [4]University of Innsbruck, Austria — [5]Universität für Musik und darstellende Kunst Graz, Austria

This contribution presents *The Sound of Entanglement*, a project at the intersection of quantum physics, music, and visual art. At its core lies a Bell experiment setup, where polarization-entangled photon pairs are generated through spontaneous parametric down-conversion in a β-BBO crystal. The experiment acts as a quantum conductor, utilizing the quantum correlations between the photons to coordinate and influence the choices of live musicians in real-time, creating a performance guided by principles beyond classical physics.

This work seeks to make these abstract concepts more accessible and engaging to broader audiences by transforming them into tangible, sensory experiences. By combining live music with a dynamic light show, both controlled by the experiment, this project illustrates how advancements in technology, like those shaping the second quantum revolution, can redefine artistic expression and bridge the gap between science and art.

DY 20.2 Wed 9:45 H37

A Solvable Model for Full Eigenstate Thermalization — •Felix Fritzsch and Pieter W. Claeys — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

The Full Eigenstate Thermalization Hypothesis (Full ETH) aims to characterize thermalization in many-body quantum systems in terms of the dynamics of higher-order spatiotemporal correlation functions, going beyond the current standard ETH paradigm. In this talk, we introduce a solvable random matrix model for many-body quantum dynamics in which the asymptotic dynamics of generalized out-of-time-order correlation functions can be exactly obtained in the thermodynamic limit. The dynamics of this model naturally maps to dynamics on the lattice of non-crossing partitions, combinatorial structures underlying the mathematics of Free Probability and Full ETH. We demonstrate how local observables approach asymptotic freeness at late times and explicitly characterize all relevant time scales. We confirm our analytical results with numerical simulations performed directly in the thermodynamic limit.

DY 20.3 Wed 10:00 H37

Scrutinizing the Mori memory function for transport scenarios — •Scott Daniel Linz, Jiaozi Wang, Robin Steinigeweg, and Jochen Gemmer — Department of Mathematics/Computer Science/Physics, University of Osnabrück, D-49076 Osnabrück, Germany

Diffusion is a phenomenological hydrodynamic transport behavior that holds over a wide range of materials. Within condensed matter physics there is the opinion that as long as the area under the current-current correlation function

converges in time, one has a criterion for diffusive behavior of the corresponding spatiotemporal density dynamics. Attempts to derive this statement are notoriously challenging. We will first demonstrate that it is possible to construct correlation functions of some local density, where the area under a current-current correlation function converges, but the system is not diffusive. After this is demonstrated, we shall introduce a method based on the recursion method and the Mori memory formalism, that yields insight into whether or not a process is truly diffusive. The only disadvantage of this strategy is that one would have to know the behavior infinitely many Lanczos coefficients, whereas in practice one can only calculate a finite number of them in most cases. In the cases examined in this talk, however, the convergence or lack thereof becomes apparent to the naked eye with the finite amount of coefficients that were calculated.

DY 20.4 Wed 10:15 H37

Long-time Freeness in the Kicked Top — •Elisa Vallini and Silvia Pappalardi — University of Cologne, Köln, Germany

Recent work highlighted the importance of higher-order correlations in quantum dynamics for a deeper understanding of quantum chaos and thermalization. The full Eigenstate Thermalization Hypothesis, the framework encompassing correlations, can be formalized using the language of Free Probability theory. In this context, chaotic dynamics at long times are proposed to lead to free independence or "freeness" of observables. We investigate these issues in a paradigmatic semiclassical model - the kicked top - which exhibits a transition from integrability to chaos. Despite its simplicity, we identify several non-trivial features. By numerically studying 2n-point out-of-time-order correlators, we show that in the fully chaotic regime, long-time freeness is reached exponentially fast. These considerations lead us to introduce a large deviation theory for freeness that enables us to define and analyze the associated time scale. The numerical results confirm the existence of a hierarchy of different time scales, indicating a multifractal approach to freeness in this model. Our findings provide novel insights into the long-time behavior of chaotic dynamics and may have broader implications for the study of many-body quantum dynamics.

Periodically and aperiodically Thue-Morse driven long-range systems: from dynamical localization to slow dynamics — •VATSANA TIWARI — Indian Institute of Science Education and Research Bhopal, Bhopal, India

In this talk, I will discuss the impact of time-periodic and aperiodic field on power-law random banded matrix (PLRBM) model where variation in the power-law exponent yields a delocalization-to-localization phase transition. We investigate the periodically driven PLRBM model with the help of the static measures such as level spacing ratio and generalized inverse participation ratio and report the drive-induced multifractal to localization transition. The transport study of the periodically driven system demonstrates the transition from diffusive to logarithmically slow relaxation at dynamical localization point. Extending our analysis to the aperiodic Thue-Morse driving, we find that specific driving parameters leads to the *exact dynamical localization* in a disordered-free long-range model regardless of the long-range parameter. In the disordered case, the localized phase exhibits a long prethermal plateau followed by diffusion to an infinite temperature state, while the delocalized phase shows immediate diffusion. Additionally, we compare this with a quasi-periodic model that also undergoes a localization-delocalization transition, noting that, unlike the delocalized side of the disordered long-range model, it features a prolonged plateau followed by diffusion to the infinite temperature state.

Symmetry-Resolved Out-of-Time-Order Correlators with Projected Matrix Product Operators — •Martina Gisti, David Luitz, and Maxime Debertolis — Institute of Physics, University of Bonn, Nußallee 12, 53115 Bonn, Germany

Out-of-Time-Order Correlators (OTOCs) are key measures of quantum many-body chaos and information spreading. We systematically analyse OTOCs as a function of particle number for interacting spinless fermions in one dimension. With the concept of generalized operator charge, we develop a formalism for the time evolution of symmetry-projected matrix product operators, which we use to resolve the scrambling behaviour by particle number sector. Our results reveal a crossover from ballistic to diffusive dynamics at early times and a saturation regime at late times.

DY 20.7 Wed 11:00 H37

Revealing ultrafast phonon mediated inter-valley scattering through transient absorption and high harmonic spectroscopies — •Kevin Lively[1], Shunsuke Sato[2,3], Guillermo Albareda[2,4], Angel Rubio[2], and Aaron Kelly[2] — [1]Deutsches Zentrum für Luft- und Raumfahrt — [2]Max Planck Institute for the Structure and Dynamics of Matter — [3]University of Tsukuba — [4]Ideaded

Processes involving ultrafast laser driven electron-phonon dynamics play a fundamental role in the response of quantum systems in a growing number of situations of interest, as evinced by phenomena such as strongly driven phase transitions and light driven engineering of material properties. To show how these processes can be captured from a computational perspective, we simulate the transient absorption spectra and high-harmonic generation signals associated with valley selective excitation and intraband charge-carrier relaxation in monolayer hexagonal boron nitride. We show that the multitrajectory Ehrenfest dynamics approach, implemented in combination with real-time time-dependent density-functional theory and tight-binding models, offers a simple, accurate, and efficient method to study ultrafast electron-phonon coupled phenomena in solids under diverse pump-probe regimes which can be easily incorporated into the majority of real-time ab initio software packages.

Chiral basis for qubits and decay of spin-helix states — •Frank Göhmann — Fakultät für Mathematik und Naturwissenschaften, Bergische Universität Wuppertal, 42097 Wuppertal, Germany

In a recent cold-atom experiment by the Ketterle group at MIT one-dimensional spin-helix states could be prepared and their time evolution induced by the XXZ Hamiltonian could be observed. The experiment allows to adjust the anisotropy parameter of the latter. For the special case of the XX model we describe the spatio-temporal decay of a transversal spin helix explicitly. The helix pattern stays stable in space, but has a non-trivial time-dependent decay amplitude which is of scaling form and is governed by a universal function that can be represented as a semi-infinite determinant related to the discrete Bessel kernel. This representation is valid for all times, is numerically utterly efficient and allows us to obtain the long-time asymptotics of the function. Our work is a rare example of a quench that has been experimentally realized and for which the full time dependence could be calculated exactly.

DY 20.9 Wed 11:45 H37

Towards the chaotic melting at low energies in large systems — •Mathias Steinhuber[1], Jonas Rigo[2], Juan Diego Urbina[1], Klaus Richter[1], and Markus Schmitt[1,2] — [1]University of Regensburg, Regensburg, Germany — [2]Forschungszentrum Jülich GmbH, Peter Grünberg Institute, Quantum Control (PGI-8), Jülich, Germany

Thinking in a classical phase space picture, a many-body ground state should be localized around the minimum of the classical mean-field energy landscape with stable integrable features. But here, we investigate many-body ground states on chaotic features, as the phase space picture is actually fragile if we increase the system size and keep the quantum scale (the effective Plank constant $\hbar_{\text{eff}}$) fixed. With the new degrees of freedom, we disturb the energy landscape in the classical limit more and more such that classical chaos is present even for low energies. We show this phenomenon, called 'chaotic melting' [1,2], is indeed happening in the Bose-Hubbard system with disorder. By using neural quantum states we can push quantum calculations for ground states to large systems and find signatures of chaos at the ground state. An intriguing application for these large systems is that the Bose-Hubbard Hamiltonian with disorder is an effective model for transmon arrays which are a prime candidate for quantum computer hardware. Therefore we also gain access to quantum states describing a possible quantum computer with chaotic features.

Period n-tupling in driven two level systems — •Dhruv Deshmukh and Joachim Ankerhold — Institute for complex quantum systems, Ulm University, Germany

This talk presents the necessary and sufficient conditions for realizing period n-tupling phenomena in periodically driven two-level systems. For the specific case of a two-level system driven linearly by a sinusoidal drive, we numerically identify the drive parameters that enable period n-tupling. Experimental results verifying period doubling in an NV centre driven by a microwave drive, are given. Further, we show that period quadrupling drives yield pulses which are much faster than the standard (Rabi) $\pi/2$ and π pulses built from weak drives. These stronger and faster pulses can be utilized for qubit manipulation, enabling faster gates and more efficient pulse sequences. Moreover, they inspire a new strategy for constructing efficient pulses using a Floquet theory approach to optimal control. Furthermore, the drive parameters could also be set to achieve period-1 (stroboscopic) dynamical freezing. The fragility of such phenomena can be exploited for sensing applications, as illustrated with an example in magnetometry.

Efficient computation of cumulant evolution and full counting statistics: application to infinite temperature quantum spin chains — •Angelo Valli[1,2], Cătălin Pascu Moca[2,3], Miklós Antal Werner[1,4], Márton Kormos[1,2], Žiga Krajnik[5], and Tomaž Prosen[6] — [1]Budapest University of Technology

and Economics, Muegyetem rkp. 3., 1111 Budapest, Hungary — [2]HUN-REN BME Quantum Dynamics and Correlations Research Group — [3]University of Oradea, 410087, Oradea, Romania — [4]HUN-REN Wigner Research Centre for Physics, P.O. Box 49, 1525 Budapest, Hungary — [5]New York University, 726 Broadway, New York, NY 10003, USA — [6]University of Ljubljana, Jadranska 19, 1000 Ljubljana, Slovenia

We propose a numerical method to efficiently compute quantum generating functions (QGF) for a wide class of observables in one-dimensional quantum systems at high temperature. We obtain high-accuracy estimates for the cumulants and reconstruct full counting statistics from the QGF. We demonstrate its potential on spin S=1/2 anisotropic Heisenberg chain, where we can reach time scales hitherto inaccessible to state-of-the-art classical and quantum simulations. Our results are in excellent agreement with a recent Google Quantum AI experiment [2] and challenge the conjecture of the Kardar-Parisi-Zhang universality for isotropic integrable quantum spin chains.

DY 20.12 Wed 12:30 H37

Machine learning approach to study the properties of ground and excited states in the 1D Bose-Hubbard model — •Yilun Gao[1], Alberto Rodríguez González[2,3], and Rudolf A. Römer[1] — [1]Department of Physics, University of Warwick, Coventry, CV4 7AL — [2]Departamento de Física Fundamental, Universidad de Salamanca, E-37008 Salamanca, Spain — [3]Instituto Universitario de Física Fundamental y Matemáticas (IUFFyM), Universidad de Salamanca, E-37008 Salamanca, Spain

Many-body quantum interacting systems continue to play a key role in theoretical developments of modern condensed matter physics. Various numerical techniques have been used to explore the features of these many-body systems. Exact diagonalization methods, which most results going beyond ground state properties are based on, can only deal with small system sizes $L \lesssim 15$ because the Hilbert dimensions grow exponentially in L. Recently, deep learning has emerged as a numerical technique that uses strategies of artificial intelligence to predict the physics of such systems. Here we focus on the Bose-Hubbard chain and use HubbardNet [1] to investigate the physics of ground and excited states. We show that the energies and wavefunctions predicted by HubbardNet agree well with the ones calculated by exact diagonalization over a broad range of interaction strengths. We investigate the properties of the eigenstates via their finite-size generalized fractal dimensions. [1] Ziyan Zhu, et al., HubbardNet: Efficient predictions of the Bose-Hubbard model spectrum with deep neural networks, Phys. Rev. Res., **5**, 043084 (2023)

DY 20.13 Wed 12:45 H37

Entanglement Transitions in Quantum Games through Reinforcement Learning — •Giovanni Cemin[1], Marin Bukov[1], and Markus Schmitt[2,3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]University of Regensburg, Regensburg, Germany — [3]Forschungszentrum Jülich, Institute of Quantum Control, Jülich, Germany

In this research, we investigate the dynamics of entanglement in Cliord circuits by employing a reinforcement learning (RL) algorithm in competition with a random agent. The RL agent is designed to strategically place gates that decrease entanglement, while the random agent aims to increase entanglement. This interaction between the two agents results in an entanglement transition, the nature of which is induced by the level of information accessible by the RL agent. By systematically varying the information provided to the RL agent, we analyze its impact on the transition characteristics. Our findings provide new insights into the interplay between entanglement manipulation and information constraints, shedding light on the fundamental mechanisms governing quantum circuit dynamics.

DY 21: Granular Matter

Time: Wednesday 9:30–11:30 Location: H43

DY 21.1 Wed 9:30 H43

Coarsening dynamics of ferrogranular networks for different granular temperatures — •Ali Lakkis[1], Matthias Biersack[1], Oksana Bilous[2], Pedro A. Sanchez[2], Sofia S. Kantorovich[2], and Reinhard Richter[1] — [1]University of Bayreuth, Experimental Physics 5, Universitätsstr. 30, 97440 Bayreuth, Germany — [2]University of Vienna, Faculty of Physics, Kolingasse 14-16, 1090 Vienna, Austria

We are exploring in experiments the aggregation process in a shaken granular mixture of glass and magnetized steel beads, filled in a horizontal vessel. After the shaking amplitude is suddenly decreased, the magnetized beads form a transient network that coarsens in time into compact clusters [1]. Recently it has been quantified how a homogeneous magnetic field B oriented in vertical direction impedes the emergence and growth of the networks [2,3], where the mean degree $\bar{k}$ of a node serves as an order parameter. Here we explore the impact of the acceleration amplitude Γ onto the velocity distribution of the particles, their granular temperature, and the coarsening dynamics of the network, i.e. $\bar{k}(\Gamma)$.

DY 21.2 Wed 9:45 H43

Decoding diffusion: insights into ferrogranulate dynamics under competing interactions — •Oksana Bilous[1], Kirill Okrugin[1], Pedro A. Sánchez[1], Ali Lakkis[2], Matthias Biersack[2], Reinhard Richter[2], and Sofia Kantorovich[1] — [1]Computational and Soft Matter Physics, University of Vienna, Vienna, Austria — [2]Experimental Physics 5, University of Bayreuth, Bayreuth, Germany

Granulates with magnetic and non-magnetic particles exhibit unique diffusion behaviors, challenging conventional models. Using experiments and Langevin dynamics simulations, we studied their dynamics under varying magnetic fields and particle compositions.

In steady states, entropic, dipolar, and field-induced forces create distinct distributions: single particles, cluster-bound particles, and migrating particles transitioning between these states. Sub-diffusion occurs exclusively in magnetic particles within clusters, independent of external fields or concentrations. Glass particles remain non-aggregated.

Velocity distributions in high-shaking experiments validate the use of Langevin dynamics, revealing an effective temperature that links structural separations to thermodynamic scaling laws. These findings deepen our understanding of diffusion and force interactions in complex granular systems.

DY 21.3 Wed 10:00 H43

Advances and challenges in experiments with granular gases of rod-like particles — •Dmitry Puzyrev[1], Torsten Trittel[2,1], Kirsten Harth[2,1], Mahdieh Mohammadi[2], Raul Cruz Hidalgo[3], and Ralf Stannarius[2,1] — [1]Otto von Guericke University, Magdeburg, Germany — [2]Brandenburg University of Applied Sciences, Brandenburg an der Havel, Germany — [3]Univerisity of Navarra, Pamplona, Spain

Granular gases, i.e., ensembles of free-moving macroscopic particles which collide inelastically, demonstrate fascinating dynamical effects like unusual cooling properties, violation of energy equipartition, clustering, and spontaneous collective movement. Our investigation is focused on 3D microgravity experiments with ensembles of rod-like particles [1] and their mixtures. With the help of machine learning methods, we have obtained various statistical properties for the mixture of thinner and thicker rods [2]. Kinetic energy partitions and collision numbers were extracted for both vibrational heating and homogeneous cooling regimes. The systems in question pose some conundrums, such as cooling rates larger that theoretically predicted or accumulation of kinetic energy in rotational DOF which is hard to observe in the experiment. Currently, the granular gas mixture of shorter and longer rods is under analysis. Our studies are funded within by the DLR projects VICKI, EVA-II, JACKS, and KORDYGA (50WM2252, 50WK2348, 50WM2340, and 50WM2242). [1] K. Harth et al., Rev. DY 21.4 Wed 10:15 H43

Force networks in granular experiments: From topology to dynamics — •Lou Kondic — Department of Mathematical Sciences, NJIT, Newark, NJ, USA

We will discuss force networks that spontaneously form in particulate-based systems. These networks, most commonly known as 'force chains' in granular systems, are dynamic structures of fundamental importance for revealing the underlying causes of many physical phenomena involved in the statics and dynamics of particulate-based systems. While these networks emerging from discrete element simulations have been analyzed extensively, the analysis of networks found in physical experiments is far less developed. The presentation will focus on applications of algebraic topology, particularly persistent homology (PH) to analysis of such networks. PH allows for a simplified representation of complex interaction fields in both two and three spatial dimensions in terms of persistent diagrams (PDs) that are essentially point clouds. These point clouds could be compared meaningfully, allowing for the analysis of the underlying systems' static and dynamic properties. The presentation will focus on applications of topological data analysis of such networks found in photoelastic experiments involving an intruder moving in a stick-slip fashion through a 2D granular domain. We will particularly focus on exploring the predictability potential of the considered topological measures.

DY 21.5 Wed 10:30 H43

Crystallization dynamics in a dense sphere system — •Frank Rietz and Matthias Schröter — Max Planck Institute for Dynamics and Self-Organization (MPIDS), Göttingen

When balls are thrown into a box and subsequently agitated, they tend to arrange themselves in a denser configuration, as observed in numerous experiments. However, a barrier is typically present at random close packing, which occupies approximately 64% of the available space. The spheres remain in their densest amorphous state and do not undergo a phase transition to a denser crystalline structure with a space-filling ratio of 74%. In our experiment, we successfully surmounted this barrier and observed the emergence of crystallization events from the disordered phase [1].

Initially, we observed the formation of groups of a few spheres that fluctuated between a disordered and a nucleated state. In rare instances when the balls remained in the ordered state, further investigation was conducted into their preceding conditions. This approach enables us to address the question of why the majority of precursors are not stable, while a few of them undergo growth to become part of the larger crystals of FCC and HCP structures that never dissolve.

Vibro-fluidized beds: A systematic dynamics study utilizing Diffusing Wave Spectroscopy — •Marlo Kunzner, Christopher Mayo, Matthias Sperl, and Jan Philipp Gabriel — Deutsches Zentrum für Luft- und Raumfahrt, Köln, Deutschland

Using a granular vibration fluidised bed, we demonstrate how our granular model system of polystyrene spheres becomes denser over time through different excitation amplitudes and how the heterogeneous dynamics of the system can be resolved with diffusing wave spectroscopy(DWS) measurements. We extract mean-square displacements from the DWS correlation functions of the sinusoidal excited system and model the excitation to extract the ballistic and diffusive time constants, as well as caging sizes, depending on applied acceleration and excitation time. At low excitations we observe a sub-diffusion power law behaviour of the MSD indicating potentially a glassy system.

Simulation of Spherical Particles as a Granular Gas in Microgravity: A Comparison with Experimental Results — •Mahdieh Mohammadi[1], Torsten Trittel[1], Rau'l Cruz Hidalgo[2], Dmitry Puzyrev[3], Ralf Stannarius[1], and Kirsten Harth[1] — [1]Department of Engineering, Brandeburg University of Applied Sciences, Magdeburger Str. 50, 14770 Brandenburg an der Havel,Germany — [2]Departamento de Física y Matemática Aplicada, Facultad de Ciencias , Universidad de Navarra, Pamplona, Spain — [3]MTRM, Otto von Guericke University Magdeburg, Universitätsplatz 2, 39106 Magdeburg, Germany

Simulation of a Granular Gas of Frictional Spherical Particles in Microgravity: A Comparison with Experimental Results

We investigate dilute granular ensembles (granular gases) of rough spheres in Microgravity, both in experiment and simulation. The experiment examines the time scale (Haff time) for energy dissipation in an initially excited granular gas, the collision statistics, and the distribution of angular and translational velocities. We aim to determine how well the experimental results can be reproduced by a DEM simulation. A variety of criteria were tested, including different restitution coefficients. One goal of the simulation is to analyze the effect of different collision parameters on the statistical properties of a granular gas. Second, we aim demonstrate how the model can effectively replicate the experimental data, with a strong correlation between the translation energy in the model and experimental data.

We thank DLR for funding in grants 50WM2242 / 50WM2340.

Aerodynamic origin of aeolian mineral dust emission — Sandesh Kamath[1,2], Yaping Shao[2], and •Eric Parteli[1] — [1]Fakultät für Physik, Universität Duisburg-Essen — [2]Institut für Geophysik und Meteorologie, Universität zu Köln

Atmospheric dust aerosol particles exert a substantial impact on climate, radiation balance, and various other components of the Earth's system. However, state-of-the-art climate models rely on empiric parameterization schemes for the vertical dust flux at emission. While such schemes are derived from wind-tunnel simulations on flat granular beds, environmental soils are often characterized by a spatial distribution of non-erodible elements and crusts. Indeed, the vertical flux predicted by the various schemes often differs from observations by orders of magnitude. Here we develop a numerical tool for the particle-based simulation of wind-blown transport of granular particles in the atmospheric boundary layer. Our model accurately reproduces the observed minimal threshold wind shear velocity for direct fluid entrainment over the entire broad range of particle diameters from dust to gravel particles. However, we show that a topographic effect in polydisperse beds and soils with large non-erodible elements lowers the minimal threshold for dust entrainment substantially. This finding challenges our understanding that dust is mainly ejected at sand grain-bed collisions, rather than being directly entrained by wind. Our simulations show that dust can be emitted as single grains, as dust agglomerates, or coated on the surface of sand grains, depending on dust grain size.

Adaptive Quasi-Monte Carlo Quadrature for Concentrated Distributions in Bayesian Inference — •Jinyi Zhou and Sebastian Matera — Fritz-Haber-Institut der MPG, Berlin

By its probabilistic formulation, Bayesian inference cures many of the problems of the traditional parameter-fitting approach, such as potential ill-posedness and the lack of reliable uncertainty estimates. However, for highly nonlinear and sensitive models, the Bayesian posterior distribution can become complex and is often concentrated in a small fraction of the parameter space. This challenges established sampling approaches, which typically perform well only for smooth distributions. We address this challenge with a novel adaptive Quasi-Monte Carlo (aQMC) quadrature method. This approach combines the highly uniform coverage of Quasi-Monte Carlo with a greedy iterative subdivision algorithm, concentrating the sampling in subdomains where the quadrature error is expected to be largest. In addition to testing on benchmark functions, we demonstrate our approach on a kinetic model from the field of catalysis. In this field, concentrated distributions are expected because, even with the best priors derived from quantum chemical calculations, uncertainties can span several orders of magnitude for the predicted catalytic response, whereas experimental data is highly accurate in comparison.

DY 22.2 Wed 10:00 P3

A novel mathematical model for the coupled binary-fluid surfactant system — •Alexandra Hardy, Steven McDonald, Abdallah Daddi-Moussa-Ider, and Elsen Tjhung — The Open University, Milton Keynes, UK

We propose a new binary-fluid surfactant mathematical model derived from modeling the surfactant molecules as dumbbells. By explicitly taking into account the molecules alignment, we gain new field variable p(r,t); the average orientation of surfactants. Combined with standard phase-field theory for binary fluids gives the system equations, which we both solve numerically and analytically. We employ a hybrid finite difference (FDM) and spectral method for the simulations. Whereas regular perturbation theory is used for the equilibrium solutions, facilitated by assuming weak coupling between surfactant and fluid. Three investigations are presented, firstly we demonstrate excellent agreement between simulation and the analytical solutions for a planar water-oil interface. Second, we prove that our model accurately predicts the decrease in surface tension with increasing surfactant concentration, in line with experiments and related theory. Finally, we show that our model is capable of preventing surfactant-laden droplet coalescence due to the added polarization field p(r,t).

DY 22.3 Wed 10:00 P3

Nonequilibrium mixture dynamics: a model for mobilities and its consequences — •Maryam Akaberian[1], Filipe C Thewes[1,3], Peter Sollich[1,2], and Matthias Krüger[1] — [1]University of Goettingen — [2]King's College London — [3]Max plank institute

extending the famous model b for the time evolution of a liquid mixture, we derive an approximate expression for the mobility matrix that couples the different mixture components. this approach is based on a single component fluid with particles that are artificially grouped into separate species labelled by "colors". The resulting mobility matrix depends on a single dimensionless parameter, which can be determined efficiently from experimental data or numerical simulations, and includes existing standard forms as special cases. we identify two distinct mobility regimes, corresponding to collective motion and interdiffusion, respectively, and show how they emerge from the microscopic properties of the fluid. as a test scenario, we study the dynamics after a thermal quench, providing a number of general relations and analytical insights from a gaussian theory. specifically, for systems with two or three components, analytical results for the time evolution of the equal time correlation function compare well to results of Monte Carlo simulations of a lattice gas. a rich behavior is observed, including the possibility of transient fractionation.

DY 22.4 Wed 10:00 P3

Transport in classical systems with fractionally charged excitations — •Jannis Waldmann, Malte Grunert, Max Grossmann, and Erich Runge — Theoretical Physics I, Institute of Physics, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Interacting systems of charged particles can show fractionally charged excitations, as is well known from the Fractional Quantum Hall Effect of electrons in a magnetic field. Fractionally charged excitations in the absence of magnetic fields have also been predicted for certain lattices with geometric frustrations, e.g. for quantum mechanical models of spinless fermions on the criss-crossed checkerboard lattice [1,2]. Here, we present result on transport properties of classical particles with nearest-neighbor repulsion on a Kagome lattice. Using Monte Carlo simulations, we study the transition from classical hopping at high temperatures to transport dominated by half-charged quasi-particles for special filling factors at low temperatures. Furthermore, we provide evidence for a residual entropy at zero temperature and Andreev-like reflection at interfaces to 'normal', i.e. not frustrated systems.

DY 22.5 Wed 10:00 P3

Diffusion and order in mixed lattice gas of hard squares — •Piotr Nowakowski[1], Niklas Raake[2], and Ana-Sunčana Smith[2,1] — [1]Institut Ruđer Bošković, Zagreb, Croatia — [2]Friedrich–Alexander–Universität Erlangen–Nürnberg, Erlangen, Germany

We study the diffusion in a crowded environment using a model system of a lattice gas composed of hard square particles of 1×1 and 2×2 size (measured in lattice constant units) undergoing a Brownian motion on a two-dimensional square lattice. For the whole range of concentrations of both types of particles, we numerically test the accuracy and efficiency of an approximation of the motion by a persistent random walk with one or two step memory. A good agreement is observed for very low and very high concentrations of particles.

Additionally, we look at the second order phase transition from a gas phase for low densities of 2×2 particles to a columnar phase. Surprisingly, it seems that the density of large particles at which the transition occurs is not affected by the presence of smaller particles. Moreover, in columnar phase the diffusion constant can be approximated by studying a one-dimensional system.

DY 22.6 Wed 10:00 P3

The bath *remembers*: how many time-scales can we probe through recoil? — •Rupayan Saha[1], Niloyendu Roy[2], Debankur Das[1], Clemens Bechinger[2], and Matthias Krüger[1] — [1]Institute for Theoretical Physics, Georg-August-Universität Göttingen, Göttingen 37073, Germany — [2]Fachbereich Physik, Universität Konstanz, Konstanz 78457, Germany

Recoil experiments, where one studies the transient dynamics of a colloidal particle after driving it externally, are of particular importance to gain insight into the non-Markovian properties prevalent in visoelastic solvents such as micellar suspensions. In an earlier experimental study by Félix Ginot et al. [*New J. Phys. 24.12 (2022): 123013*], the *translational* recoil was found to be governed by a small number of distinct time scales, reproduced by a microscopic model using a small number of so-called bath particles. In this contribution, we investigate *orientational* recoil of such a colloidal probe in a viscoelastic fluid, which, in contrast, appears to exhibit a large number of time scales. In collaboration with experiment, we develop microscopic models to account for such observations, and develop driving protocols to dissect the various time scales involved in this process.

DY 22.7 Wed 10:00 P3

Large-deviation simulation of the coupling time distribution for the CFTP method applied to the heat bath Ising process — •Mathis Groenhagen, Alexander K. Hartmann, and Peter Werner — Institut für Physik, Carl von Ossietzky Universität Oldenburg, 26111 Oldenburg, Germany

Coupling from the past (CFTP), introduced by Propp and Wilson [1], is a version of the Markov-chain Monte Carlo method, which is capable of generating exact samples from a finite set with a particular distribution. The performance of the CFTP method for a given application can be characterized by the distribution of the CFTP method's random running time, the *coupling time* τ, for this application.

A large-deviation Monte Carlo algorithm, as described for example in [2], is used to sample these coupling times for the application of the CFTP method to a single-spin-update heat-bath process for the ferromagnetic two-dimensional square lattice Ising model without an external field. This yields the coupling time distributions over a wide range of coupling times τ down to probability densities of 10^{-80} for different lattice sizes L and temperatures T. These results give additional numerical evidence for the analytical results shown in [3].

DY 22.8 Wed 10:00 P3

Large-deviation simulations of non-equilibrium stochastic processes — •Chinmay Chandratre — Heinrichstr. 16, 26131 Oldenburg

For N non-interacting diffusing particles in a harmonic trap where the stiffness is switched randomly between μ_1 and μ_2, the joint distribution of particle positions has been exactly computed [1]. This allowed the computation, in the limit of $N \to \infty$, of the distribution of the position M_k of the k-th rightmost particle. It is governed by a universal scaling function with finite support and tunable shape. However, the behaviour for finite numbers of particles, where the large-deviation corrections become relevant, is analytically not known. Numerically, standard algorithms fail to access the majority of the support, particularly in the tails. Here, special large-deviation algorithms [2] are used to access the tails of the distribution, reaching probabilities as small as 10^{-200} or even smaller. This includes a highly general *black-box* algorithm suitable for studying a wide range of stochastic processes.

Residual entropy of ice: A study based on transfer matrices — •De-Zhang Li[1], Yu-Jie Cen[2], Xin Wang[3], and Xiao-Bao Yang[4] — [1]Quantum Science Center of Guangdong-Hong Kong-Macao Greater Bay Area — [2]Institute of Materials Chemistry, Vienna University of Technology — [3]Department of Physics, City University of Hong Kong — [4]Department of Physics, South China University of Technology

The residual entropy of ice systems has long been a significant and intriguing issue in condensed-matter physics and statistical mechanics. This study focuses on two typical realistic ice systems: hexagonal ice (ice Ih) and cubic ice (ice Ic). We present a transfer-matrix description of the number of ice-ruled configurations for these systems. A transfer matrix M is constructed for ice Ic, where each element represents the number of ice-ruled configurations of a hexagonal monolayer under certain conditions. The product of M and M^T corresponds to a bilayer unit in the ice Ih lattice, thus forming an exact transfer matrix for ice Ih. Utilizing this, we show that the residual entropy of ice Ih is not less than that of ice Ic in the thermodynamic limit, first proved by Onsager in the 1960s. Additionally, we introduce an alternative transfer matrix M' for ice Ih based on a monolayer periodic unit. Various interesting properties of M, MM^T and M' are analyzed, including the sum of all elements, the element in the first row and first column, and the trace. Each property corresponds to the residual entropy of a certain 2-d ice model. This work provides an effective description, based on transfer matrices, for the residual entropies of various 2-d ice models.

DY 22.10 Wed 10:00 P3

Beyond mean-field kinetic theory of nematic self-propelled particles — •Benjamin Kohler, Horst-Holger Boltz, and Thomas Ihle — Institute for Physics, University of Greifswald, 17489 Greifswald, Germany

We present Landau kinetic theory and direct simulation results for systems of self-propelled particles with alignment interactions of higher-order symmetry with a particular focus on nematic couplings. Systematically expanding the BBGKY-hierarchy approximation beyond the mean-field contributions, we employ the one-sided molecular chaos assumption and an diagrammatic approach to account for higher order correlations. Our calculations yield predictions with no free parameters that are in quantitative agreement with direct agent-based simulations without being restricted to low densities.

DY 22.11 Wed 10:00 P3

Barrier crossing and rare fluctuations of active Brownian particles — •Rafael Diaz Hernandez Rojas[1], Karthik Cheruvary[1,2], and Peter Sollich[1] — [1]University of Göttingen — [2]IISER Pune

Understanding noise-induced transitions is crucial for modelling complex systems where random fluctuations can affect both the local stability and the global behaviour of a system. Noise-activated escape processes are a key instance, and were solved by Kramers long ago for barrier crossing driven by thermal noise. A natural question is how different noise sources might change the picture, in particular those postulated in active matter models. Here we study the escape problem for the paradigmatic case of an Active Brownian Particle, where the direction of the self-propulsion velocity rotates randomly on a timescale known as persistence time. Using a path integral formalism in the weak thermal noise limit. We map the problem of finding the most likely escape trajectory to the minimisation of an appropriate action. We show that optimal trajectories always consist of an initial relaxation in a tilted potential, beyond which the escape becomes genuinely activated. We apply our approach to convex potentials (to study barrier climbing by rare fluctuations) as well as potentials with multiple minima (to analyse barrier crossing). We highlight the effects of directionality induced by the self-propulsion and its non-trivial interplay with the shape of the potential. A key result is that, for potentials with a symmetry axis along the line between two minima, activity can generate optimal escape paths that break this symmetry.

DY 22.12 Wed 10:00 P3

Rarefied gas transport in a narrow channel induced by an asymmetric wall geometry — •Constantin Rein[1], Klaus Kroy[1], and Viktor Holubec[2] — [1]Brüderstr. 16, D-04103 Leipzig — [2]V Holešovičkách 747/2, Praha 8, Czech Republic

Since the work of Knudsen on gas transport in a narrow channel, it is known that gases in the dilute limit, where the mean free path is larger than the characteristic length scale, behave different as compared to the well known finite density regime[1]. So-called Knudsen pumps use temperature differences along channel walls to induce gas particle transport along the channel[2]. Inspired by the working principle of our recently introduced active Brownian ratchet[3], we investigate numerically and analytically the gas transport phenomenon appearing in a narrow channel with specular walls, except for a diffusively reflecting triangle that protrudes into the channel from one of the walls. Despite the absence of a variation in the wall temperature, a flow emerges. It arises solely from an asymmetry of the incoming and outgoing orientational distribution. The magnitude, direction and flow pattern of the induced transport is discussed.

Dielectric response and fluctuation-dissipation-theorem for moving bodies — •Daniele Gamba, Philip Rauch, and Matthias Krüger — Georg-August University, Göttingen

Casimir forces operate at microscopic scales and are integral to phenomena such as gecko adhesion and functionality of nano-devices. Recent research has unveiled new effects, arising from thermal and mechanical non-equilibrium, such as levitation or propulsive forces capable to driving heat engines, or novel effects tied to optically non-reciprocal materials [1,2]. In this contribution we formulate scattering theory for objects in respective motion. Specifically, we find the dielectric response and the fluctuation-dissipation theorem for arbitrary moving bodies. The dielectric response of a moving body is found to be nonlocal in space, optically non-reciprocal, and can also appear as being active. Conversely, it is possible to design an active medium that appears optically passive when in motion. Finally, we derive closed expressions for Casimir forces and heat transfer between moving bodies using scattering theory.

DY 22.14 Wed 10:00 P3

Criticality in non-reciprocal spin modells — •Max Hässler and Martin Weigel — TU Chemnitz, Chemnitz, Deutschland

Equilibrium statistical physics is based on symmetric, Hamiltonian interactions fulfilling Newton*s Third Law. On the other hand, active matter like bacteria or other self-propelled particles such as bird flocks violates time-reversal symmetry and is often characterized by non-reciprocal interactions. Simple models are of interest for exploring fundamental features of such systems. We examine classical spin systems including the Ising model with non-reciprocal interactions, using Monte Carlo simulations to study criticality in such models. For several systems we determine critical exponents and compare the observed universality classes to those of the corresponding reciprocal, equilibrium models.

DY 22.15 Wed 10:00 P3

Harnessing finite-size effects to gauge aging in the $2D$ Ising model — •Dustin Warkotsch[1,2], Malte Henkel[2,3], and Wolfhard Janke[1] — [1]Institut für Theoretische Physik, Universität Leipzig, Leipzig, Germany — [2]Laboratoire de Physique et Chimie Théoriques (CNRS UMR 7019), Université de Lorraine, Nancy, France — [3]Centro de Física Teórica e Computacional, Universidade de Lisboa, Lisbon, Portugal

The finite-size effects in a $2D$ Ising model with nearest-neighbor interactions are investigated at low temperature with respect to the two-time autocorrelation function $C(t,s)$, where t is the observation and s the waiting time. Using a finite-size scaling ansatz established for the spherical model linking the resulting plateaus in $C(t,s)$ to waiting time s and lattice size L, a precise and reproducible estimation for the autocorrelation exponent λ and dynamical exponent z is developed.

DY 22.16 Wed 10:00 P3

Theoretical and Experimental Advances in Non-Equilibrium Statistical Physics — •Anton Zizenko — Bolshaya Semenovskaya 38

Research helps to understand how complex systems behave when they are far from equilibrium, such as in cases of anomalous transport or phase transitions. Main achievements: Relaxation and fluctuations: Describing the behavior of systems after external influence. Critical phenomena: Studying changes in systems out of equilibrium. Entropy production: Connection with energy loss processes and irreversibility. Applications: Development of materials with new properties, improvement of thermal conductivity, and optimization of processes in chemistry and biology.

DY 22.17 Wed 10:00 P3

Frustrated Self-Assembly — •Andrey Zelenskiy and Martin Lenz — Université Paris-Saclay, CNRS, LPTMS, 91405, Orsay, France

Biomolecular self-assembly lies at the very heart of the function of living cells, where it organizes individual components into functional biological machines. The macromolecular sub-units typically correspond to proteins, whose shapes have been optimized over millions of years of evolution to ensure a proper functionality of the self-assembled structures. However, in pathological cases, proteins fail to achieve the optimal folding, which often leads to complex ill-fitting shapes. This produces geometrical incompatibility, which leads to frustrated interactions between the sub-units. Surprisingly, despite a huge variability in protein structure, such misfolded units tend to robustly self-assemble into aggregates with well-defined morphologies. Interestingly, these structures display a clear preference for slimmer topologies, such as fiber aggregates. This emergent principle of dimensionality reduction suggests that the aggregation of irregular components derives from the generic physical principles, rather than the microscopic details of the interactions.

Inspired by this idea, we model the frustrated self-assembly of ill-shaped proteins as coarse-grained anisotropic particles, whose interactions depend on their relative orientations and positions in space. This simple model successfully reproduces a hierarchy of aggregate morphologies and gives pointers to the origins of dimensionality reduction.

DY 22.18 Wed 10:00 P3

Topological and thermodynamic inference in Markov networks with observed and hidden transitions — •Alexander M. Maier[1], Udo Seifert[1], and Jann van der Meer[2] — [1]II. Institut für Theoretische Physik, Universität Stuttgart, 70550 Stuttgart, Germany — [2]Kyoto University, Graduate School of Science, Division of Physics and Astronomy, Oiwakecho 145-10, Kyoto 606-8224, Japan

The number of observable degrees of freedom is typically limited in experiments. Here, we consider discrete Markov networks in which an observer has access to a few visible transitions. We present what information, locally and globally, of such a Markov network can be inferred from the observed data. In particular, we shed light on operationally accessible information about the topology of shortest paths between visible transitions in the underlying graph and show a rule that allows us to identify potential clusters of states or exclude their existence. Moreover, we show how to estimate entropy production along an observable, coarse-grained path. Combining this with further inferable information, we propose two strategies to reconstruct a graph that is compatible with the observations and part of the original graph underlying the Markov network. This approach highlights how much information waiting-time distributions contain while also paving the way to infer thermodynamically consistent models of observed partially accessible systems.

DY 22.19 Wed 10:00 P3

Stroboscopic measurements in Markov networks: Thermodynamic inference vs. exact generator reconstruction — •Malena Thea Bauer[1], Udo Seifert[1], and Jann van der Meer[2] — [1]II. Institut für Theoretische Physik, Universität Stuttgart, 70550 Stuttgart, Germany — [2]Kyoto University, Graduate School of Science, Division of Physics and Astronomy, Oiwakecho 145-10, Kyoto 606-8224, Japan

A major goal of stochastic thermodynamics is to estimate the inevitable dissipation that accompanies particular observable phenomena in an otherwise not fully accessible system. Quantitative results are often formulated as lower bounds on the total entropy production, which capture a part of the total dissipation that can be determined based on the available data alone. In this work, we discuss the case of a continuous-time dynamics on a Markov network that is observed stroboscopically, i.e., at discrete points in time in regular intervals. We compare the standard approach of deriving a lower bound on the entropy production rate in the steady state to the less common method of reconstructing the generator from the observed propagators by taking the matrix logarithm. Provided that the timescale of the stroboscopic measurements is smaller than a critical value that can be determined from the available data, this latter method is able to recover all thermodynamic quantities like entropy production or cycle affinities and is therefore superior to the usual approach of deriving lower bounds. We conclude the comparison of both methods with numerical illustrations and a discussion of the requirements and limitations of both methods.

DY 22.20 Wed 10:00 P3

Brownian particles for unconventional computing — •Alessandro Pignedoli, Atreya Majumdar, and Karin Everschor-Sitte — Faculty of Physics and Center for Nanoin- tegration Duisburg-Essen (CENIDE), University of Duisburg-Essen

Brownian particles naturally explore a system's configuration space offering an energy efficient approach to optimisation problems [1]. We demonstrate that

interacting Brownian particles can solve optimisation problems [2,3] more efficiently than individual particles acting alone. This collective efficiency arises from their local interactions, which mimic the principles of swarm intelligence, where the whole systems emergent behaviour outperforms the sum of its individual components [4].

Investigating hydrogen isotopologues at cryogenic temperature in the gas, liquid, and solid phase with the T2ApIR experiment — •Alexander Marsteller, Dominic Batzler, Beate Bornschein, Lutz Bornschein, Tobias Falke, Florian Hanss, Joshua Kohpeiss, Bennet Krasch, Simone Wadle, and Robin Grössle — Karlsruher Institut für Technologie, Karlsruhe, Deutschland

Cryogenic hydrogen is of interest for a wide range of research topics such as fundamental phyiscs of liquids, astrophysics or energy storage. Tritium, the radioactive isotope of hydrogen, is of particular use as an electron source for neutrino mass measurement, and also the most promising contender for fuel in nuclear fusion for power generation. In spite of this, literature on the material properties of tritium is sparse. To improve upon this, the Tritium Absorption InfraRed Spectroscopy 2 (T2ApIR) Experiment has been designed and built at the Tritium Laboratory Karlsruhe (TLK), and is currently in its scientific commissioning phase. The main focus of this experiment is to enable the investigation of the properties of all six hydrogen isotopologues and their mixtures in the gaseous, liquid, and solid phase. This is achieved using infrared absorption spectroscopy, a polariscope setup, Raman spectroscopy, as well as a temperature and pressure measurement. On this poster I will present the T2ApIR setup as well as some of the first measurements performed with it.

DY 22.22 Wed 10:00 P3

GEANT4 based design to measure the solubility of tritiated molecules in dual phase xenon — •J.R. Braun[1], V. Aures[2], D. Forck[1], R. Grössle[1], and M. Röllig[1] — [1]Tritium Laboratory Karlsruhe, Eggenstein-Leopoldshafen, Germany — [2]Technische Universität München, Garching bei München, Germany

Detection of trace amounts of tritium is a challenging task that can be tackled using scintillation. Liquid xenon is an excellent scintillator for this purpose. A fundamental property in designing analytical systems for tritium detection is the solubility of tritiated molecules. Trace detection of tritium is critical for experiments aimed at the detection of rare physical interactions, such as the direct detection of dark matter, where naturally occurring tritium background is a challenge to overcome. Consequently, systems for both detection and removal of tritium are required. The aim of the "Tritium in Xenon" (TriXe) experiment is to determine the Henry solubility and the diffusion constant of tritiated hydrogen, water and methanes in dual-phase xenon in thermal equilibrium. TriXe employs a dual-phase chamber in which the xenon is present at operating conditions of DARWIN. By detecting VUV scintillation light with photomultipliers, the concentration of the tritiated molecules in each phase can be determined, as the concentration is proportional to the counting rate. Together with the second diffusion law, the diffusion constant can be deduced from the change in the count rate over time. The results of TriXe can be used to make qualitative and quantitative suggestions for changes in background reduction and direct tritium monitoring by cryogenic distillation.

DY 22.23 Wed 10:00 P3

Precise Estimation of the Liquid-Gas Critical Point of Water — •Mayank Sharma and Peter Virnau — Institute of Physics, Johannes Gutenberg University Mainz

We perform Molecular Dynamics simulations to investigate the liquid-gas critical point for the TIP4P water model. In the canonical (NVT) ensemble, density fluctuations are quantified and analyzed using a recently developed method [1] based on cumulant crossings. Complementary simulations in the isothermal-isobaric (NPT) ensemble yield density and energy distributions, which are mapped onto the universal 3D Ising master curve via histogram reweighting. The critical points determined by the two approaches exhibit very good agreement, highlighting the robustness of this methodology. This work establishes a reliable framework for accurately locating the critical point which is applied to test the influence of ionic conditions on the latter.

Linking Local and Macroscopic Transport Properties in Confined Electrolyte Systems: Molecular Dynamics Simulations of Water Swollen Hectorite — •Bastian Füsser, Aqsa Nisar, and Michael Vogel — Technische Universität Darmstadt, Darmstadt, Germany

In this work, we study the structural and dynamic properties of water and ions in hectoriete slit confinements using molecular dynamics simulations. Our goal is to develop a detailed understanding of the relationship between local interactions and macroscopic ion transport.

This study is part of a collaboration aiming to bridge experimental observations and theoretical models. Initially, we simulate hectorite systems as realistically as possible to compare the simulation results with experimental results. Subsequently, we investigate artificial systems to systematically analyze the role of specific parameters, such as layer charge. In doing so, we vary the interlayer spacing, solvent composition, and ion concentration.

Our goal is to develop an understanding of the relation between local interactions and dynamics with the long-range transport in confined electrolyte systems. These insights provide valuable contributions to the development of more efficient electrochemical systems, e.g., devices for energy storage and conversion.

DY 22.25 Wed 10:00 P3

Phase transitions in mesoporous solids with structural disorder — •Ali Alzaidi[1], Georgiy Baroncha[1], Dirk Enke[1], Eustathius Kikkinides[2], and Rustem Valiullin[1] — [1]Leipzig University, Leipzig, Germany — [2]Aristotle University of Thessaloniki, Thessaloniki, Greece

Phase transitions within the pore spaces of structurally disordered porous solids exhibit complex behavior with many aspect remaining poorly understood. This complexity arises from cooperative effects emerging during first-order phase transitions in pore networks. Building on the microscopic mechanisms of phase transitions occurring in single pores and between neighboring pores, we propose a statistical thermodynamic model to describe phase transitions in pore networks driven by two competing mechanisms: invasion and nucleation. We solve this model for two types of statistically disordered pore networks, linear pore chains and Bethe lattices, and correlate the results with experimental data on gas-liquid and solid-liquid equilibria in disordered porous glasses.

DY 22.26 Wed 10:00 P3

Cluster Formation and Phase Transitions Induced by Non-Reciprocal Interactions — •Thomas Richard Ullmann and Klaus Kroy — Institute for Theoretical Physics, Leipzig University, 04103 Leipzig, Germany

The emergence of cluster formation in a two-dimensional lattice spin system driven by non-reciprocal interactions (NRI) is investigated. The development of a novel phase, characterized by clusters distinct from the quasi-long-range order (QLRO) state of the conventional XY model, is unveiled through the use of a tunable non-reciprocal parameter. Cluster formation is shown to result from particular local spin alignment due to non-reciprocal coupling, which dynamically reshapes the stability landscape of defects and topological structures. The stability of the system is analyzed using nearest-neighbour interactions and stochastic dynamics, and critical points are identified indicating phase transitions associated with clustering. The stability and evolution of defects and structures within this regime are further examined, providing insights into the interplay between non-reciprocity and the dynamics of spin textures. Broader implications for understanding collective behaviour in non-equilibrium systems are suggested, offering a framework for exploring non-reciprocity-induced phases and their stability in both physical and biological contexts.

DY 22.27 Wed 10:00 P3

Criticality and Percolation in the Off-Lattice XY Model — •Manthan Chattopadhyay, Thomas Richard Ullmann, and Klaus Kroy — Institute for Theoretical Physics, Leipzig University, 04103 Leipzig, Germany

We investigate the critical behavior of the 2D XY model with quenched positional disorder by distributing spins randomly via a spatial Poisson point process. This off-lattice approach allows us to study how quenched disorder affects phase transitions and critical phenomena, with the primary focus being the critical power-law scaling between the Kosterlitz-Thouless transition temperature T_c and the mean spin density $\langle\rho\rangle$. Using both a homogeneous coarse-graining method and percolation theory, we derive predictions for the scaling $T_c \propto (\langle\rho\rangle - \langle\rho_c\rangle)^{\zeta}$. By considering the fractal nature of the spin network near the percolation threshold, characterized by the fractal dimension D_f, the exponent is estimated. Simulation results confirm the existence of a percolation threshold with an exponent obtained from simulations similar to those of our analytic work, aligning closely with theoretical prediction. The fractal nature of the spin network near $\langle\rho_c\rangle$ is validated through the box-counting method, which is consistent with the value for 2D percolation. At high densities well above the percolation threshold, critical exponents approach expected values of the XY universality class, and the magnetization exponent β conforms to empirical observations in ultrathin magnetic films.

DY 22.28 Wed 10:00 P3

The random-field Ising model and two-phase flow in disordered media — •Peter Henning and Martin Weigel — Institut für Physik, Technische Universität Chemnitz, 09107 Chemnitz, Germany

Two-phase flow in disordered media exhibits a rich phenomenology of behaviors with manifold applications for example in oil extraction [1]. A simplified model for such flows might be provided by the zero-temperature dynamics of the random-field Ising model (RFIM) that exhibits interfaces between the pure

phases that propagate through avalanches and show a roughening transition as a function of disorder strength. In the present study we focus on several properties of the interface between the phases such as its fractal geometry which can be characterized by critical exponents [2]. Furthermore we investigate abrupt changes in the propagation of the interface also known as crackling noise. By applying the RFIM to this problem we hope to gain insights into the underlying mechanisms of two-phase flow in disordered media and to provide a framework for interpreting experimental observations.

Relating Thermodynamics and Dynamics in a Trap-like Model of Supercooled Liquids — •Simon Kellers, Anshul D. S. Parmar, and Andreas Heuer — Institute of Physical Chemistry, University of Münster, Corrensstraße 28/30, 48149 Münster, Germany

Previous studies on 2D non-network glass formers utilized the million-fold acceleration of Swap Monte-Carlo and potential energy landscape (PEL) analysis to establish a connection between deviations from Gaussian behavior of the inherent structure (IS) density function, Fragile-to-Strong-Crossover [1] and a low-energy depletion regime. In recent work [2] a specific low-temperature behavior for thermodynamical (IS-energy) and dynamical (apparent activation energy) observables could be observed with basically the same onset temperature. To understand the physical background we investigate various model IS distributions in a trap-like picture and their derived dynamic and thermodynamic properties. Indeed, for different realizations of non-Gaussianity in the PEL strong correlations between the respective onset temperatures are observed as well, suggesting indeed a strong correlation between thermodynamics and dynamics. These results contribute to our understanding of the PEL picture of glass formers.

DY 23: Poster: Active Matter, Soft Matter, Fluids (joint session DY/CPP)

Time: Wednesday 10:00–12:00 Location: P3

DY 23.1 Wed 10:00 P3

Enhanced stability and chaotic condensates in multi-species non-reciprocal mixtures — •Laya Parkavousi[1], Navdeep Rana[1], Ramin Golestanian[1,2], and Suropriya Saha[1] — [1]Max Planck Institute for Dynamics and Self-Organization (MPI-DS), D-37077 Göttingen, Germany — [2]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, Oxford OX1 3PU, United Kingdom

Random non-reciprocal interactions between a large number of conserved densities are shown to enhance the stability of the system towards pattern formation. The enhanced stability is an exact result when the number of species approaches infinity and is confirmed numerically by simulations of the multi-species non-reciprocal Cahn-Hilliard model. Furthermore, the diversity in dynamical patterns increases with increasing number of components and novel steady states such as pulsating or spatiotemporally chaotic condensates are observed. Our results may help to unravel the mechanisms by which living systems self-organise via metabolism.

DY 23.2 Wed 10:00 P3

Non-reciprocal Model B and the role of mobilities and non-reciprocal interfacial forces — •Bibhut Sahoo[1] and Peter Sollich[1,2] — [1]Institut für Theoretische Physik, Georg-August-Universität Göttingen, 37077 Göttingen — [2]Department of Mathematics, King's College London, London

Recently the effects of non-reciprocal interactions have been widely studied in the Cahn-Hilliard model for phase separation, which is based on a magnetic analogy. Here we explore the corresponding nonreciprocal model B, as the continuum theory for non-reciprocal particle mixture. We focus on the effect of mobility matrix on topology of the phase diagram and find that changing mobility can change stability of a homogeneous state, which for reciprocal interactions would be impossible. We study spinodal dynamics in regions of instability, where static or travelling spinodal patterns can occur. This aspect is as in non-reciprocal Cahn-Hilliard but, the transitions between these instabilities are novel: they occur not via exceptional points, but via first order transitions in the length scale of the dominant unstable modes. At transition, a static and a travelling spinodal pattern with two different scales coexist. We show that more complicated transitions involving coexistence of three length scales can also occur. We finally argue, based on a nonreciprocal version of Dean's equation, that coarse graining into a model B description should lead to non-reciprocal interface terms, rather than only in the bulk as assumed in theories to date. We show that such interfacial terms can significantly enlarge the travelling spinodal regions in the phase diagram.

DY 23.3 Wed 10:00 P3

Mixed active fluids of two kinds — •Astik Haldar — Universität des Saarlandes, Saarbrücken 66123, Germany

We explore here the polar active fluids of two types, characterizing by their different aligning and propulsion strengths. We example here the fluids as the collections of moving living creatures, which could fuel itself through chemical reactions in their body . We called this system as active system, and consider their brilliant interactions. We here try to model those through considering some parameters and physically observable quantities. We find the parameters region where they have their oriented flocking as parallel or antiparallel, ordered rotating phase coherently meaning chiral phase. Our study finds the transition between the phases as saddle node as well as pitchfork bifurcation in mean field theory scheme. We find different kind of pattern formed states appear through the analytical as well as numerical study.

DY 23.4 Wed 10:00 P3

Verification, efficiency analysis and extension of the kinetic Event-Chain Algorithm — •Nico Schaffrath, Tobias Kampmann, and Jan Kierfeld — TU Dortmund, Dortmund, Germany

The novel cluster kinetic Monte-Carlo algorithm, which is based on the event-chain Monte-Carlo method, is specifically designed to simulate systems of two-dimensional self-propelled hard particles. We verify this algorithm from scratch by analysing various single-, two- and many-body systems, as well as some algorithm-specific quantities. To gain insight about the applicability of the algorithm, we compare its performance to that of an Event-Driven Brownian-Dynamics simulation. Finally, we investigate the possibility to simulate particles with soft interaction energies as well as an extension to three-dimensional systems. Regarding the latter, the phase diagram of self-propelled hard spheres is calculated.

AMEP: Analyzing Active Matter Simulations in Python — Kay-Robert Dormann[1], Lukas Hecht[1], Kai Luca Spanheimer[2], Aritra K. Mukhopadhyay[1], Mahdieh Ebrahimi[1], Suvendu Mandal[1], and •Benno Liebchen[1] — [1]Institut für Physik kondensierter Materie, Technische Universität Darmstadt, Darmstadt, Germany — [2]Institut für Theoretische Physik II, Heinrich-Heine-Universität, Düsseldorf, Germany

The **A**ctive **M**atter **E**valuation **P**ackage (AMEP)[1] is an easy-to-use Python library for analysing simulation data of particle-based and continuum simulations. It provides a powerful interface for handling complex analysis of large data sets from different simulation software such as LAMMPS, HOOMD-blue, GROMACS and others. A plethora of methods to calculate observables and visualise results make AMEP suitable to calculate complex observables not only for beginners but also for advanced studies of active and soft matter. AMEP is written in pure Python and leverages powerful and well-known libraries such as NumPy, SciPy and Matplotlib. Computationally expensive methods are parallelized to run on laptops and workstations as well as high-performance computing clusters.

The methods range from order parameters, cluster methods, spatial and time correlation functions to thermodynamic properties and coarse-graining methods. More information and examples are available at https://amepproject.de. AMEP can be installed via conda and pip.

DY 23.6 Wed 10:00 P3

Fluctuation induced network patterns in spatially correlated noise — •Sebastian Fehlinger[1], Kai Cui[2], Arooj Sajjad[1], Heinz Koeppl[2], and Benno Liebchen[1] — [1]Technische Universität Darmstadt, Institut für Physik Kondensierter Materie, Hochschulstraße 8, 64289 Darmstadt — [2]Technische Universität Darmstadt, Selbstorganisierende Systeme, Merkstraße 25, 64283 Darmstadt

Fluctuations play an important role in many fields of physics, from quantum electrodynamics to statistical mechanics. In active matter physics, so far, most works have focused on active particles that are subject to thermal fluctuations caused by the surrounding solvent. Here, we explore the collective behaviour of active particles under the influence of spatially correlated noise, that can arise, e.g., from fluctuating external fields. Therefore, we introduce a minimal model which describes the dynamics of (chiral) active particles with alignment interactions in a time-dependent Gaussian random field, that features a characteristic spatial correlation length, but no temporal correlations. Using Brownian dynamics simulations, we find, that the active particles aggregate to system spanning,

percolated networks. These structures are (i) fluctuation-induced, (ii) feature local alignment of the contained particles, but no global alignment, and (iii) hardly show any coarsening. We systematically characterize the emerging patterns with tools from topological data analysis (persistence diagrams, Vietoris-Rips complexes and Betty numbers).

DY 23.7 Wed 10:00 P3

Reconfiguring hydrodynamic flow fields of active particles by light — Lisa Rohde, Tom-Hannes Hemann, Gordei Anchutkin, and •Frank Cichos — Molecular Nanophotonics Group, Peter Debye Institute for Soft Matter Physics, University Leipzig, Leipzig, Germany

Microscopic active particles propel themselves via localized energy conversion, generating hydrodynamic flow fields that govern their boundary interactions and collective behaviour. The long-range behaviour of the flow patterns classifies them as either pushers, which expel fluid along their swimming axis, or pullers, which draw fluid inward. In nature, some microorganisms can adaptively switch between pusher and puller modes in response to their environment. However, synthetic active particles are currently limited to a fixed pusher or puller configuration during fabrication, constraining our ability to study their dynamic responses to environmental cues. Here, we present a self-thermophoretic active particle that can reconfigure its flow field on demand during the experiment. This is achieved by illuminating the particle with an inhomogeneous light field shaped by a spatial light modulator. The illumination patterns create surface temperature fields inducing thermo-osmotic flow fields that propel the particle and shape the hydrodynamic interactions. By using gold nanoparticles, we trace and characterize the hydrodynamic flow field of the active particle. The ability to dynamically alter the propulsion characteristics will enable us to investigate and control their interactions and collective dynamics.

DY 23.8 Wed 10:00 P3

Brainbots as smart autonomous active particles with programmable motion — •Isa Mammadli[1], Martial Noirhomme[2], Nathan Vanesse[2], Jayant Pande[3], Ana-Sunčana Smith[1], and Nicolas Vandewalle[2] — [1]PULS, Institute for Theoretical Physics, FAU Erlangen-Nürnberg, 91058, Erlangen, Germany — [2]GRASP, Institute of Physics B5a, University of Liege, B4000 Liege, Belgium — [3]Department of Physical and Natural Sciences, FLAME University, Pune, India

We introduce an innovative robotic device designed to enable controlled motion for the study of active matter. Motion is driven by an internal vibrator, powered by a compact rechargeable battery. The system integrates acoustic and magnetic sensors alongside a programmable microcontroller. Unlike conventional vibrobots, this device employs a motor that generates horizontal vibrations, producing cycloidal trajectories that have been thoroughly characterized and optimized. Specific segments of these trajectories can be harnessed to create tailored motion patterns. As a proof of concept, we demonstrate how this versatile system can be used to develop active particles exhibiting diverse dynamics, ranging from ballistic motion to run-and-tumble diffusive behavior. Based on experimental data, we provide a simulation routine capable of replicating these trajectories, enabling the generation of extended datasets and the exploration of various input velocity configurations. This approach facilitates the determination and prescription of optimized input parameters for applications such as enhanced search strategies and precise path following.

DY 23.9 Wed 10:00 P3

Fundamental Measure Theory for active hard discs — •Jonas Buba and Michael Schmiedeberg — Theoretical Physics: Lab for Emergent Phenomena, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

The behavior of active soft particles has been studied extensively and provides a good model for many active matter systems [1]. However, some systems might be described more accurately by considering hard particles instead. While active soft particles have been described with a Phase Field Crystal approach (e.g., in [2]), a similar description of active hard particles is still lacking. In our approach we use Fundamental Measure Theory [3] to model hard discs and add activity. We expect to gain further insight into the role that the particle type can play in dynamical pattern formation.

DY 23.10 Wed 10:00 P3

Many-Body Dynamics of actively rolling fibers — •Alex Arnold[1], Falko Ziebert[1,2], and Igor M Kulic[3,4] — [1]Institute for Theoretical Physics, Heidelberg University, Philosophenweg 19, 69120 Heidelberg, Germany — [2]BioQuant, Heidelberg University, Im Neuenheimer Feld 267, 69120 Heidelberg, Germany — [3]Institut Charles Sadron UPR22-CNRS, 67034 Strasbourg, France — [4]Institute Theory of Polymers, Leibniz-Institute of Polymer Research, D-01069 Dresden, Germany

Fiberboids are active filaments, capable of self-propulsion, whose dynamics were recently described in [A. Bazir, A. Baumann, F. Ziebert, I. M. Kulić, Soft Matter 2020]. So far, only single and simple 2-body dynamics of fiberboids were described.

In this work we will take a first look at the many-body dynamics. Specifically, we analyze a system of multiple nylon-rods, which when heated from below display self-propelled rolling motion. Confining the rods to roll on a single axis only, implements a simple realization of an 1D active gas. We analyze the experiments concerning clustering and nonequilibrium fluctuations and rationalize the system by simple lattice models.

DY 23.11 Wed 10:00 P3

Pumping currents and formation of flocks in 1D Ising model — •Adrian Morais Cabral and Achim Rosch — Institute for Theoretical Physics, University of Cologne, Germany

Non equilibrium systems create phenomena that are not observed in equilibrium counterparts, such as long range order in two or less dimensions and breaking of detailed balance.

We use an effective description of coupled Langevin equations to study a 1D system where an Ising order parameter is coupled to a charge density. Our assumption is that the charge current has a contribution proportional to the order parameter for the driven system. The formation of domain walls leads to a source of dynamical frustration for the charge. Driving disallows the formation of domain walls and creates flocking blob like states in addition to constant ordered and disordered states and a non moving spike phase. These solutions are studied numerically in 1D for $T \geq 0$.

At $T = 0$, we characterize existing flocking solutions and compare analytical predictions to numerical simulations which agree well with only one fitting parameter.

At finite temperatures we find new dynamics for the flocking state such as reversals similar to the active Ising model and (quasi) crossings. However, we have not yet been able to answer whether the existing ordered phase is stable in 1D.

DY 23.12 Wed 10:00 P3

Statistical Field Theory for Vicsek-type models — •Carsten Littek, Falko Ziebert, and Matthias Bartelmann — Institut für Theoretische Physik, Universität Heidelberg, Germany

Dry, aligning, dilute active matter systems display a wide range of emergent phenomena such as collective, orientationally ordered motion and phase separation. The self-propelled particles in such systems undergo noisy aligning interactions with their neighbours, but they do not exchange momentum with their surrounding. While microscopic and hydrodynamic descriptions, whose connection involves approximations, exist, their predicted behaviour - such as scaling exponents - do not match.

Here we present a microscopic statistical field theory for active Brownian particles inspired by Mazenko (2010). In our formulation we interpret the particles' two-dimensional positions and their direction of motion as Martin-Siggia-Rose (MSR) fields to obtain a path integral representation of the N-particle partition function. The MSR action is augmented by a two-particle interaction that aligns particle directions either ferromagnetically as in the Vicsek model or nematically. Similar to quantum many-body theory the benefit of our field theoretic formulation of Vicsek-type models is that it allows for developing a self-consistent perturbation theory and using renormalization techniques. Our aim is the calculation of density and velocity correlation functions in the homogeneous ordered phase and the transition into the ordered phase.

DY 23.13 Wed 10:00 P3

Coupling reaction-diffusion and locomotion in vegetative cells — •Blaž Ivšić[1], Piotr Nowakowski[2], Igor Weber[2], and Ana Sunčana Smith[3,2] — [1]Institut za fiziku, Zagreb, Croatia — [2]Institut Ruđer Bošković, Zagreb, Croatia — [3]Friedrich-Alexander- Universität, Erlangen, Germany

Cellular locomotion involves the dynamic interplay between signaling molecules, cytoskeletal activity, and membrane deformation. We present a computational model coupling protein Rac1 reactiondiffusion dynamics to cell locomotion to study vegetative state of amoeba Dictyostelium discoideum. Rac1 regulates actin polymerization via effectors like WASP and Arp2/3, while GAP modulates its activity. The model captures Rac1 dynamics on a deforming membrane, reproducing experimentally observed spatiotemporal patterns.

Cell shape is modeled using a Level-set method to track membrane dynamics, driven by forces linked to Rac1 concentration. Specifically, surface tension and normal forces (due to interaction of the cell with the substrate) proportional

to Rac1 concentration influence membrane movement. The dynamics are conveyed through a fluid velocity field obtained by solving a time-dependent Stokes equation.

Our model replicates Rac1 activity patterns seen in live-cell imaging and links these patterns to cell motility. By bridging Rac1 reactiondiffusion dynamics with membrane mechanics, the model provides insights into the mechanisms of actin-driven locomotion in vegetative cells.

DY 23.14 Wed 10:00 P3

Numerical Simulation of Microplastic Permeation in Soil: from Solutes to Particles — •Hao Liu[1], Yifan Lu[2], Christina Bogner[2], Martin Lörder[1], and Stephan Gekle[1] — [1]University of Bayreuth, Bayreuth, Germany — [2]University of Cologne, Cologne, Germany

Microplastics have become significant environmental pollutants, raising concerns about their accumulation and distribution across ecosystems. Although terrestrial environments, particularly soils, often exhibit high levels of microplastic contamination, they remain relatively understudied. Microplastic transport in soil involves complex interactions among particle properties, soil structure, and fluid dynamics. Understanding mechanisms such as permeation, aggregation, and degradation is essential for effective environmental risk assessments and strategies to control microplastic pollution.

This study aims to simulate and predict soil hydraulic conductivity in microplastic-laden flows. Challenges include modeling behaviors of microplastic particles as they transport in soil with complex porous structures. High-resolution μCT scans of soil samples will provide the necessary porous media data, and simulations will be conducted using FluidX3D software. The research progresses in two phases: first, disregarding particle size and shape to analyze solute transport mechanisms; second, incorporating detailed particle properties to study transport and accumulation in pores. The goal is to model microplastic dynamics for accurate predictions of microplastic distribution in soil systems.

DY 23.15 Wed 10:00 P3

Thermo-Osmotic Flows via Anti-Stokes Cooling — •akshay kallikkunnath[1], kamil bruchal[2], pawel karpinski[2], and frank cichos[1] — [1]Molecular Nanophotonics, Peter Debye Institute for Soft Matter Physics, Faculty of Physics and Earth System Sciences, Leipzig University, Germany — [2]Faculty of Chemistry, Institute of Advanced Materials, Wroclaw University of Science and Technology, Poland

Fluidic manipulation has gained huge interest over time especially with the studies on metal nanoparticles as optically controlled heat sources generating temperature gradients. With recent developments in the synthesis of lanthanide doped crystals which can be cooled by anti- stokes cooling, we try to bring laser cooling of microcrystals to the field of fluidics. In this work, we optically trap and cool ytterbium doped NaYF4 crystals by means of anti-stokes cooling. Temperature measurements for such microscale cooled crystals are done using a technique which utilizes the phase transition of liquid crystals. With such a thermal gradient created using cold sinks in liquid, we study and provide for the first time experimental and numerical results for flows generated at solid-liquid boundary, i.e., thermo-osmotic flows. The results will provide further scope for studying dipolar thermo-osmotic and corresponding thermo-electric fields in an electrolyte solution generated by arranging optically heated and cooled particles together. Our findings can have direct implications on the study of temperature-dependent biochemical processes which inhibit with lower temperature or on response of a biological specimen to low temperature stress or may even find application in local cryotherapy.

DY 23.16 Wed 10:00 P3

Thermodynamically consistent coarsening model of crossover placement in meiosis — •Marcel Ernst[1,2] and David Zwicker[1] — [1]Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — [2]Universität Göttingen, Germany

Crossovers play an important role in meiosis, ensuring correct segregation of homologous chromosomes and increasing genetic variability. A recently proposed model suggests that crossover placement is determined by biomolecular condensates that coarsen by exchange and diffusion of a protein along chromosomes, consistent with experiments. We here present an extended model including exchange with the nucleoplasm based on thermodynamic principles. We study theoretically and numerically the initial protein loading onto the chromosome, the droplet growth regime, the coarsening regime, and the final equilibrium. We derive scaling laws for the number of crossovers analogous to Lifshitz-Slyozov-Wagner theory in different limits. Finally, we investigate the effect of protein exchange with the nucleoplasm on crossover placement and compare the results with empirical data from several species. In conclusion, our model allows us to explain key features of meiotic crossover placement in wild type and several mutants.

DY 23.17 Wed 10:00 P3

A lattice Boltzmann approach to electrolytic multiphase flows — •Alexander Reinauer and Christian Holm — Institute for Computational Physics, Stuttgart, Germany

Simulating electrolytic multiphase flow presents significant challenges, often requiring either the detailed modeling of large numbers of particles or solving complex, nonlinear partial differential equations, such as the Navier-Stokes and Nernst-Planck equations. While particle-based simulations provide molecular details, continuum-scale approaches, including the Navier-Stokes and Nernst-Planck equations, enable the study of larger systems relevant to applications in oil recovery, biological processes, and waste treatment.

In this work, we extend the Lattice Boltzmann Method using a Color-Gradient approach to simulate immiscible two-phase flow, coupled with a custom Nernst-Planck solver for the transport of dissolved charged species. This coupling allows to incorporate the preferential solubilities of chemical species.

Our implementation, based on the pystencils/lbmpy framework, generates highly optimized code for both CPU and GPU architectures. To validate the model, we performed simulations of freely suspended liquid droplets subjected to an external electric field. Additionally, we explored contact angle models and initiated studies on applying the approach to porous media under varying conditions.

DY 23.18 Wed 10:00 P3

Coarsening of chemically active droplets — •Stefan Köstler[1,2], Yicheng Qiang[1], and David Zwicker[1] — [1]Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, 37077 Göttingen, Germany — [2]University of Göttingen, Institute for the Dynamics of Complex Systems, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

Droplets formed by phase separation play an important role in cellular organization and are widely used in the design of synthetic cells and lab-on-chip devices. Droplet emulsions typically coarsen due to surface tension and hydrodynamic effects, which generally prevents precise control over droplet sizes. While coarsening can be suppressed by active chemical reactions, it is unclear how these reactions affect the coarsening dynamics and control droplet sizes. To elucidate this, we numerically simulate a binary mixture that phase separates and undergoes reactions. We find three different dynamical regimes: Small droplets are dominated by coalescence due to hydrodynamic advection, then transition to an Ostwald ripening regime dominated by diffusion, and finally exhibit size control by active chemical reactions. We predict the transition from ripening to size control analytically, and we validate our analytical estimate of the final size using a numerical minimization of a surrogate equilibrium free energy. Our theory provides an improved understanding of coarsening mechanisms, allowing to achieve greater control of emulsions.

DY 23.19 Wed 10:00 P3

Zetapotential of Gold Surfaces in a Flow Cell — •Mattis Rasenat, Peter Vogel, Marcus Witt, and Thomas Palberg — Johannes gutenberg Universität Mainz

We present a case study on the zeta-potential of gold surfaces in a continuous flow cell. The charge of dielectric surfaces is of high interest for technological applications. Therefore, we measure the zeta potential of polymer particles in a custom-made electrokinetic flowthrough cell with exchangeable sidewall. The zeta potential is measured with a super-heterodyne light scattering setup.

DY 23.20 Wed 10:00 P3

Use of molecular CO_2 for surface charge regulation — Peter Vogel[1], Markus U. Witt[1], David Beyer[2], Christian Holm[2], Muhammad Navaz Qaisrani[3], Marialore Sulpizi[4], and •Thomas Palberg[1] — [1]Inst. of Physics, JGU, Mainz, Germany — [2]Inst. of Computational Physics (ICP), U Stuttgart, Stuttgart, Germany — [3]MPI for Polymer Research, Mainz, Germany — [4]Dept. of Physics, RU Bochum, Bochum, Germany

In deionized water CO_2 forms carbonic acid which partially dissociates. Such 'realistic' salt free systems contain a significant background electrolyte concentration and a pH of 5.5. Both lowers the effective charge of dielectric surfaces. Surprisingly, the remaining molecular CO_2 causes an additional drastic decharging effect, even to complete decharging in water equilibrated against pure CO_2. Molecular CO_2 acts directly on the degree of dissociation and thus lowers the bare charge, while effective charges merely follow suit. MD simulations show the formation of a diffusely adsorbed monolayer of CO_2, which locally lowers the dielectric constant. Based on this we suggested dielectric charge regulation as novel decharging mechanism. If then salts are added to the carbonized surfaces, one finds recharging by co-ion adsorption. This process is favoured by hydrophobicity, by co-ion size and, most important, also by the amount of adsorbed CO_2. Given the ubiquity of dielectric surfaces in contact with aqueous electrolytes, this very general charge regulation processes appear to be of great fundamental and practical importance.

DY 24: Focus Session: Broken Symmetries in Statistical Physics - Dynamics of Odd Systems

In recent years, the effect of broken microscopic symmetries on emergent mesoscopic and macroscopic behavior has gained significant attention in non-equilibrium statistical physics. For example, breaking Newton's third law leads to so-called "non-reciprocal interactions" among species and gives rise to odd transport coefficients. These are primarily investigated in active systems. However, even with Newton's third law valid, odd transport can emerge, and even in equilibrium systems. In both cases, many novel phenomena have been reported over the last years, such as asymmetric clustering, oscillatory phase behavior, crowding-enhanced diffusion in in- and out-of-equilibrium systems, as well as off-diagonal correlation functions, topologically protected edge flows, and many more. With this symposium, we bring together the communities working on odd transport systems in the context of (non)equilibrium statistical physics, to stimulate discussions about the physical background and implications of such broken symmetries in transport-related phenomena.

Organized by Erik Kalz (Potsdam), Ralf Metzler (Potsdam), and Abhinav Sharma (Augsburg)

Time: Wednesday 15:00–18:30 Location: H43

Invited Talk DY 24.1 Wed 15:00 H43

Dynamics of odd and chiral active systems — •Hartmut Löwen — Heinrich-Heine-Universität Düsseldorf

After a brief introduction into "odd" systems characterized by odd viscosity, odd elasticity or odd diffusivity, we focus on *odd diffusive dynamics*. For normal diffusive systems, repulsive interactions typically reduce the dynamics as signalled by a reduction of the long-time self-diffusion coefficient. Contrarily, in odd-diffusive systems, collisions can enhance the self-diffusion due to a mutual rolling effect. We further address *active chiral particles* which break the discrete left-right symmetry in their motion. Examples include spinners, circle swimmers and particles moving on helical trajectories. We explore phase separation, glassy dynamics as well as crystallization and polymerisation in these chiral systems. New phenomena absent for achiral objects are observed including active surfactants, rotating crystallites, self-wrapping of chiral polymers and a hammering effect in supercooled fluids. Also the realization of such odd systems in granular or colloidal experiments is discussed.

DY 24.2 Wed 15:30 H43

A route from force to velocity autocorrelation in over-damped odd dynamic and its applications to the study of diffusion — Filippo Faedi and •Abhinav Sharma — University of Augsburg, Augsburg, Germany

In this work we present a derivation of the relation between the velocity and force autocorrelation in over-damped dynamic starting from the underdamped Langevin equation. Time reversal symmetries are used to simplify the noise force autocorrelation and this procedure can be applied both in the presence and in the absence of magnetic field. Thanks to these relation we can prove that off diagonal element of the force autocorrelation matrix contribute to the self diffusion coefficient in the presence of a magnetic field. In addition the result is applied to study the dynamics of two odd dimers with same and opposite charges.

DY 24.3 Wed 15:45 H43

A model collective system made of spinning micro-disks: from fundamentals to microrobot swarms — •Gaurav Gardi — Max Planck Institute fort Intelligent Systems, Stuttgart, Germany

Collective systems such as bird flocks and fish schools in nature and colloidal and robotic artificial collectives, display order in their spatiotemporal patterns. Although they are inherently out-of-equilibrium systems, the order in their patterns may share similarities with well-understood phases of matter in equilibrium and thus may be characterized by similar metrics. These phases also contain information, which is embedded in their spatiotemporal structures and can be quantified by information entropy. Although order and information are connected fundamentally in thermodynamics, their relation in collective systems is seldom explored. Here we combine the approaches of statistical mechanics and information sciences to demonstrate the order and the information in the phases of a two-dimensional (2D) small-scale robotic collective system consisting of hundreds of spinning micro-disks at the air-water interface. We design and control the balances of local interaction forces between micro-disks so that distinct globally ordered phases emerge. We relate the order and information in the global phases using concepts from statistical physics and information theory. Lastly, we design experiments to demonstrate the diverse self-organised behaviours of our system and its ability to transition to non-reciprocal regime. Overall, this talk highlights our system's capability to act as an adaptable and versatile model system for dynamic self-organisation and for development of versatile microrobot collectives.

DY 24.4 Wed 16:00 H43

Active pattern formation emergent from single-species nonreciprocity — Zhi-Feng Huang[1], •Michael te Vrugt[2], Jonas Mayer Martins[3], Raphael Wittkowski[3,4], and Hartmut Löwen[5] — [1]Department of Physics and Astronomy, Wayne State University, Detroit, Michigan 48201, USA — [2]Institut für Physik, Johannes Gutenberg-Universität Mainz, 55128 Mainz, Germany — [3]Institut für Theoretische Physik, Universität Münster, 48149 Münster, Germany — [4]Center for Soft Nanoscience, Universität Münster, 48149 Münster, Germany — [5]Institut für Theoretische Physik II: Weiche Materie, Heinrich-Heine-Universität Düsseldorf, 40225 Düsseldorf, Germany

Nonreciprocal interactions violating Newton's third law are common in a plethora of nonequilibrium situations ranging from predator-prey systems to the swarming of birds and effective colloidal interactions under flow. Here (arXiv:2404.10093), we systematically derive a field theory for the basic case of a single-component system breaking the *actio* and *reactio* equality of force within the same species from the microscopic particle dynamics, leading to a generic continuum model termed *Active Model N*. One particular new characteristic pattern found in this model is an interwoven self-knitting "yarn" structure with a unique feature of simultaneous development of micro- and bulk phase separations. The growth dynamics of a "ball-of-wool" active droplet towards these self-knitted yarn or branched states exhibits a crossover between different scaling behaviors.

DY 24.5 Wed 16:15 H43

Dance of odd-diffusive particles: A Fourier approach — •Amelie Langer[1], Abhinav Sharma[2,3], Ralf Metzler[4], and Erik Kalz[4] — [1]University of Heidelberg — [2]University of Augsburg — [3]IPF Dresden — [4]University of Potsdam

Odd-diffusive systems are characterized by transverse responses and exhibit unconventional behaviors in interacting systems. To address the dynamical interparticle rearrangements in a minimal system, we here exactly solve the problem of two hard disklike interacting odd-diffusing particles. We calculate the probability density function (PDF) of the interacting particles in the Fourier-Laplace domain and find that oddness rotates all modes except the zeroth, resembling a mutual rolling of interacting odd particles. We show that only the first Fourier mode of the PDF, the polarization, enters the calculation of the force autocorrelation function (FACF) for generic systems with central-force interactions. An analysis of the polarization as a function of time reveals that the relative rotation angle between interacting particles overshoots before relaxation, thereby rationalizing the recently observed oscillating FACF in odd-diffusive systems. — [Langer et al., Phys. Rev. Res. 6, 043036 (2024)]

DY 24.6 Wed 16:30 H43

Odd mobility in interacting particle systems — •Erik Kalz[1], Shashank Ravichandir[2], Johannes Birkenmeier[1], Ralf Metzler[1], and Abhinav Sharma[2,3] — [1]University of Potsdam — [2]IPF, Dresden — [3]University of Augsburg

Colloidal mobility characterises the response of an overdamped particle to an external drift. We present a many-body theory where the diffusion of particles is modelled in the presence of interactions with other colloids. A tracer particle therefore can respond to its own applied force as well as to the external drift of the host particles, an effect transferred via particle-particle interactions. We examine these direct and transferred mobilities in the context of odd systems and show that they display qualitatively different behaviours. Odd systems are characterized by a transverse — Hall-like response which occurs in addition to the ordinary, parallel response. We show that both components, the parallel and transverse are drastically altered by particle-particle interactions up to a complete reversal for each component. Our findings are validated by Brownian dynamics simulations.

Invited Talk DY 24.7 Wed 16:45 H43

Odd dynamics and universal flows of passive objects in a chiral active fluid — •Cory Hargus[1], Federico Ghimenti[1,2], Julien Tailleur[1,3], and Frédéric van Wijland[1] — [1]Laboratoire Matière et Systèmes Complexes (MSC), Université Paris Cité & CNRS (UMR 7057), 75013 Paris, France — [2]Department of Applied Physics, Stanford University, 348 Via Pueblo, Stanford, CA 94305, United

States of America — [3]Department of Physics, Massachusetts Institute of Technology, Cambridge, MA 02139, United States of America

A passive object submerged in a chiral active fluid is imbued with odd diffusivity, odd mobility, and rotational ratchet motion. We show how these different effects are interrelated, obtaining a Langevin equation for a sufficiently heavy object, and how they are determined by the symmetry properties of the object, as well as its size and mass. Finally, spontaneous flows of the chiral active fluid around the object are understood through a multipole expansion, and connected through odd diffusion to equations of state involving only bulk fluid properties.

DY 24.8 Wed 17:15 H43

Vortex formation and odd viscosity in a chiral active fluid — •Joscha Mecke[1,2], Yongxiang Gao[1], Gerhard Gompper[2], and Marisol Ripoll[2] — [1]Institute for Advanced Study, Shenzhen University, Shenzhen, PR China — [2]Institute of Advanced Simulation, Forschungszentrum Jülich, Germany

Materials consisting of active particles with an intrinsic rotation can be considered as chiral active matter. We study a colloidal chiral active system, consisting of magnetic microrotors of diameter 0.8 μm in an externally applied rotating magnetic field. The stabilised colloids synchronously rotate with the rotating field and solely interact via steric and hydrodynamic interactions, granting odd and active stresses already at low densities and large colloidal separations. We address the system by means of experiments as well as particle based hydrodynamics simulations (MPC) of the active colloidal suspension. The rotors' transverse, anti-symmetric, and non-reciprocal interactions lead to a pair-rotation about the centre of mass and subsequently to the formation of multiscale vortices. Energy is injected on the particle level and is transported to the largest scales in the system, unless it is dissipated at a hydrodynamic damping length, a process reminiscent of turbulence, even in the absence of dominant inertial contributions. The rich phenomenology of our system additionally includes odd diffusion and enhancement of effective diffusive transport by the introduction of obstruction, directed transport by virtue of symmetry breaking at confining walls, and correlations between vorticity and density which allow for a measurement of the system's odd viscosity.

DY 24.9 Wed 17:30 H43

Chirotactic response of microswimmers in 3D chiral active fluids with odd viscosity — •Yuto Hosaka[1], Michalis Chatzittofi[1], Ramin Golestanian[1,2], and Andrej Vilfan[1,3] — [1]Max Planck Institute for Dynamics and Self-Organization (MPIDS), 37077 Göttingen, Germany — [2]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, Oxford OX1 3PU, United Kingdom — [3]Jožef Stefan Institute, 1000 Ljubljana, Slovenia

Odd viscosity is a property of chiral active fluids with broken time-reversal and parity symmetries. We show that the flow of such a fluid around a rotating axisymmetric body is exactly solvable [1]. Using this solution and the generalized Lorentz reciprocal theorem [2], we determine the orientational dynamics of microswimmers with an arbitrary surface slip velocity. Swimmers with a force-dipole moment exhibit precession around the axis of the odd viscosity. In addition, pushers show *bimodal chirotaxis*, i.e., alignment parallel or antiparallel to the axis, while pullers orbit in a plane perpendicular to it. A chiral swimmer that itself has a broken parity symmetry can exhibit *unimodal chirotaxis* and always align in the same direction. Since the chirotactic response of microswimmers is prohibited in 2D fluids, our theoretical results highlight the critical role of three-dimensionality in transport phenomena in chiral active fluids.

DY 24.10 Wed 17:45 H43

Chirality and symmetry breaking in Dictyostelium Discoideum: Probing odd dynamics in cellular behavior — •Fereydoon Taheri — IMSEAM, Heidelberg University, Heidelberg, Germany

The interplay between chirality and symmetry breaking is a fundamental aspect of many biological systems, and Dictyostelium discoideum offers a unique model to explore these phenomena. This bacteria-guzzling amoeba that lives in soil, serves as a powerful model organism for studying fundamental cellular processes such as cell-cell signalling, collective movement, and self-organization in multicellular complexes. In this study, we present an in-depth investigation into the motility patterns of D. discoideum, with a focus on the inherent chirality observed during intercellular interactions. By analyzing the off-diagonal components of the diffusion tensor, we connect this chirality to asymmetries in the velocity correlation function. These off-diagonal terms capture the coupling between orthogonal velocity components, providing a quantitative measure of non-reciprocal motion and breaking of time-reversal symmetry. Our analysis reveals that these contributions are directly linked to chiral trajectories and it is not merely a byproduct of individual behavior but plays a functional role in mediating the efficiency and directionality of cell-cell communication influencing both individual and collective behaviors during aggregation and morphogenesis.

Invited Talk DY 24.11 Wed 18:00 H43

How to model frictional contacts in sheared and active colloids — •Friederike Schmid[1], Kay Hofmann[1], Kay-Robert Dormann[2], and Benno Liebchen[2] — [1]Johannes Gutenberg Universität Mainz — [2]Technische Universität Darmstadt

In simulations of colloidal matter, frictional contacts between particles are often neglected. For spherical colloids, such an approximation may have a significant impact on the results in certain situations (e.g., colloids under shear, chiral active matter), since frictional contacts induce a coupling between translational and orientational degrees of freedoms of particles which is otherwise absent. Models for implementing frictional contacts have been proposed in the granular matter community. Owing to the large size of granular particles, these models do not include thermal noise. On the colloidal scale, thermal fluctuations are important and should be incorporated in a thermodynamically consistent manner.

In the present talk, we show how to derive the correct fluctuation-dissipation relation for frictional contacts with arbitrary - linear or nonlinear - relation between the friction force and the relative velocity at the contact point, and how to implement the corresponding stochastic force terms. Among other this results in a new generalized class of dissipative particle dynamics (DPD) thermostats with rotation-translation coupling. Possible effects of frictional contact interactions are demonstrated using the example of Poiseuille flow and motility induced phase separation in active Langevin particles.

DY 25: Statistical Physics of Biological Systems I (joint session BP/DY)

Time: Wednesday 15:00–18:00 Location: H44

DY 25.1 Wed 15:00 H44

Separating bio-condensates with surfactant-like proteins — Jannik Kindermann and •Tyler Harmon — Leibniz Institute for Polymer Research, Dresden, Germany

Biocondensates are prevalent in cells as individual compartments that separate material and reactions in space. Many condensates share similar components and/or chemical interactions that drive their formation. This would suggest that the condensate:condensate interface would have a very low surface tension compared to the condensate:solvent interfaces. Supported by in vitro results, this leads to condensate-inside-condensate or dumbbell-like architectures which minimize the condensate:solvent interfaces. However, in vitro, condensates are most often isolated in space from each other. This could play important roles such as limiting the direct flow of material from one condensate to another. The mechanism in cells that separates droplets in space is unknown.

We show using simulations and theory that proteins or other biopolymers that have surfactant like molecular architectures can separate condensates in space. We show how robust this mechanism can be with respect to condensate specificity and the expression levels of surfactant-like molecules in cells.

DY 25.2 Wed 15:15 H44

Phase separation in membranes and compartments with binding reactions — •Riccardo Rossetto, Gerrit Wellecke, and David Zwicker — Max Planck Institute for Dynamics and Self-Organization

Biological cells exhibit a hierarchical spatial organization, where various compartments and membranes harbor condensates that form by phase separation. Cells can control the emergence of these condensates by affecting the physical interactions of the involved biomolecules, thus also tuning the binding affinity to the compartments. We describe this situation with a thermodynamically-consistent kinetic model considering passive and active binding reactions to elucidate their role in controlling the occurrence and timescales of phase separation in compartments. On the one hand, binding reactions can lead to the emergence of new equilibrium phenomena, such as re-entrant phase transitions and multistability. On the other hand, they can also affect the kinetics of phase separation. As a particular example, we consider protein droplets in cellular membranes when proteins can also unbind to the cellular bulk. For fast bulk diffusion, this leads to effective nonlocal transport, which fundamentally affects droplet dynamics. For instance, the seminal Lifshitz-Slyozov coarsening can be abolished. Furthermore, active binding reactions can both accelerate or fully suppress coarsening, leading to protein patterns on the membrane. The general conclusions from our model unveil fundamental mechanisms of phase separa-

tion in membranes and compartments, and will help us explain more biological observations in the future.

Reconciling conflicting selection pressures in the plant collaborative non-self recognition self-incompatibility system — Amit Jangid[1], Keren Erez[1], Ohad-Noy Feldheim[2], and •Tamar Friedlander[1] — [1]Faculty of Agriculture, food and environment, The Hebrew University of Jerusalem, Rehovot, Israel — [2]Einstein Institute for Mathematics, The Hebrew University of Jerusalem, Jerusalem, Israel

Complex biological systems should often reconcile conflicting selection pressures. Specifically, in systems relying on molecular recognition, molecules should recognize particular partners, but avoid others. Here we study how such selection pressures shape the evolution of the self-incompatibility system in plants. This system inhibits self-fertilization using specific molecular recognition between proteins, expressed in the plant female and male reproductive organs. We study the impact of these opposing selection pressures on the amino acid frequencies in these proteins' recognition domain. We construct a theoretical framework enabling promiscuous recognition between proteins and multiple partners each, as found empirically, and employ stochastic simulations. We find asymmetric responses to selection affecting mostly the female, but not the male protein composition. Using large deviations theory, we well-approximate the simulated frequencies and find agreement with genomic data. Our work offers a general theoretical framework to study the impact of multiple selection pressures, applicable to additional biological systems.

DY 25.4 Wed 15:45 H44

Learning the Equilibrium Free Energy from Non-Equilibrium Steady States with Denoising Diffusion Models — •Daniel Nagel and Tristan Bereau — Institute for Theoretical Physics, Heidelberg University, Germany

Estimating accurate free energy profiles is crucial for predicting the behavior of complex molecular systems. While biased molecular dynamics simulations enhance the sampling of rare events, extracting reliable free energy landscapes from these simulations remains challenging. On the other hand, stochastic thermodynamics, i.e. the concept of entropy production, provides valuable insights into the dynamics of complex systems in non-equilibrium states. However, its computational complexity, due to dependence on time-dependent probability distributions, limits its application to smaller systems.

This work presents a novel approach that combines stochastic thermodynamics with the established machine learning technique of denoising diffusion models to efficiently estimate free energy profiles from biased non-equilibrium steady states. By linking the diffusion and simulation times, we show that the training objective, known as the score, can be decomposed into a non-trivial conservative contribution from the equilibrium potential and a trivial non-conservative part determined by external driving forces. To showcase the effectiveness of our approach and its ability to learn equilibrium free energy profiles, we apply it to a driven toy model and a Martini force field molecular dynamics simulation of a small molecule biased through a lipid bilayer.

DY 25.5 Wed 16:00 H44

Multiple Pareto-optimal solutions of the dissipation-adaptation trade-off — •Jorge Tabanera-Bravo and Aljaz Godec — Max Planck Institute for Multidisciplinary Sciences, Göttingen

Adaptation refers to the ability to recover and maintain "normal" function upon perturbations of internal or external conditions and is essential for sustaining life. Biological adaptation mechanisms are dissipative, i.e. they require a supply of energy such as the coupling to the hydrolysis of ATP. Via evolution the underlying biochemical machinery of living organisms evolved into highly optimized states. However, in the case of adaptation processes two quantities are optimized simultaneously, the adaptation speed or accuracy and the thermodynamic cost. In such cases one typically faces a trade-off, where improving one quantity implies worsening the other. The solution is no longer unique but rather a Pareto set—the set of all physically attainable protocols along which no quantity can be improved without worsening another. We investigate Pareto fronts in adaptation-dissipation trade-offs for a cellular thermostat and a minimal ATP-driven receptor-ligand reaction network. We find convex sections of Pareto fronts to be interrupted by concave regions, implying the existence of distinct optimization mechanisms. We discuss the implications of such "compromise-optimal" solutions and argue that they may endow biological systems with a superior flexibility to evolve, resist, and adapt to different nvironments.

Centrosome positioning in cell migration and immune response — •Heiko Rieger — Department of Physics and Center for Biophysics, Saarland University, Saarbrücken, Germany

Leukocytes are the key players of the immune system in eliminating pathogen-infected or tumorigenic cells. During these processes centrosome positioning plays a crucial role for establishing cell polarization and directed migration, targeted secretion of vesicles for T cell activation and cellular cytotoxicity as well as the maintenance of cell integrity. Here, we give an overview over microtubule organization and dynamics during immune processes and present models for centrosome repositioning during the formation of the immunological synapse and during cell migration. We focus particularly on actin-myosin crosstalk, which is involved in regulating the polarity and morphology of migrating cells and encompasses mechanical interactions, mediated by crosslinkers and molecular motors, as well as cytoskeletal regulators. Based on recent experimental results we develop a computational whole-cell model involving dynamical microtubules that interact not only mechanically but also via signaling with an active cell boundary. A rich self-organized dynamical behavior emerges, comprising varying positions of the microtubule organizing center relative to the nucleus in the migration direction, varying migration characteristics and cell shapes, and complex migratory behavior in obstacle parks and microfluidic setups. Specific dependencies of these behaviors from parameters like the average microtubule length or the cell-boundary stiffness are predicted and compared with experimental observations.

Modelling neuron growth dynamics and role of extra-cellular matrix — •Pritha Dolai, Federica Furlanetto, Sven Falk, Marisa Karow, and Vasily Zaburdaev — Friedrich-Alexander-Universität (FAU) Erlangen-Nürnberg, Erlangen

Biological tissues are composed of cells embedded in extracellular matrix (ECM) and extracellular fluid. We study the role of cell-matrix interactions in the context of brain tissues and the mechanism of neuron growth through this matrix. We consider two modes for the neurite growth: linear growth by tip extension and growth by the traction force at the tip of the neurite with the ECM. In the second mechanism, growth happens solely due to the interaction of the growing appendages with the particles modeling the matrix. With an agent based model we recapitulate experimentally observed neuron growth patterns in healthy neurons and neurons with mutations corresponding to a disease state performed in organoid models. In experiments, neuron growth is quantified by the dynamics of the growing tips. Additionally we compare further growth characteristics such as track length and velocity of the tip, tortuosity, and angular correlation of growth direction. Our model provides mechanistic description of the neurite growth and can be useful in describing neuronal network formation during early development.

DY 25.8 Wed 17:15 H44

Cellular morphodynamics as quantifiers for functional states of resident tissue macrophages in vivo — •Miriam Schnitzerlein[1,2], Eric Greto[3,4], Anja Wegner[3,4], Anna Möller[3,4], Oliver Aust[3,4], Oumaima Ben Brahim[3,4], Stefan Uderhardt[3,4], and Vasily Zaburdaev[1,2] — [1]Department of Biology, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU) — [2]Max-Planck-Zentrum für Physik und Medizin, Erlangen — [3]Department of Medicine 3 - Rheumatology and Immunology, FAU und Universitätsklinikum Erlangen — [4]Deutsches Zentrum für Immuntherapie, FAU

Resident tissue macrophages (RTMs) perform essential tasks such as clearing cellular debris to ensure tissue homeostasis. Such actions are accompanied by morphological changes in cell shape which reflect their functional states. Until now, RTMs were mostly studied *in vitro*, even though their dynamic behaviour *in vivo* is fundamentally different.

We employed a high-resolution, intravital imaging protocol to generate dynamic data of *in vivo* peritoneal RTMs of mice. Next we built a custom image processing pipeline to assess RTM morphodynamics via a set of human-interpretable cell shape and size features. Those features could quantitatively and also qualitatively differentiate between cells in different activation states. Furthermore, we showed that unperturbed RTMs exhibit a wide range of morphodynamical phenotypes, constituting a naive morphospace of behavioural motifs. Analysing cells challenged by chemical stimulations or due to aging gave us insights into how RTMs respond and adapt to inflammatory stimuli.

DY 25.9 Wed 17:30 H44

Slimming down through frustration — •Martin Lenz — Université Paris-Saclay, CNRS, LPTMS, 91405, Orsay, France — PMMH, CNRS, ESPCI Paris, PSL University, Sorbonne Université, Université Paris-Cité, F-75005, Paris, France

In many disease, proteins aggregate into fibers. Why? One could think of molecular reasons, but here we try something more general. We propose that when particles with complex shapes aggregate, geometrical frustration builds up and fibers generically appear. Such a rule could be very useful in designing artificial self-assembling systems.

DY 25.10 Wed 17:45 H44

RNA fitness prediction with sparse physics based models - A way to explore the sequence space — •Christian Faber[1], Francesco Calvanese[2], Alexander Schug[1], and Martin Weigt[3] — [1]Forschungszentrum Jülich, Jülich, Germany — [2]Sorbonne-Université, Paris, France — [3]CNRS, Paris, France

The field of medicine uses macromolecules as a means of therapeutic intervention. Consequently, the functional attributes of these novel molecules are assuming greater significance. To complement the wet-lab experiments, we have devised a series of statistical physics based models that are capable of predicting the fitness of RNA molecules based on one- and two-point mutation scans. The experimental data were employed as training data to fit models of increasing complexity, commencing with an additive model and concluding with a model that accounts for global and local epistasis. The models were validated using fitness data from scans with higher order mutations of the wild-type. In contrast to conventional AI algorithms, the parameters of our models were designed for direct interpretation. In examining more distant sequences, we can distinguish the corresponding RNA family from random sequences with a high degree of accuracy. Moreover, the models facilitate interpretations of evolutionary processes and the significance of epistatic terms. Our model can be used to create a fitness landscape far beyond the experimental sequence space, thus identifying promising RNA molecules. Furthermore, the extension to the entire sequence space can be used as a blueprint for other molecules, providing a novel avenue for questions in biomolecular design.

Statistical field theory of linear spatio-temporally extended systems with multiplicative noise — •Frederik Gareis, David Aderbauer, and Michael Wilczek — Theoretische Physik I, Universität Bayreuth, Universitätsstr. 30, 95447 Bayreuth

Linear systems with multiplicative stochastic noise commonly exhibit non-Gaussian behavior in both space and time. We consider a classic example from statistical hydrodynamics, the Kraichnan model for a passive scalar convected in a stochastic velocity field. Describing such systems via a characteristic functional elegantly encodes the full statistics of the fields. However, the analysis of the resulting functional differential equations remains challenging due to the mathematical intricacy of treating second-order functional derivatives. Here, we show that a broad variety of such problems permit a solution of the functional differential equations in the form of a superposition of Gaussian functionals, even if the noise is correlated in space and time. While the linear terms, excluding the multiplicative noise, are compatible with Gaussian solutions, averaging over the multiplicative advection term introduces non-Gaussian statistics. Our approach provides a starting point for various systematic approximations such as a perturbation theory in terms of small multiplicative noise strength. On a conceptual level, it allows us to gain insights into the emergence of non-Gaussianity and intermittency, which could be relevant beyond statistical hydrodynamics.

Identifying Change Points in Local Air Temperature Time Series — •Fatemeh Aghaei A., Ewan Thomas Phillips, and Holger Kantz — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

Global air temperature reconstructions consistently reveal a warming trend beginning around 1975, with signs of earlier increases since the early 20th century. However, regional temperature variations display complex, heterogeneous patterns that warrant deeper exploration. Understanding local climate change is critical for effective adaptation in health, agriculture, water management, and infrastructure sectors. By analyzing change points in regional warming trends, this study aims to identify periods of intensified climate change, suggesting potential historical tipping events.

In this paper, we analyze 2-meter mean daily temperature data from the ERA5 reanalysis project to track warming trends across a 1x1 degree global grid. By removing seasonal cycles, we capture temperature anomalies that reveal significant regional warming variations, with standard deviations of 4-6K depending on location. Recognizing that local warming is rarely linear, we fit two linear slopes with a change point to each grid point to capture change in warming trends. This approach produces global maps indicating the timing and magnitude of trend changes, highlighting regions where local warming has intensified.

Causal inference in nonlinear Covid-19 time series — •Adrian Pelcaru and Dirk Brockmann — SynoSys/TU Dresden, Dresden, Germany

Covid-19 pandemic exemplifies a spatio-temporal dynamic system which can hardly be studied by controlled experiments with "laboratory settings". Advances of computational power and availability of large datasets, causal discovery frameworks enable one to gain insight into the dynamics and couplings between observables of the system. We employ an approach rooted in state space reconstruction called Convergent Cross-Mapping (CCM) and investigate time-lagged interactions between multiple observables (temperature, interventions, human mobility, reproduction rate) of Covid-19 in 114 countries and 38 regions in Germany. Central, is the interrelationship between human mobility and reproduction rate. We find evidence for time lagged feedback couplings between human mobility and reproduction rate and identify other drivers of the reproduction rate acting either directly or indirectly through human mobility. Furthermore, we detect latitudinal dependence of coupling strengths and clear segregation of coupling strengths between historic east and west Germany. Finally, we measure dynamic tipping points of strong unidirectional forcing between human mobility and reproduction rate leading to distinct periods with characteristic dynamics. While many causal discovery frameworks and previous studies related to Covid-19 a priori reject potential feedback mechanisms between observables of a system, this study, to our knowledge, shows their existence for the first time.

DY 27.4 Wed 15:00 P4

Numerical Differentiation by Integrated Series Expansion (NDBISE) in the Context of Ordinary Differential Equation Estimation Problems — •Oliver Strebel — Angelstr. 17, D-75392 Deckenpfronn

Parameter or model estimation of ordinary differential equations (ODE) involves nowadays frequently the numerical calculation of derivatives from noisy data. This article presents a novel differentiation method (NDBISE) for such calculations. The method is benchmarked against 57 differential equations and compared to other numerical differentiation methods. The hyperparameters of all these methods are optimized in order to get a reasonable comparison. The resilience against larger noise or fewer data points per time interval is examined. It turns out that the novel method is overall superior to the other methods.

The derivative for the 42 real world data points of the Hudson bay lynx hare data (years 1900-1920) is also calculated. The results match the derivative of a curve fit to the data points astonishingly close. Using a Savitsky-Golay filter the method can be leveraged to calculate second and third order derivatives, so that the results are close to the theoretically expected outcome.

Origin of Frequency Clusters in Globally Coupled Phase Oscillators — •Yannick Schöhs, Nicolas Thomé, and Katharina Krischer — Technische Universität München

Frequency clusters arise in a wide range of physical, technological, and biological systems, making them a topic of significant interest both for their practical implications and for advancing the fundamental understanding of collective dynamics. Despite their importance, their origin remains relatively unexplored. In this study, we investigate the origin of frequency clusters using a model of globally coupled phase oscillators with adaptive coupling strength. By numerically solving the differential equations for a network of 100 oscillators, the formation of up to four distinct frequency clusters was confirmed. Additionally, we conducted a bifurcation analysis on a system of four oscillators. The reduced system size allowed for an analytical bifurcation analysis of the fixed points, while the bifurcation analysis of the limit cycles was performed numerically. The results reveal that the frequency clusters originate from a homoclinic bifurcation and lose their stability through a transcritical bifurcation.

DY 27.6 Wed 15:00 P4

Optimal Control of Fractional Bistable System — •Finn Biesterfeldt[1], Andreas Rauh[2], and Alexander K. Hartmann[1] — [1]Institut für Physik, Carl von Ossietzky Universität Oldenburg, 26111 Oldenburg, Germany — [2]Department für Informatik, Carl von Ossietzky Universität Oldenburg, 26111 Oldenburg, Germany

In this work, a classic bistable system in continuous time and space and described by an ordinary integer-order differential equation is generalized to fractional order using the principles of Fractional Calculus. This results in an intrinsic mem-

ory effect and the time evolution depends on the full history of its prior configurations. In numerical simulations we observe that depending on the initial conditions, the system drives towards one of two possible fixed points of the integer order system. Initializing the system with a non-constant history leads to a complex time evolution that is highly dependent on the fractional order. In this study, the non-constant history can be interpreted as an external influence or control input that drives the system from one fixed point to the other. Influenced by the fractional order, the system may converge back to the initial fixed point. The optimal control strategy for transitioning the system from one to the other fixed point is computed numerically, revealing a dependence on the fractional order of the system.

Phase separation with long-range interactions — •Filipe Thewes, Yicheng Qiang, Oliver Paulin, and David Zwicker — Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany

It is well known that long-range interactions affect phase separation. For instance, such interactions can suppress droplet coarsening, leading to microscopic pattern with selected length scales. This effect is widely exploited by nature – from structure formation in living cells to food engineering by humans. Although the details of the transition from macroscopic phase separation to microscopic pattern formation are understood for particular systems, the general conditions for the existence of such transition remain unclear.

We propose a general field theoretical model that combines Flory's theory of phase separation and a broad class of long-range interactions. We then show that the particular details of these interactions are not relevant to the transition from macro phase separation to micro pattern formation and the most important parameter is the length-scale associated with the long-range interactions. We uncover the possibility of both first-order and second-order transitions as this length-scale crosses a threshold value, and we show how two macro phases can coexist with patterned phases. Extending these results to multi-component mixtures reveals even richer physics with multiple coexisting patterns. Our results open the possibility of systematic control of droplet sizes via different pathways, and depending on the nature of the phase transition, allow for an intricate design of pattern formation.

Rapid Control of Soliton Dynamics in Dual-Comb Lasers via Intra-Cavity Modulation — Julia Lang[1], •Simeon Schmitt[1], Luca Nimmesgern[1], Sarah Hutter[2], Alfred Leitenstorfer[2], and Georg Herink[1] — [1]Universität Bayreuth, Germany — [2]Universität Konstanz, Germany

We present a novel approach for controlling the timing of solitons in ultrafast mode-locked lasers, enabling the programmable synthesis of ultrashort soliton pulse patterns. The approach utilizes intra-cavity acousto-optic modulation in a single, harmonically mode-locked Er:fiber laser. By employing single-pulse modulation, we induce precise timing shifts between the two temporally separated, interlaced soliton combs. Through external splitting and recombination, we obtain temporally overlaying ultrashort soliton pulse-sequences that can be rapidly tuned above kHz scanning rates. We present real-time spectral interferometry data based on the dispersive Fourier transformation and corresponding simulations that resolve the underlying intersoliton motion due to ultrafast nonlinearities and laser gain dynamics. [1]

Driven BHD - onset of chaos and extendet KNH-Theorem — •Nico Fink, Viviane Bauer, and James Anglin — Physics Department and Research Center OSCAR, RPTU Kaiserslautern-Landau

When we investigate physical systems the method of description changes in dependence of scale: mechanics for individual particles but statistical methods for many. Indeed the latter should derive from mechanics, but how exactly do they relate? In other words: how does an increse in degrees od freedom influences the behaviour of a system and what kind of effects appear? In a Bose-Hubbard-dimer as a modelsystem it has been shown, that the existence of an instable fixpoint - and thereby a separatrix - can give rise to irreversibility. This is realised by adiabatically varying the potentialdifference of the sites, causing the ensemble to split into two sub-ensembles when crossing the separatrix. If the consicered meanfield Bose-Hubbard-Dimer is extendet by periodic driving a chaotic band emerges in the neighbourhood of the separatrix. We investigate the onset of chaos and the characteristic behaviour of the system in general and under the change of potential as described above.

QH plateau and CMB- CR near nontrivial zeros of the zeta function — •Otto Ziep — 13089 Berlin, Am Wasserturm 19a

Chaotic one-dimensional period-doublings as iterated hyperelliptic-elliptic curves are used to derive n-dim Kepler- and Coulomb singularities. Millikan experiment, quantum Hall (QH) effect, atmospheric clouds and universe clouds are self-similar of mass ratio 10^20 in a fractal zeta universe (FZU) of ripped spacetime [1]. The cosmic microwave background (CMB) and cosmic rays (CR) are explained as bifurcating ripped spacetime tensile forces below and above first Sharkovsky cycles from the tree root up to third branch. At QH CMB emissions 1...1000 GHz are predicted by the iterated binary tree cloud which are possibly already detected [2]. An interaction-independent universal vacuum density allows to predict large area correlated CR in QH-experiments which would generate local nuclear disintegration stars, enhanced damage of layers and enhanced air ionization [1]. A 10^20 self-similarity between conductivity plateau and atmospheric cloud as a superfluid having two cycles of entropy and temperature allows us to conclude that CMB and CR correlations in atmospheric layer influence global temperature and climate.

[1] The poster is based on trilogy Nucleosynthesis in Thin Layers, Fractal zeta universe and cosmic-ray-charge-cloud superfluid, The sensitive balance by O. Ziep www.epubli.de in 03/24,11/24, 01/25

DY 27.11 Wed 15:00 P4

Detection and Analysis of Topological Defgnetic Systems via Enhanced Topological Data Analysisects in Ma — •Kyra Klos[1], Karin Everschor-Sitte[2], and Friederike Schmid[1] — [1]Insitute of Physics, Johannes Gutenberg-University Mainz, Mainz, Germany — [2]Faculty of Physics & Center for Nanointegration Duisburg-Essen, University of Duisburg-Essen, Duisburg, Germany

Complex data structures, marked by multi-dimensional correlations and noise, pose significant challenges in various fields like genetics and complex dynamical quantum systems. Topological Data Analysis (TDA) [1], rooted in Persistent Homology can address this, e.g. by effective characterizing phase transitions in dynamical systems [2], enhancing large genome data analysis [3] and preprocessing data for machine learning [1]. By introducing series of graph structures into data point clouds intrinsic topological information can be extracted. Focusing on magnetic systems with topological defects, localized perturbations in the ordering field, we propose using TDA to enhance their detection and analysis. By combing conventional persistence diagram analysis with geometrical, topological, and graph-based measures applied directly to the representative clustering, our approach can provide an additional insight into the topological landscape and multi-scale nature of topological defects in magnetic systems.

Force enhancement in-between suszeptible dipolar hard spheres - measurement vs computation — Andree Smolla[1], Alexandros G. Sourais[2], Sofia S. Kantorovich[3], Andreas Boudouvis[2], and •Reinhard Richter[1] — [1]Experimentalphysik 5, Universität Bayreuth, 95447 Bayreuth, Germany — [2]School of Chemical Engineering, National Technical University of Athens, Zografu Campus, 15780 Athens, Greece — [3]Computational Physics, University of Vienna, 1090 Vienna, Austria

We measure the force acting in-between two magnetized steel spheres used previously in ferrogranular model experiments [1]. When reducing the mutual distance r of the spheres the force r exceeds considerably the scaling $\sim r^{-4}$ known from dipolar hard spheres (DHS). To elucidate this deviation we measure the magnetization curves $M(H)$ of both steel spheres by means of a vibrating sample magnetometer. Their magnetization curves show a remanent magnetization plus a contribution which depends on an outer magnetic field, i.e. we have suszeptible dipolar hard spheres (SDHS). Taking into account $M(H)$ we solve the governing equations with the finite element method using FEniCS and COMSOL [2], showing a peak of the magnetization in the contact zone. The estimated force captures the enhanced force measured before.

Athermal jamming as a Manna class transition with a deterministic protocol — •Thomas Axmann, Mishael Derla, and Michael Schmiedeberg — Theoretical Physics: Lab for Emergent Phenomena, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

Athermal jamming can be understood as the transition point of an overlap reducing dynamical protocol of soft particles, where the absorbing (non-overlapping) states become inaccessible during configuration space sampling when increasing the density above the transition. The properties of this transition appear to be of $d + 1$ conserved directed percolation (Manna) universality, largely independent of the details of the dynamics implemented. To demonstrate this, we present a fully deterministic protocol that remains in the Manna class. The study was conducted numerically, but we further endeavor to illuminate the situation an-

alytically, by exploring possibilities for relating athermal jamming to directed percolation in time. We aim to determine the transition density for systems with Random Organization and Jamming and conditions to be in the Manna class.

(Note: Thomas Axmann and Mishael Derla contributed equally and will present the poster together)

Thermal Neural Quantum States — •Atiye Abedinnia and Annabelle Bohrdt — Institute of theoretical physics, University of Regensburg

Finite-temperature effects play an important role in the design and optimization of quantum devices, as decoherence and noise often originate from thermal fluctuations. At finite temperatures, quantum systems are described by a statistical ensemble of states rather than a single pure state. Simulating such thermal states requires constructing the thermal density matrix, which suffers from significant computational challenges due to the exponential growth of the Hilbert space with system size. So far, purification methods(thermofield) in the context of MPS and Minimally Entangled Typical Thermal States (METTS) approach have been developed in the context of tensor networks. In this work, we propose using neural quantum states (NQS), leveraging the expressivity and scalability of transformer-based architectures to address the challenges of thermal equilibrium density matrix representation.

Neural Networks for Phase Recognition on Lattice Systems — •Shashank Kallappara and Martin Weigel — Institut für Physik, Technische Universität Chemnitz, Chemnitz, Germany

The Ising model undergoes a phase transition in dimensions d > 1, with its magnetisation as the order parameter. Fully connected neural networks have been shown to learn the translational invariance of the Ising model when learning its phases. This requires only a single hidden layer; analytic solutions for the same exist for highly compact networks that are constructed to obey the translational invariance automatically. Here, we show this learning of the invariance in single-layer networks of different widths and compare the networks performance in classifying the phases. We also consider a highly compact network to study the gradient descent dynamics during training over its loss landscape; we suggest a few changes to this that greatly improve its performance while preserving interpretability. Another problem we consider is percolation on a square two-dimensional lattice. Here, we leverage convolutional neural networks to detect the phase transition by training on different properties of the systems and evaluate its effectiveness.

Stability of Machine-Learned Interatomic Potentials in Molecular Dynamics Simulations for Complex Organic Crystals — •Martin Tritthart, Florian Linder, Lukas Legenstein, Florian Unterkofler, Martin Klotz, and Egbert Zojer — Institute of Solid State Physics, Graz University of Technology, NAWI Graz, AUSTRIA

Understanding thermal conductivity and mechanical stability is crucial for several applications of organic semiconductors (OSCs) and metal-organic frameworks (MOFs). Molecular dynamics (MD) simulations are commonly used to deduce these properties, and in recent years, machine Learned interatomic potentials (MLIPs) have been employed to enhance accuracy compared to classical force fields. MLIPs are orders of magnitude faster than ab initio methods and can achieve close to DFT accuracy. Their accuracy,however, heavily depends on the quality of the training data. Incorrect predictions of forces and energies for atomic configurations outside the training dataset can accumulate in the MD trajectory, potentially even leading to disintegration of the (molecular) building blocks. This, however, limits long-time simulations, which are necessary to investigate thermal transport properties. To mitigate these issues and to realize a robust MLIP, reliable uncertainty estimates are needed especially for atomic configurations outside the region of the phase space sampled during training. Structures characterized by high uncertainties can then be calculated by ab initio methods and incorporated into the training dataset. This approach is tested in my contribution for prototypical MOF and OSC materials.

Estimating parameters for a simple tipping model from complex Earth system model output — •Jonathan Krönke[1,2], Jonathan F. Donges[1], Johan Rockström[1], Nils Bochow[3], and Nico Wunderling[1,2] — [1]Earth Resilience Science Unit, Potsdam-Insitute for Climate Impact Research, Potsdam, Germany — [2]Center for Critical Computational Studies, Goethe University Frankfurt, Frankfurt am Main, Germany — [3]Department of Mathematics and Statistics, UiT - The Arctic University of Norway, Tromsø, Norway

The existence of large-scale tipping points - thresholds where small changes can trigger drastic, often irreversible shifts in the climate system - has been a major concern of climate science in the past two decades. The ability to evaluate tipping risks using computationally manageable models is crucial to assess the resilience of the climate system and also to identify safe global warming trajectories for tipping elements. Here, we present an approach to estimate parameters of a simple tipping model based on complex Earth system model output. We validate our results by reproducing simulations that have not been used in the training process and apply the model to major earth system tipping elements such as the Greenland Ice Sheet. A simple model that captures essential behaviour of complex earth system models provides an important step towards a tipping point emulator for extensive tipping risk analyses.

DY 28.6 Wed 15:00 P4

Advanced Framework for State of Health Estimation Using Equivalent Circuit Models and Machine Learning — •Limei Jin[1,2], Franz Bereck[2], Josef Granwehr[2], Rüdiger-A. Eichel[2], and Christoph Scheurer[1,2] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]IET-1, Forschungszentrum Jülich

Traditional Electrochemical Impedance Spectroscopy (EIS) techniques for characterizing a battery's behavior face several limitations, including time-consuming data collection, assumptions of system linearity, and difficulties in accurately assessing State of Charge (SoC) and State of Health (SoH). To address these challenges, we developed a robust framework for estimating SoH within a low-dimensional latent space using an autoencoder applied to raw time-domain battery data. This methodology combines synthetic training data from equivalent circuit models with machine learning techniques, specifically utilizing Chebyshev-based parameter space expansion to vary models on the SoC and SoH scale. Thereby, our framework effectively captures dynamic aging patterns while ensuring efficient data generation with minimal experimental input. Additionally, we introduced a stochastic pulse load profile to the models, which overcomes limitations of conventional frequency-based EIS measurements to better reflect real-world battery usage. This approach was initially validated on coin cell batteries in the lab, requiring only three standard spectroscopy experiments to train the framework. It will be extended to larger batteries, such as LFP batteries commonly used in automotive applications, offering scalable solutions for real-time monitoring and enhanced longevity.

DY 28.7 Wed 15:00 P4

Parameter estimation and Bayesian comparison of Langevin models describing cell motility — •Yusuke Kato[1,2], Jan Albrecht[1], Hiroshi Kori[2], Robert Grossmann[1], and Carsten Beta[1] — [1]Institute of Physics and Astronomy, University of Potsdam, Germany — [2]Department of Complexity Science and Engineering, Graduate School of Frontier Sciences, The University of Tokyo, Kashiwa, Japan

In nature, motile bacteria and eukaryotic cells exhibit spontaneous movement. This cell motility plays an essential role in both maintaining homeostasis (such as the migration of immune cells to a wound site) and the pathogenesis of certain diseases (like the aggregation of cancer cells to other organs in metastasis). Various SDE-based Langevin models have been proposed to describe cell motility.

In this study, we adopt a Bayesian approach using the likelihood approximation technique introduced in Ref. [arxiv:2411.08692] to estimate parameters of tentative first- and second-order models. In order to compare the different models, we develop a framework that ranks them using Bayesian model comparison. We test and benchmark the approach using synthetic data and subsequently apply it to time-series data of ameboid cells in order to find the best model for their ameboid motility.

DY 29: Poster: Quantum Dynamics and Many-body Systems

DY 29.1 Wed 15:00 P4

Prethermalization in Open Quantum Systems — •Saptarshi Saha[1] and Rangeet Bhattacharyya[2] — [1]Institute of Theoretical Physics, Technical University of Berlin Hardenbergstr. 36, Sekr. EW 7-1, 10623 Berlin, Germany. — [2]Department of Physical Sciences, Indian Institute of Science Education and Research Kolkata, Mohanpur-741246, West Bengal, India

A nearly-integrable isolated quantum many-body system reaches a quasi-stationary prethermal state before a late thermalization. Here, we revisit a particular example in the settings of an open quantum system (OQS). We consider a collection of non-interacting atoms coupled to a spatially correlated bosonic bath characterized by a bath correlation length. Our result implies that the integrability of the system depends on such a correlation length. If this length is much larger than the distance between the atoms, such a system behaves as a nearly-integrable OQS. We study the properties of the emerging prethermal state for this case, i.e. the state's lifetime, the extensive number of existing quasi-conserved quantities, the emergence of the generalized Gibbs state, and the scaling of von Neumann entropy, etc. We find that for the prethermal state, the maximum growth of entropy is logarithmic with the number of atoms, whereas such growth is linear for the final steady state, which is the Gibbs state in this case.

DY 29.2 Wed 15:00 P4

Quantum Fluctuations Approach to Many-Body Systems for Weak and Strong Coupling — •Erik Schroedter, Jan-Philip Joost, Tim Kalsberger, and Michael Bonitz — CAU, Kiel, Germany

The theoretical description of correlated quantum many-body systems out of equilibrium is a significant challenge across many areas, including condensed matter, ultracold atoms, and dense plasmas. Standard approaches used for their description include the formalisms of reduced density matrices (RDM) and nonequilibrium Green functions (NEGF). However, all approaches suited for the description of nonequilibrium systems are limited in their applicability due to their accuracy or numerical scaling. Here, we present an alternative approach based on fluctuations of field operator products and their correlation functions[1,2]. It is closely related to NEGF and RDM theory and offers an alternative approach to the GW and T-matrix approximations while exhibiting interesting complementary features, such as the capability to simulate many-body effects using stochastic methods[3]. This significantly reduces numerical complexity while preserving accuracy and allows for the description of both weakly and strongly coupled systems. Additionally, this improves numerical stability and allows for direct access to spectral two-particle quantities, such as the density response function or dynamic structure factor.

DY 29.3 Wed 15:00 P4

Dynamics of topological defects in non-equilibrium magnon condensates — •Alexander Wowchik and Achim Rosch — Institut für Theoretische Physik, Universität zu Köln, 50937 Cologne, Germany

It has been demonstrated in the past that thin Yttrium Iron Garnet (YIG) films exhibit condensation of magnons in two degenerate minima of the band structure when driven with microwave radiation in the presence of an external magnetic field.

This creates a non-equilibrium many-body system at room temperature, which provides a framework to study the dynamics of self-propelling units that violate the conservation of energy, analogous to models of active matter.

We examine the behaviour of a single topological vortex defect in the magnon condensate after explicitly breaking the spatial inversion symmetry that restricts the dynamics of the ideal system. This is motivated by an asymmetric configuration in the typical experimental setup.

The study is performed by solving the driven-dissipative Gross-Pitaevskii equation for the emergent condensate degrees of freedom. It is derived from the semi-classical limit of an effective U(1) x O(2) symmetric Keldysh field theory.

The results are compared to micromagnetic simulations of the underlying ferromagnetic spin-Hamiltonian.

DY 29.4 Wed 15:00 P4

Wiedemann-Franz law violation domain for graphene and nonrelativistic systems — •Thandar Zaw Win, Cho Win Aung, Gaurav Khandal, and Sabyasachi Ghosh — Department of Physics, Indian Institute of Technology Bhilai, Kutelabhata, Durg 491002, India

Systematic and comparative research on Lorenz ratios for graphene and nonrelativistic systems has been studied to identify their Wiedemann-Franz law violation domain. Fermi energy and tem- perature are the main governing parameters for deciding the values of the Lorenz ratio, which is basically thermal conductivity divided by electrical conductivity times temperature times Lorenz number. Metals as three-dimensional nonrelativistic electron gas locate at higher Fermi energy by temperature domain, where Lorenz ratio remains one. Hence, they obey the Wiedemann-Franz law. By creating higher doping in a two-dimensional graphene system, one can again reach a higher Fermi energy by temperature domain and get a constant Lorenz ratio. For both graphene and nonrelativistic systems, the Lorenz ratio goes below one if we go lower Fermi energy by temperature domain, which is possible for the graphene system by decreasing the doping concentration. Experimentally observed greater than one Lorenz ratio in this lower Fermi energy by temperature domain or Dirac fluid domain indicates that non-fluid expressions of Lorenz ratio should be replaced by fluid-type expressions. We have noticed a divergent trend of Lorenz ratio in the Dirac fluid domain using its fluid-type expression, and it matches with the trend of experimental data.

DY 29.5 Wed 15:00 P4

Anisotropic Dicke model in the presence of periodic and quasiperiodic drive — •Pragna Das[1], Devendra Singh Bhakuni[2], Lea F. Santos[3], and Auditya Sharma[4] — [1]Department of Theoretical Physics, J. Stefan Institute, SI-1000 Ljubljana, Slovenia — [2]The Abdus Salam International Centre for Theoretical Physics (ICTP), Strada Costiera 11, 34151 Trieste, Italy — [3]Department of Physics, University of Connecticut, Storrs, Connecticut 06269, USA — [4]Indian Institute of Science Education and Research, Bhopal 462066, India

We analyze the anisotropic Dicke model in the presence of a periodic drive and under a quasiperiodic drive. We show that under a quasiperiodic Fibonacci (Thue-Morse) drive, the system features a prethermal plateau that increases as an exponential (stretched exponential) with the driving frequency before heating to an infinite-temperature state. In contrast, when the model is periodically driven, the dynamics reaches a plateau that is not followed by heating. In either case, the plateau value depends on the energy of the initial state and on the parameters of the undriven Hamiltonian. Surprisingly, this value does not always approach the infinitetemperature state monotonically as the frequency of the periodic drive decreases. We also show how the drive modifies the quantum critical point and discuss open questions associated with the analysis of level statistics at intermediate frequencies.

DY 29.6 Wed 15:00 P4

Enhancing quantum metric using periodic driving — •Dhruv Tiwari, Roderich Moessner, and Johannes S. Hofmann — Max Planck Institute for Physics of Complex Systems, Nöthnitzer Str., 01187, Dresden

The advent of periodically driven systems has revolutionized modern condensed matter physics by offering two transformative opportunities. First, they allow the realization of nonequilibrium analogs of well-established equilibrium phases under highly tunable conditions. Second, they facilitate the emergence of novel phases with no equilibrium counterparts. In this work, we focus on the former, leveraging the tunable parameters of periodically driven systems to enhance the quantum metric in flat-band systems. The quantum metric, a fundamental geometric property of the band structure, plays a critical role in the formation of superconductivity in flat-band systems with attaractive density interactions. Here, we present preliminary results demonstrating how the interplay between periodic driving and electron correlations can amplify the quantum metric, leading to enhanced physical properties compared to the equilibrium case. These findings pave the way for designing engineered quantum states and exploring the interplay of nonequilibrium dynamics and strong correlations in flat-band systems.

DY 29.7 Wed 15:00 P4

Phase-space correlations of resonances in chaotic scattering systems — •Florian Lorenz and Roland Ketzmerick — TU Dresden, Institute of Theoretical Physics, Dresden, Germany

Chaotic eigenfunctions in closed quantum systems show strong phase-space correlations along classical trajectories [1]. These correlations extend across the whole system size and persist in the semiclassical limit [1]. We here expand this analysis to open quantum maps and scattering systems, in particular the kicked rotor and a dielectric cavity. To this end, we generalize a time-dependent correlator suggested in [1] to the case of an open system using left- and right resonance states. For quantum maps we find similar results as for closed systems. For the dielectric cavity the correlations propagate as wave fronts through the system.

DY 29.8 Wed 15:00 P4

Generalizing Quantum Question Equalities: Measurement Order Effects in Cognitive Decision-Making — •Michael Schnabel — Vanderbilt University, Nashville, TN (USA)

The quantum question (QQ) equality, formulated by Wang and Busemeyer [1] provides a non-parametric prediction for the pairwise probabilities of binary questions represented by two non-commutative observables A and B and their associated projection operators P_A and P_B. The QQ equality has played a significant role in the development of the quantum cognition research program as it enabled testing whether the order effects observed in a representative dataset of questionnaires could be represented as quantum interference within a quantum probability framework, providing compelling evidence [2]. Here, I formulate QQ equalities that extend beyond pairwise comparisons and binary outcomes, accommodating situations with $N \geq 3$ questions under the assumption that measurements are represented by idempotent projection operators. These results may be applicable to low-dimensional discrete quantum systems, such as qubits and qtrits, and potentially provide a generalizable framework for understanding order effects in cognitive decision-making across various domains of questionnaire design and experimental psychology.

[1] Wang and Busemeyer. *Top.Cogn.Sci.,* 5(4), (2013). [2] Wang, Solloway, Shiffrin, and Busemeyer.*PNAS,* 111(26), (2014).

DY 29.9 Wed 15:00 P4

Subordination approach for derivation of generalized quantum models in non-relativistic and relativistic cases — •Irina Petreska[1], Trifce Sandev[1,2,3], and Alexander Iomin[4,5] — [1]Ss. Cyril and Methodius University in Skopje, Macedonia — [2]Macedonian Academy of Sciences and Arts, Skopje, Macedonia — [3]Korea University, Seoul, Korea — [4]Solid State Institute, Technion, Haifa, Israel — [5]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

The generalized Schrödinger equation and the generalized Klein-Gordon equation are derived by applying the subordination approach to conventional quantum mechanics. The special cases of the fractional Schrödinger equation and the fractional Klein-Gordon equation are adequately introduced. Additionally, the subordination approach is also applied to derive the special case of the generalized Dirac equation for spin 1/2 particles and the directions for future research are discussed. It is evident that according to the subordination approach, the time fractional derivatives in quantum mechanics, including the relativistic one, can be related to the Lévy stable processes in time.

DY 31: Focus Session: Nonequilibrium Collective Behavior in Open Classical and Quantum Systems

Nonequilibrium classical and quantum systems coupled to thermal or (driven) non-equilibrium environments have recently been shown to exhibit rich collective phenomena and phase transitions without equilibrium counterparts. From the classical side, intriguing examples are flocking and phase separation in active matter, but also patterns and bifurcations in driven-diffusive systems and spontaneous parity-time symmetry breaking in systems involving nonreciprocal couplings. From the quantum side much interest has been devoted, e.g., to ordering and phase transitions in non-equilibrium steady states, the formation of time crystals, superradiance, as well as phase transitions or critical behavior in time. The symposium and the accompanying focus session is devoted to connections between the quantum and the classical realms, as they have been explored recently both in theory and experiment.

Organized by Sabine Klapp (TU Berlin) and André Eckhardt (TU Berlin)

Time: Thursday 9:30–12:45 Location: H37

DY 31.1 Thu 9:30 H37

Ultra-critical Fermi Surfaces, Quantum Oscillations, and Bosonic Metals — •Likun Shi and Inti Sodemann Villadiego — Institut für Theoretische Physik, Leipzig, Germany

Periodically driven quantum systems exhibit rich non-equilibrium phenomena that transcend equilibrium paradigms. We demonstrate the emergence of novel Fermi surface physics in particle-number-conserved fermionic and bosonic systems coupled to heat baths. In the fermionic case, we uncover "ultra-critical" Floquet non-Fermi liquid states characterized by persistent non-analyticities in momentum space occupation that remarkably retain their sharpness at finite temperature - a phenomenon without equilibrium analogues. These non-equilibrium Fermi surfaces manifest in quantum oscillation signatures and display power-law correlations immune to the finite-temperature bath. Extending beyond fermions, we discover analogous Fermi surface physics in bosonic systems, pointing to universal features in driven quantum systems that transcend particle statistics. Our findings open new avenues for realization of exotic non-equilibrium phases in driven quantum materials.

DY 31.2 Thu 9:45 H37

Giant Dynamical Paramagnetism in the driven pseudogap phase of YBa2Cu3O6+x — •Marios Michael[1], Duilio De Santis[2], Eugene Demler[3], and Patrick Lee[4] — [1]Max Planck Institute for the Structure and Dynamics of Matter, Luruper Chausse 149, 22761 Hamburg, Germany — [2]Physics and Chemistry Dept., Interdisciplinary Theoretical Physics Group, Palermo University, 90128 Palermo, Italy — [3]Institute for Theoretical Physics, ETH Zurich, 8093 Zurich, Switzerland — [4]Department of Physics, MIT, 77 Massachusetts Avenue, 02139 Cambridge, MA, USA

In this talk, I will discuss theory aimed at understanding recent experimental data on driven YBa2Cu3O6+x published recently in Nature: Fava, S., De Vecchi, G., Jotzu, G. et al. Magnetic field expulsion in optically driven YBa2Cu3O6+x Nature 632,75-80 (2024). Experiments on optically pumped YBa2Cu3O6+x in the pseudogap phase far above Tc have shown evidence of dynamical Meissner effect. In our effort to understand the new experimental signatures, we have uncovered a universal instability triggered in Josephson junctions under a magnetic field that are strongly driven with an AC field. The instability leads to the generation of giant paramagnetic currents at the edges of Josephson junctions. For strong enough drive such instabilities ultimately lead to a soliton ratchet after driving. I will focus on why this instability of a generic Josephson junction is applicable to the pseudogap YBa2Cu3O6+x far above Tc and how it matches the experimental observations.

DY 31.3 Thu 10:00 H37

entropy production in ultrafast quantum stochastic dynamics — •Yulong Qiao and Matthias Geilhufe — Department of Physics, Chalmers University of Technology, Gothenburg, Sweden

Thanks to advancements in femto- and atto-second laser technologies, thermodynamics has entered the ultrafast era. Ultrafast dynamics provides a unique way to probe the transient properties of materials. In [1], ultrafast stochastic

thermodynamics was developed based on X-ray scattering experiments [2], and has been successfully applied to the study of entropy production in laser-excited phonons. However, how to develop a unifying theory for both classical and quantum systems remains an open challenge [3].

In the quantum realm, fluctuations arising from the uncertainty principle do not depend on temperature, meaning they are inevitable even in a vacuum. As a result, in the quantum analogues of the Langevin equations, classical stochastic forces are replaced by quantum noise operators. In this talk, I will discuss how to handle the quantum nosies in the frame of open quantum systems. I will also present the impact of quantum effects on the entropy production in the ultrafast processes.

Cooling dynamics of the 2D Kitaev honeycomb model coupled to phonons — •Arkadeep Mitra, Francesco Piazza, and Markus Heyl — Theoretical Physics III, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, 86135 Augsburg, Germany

The ground state of the Kitaev spin-1/2 model on a 2D honeycomb lattice hosts a quantum spin liquid (QSL) phase where excitations fractionalize into Majorana fermions. At high temperatures, however, it has recently been observed to enter a disorder-free localized phase, so that any experimental cooling of a Kitaev material has to cross this localized and associated phase transition. Motivated from this, we study theoretically the cooling dynamics upon coupling the Kitaev model to phonons. We envisage that signatures obtained from this dynamics could act as probes for QSL.

DY 31.5 Thu 10:30 H37

Hydrodynamic description of emergent long-range coherence in active quantum flocks — •Byjesh N Radhakrishnan[1,2], Thomas L. Schmidt[1], and Markus Heyl[2] — [1]Department of Physics and Material science, University of Luxembourg — [2]Theoretical Physics III, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, D-86135 Augsburg, Germany

The quantum analog of classical active matter flocking has recently been reported in [arXiv:2308.01603]. The reported model introduces the concept of active quantum matter in a system of hard-core bosons in a one-dimensional lattice. The results provide both analytical and large-scale numerical evidence that these systems can give rise to quantum flocks due to the interplay of spin-flipping and alignment interactions. One of the key findings is that these flocks, unlike classical ones, exhibit distinct quantum properties by developing strong quantum coherence over long distances. Our work focuses mainly on developing a hydrodynamics description to study the origin and properties of this long-range quantum coherence. We systematically explore the relationship between long-range coherence and system parameters like alignment strength and quantum amplitude and compare our analytical results with large-scale numerical simulations.

Invited Talk DY 31.6 Thu 10:45 H37

Strong coupling and coherence in quantum thermodynamics — •Janet Anders[1,2], Federico Cerisola[2], James Cresser[2], and et al[2] — [1]Universität Potsdam, Germany — [2]Exeter University, UK

The interaction of nanoscale and quantum systems with their environment can be relatively strong, and alter the equilibrium state. For open quantum systems, explicit expressions of these so-called mean force (MF) equilibrium states have been missing. In this talk I will report on useful analytic expressions of these states, valid for a general quantum system in contact with a bosonic bath [1]. The results are illustrated with the well-known spin-boson model, for which we provide the first classification of coupling regimes, from weak to ultrastrong, and for both the quantum and classical setting [2].

In the second part of the talk, I will briefly comment on quantum signatures that arise in thermodynamic processes due to the presence of coherences. For example, the work distribution of time-varying quantum systems violates the corresponding classical fluctuation-dissipation relation for slowly driven processes [3]. A geometric framework is proposed to find optimal trade-offs between dissipation and fluctuations. Coherences also give rise to quantum irreversibility. We unravel how this irreversibility manifests itself in energetic exchanges that differ from those in the classical regime [4].

Ultrafast Dynamics Across the Phase Transition of the Charge Density Wave in $K_{0.3}MoO_3$ — •Rafael T. Winkler[1], Larissa Boie[1], Yunpei Deng[2], Matteo Savoini[1], Serhane Zerdane[2], Abhishek Nag[2], Sabina Gurung[1], Davide Soranzio[1], Tim Suter[1], Vladimir Ovuka[1], Janine Zemp[1], Elsa Abreu[1], Simone Biasco[1], Roman Mankowsky[2], Edwin J Divall[2], Alexander R. Oggenfuss[2], Mathias Sander[2], Christopher Arrell[2], Danylo Babich[2], Henrik T. Lemke[2], Paul Beaud[2], Urs Staub[2], Jure Demsar[3], and Steven L. Johnson[1,2] — [1]Institute for Quantum Electronics, Physics Department, ETH Zurich, Zurich, Switzerland — [2]SwissFEL, Paul Scherrer Institute, Villigen, Switzerland. — [3]Faculty - Institute of Physics, Johannes Gutenberg-University Mainz

Blue Bronze ($K_{0.3}MoO_3$) is a quasi 1D material exhibiting a charge density wave (CDW) with a periodic lattice distortion (PLD). In a time resolved x-ray experiment, we study the dynamics of the PLD by pumping $K_{0.3}MoO_3$ with short laser pulses and probing it using x-ray diffraction. We construct reciprocal space maps (RSM) of superlattice reflections at different delays. The RSMs indicate a transient inversion of the phase of the CDW. We attribute the suppression of the diffracted x-ray intensity after this phase inversion to a fast decoherence of the CDW driven by local pinning of the phase of the CDW in the material. These observations were confirmed by numerical simulations of the time dependent Ginzburg-Landau equations, extended by including defects which favor a particular phase of the CDW in combination with a temperature dependent coherence factor.

DY 31.8 Thu 11:45 H37

Optimal dynamical regimes for reservoir computing with soft matter — •Mario U. Gaimann and Miriam Klopotek — Stuttgart Center for Simulation Science (SimTech), Cluster of Excellence EXC 2075, University of Stuttgart, Germany

Reservoir computing with physical systems is a promising approach for next-generation and *in materio* computing. Recently, active matter systems for reservoir computing were introduced by Lymburn *et al.* (*Chaos* 31(3), 033121, 2021). However, the optimal properties of active matter systems for reservoir computing remain poorly understood. Here we show that viscoelastic, overdamped dynamics yield high predictive performances. This is remarkable since it was previously believed that optimal swarm dynamics are found at a gas-to-liquid phase transition. We relate predictive performance to correlations of agent velocities and their fluctuations. The optimal overdamped swarms show rich phenomenology: interface formation and breaking, local shear thinning, and self-healing. We show that the overdamped regime is optimal across a range of different chaotic attractors. Notably the optimal dynamics are already uncovered by studying reservoir computing with a single particle. Our results demonstrate the importance of tuning basic dynamical properties in physical reservoir substrates to generate optimal correlative effects. Reservoir computing with viscoelastic soft matter inspires novel mechanisms for computing in matter and novel computing devices based on these principles.

DY 31.9 Thu 12:00 H37

Universality in time-crystalline matter — •Carl Philipp Zelle, Romain Daviet, Achim Rosch, and Sebastian Diehl — University of Cologne

Dynamical phases of matter in which time translation symmetry is broken spontaneously are fascinating examples of phases that can only occur far from equilibrium. In this talk, we show that paradigmatic O(N) models display time-crystalline order once driven suitably out of equilibrium.

We employ dynamic RG techniques to determine the universal phenomena at the ensuing transitions as well as within the time-crystalline phase: The transition between an ordered phase and the time-crystal occurs through a critical exceptional point which we show cause a fluctuation-induced first order transition. The transition between a symmetric and a time-crystalline phase defines a new, genuinely nonthermal universality class. We show, that the Goldstone-modes within the dynamical phases are a realisation of the KPZ universality class and offer new generalisations of KPZ to larger symmetry groups.

Surprisingly, these phenomena can be realized by rather simple driving protocols, i.e. weakly irradiating a ferrimagnetic spin system. Furthermore, we connect our results to recent advances in nonreciprocal active matter.

Thermalizing Lindbladians for many-body systems — •Nico Albert[1], Shovan Dutta[2], and Masudul Haque[1] — [1]Technische Universität Dresden, Dresden, Germany — [2]Raman Research Institute, Bangalore, India

Thermalization is closely associated with the effect of a bath. For quantum systems, the most prominent type of bath is a Markovian bath, whose dynamics are governed by a Lindblad master equation. Therefore, it is important to understand Lindbladians that lead to a thermal (Gibbs) steady state. We will present some properties of thermalizing Lindbladians for many-body systems.

DY 31.11 Thu 12:30 H37

Signatures of Quantum Chaos and fermionization in the incoherent transport of bosonic carriers in the Bose-Hubbard chain — Pavel Muraev, Dmitri Maksimov, and •Andrey Kolovsky — Krasnoyarsk, Russia

We analyse the stationary current of Bose particles across the Bose-Hubbard chain connected to a battery, focusing on the effect of inter-particle interactions. It is shown that the current magnitude drastically decreases as the strength of inter-particle interactions exceeds the critical value which marks the transition to quantum chaos in the Bose-Hubbard Hamiltonian. We found that this transition is well reflected in the non-equilibrium many-body density matrix of the system. Namely, the level-spacing distribution for eigenvalues of the density matrix changes from Poisson to Wigner-Dyson distributions. With the further increase of the interaction strength, the Wigner-Dyson spectrum statistics changes back to the Poisson statistics which now marks fermionization of the Bose particles. With respect to the stationary current, this leads to the counter-intuitive dependence of the current magnitude on the particle number.

DY 32: Nonlinear Stochastic Systems

Invited Talk DY 32.1 Thu 9:30 H43

Fluctuation-Response Relations for Non-equilibrium Systems — •Benjamin Lindner — Institut für Physik, Humboldt-Universität Berlin

The fluctuations and the response of stochastic systems are related by fluctuation-dissipation theorems or, equivalently, fluctuation-response relations (FRRs). Originally introduced for systems in thermodynamic equilibrium, generalizations of such relations for non-equilibrium situations have been discussed since the 1970's and are particularly appealing for biological systems. FRRs may be used to e.g. (i) prove that a system is outside of equilibrium, (ii) prove that it does not follow Markovian dynamics, (iii) extract statistics of intrinsic noise sources. In my talk I report several FRRs in systems far from equilibrium. I discuss a nonlinear FRR for systems that can be perturbed by a step stimulus, which can be used as an efficient test of Markovianity. I present a universal description for stochastic oscillators, that results in a simple FRR in terms of a new complex-valued transform of the original oscillator variables. Last but not least, I derive a new class of FRRs for spiking neurons that relate the pronounced fluctuations of spontaneous neural firing to their average response to sensory stimuli, i.e. to the processing of sensory information that is the raison d'etre of neural systems.

Oscillations and self-generated noise in a nonreciprocal single-species XY-model — •Thomas Suchanek[1] and Sarah Loos[2] — [1]Institut für Theoretische Physik, Universität Leipzig, Leipzig, Germany — [2]DAMTP, University of Cambridge, Cambridge, United Kingdom

We study the low temperature dynamics of an XY-model with random nonreciprocal couplings. Upon increasing average nonreciprocity, we observe a transition from a state of coherent oscillations to a chaotic stationary state. For a randomly selected degree of freedom, we derive an effective description of the dynamics in terms of a stochastic differential equation. This allows us to analyze the properties of the stochastic motion as well as the response of the system to perturbations.

DY 32.3 Thu 10:15 H43

Cross-correlation-response relations for systems driven by shot noise — •Jakob Stubenrauch and Benjamin Lindner — BCCN Berlin and Physics Department HU Berlin, Germany

In the analysis of stochastic dynamics, the Furutsu-Novikov [1,2] theorem (FNT), linking the input-output cross-correlation of a system driven by Gaussian noise to the response function of the system, has proven important in various applications.

In several situations, such as photon-detectors or neurons, it is inaccurate to model the input process as Gaussian noise; in the two examples the input is instead a sequence of pulses at random times (shot noise). Here, we present recently discovered analogues of the FNT for systems driven by shot noise [3]. Specifically, we show that the input-output cross-correlation of any system driven by Poissonian shot noise is linearly related to the linear response of the system to modulations of the intensity of input shots. We further present extensions for colored shot noise and for shot noise with random amplitudes.

To illustrate the wide applicability of our general result, we further present a fluctuation-response relation of a leaky integrate-and-fire neuron: Building on previous work [4], we show how the spontaneous output fluctuations of a spike-driven neuron are related to its susceptibility. Lastly, as teasers, we present applications to single-photon-detection, remote control in neural networks, and synaptic plasticity.

DY 32.4 Thu 10:30 H43

A Framework for Sparse Kinetic Monte-Carlo Models — •Bat-Amgalan Bat-Erdene, Roya Ebrahimi Viand, Karsten Reuter, and Sebastian Matera — Fritz-Haber-Institut der MPG, Berlin

The long-time dynamics of many problems in condensed matter physics are controlled by the interplay of rare events, e.g. chemical kinetics or crystal growth. Such problems are typically formulated as discrete-state Markov jump processes and can be simulated by kinetic Monte Carlo (kMC) methods. We are developing a software framework for implementing efficient kMC simulation models for arbitrary such processes. The key ingredients are i) a code generator for an optimized C++ skeleton where the user specifies the problem via a Python interface, and ii) the possible formulation as a sparse kMC model. Prototypical examples for sparsity appear in spatially extended models, where in each step the state changes only locally and interactions are only short ranged. This can then be exploited to achieve near-constant computational complexity per kMC time step. We evaluate the framework's efficiency on a dynamical Ising and a CO oxidation model on regular lattices. We find that our framework achieves a similar performance as specialized state-of-the-art kMC software for lattice kMC. Moreover, our framework offers a much larger flexibility, which we demonstrate on an implementation of Coupled Finite Differences for parameter sensitivity.

DY 32.5 Thu 10:45 H43

Dynamic instability in dissipative self-assembly: common principles in single and multi-filament polymers — •Seeralan Sarvaharman and Aljaž Godec — Max Planck Insitute for Multidisciplinary Sciences, Göttingen, Germany

Dissipative self-assembly underpins the formation of complex biological structures by breaking time-reversal symmetry. Microtubules, essential cytoskeletal polymers, exemplify this through "dynamic instability", where the growth and shrinkage of the polymer are governed by the instantaneous composition of the constituent filaments. The microtubule length, the observable most commonly used to quantify this behaviour, obscures the many-body physics involved. As such, the principles underpinning this instability have remained elusive.

Here, we address this challenge by modelling the dynamics using a three-state Potts framework with thermodynamically consistent driving, capturing the stochastic interactions within and between filaments. By employing a pair approximation and local equilibrium reasoning, we derive a chemical master equation that describes the system's probabilistic evolution in terms of the length and composition. To uncover the macroscopic dynamics, we apply WKB analysis and use Filippov theory to analyse the resultant piecewise continuous ODEs that describe the evolution of the most probable paths. This analysis allows us to construct a dynamical phase diagram, revealing distinct regimes of behaviour, including dissipative limit cycles that underlie the observed macroscopic fluctuations in microtubule length.

DY 32.6 Thu 11:00 H43

The effect of noise on the breather solutions of the discrete nonlinear schrödinger equation — •Mahdieh Ebrahimi[1], Barbara Drossel[1], and Wolfram Just[2] — [1]Institute of Condensed Matter Physics, Technical University of Darmstadt, Hochschulstr. 6, 64289 Darmstadt, Germany — [2]Institute of Mathematics, University of Rostock, D-18057 Rostock Germany

The Discrete Nonlinear Schrödinger Equation (DNSE) finds applications across diverse scientific fields, including physics, chemistry, and biology. This dynamical equation is characterized by localized solutions known as breathers. Gaining insights into the processes governing discrete systems is crucial for understanding phenomena such as excitations in crystal lattices and molecular chains, light propagation in waveguide arrays, and the dynamics of Bose-condensate droplets. In this study, we treat the DNSE as an effective macroscopic equation for a quantum many-particle system and investigate the impact of two types of noise (additive and multiplicative noise) on its Hamiltonian equations of motion using symplectic integration. Our findings reveal that the system's normalization increases linearly with time under additive noise, leading to unbounded energy. Conversely, multiplicative noise preserves normalization but causes the system to heat up, ultimately destabilizing the breather in the presence of noise. Our results vividly illustrate the relevance of conserved quantities for the stochastic dynamics in Hamiltonian systems.

DY 33: Machine Learning in Dynamics and Statistical Physics I

DY 33.1 Thu 9:30 H47

Learning Mechanisms of Neural Scaling Laws — •Konstantin Nikolaou[1], Samuel Tovey[1], Sven Krippendorf[2], and Christian Holm[1] — [1]Institute for Computational Physics, University of Stuttgart, Germany — [2]Cavendish Laboratory and DAMTP University of Cambridge, United Kingdom, CB3 0WA

Recent works have identified neural scaling laws, which describe the trade-off between neural network performance and computation cost. Understanding the underlying mechanisms leading to scaling behavior might be one of the most important questions in current machine-learning research.

We compare the behavior of neural networks for data and model scaling by analyzing the learning dynamics through the lens of the neural tangent kernel. We find similar performance scaling in both regimes but uncover fundamentally distinct internal model mechanisms underlying the scaling. Additionally, we investigate scaling towards the infinite-width limit of neural networks and identify a transition, we coin the Feature-Kernel Transition, separating two regimes: Below, a model refines features to resolve a task, while above the transition the refinement declines and the initial state becomes the dominant factor. We argue that the transition marks the trade-off between model size and maximum feature learning.

DY 33.2 Thu 9:45 H47

Finite integration time drives optimal dynamic range into subcritical regime — Sahel Azizpour[1,2], Viola Priesemann[3,4], •Johannes Zierenberg[3,4], and Anna Levina[1,2] — [1]Eberhard Karls University of Tübingen, Germany — [2]Max Planck Institute for Biological Cybernetics, Tübingen, Germany — [3]Max Planck Institute for Dynamics and Self Organisation, Göttingen, Germany — [4]Institute for the Dynamics of Complex Systems, University of Göttingen, Germany

Sensitivity to small changes in the environment is crucial for many real-world tasks, enabling living and artificial systems to make correct behavioral decisions. It has been shown that such sensitivity is maximized when a system operates near the critical point of a second-order phase transition. However, proximity to criticality introduces large fluctuations and diverging timescales. Hence, it would require impractically long integration periods to leverage the maximal sensitivity. Here, we analytically and computationally demonstrate how the optimal tuning of a recurrent neural network is determined given a finite integration time. Rather than maximizing the theoretically available sensitivity, we find networks to attain different sensitivity depending on the time available. Consequently, the optimal dynamic regime shifts from critical to subcritical when integration times are finite, highlighting the necessity of incorporating finite-time considerations into studies of information processing.

DY 33.3 Thu 10:00 H47

Self-Organizing Global Computation from Local Objective Functions Based on Partial Information Decomposition — Andreas C. Schneider[1,2], •Valentin Neuhaus[2,1], David A. Ehrlich[3], Abdullah Makkeh[3], Alexander S. Ecker[4,2], Viola Priesemann[2,1], and Michael Wibral[3] — [1]Institute for the Dynamics of Complex Systems, University of Göttingen, Germany — [2]Max Planck Institute for Dynamics and Self Organisation, Göttingen, German — [3]Campus Institute for Dynamics of Biological Networks, University of Göttingen — [4]Institute of Computer Science and Campus Institute Data Science, University of Göttingen

In modern deep neural networks, individual neuron learning dynamics are often obscure due to global optimization. In contrast, biological systems use self-organized, local learning to achieve robustness and efficiency with limited global information. We propose a method for achieving self-organization in artificial neurons by defining local learning goals based on information theory. These goals leverage Partial Information Decomposition (PID), which breaks down information from sources into unique, redundant, and synergistic contributions. Our framework enables neurons to locally determine how input classes contribute to the output, expressed as a weighted sum of PID terms derived from intuition or numerical optimization. This approach enhances task-relevant local information processing and neuron-level interpretability while maintaining strong performance, providing a principled foundation for local learning strategies.

DY 33.4 Thu 10:15 H47

Explaining Near-Zero Hessian Eigenvalues Through Approximate Symmetries in Neural Networks — •Marcel Kühn and Bernd Rosenow — Institute for Theoretical Physics, University of Leipzig, 04103 Leipzig, Germany

The Hessian matrix, representing the second derivative of the loss function, offers crucial insights into the loss landscape of neural networks and significantly influences optimization algorithms, model design, and generalization in deep learning. A common characteristic of the Hessian eigenspectrum is the presence of a few large eigenvalues alongside a bulk of near-zero eigenvalues. We propose that this bulk structure arises from approximate symmetries inherent in network architectures – an often overlooked aspect. First, we demonstrate that in deep, fully connected linear networks, exact continuous symmetries that leave the loss invariant lead to zero eigenvalues in the Hessian. These zero eigenvalues and their corresponding eigenvectors can be attributed to symmetries such as rotations between weight layers. Extending this concept, we suggest that in networks with nonlinear activation functions, approximate symmetries introduce a large number of small but finite eigenvalues, viewed as perturbations of the linear case. We illustrate this phenomenon in a two-layer ReLU student-teacher setup and in a multi-layer network trained on CIFAR-10, showing that eigenvectors with small eigenvalues predominantly align with symmetry directions. Finally, we apply our symmetry-based analysis to convolutional networks, demonstrating the generality of our approach in understanding the Hessian eigenspectrum across different architectures.

DY 33.5 Thu 10:30 H47

Efficient mapping of phase diagrams with conditional Boltzmann Generators — •Maximilian Schebek[1], Michele Invernizzi[2], Frank Noé[1,2,3,4], and Jutta Rogal[1,5] — [1]Fachbereich Physik, Freie Universität Berlin, 14195 Berlin — [2]Fachbereich Mathematik und Informatik, Freie Universität Berlin, 14195 Berlin — [3]Department of Chemistry, Rice University, Houston, 77005, Texas, USA — [4]AI4Science, Microsoft Research, 10178 Berlin — [5]Department of Chemistry, New York University, New York, NY 10003, USA

The accurate prediction of phase diagrams is of central importance for both fundamental and applied material sciences. However, the computational prediction of the relative stability between phases based on their free energy is a daunting task, as traditional free energy estimators require a large amount of uncorrelated equilibrium samples over a grid of thermodynamic states. In this work, we develop deep generative machine learning models based on the Boltzmann Generator approach for entire phase diagrams, employing normalizing flows conditioned on the thermodynamic states that they map to. By training a single model to transform the equilibrium distribution sampled at only one reference thermodynamic state to a wide range of target temperatures and pressures, we can efficiently generate equilibrium samples across the entire phase diagram. We demonstrate our approach by predicting the solid-liquid coexistence line for a Lennard-Jones system in excellent agreement with state-of-the-art free energy methods while significantly reducing the number of energy evaluations needed.

DY 33.6 Thu 10:45 H47

Sampling rare events with neural networks: Machine learning the density of states — •Moritz Riedel[1], Johannes Zierenberg[2], and Martin Weigel[1] — [1]Institute of Physics, Technische Universität Chemnitz, 09107 Chemnitz, Germany — [2]Max Planck Institute for Dynamics and Self-Organization, 37077 Göttingen, Germany

Neural networks can be trained to generate samples from the Boltzmann distribution of many-particle systems. If suitable architectures such as normalizing flows or variational autoregressive networks are chosen, exact generation weights are known and hence present biases can be corrected for. Still, such networks typically struggle to learn and reproduce configurations from the full range of configuration space since effects such as mode collapse occur. For the simulation of rare events and suppressed states accessible in generalized frameworks such as the multicanonical ensemble such broad exploration is crucial. Here, we show how a combination of variational autoregressive network and autoencoder allows for a systematic exploration of configuration space in spin models, during which the network is able to learn the density of states. We demonstrate the efficacy of the approach in the Potts system in the strong first-order regime.

DY 33.7 Thu 11:00 H47

stable diffusion for microstructure: from microstructural properties to 2D-to-3D reconstruction — •Yixuan Zhang[1], Teng Long[2], Mian Dai[1], and Hongbin Zhang[1] — [1]TU Darmstadt, Darmstadt, Germany — [2]Shandong University, Jinan, China

We propose a novel framework that combines Stable Diffusion and ControlNet to generate microstructures tailored to specific properties, such as coercivity. By leveraging latent alignment techniques, our method enables direct reconstruction of 3D microstructures from 2D inputs, ensuring geometric and property consistency across dimensions. This approach not only facilitates accurate 2D-to-3D reconstruction but also opens possibilities for studying and predicting microstructural transformations during various manufacturing processes. By integrating generative AI with material design, this work provides a robust foundation for property-driven microstructure generation, offering a potential pathway to optimize materials for targeted applications.

DY 33.8 Thu 11:30 H47

Machine learning for prediction of dynamical clustering in granular gases — •Sai Preetham Sata[1], Dmitry Puzyrev[2,1], and Ralf Stannarius[3,2] — [1]AMS, Otto von Guericke University, Germany — [2]MTRM and MARS, Otto von Guericke University, Germany — [3]Department of Engineering, Brandenburg University of Applied Sciences, Germany

Granular gases are sparse ensembles of free-moving macroscopic particles that interact via inelastic collisions. One peculiar property of granular gas is dynamical clustering, i.e. spontaneous increase of local number density. To quantify this effect, microgravity experiments and simulations were performed [1-3] and two gas-cluster transition criteria were established:Kolmogorov-Smirnov test, and caging effect criterion [2]. We perform simulations based on the VIP-GRAN experiment [3] and test these criteria for various combinations of system parameters, revealing their advantages and drawbacks. In addition, we investigate additional criteria that can help to understand the dynamical properties of gas-cluster transition. Based on the simulation data, machine learning can be used to detect dynamical clusters and predict the state of the system for a given set of system parameters. This study is funded by the German Aerospace Center (DLR) within projects VICKI (50WM2252) and EVA II (50WK2348). References: [1] É. Falcon et al., Phys. Rev. Lett., 83:440, 1999. [2] E. Opsomer et al., Europhys. Lett., 99:40001, 2012. [3] S. Aumaître et al., Rev. Sci. Instr., 89:075103, 2018.

DY 33.9 Thu 11:45 H47

Automated construction of complex reaction networks — •Weiqi Wang[1], Xiangyue Liu[1], and Jesús Pérez Ríos[2] — [1]Fritz-Haber-Institut, Berlin — [2]Department of Physics and Astronomy, Stony Brook University, Stony Brook, New York 11794, USA

Kinetic models are essential for understanding chemical reaction mechanisms and estimating reaction rates. Typically, kinetic models are constructed based on transition state theory, using stable and intermediate species with zero-Kelvin energy calculations. However, they often fail to account for temperature effects and anharmonic influences, limiting their accuracy for real-world reactions.

This talk will discuss our method for automatically constructing reaction networks at finite temperatures using *ab initio* molecular dynamics simulations. Based on extensive sampling of configurational space, temperature-dependent free energies, and transition probabilities can be derived, enabling the construction of reaction networks to analyze temperature effects.

DY 33.10 Thu 12:00 H47

Data-Driven Sparse Identification with Adaptive Function Bases — •Gianmarco Ducci, Maryke Kouyate, Karsten Reuter, and Christoph Scheurer — Fritz-Haber-Institut der MPG, Berlin

Interpretable data-driven methods have proven viable for deriving kinetic equations directly from experimental data. However, such numerical methods are inherently susceptible to noise, which affects the sparsity in the resulting models. In order to promote such a sparsity condition, finding the optimal set of basis functions is a necessary prerequisite, but yet a challenging task to determine in advance.

We here present our in-house developed `ddmo` (Data-Driven Model Optimizer) software, which allows precise control over the space of candidate constituent terms. Such a complete framework comprises two main novel features. The first feature permits to include parametric functions in the library. The second feature is an adaptive library sizing routine that progressively adds or removes elements based on the learning from the dataset. We show a practical application of our algorithm tailored at identifying Langmuir-Hinshelwood mechanisms from experimental data.

DY 33.11 Thu 12:15 H47

Kalman filter enhanced adversarial Bayesian optimization for active sampling in inelastic neutron scattering — Yixuan Zhang[1], •Nihad Abuawwad[2], Samir Lounis[2], and Hongbin Zhang[1] — [1]TU Darmstadt, Darmstadt, Germany — [2]Peter Grünberg Institute (PGI), Jülich, Germany

Spin waves, or magnons, are fundamental excitations in magnetic materials that provide insights into their dynamic properties and interactions. Magnons are the building blocks of magnonics, which offer promising perspectives for data storage, quantum computing, and communication technologies. These excitations are typically measured through inelastic neutron or x-ray scattering techniques, which involve heavy and time-consuming measurements, data processing, and analysis based on various theoretical models. Here, we introduce a machine learning algorithm that integrates adaptive noise reduction and active learning sampling, which enables the restoration from minimal inelastic neutron scattering point data of spin wave information and the accurate extraction of magnetic parameters, including hidden interactions. Our findings, benchmarked against the magnon spectra of CrSBr, significantly enhance the efficiency and accuracy in addressing complex and noisy experimental measurements. This advancement offers a powerful machine learning tool for research in magnonics and spintronics, which can also be extended to other characterization techniques at large facilities.

DY 33.12 Thu 12:30 H47

Accelerating the Training and Improving the Reliability of Machine-Learned Interatomic Potentials for Strongly Anharmonic Materials through Active Learning — •Kisung Kang, Thomas A. R. Purcell, Christian Carbogno, and Matthias Scheffler — The NOMAD Laboratory at the FHI of the Max Planck Society

Machine-learned interatomic potentials (MLIP) can efficiently implement molecular dynamics (MD) simulations with large spatial and long time scales. However, immature training for rare dynamical events, such as defect creation, may happen due to their absence or insufficiency in training data or their fade-out during regularization, leading to the critical deterioration of MLIP predictions regarding dynamical properties like transport phenomena. To improve the MLIP's reliability and accelerate the whole training process, we adopt a sequential active learning ($\mathscr{AL}$) scheme via MD employing MLIP (MLIP-MD) and uncertainty estimates [1]. In each iterative step, MLIP-MD serves as an efficient exploration tool for configurational space to generate training data, while uncertainty estimates identify unfamiliar data to be sampled for subsequential MLIP models. The representative examples of CuI and $AgGaSe_2$ among 112 materials display erroneous MLIP predictions of missing and fictitious rare events. We demonstrate how $\mathscr{AL}$ addresses these issues, specifically correcting unfamiliar regions for the MLIP potential energy surface. At last, the over(under)estimation of their phonon lifetimes is rectified after the $\mathscr{AL}$ steps.

DY 33.13 Thu 12:45 H47

Molecular Dynamics of Endohedral CaX@C60 Fullerenes: Reproducing Correlated Movement Features Using Machine Learning Applications — •Mihaela Cosinschi[1,3], Amanda Teodora Preda[1,3], Calin Andrei Pantis Simut[1,3], Nicolae Filipoiu[1,3], Ioan Ghitiu[4], Mihnea Alexandru Dulea[3], Andrei Manolescu[5], and George Alexandru Nemnes[1,2,3] — [1]University of Bucharest, Faculty of Physics, Magurele, Romania — [2]Research Institute of the University of Bucharest, Bucharest, Romania — [3]Horia Hulubei National Institute for Physics and Nuclear Engineering, Magurele, Romania — [4]National Institute for Laser, Plasma and Radiation Physics, Magurele, Romania — [5]Department of Engineering, School of Technology, Reykjavik University, Reykjavik, Iceland

Fullerenes are allotropes of carbon with remarkable properties due to their high degree of symmetry, cage-like structures and ability to support addition of internal or external atoms. In the present work, we have conducted a molecular dynamics (MD) study on the C60 fullerene containing one to four encapsulated calcium atoms. All-atomistic ab initio DFT methods were employed to perform calculations through the Orca MD Module, albeit at a high computational cost. Results proved that the internal atoms adopt minimal-energy configurations and exhibit coupled motion, maintaining constant characteristics after a period of equilibration. Furthermore, we have built an artificial neural network (ANN) that can pick up the dynamics patterns and recreate trajectories to reasonable accuracy, allowing for MD calculations in significantly shorter times, even under small perturbations.

DY 34.1 Thu 11:30 H43

Hierarchical Clustering in Mean-Field Coupled Stuart-Landau Oscillators — •Nicolas Thomé and Katharina Krischer — Technische Universität München

Coupled oscillator networks are fundamental in many physics, chemistry, and biology fields, representing a captivating subject of study in nonlinear science. A persistent challenge is understanding the transition from a coherent synchronous solution to a completely incoherent one. This work explores this transition using globally coupled Stuart-Landau oscillators under mean-field interactions. We show that a cascade of codimension-2 points, coined Type-II cluster singularities, organizes the transition from two- to three-cluster solutions. These Type-II cluster singularities naturally induce a hierarchal structure to the clustering behavior and pave the way for the formation of chimera and incoherent solutions. Based on numerical bifurcation and Floquet multiplier analyses, our findings offer new insights into intermediate synchronization states and their role in complex oscillator systems.

DY 34.2 Thu 11:45 H43

Synchronization in the Fully Disordered Kuramoto Model of Coupled Oscillators — •Axel Prüser, Sebastian Rosmej, and Andreas Engel — Carl von Ossietzky University Oldenburg, Institut für Physik, D26111 Oldenburg, Germany

We investigate the dynamics of phase oscillators in fully disordered Kuramoto networks with defined degree of asymmetry. Both disordered couplings and disordered phases are considered. Employing the dynamical cavity method, the mean-field dynamics is reduced to a self-consistent stochastic single-oscillator problem which we analyze perturbatively and by numerical simulations. We elucidate the influence of the disorder characteristics on the correlation and response function of the system, together with their impact on the distribution of the order parameter. The mechanism of the so-called volcano transition and its relation to the existence of an oscillator glass phase is clarified.

DY 34.3 Thu 12:00 H43

Training of neuromorphic systems based on coupled phase oscillators via equilibrium propagation: effects of network architecture — •Qingshan Wang[1], Clara Wanjura[1], and Florian Marquardt[1,2] — [1]Max Planck Institute for the Science of Light, Staudtstrasse 2, Erlangen, Germany — [2]Department of Physics, University of Erlangen-Nuremberg, 91058 Erlangen, Germany

The increasing scale and resource demands of machine learning applications have driven research into developing more efficient learning machines that align more closely with the fundamental laws of physics. A key question in this field is whether both inference and training can exploit physical dynamics to achieve greater parallelism and acceleration. Equilibrium propagation, a learning mechanism for energy-based models, has shown promising results in physical systems with energy functions more complex than Hopfield-like models.

In this study, we focus on equilibrium propagation training of coupled phase oscillator systems. We investigate the influence of different experimentally feasible network architectures on the training performance. We analyze lattice structures, convolutional networks, and autoencoders, examining the effects of network size and other hyperparameters. Our findings lay the ground work for future experimental implementations of energy-based neuromorphic systems for machine learning, encompassing systems such as coupled laser arrays, CMOS oscillators, Josephson junction arrays, coupled mechanical oscillators, and magnetic systems

DY 34.4 Thu 12:15 H43

Stability of Grid-Following Inverters Under Forced Oscillations and Sequential Load Switching — •Benedikt Grüger and Florian Steinke — Technical University of Darmstadt, Darmstadt, Germany

The growing integration of renewable energy sources has led to a proliferation of inverter technologies in modern distribution grids. This shift introduces new dynamic stability challenges, particularly during periodic fluctuations in demand or generation caused by equipment malfunctions or cyber-physical attacks. Our work investigates the dynamic stability of grid-following inverters subjected to periodic grid voltage fluctuations. While forced oscillations in high-voltage grids have been widely studied, related research at the low-voltage level has primarily focused on bifurcations in inverter dynamics (e.g., Ma et al., 2020) or the impact of current limits (Zhang et al. 2024). However, the behavior of inverter-dominated distribution grids under forced oscillations remains largely unexplored. Our study employs a dynamic grid model that includes control mechanisms operating on time scales comparable to load switching, such as direct voltage control and phase-locked loop. This approach results in a fourth-order differential-algebraic system, akin to that proposed by Ma et al. (2023). We show that periodic grid voltage fluctuations can destabilize controllers, leading to inverter failures. By varying internal controller time scales, we identify different stability regimes and destabilizing effects are characterized. In sum, these findings highlight dynamic vulnerabilities in inverters and point out cyber-physical risks in inverter-dominated grids.

DY 34.5 Thu 12:30 H43

Shrimp structure as a test bed for ordinal pattern measures — Yong Zou[1], Norbert Marwan[2,3], Xiujing Han[4], •Reik V. Donner[2,5], and Jürgen Kurths[2] — [1]East China Normal University, Shanghai, China — [2]Potsdam Institute for Climate Impact Research, Potsdam, Germany — [3]University of Potsdam, Germany — [4]Jiangsu University, Zhenjiang, China — [5]Magdeburg-Stendal University of Applied Sciences, Magdeburg, Germany

Identifying complex periodic windows surrounded by chaos in the two or higher dimensional parameter space of certain dynamical systems is a challenging task for time series analysis. This holds particularly true for the case of shrimp structures, where different bifurcations occur when crossing different domain boundaries. Here we propose to use ordinal pattern transition networks (OPTN) to characterize shrimp structures. Our results demonstrate that among different ordinal characteristics, the OPTN out-link transition entropy exhibits better classification accuracy between chaotic and periodic time series than other existing measures like permutation entropy. This improved performance results from the fact that the transition behavior between ordinal patterns encodes additional dynamical information that is not captured by traditional ordinal measures that are solely based on pattern occurrence frequencies. Ultimately, the new OPTN based entropy measure also outperforms previously used measures based on recurrences in phase space.

DY 34.6 Thu 12:45 H43

Designing Robust Edge Oscillations with Topological Protection in Nonlinear Coupled Systems — •Sayantan Nag Chowdhury and Hildegard Meyer-Ortmanns — School of Science, Constructor University, 28759 Bremen, Germany

Topological protection, a powerful concept in physics, ensures robust states across quantum and classical systems. While topological insulators exemplify its applications in quantum systems with electric currents protected along the edges, an example from classical physics is provided by topoelectrical circuits with stable signal transduction. However, the role of topological protection in the context of classical oscillatory systems has been much less explored. Our study applies tools from band theory of condensed matter physics to systems with nonlinear dynamics to achieve robust edge oscillations. This means that oscillations are restricted to the edge of a two-dimensional grid, while those in the bulk settle into near-steady-state dynamics. This pattern is resilient to parameter mismatches, structural defects, and blockages. By calculating the Zak phase as topological characteristic for this phenomenon, we explain edge-localized oscillations through bulk-boundary correspondence. We further analyze the collective behavior by examining the limiting case of weak coupling strength in our directed network, which alternates between strong and weak values. We validate our findings for different prototypical oscillator models with possible applications in biochemical systems. Our findings establish a robust design for controlling the state of oscillation of units that are attached to a spatial grid.

Light-Driven Manipulation of Passive and Active Microparticles — •Svetlana Santer — Institute of Physics and Astronomy, University of Potsdam, Germany

Chemical gradient near a solid/liquid can result in lateral long-range fluid transport termed diffusioosmotic (DO) flow. For instance, when photosensitive surfactant is irradiated with light converting the majority of the molecules in one of the possible isomers, emerging concentration gradient of isomers generates an osmotic pressure gradient tangent to the wall actuating the surrounding liquid to flow. [1-3] In my talk I will show how one can manipulate microparticles and even induce their self-propulsion by light urtilizing light driven diffusioosmotic (LDDO) phenomenon. Depending on the applied wave length one can either disperse/remove or gather particles. We will discuss how to establish light-driven hydrodynamics as a useful and versatile tool for investigating collective motion of self-propelled particles and aggregation

[3] Arya, P.; Umlandt, M.; Jelken, J.; Feldmann, D.; Lomadze, N.; Asmolov , E. S.; Vinogradova, O. I.; Santer, S. A. The European Physical Journal E, 44(50) (2021), 1-10.

DY 36.2 Thu 15:30 H37

Regulated polarization of active particles in local osmotic flow fields — •Lisa Rohde, Desmond Quinn, Diptabrata Paul, and Frank Cichos — Molecular Nanophotonics Group, Peter Debye Institute for Soft Matter Physics, University Leipzig, Leipzig, Germany

Regulation in living systems is a fundamental principle for achieving robust functionality and maintaining specific non-equilibrium states. The control of certain properties and functionalities of systems on the microscale presents particular challenge since thermal fluctuations and environmental perturbations dominate. While synthetic active matter has demonstrated remarkable self-organization capabilities, examples of autonomous regulation processes at the single-particle level remain scarce. Here, we show experimentally that the interplay of two non-equilibrium processes leads to a regulated polarization state of active particles in local osmotic flow fields. Based on thermophoretic repulsive and attractive forces that are generated by a single heat source at the boundary, the active particles encircle the heat source at a stable distance depending on the heat source temperature. The balance of these temperature-induced processes causes a polarization of the active particles that is independent of the heat source temperature. The individual control of heat source and active particles in the experiment allows detailed investigation of the self-regulated polarization effect in which we find hydrodynamic interactions to dominate. As the effects rely on osmotic flows and phoretic interactions, we expect that the observed phenomena can be generalized to other active systems and flow fields.

DY 36.3 Thu 15:45 H37

Active particle steering in three dimensions — •Gordei Anchutkin and Frank Cichos — Molecular Nanophotonics Group, Peter Debye Institute for Soft Matter Physics, Leipzig University, Leipzig, Germany

Synthetic active particles serve as a model system that mimic the self-propulsion of living matter to explore fundamental aspects of non-equilibrium physics. Various collective phenomena of active agents have been studied, but mostly in the presence of hydrodynamic and physicochemical boundary effects. While theoretical works predict different collective dynamics in 3D, experimental investigations remain limited due the lack of experimental control over active swimmers in three dimensions.

Here we introduce three-dimensional control to the study of synthetic active matter. We demonstrate simultaneous control of thermophoretic microswimmers in 3D using single-particle tracking through digital holography and dark-field pattern tracking, with real-time wavefront shaping for steering. With the help of these experiments, we explore the interplay of thermophoretic propulsion, gravity, and optical forces for the active particles. By creating a three-dimensional active ensemble, we reveal how bulk interactions and boundary effects shape the collective behavior of active particles.

***Trypanosoma brucei* in microchannels: the role of constrictions** — •Zihan Tan, Julian I. U. Peters, and Holger Stark — Institute of Theoretical Physics, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin, Germany

Trypanosoma brucei (*T. brucei*), a single-celled parasite and natural microswimmer, is responsible for the fatal sleeping sickness in infected mammals, including humans. Understanding how *T. brucei* interacts with fluid environments and navigates through confinements is crucial for elucidating its movement through blood vessels and tissues, and across the blood-brain barrier.

Using a hybrid multiparticle collision dynamics (MPCD)–molecular dynamics (MD) approach, we investigate the locomotion of an in-silico *T. brucei* in three types of fluid environments: bulk fluid, straight cylindrical microchannels, and microchannels with constrictions. We observe that the helical swimming trajectory of the in-silico *T. brucei* becomes rectified in straight cylindrical channels compared to bulk fluid. The swimming speed for different channel widths is governed by the diameter of the helical trajectory. The speed first slightly increases as the channel narrows and then decreases when the helix diameter is compressed. An optimal swimming speed is achieved when the channel width is approximately twice the bulk helix diameter. Furthermore, *T. brucei* notably slows down when entering the narrow constriction in a microchannel and strongly speeds up upon exiting due to a release of deformation energy of the straightened cell body.
