Machine learned interatomic potentials (MLIP) have gained popularity in materials science for their scalability and accuracy on par with the Density Functional Theory (DFT) training data. Based on the linear scaling with the number of neighbors, the primary focus in the recent years was increasing the flexibility of MLIPs to further improve their accuracy, as demonstrated by approaches such as Neural Network potentials and the Atomic Cluster Expansion (ACE). The Bessel functions and Chebyshev polynomials gained popularity as basis sets to represent the atomic bonds and orbitals. Nonetheless, the connection between an MLIP's basis set and its capability to represent the chemical complexity of various elements is not yet well understood.

In this study, we use ACE, as implemented in the Pacemaker software package, to investigate three non-magnetic transition metals (i.e., Al, Au, and Cu). For each element, we parameterize computationally efficient ACE potentials based on a minimal basis set to achieve a given root-mean-square error (RMSE) across both training and testing datasets. We find that the complexity of the MLIP primarily depends on the scaling of the per-atom energy distribution rather than the chemical complexity of the elements. Consequently, it is primarily a numerical effect rather than a chemical effect.

MM 18.2 Wed 10:30 H23

Physics-Based Generative Models: Enhanced Structure-Property Sampling in Inverse Materials Design — •Patricia König[1], Nicolas Bergmann[1], Piero Coronica[2], Chiara Panosetti[1], Hanna Türk[1], Karsten Reuter[1], and Christoph Scheurer[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Max Planck Computational and Data Facility, Munich

Data-driven approaches for the inverse design of novel materials with desired properties have become a key tool in materials discovery. Here, we introduce a framework using physics-based Generative Adversarial Networks for enhanced structure-property sampling via latent space design.

We are interested in sampling structures of two chemical systems associated with different relevant physical quantities, like the work function in the electrochemical adsorption of iodide and hydroxide on copper surfaces, and the oxygen chemical potential in the CO to CO_2 conversion over an amorphous RuO_2 catalyst. As part of our framework, we track and evaluate the structural diversity and convergence of our generator with machine-learning interatomic potentials and quantitative metrics. This enables a high throughput and cost-effective evaluation of structural guesses and their related properties to leverage the full potential of generative models. Concluding, we are showing on two model systems how to explore a vast chemical space of datasets with sparse areas, particularly structures with high free energies in transition states and diverse amorphous surface structures, thereby advancing the understanding and design of novel materials.

MM 18.3 Wed 10:45 H23

Active learning-based automated construction of Hamiltonian for structural phase transitions: a case study on $BaTiO_3$ — •Mian Dai[1], Yixuan Zhang[1], Nuno Fortunato[1], Peng Chen[2], and Hongbin Zhang[1] — [1]Institute of Materials Science, Technical University of Darmstadt, Darmstadt 64287, Germany — [2]Physics Department and Institute for Nanoscience and Engineering, University of Arkansas, Fayetteville, Arkansas 72701, USA

The effective Hamiltonians have been widely applied to simulate the phase transitions in polarizable materials, with coefficients obtained by fitting to accurate first-principles calculations. However, it is tedious to generate distorted structures with symmetry constraints, in particular when high-ordered terms are considered. In this work, we implement and apply a Bayesian optimization-based approach to sample the potential energy surface, automating the Hamiltonian construction by selecting distorted structures via active learning. Taking $BaTiO_3$ (BTO) as an example, we demonstrate that the Hamiltonian can be obtained using fewer than 30 distorted structures. Follow-up Monte Carlo simulations can reproduce the structural phase transition temperatures of BTO, comparable to experimental values with an error < 10%. Our approach can be straightforwardly applied on other polarizable materials and paves the way for quantitative atomistic modelling of diffusionless phase transitions.

MM 18.4 Wed 11:00 H23

Comparing linear and deep learning surrogate models of materials electronic structure — •Valdas Vitartas, Chen Qian, James Kermode, and Reinhard Maurer — University of Warwick, Coventry, UK

The self-consistent electronic Hamiltonian matrix from Density Functional Theory (DFT) gives access to the electronic band structure and the density of states of a material, albeit at a large computational cost. Over recent years, several surrogate models based on linear parametrization and deep learning have been proposed to efficiently learn the electronic Hamiltonian as a function of the configuration and composition of materials. In this work, we compare two such models, the ACEhamiltonians [npj Comput. Mater. 8, 158] and MACE-H. Both provide a representation of the Hamiltonian in atomic orbital basis in terms of an equivariant many-body expansion of local atomic environments. In the case of ACEhamiltonians, the model parametrization is linear; for MACE-H, the representation serves as input to a message-passing neural network. The models are trained on reduced, valence-only Hamiltonian matrices for bulk gold and silicon generated from all-electron DFT via an approximately eigenspectrum-conserving transformation. We discuss the inherent strengths and weaknesses of the models by illustrating their accuracy, performance, data efficiency, and their ability to predict electronic quantities of interest for out-of-distribution configurations.

MM 18.5 Wed 11:15 H23

MACE-H: Equivariant Hamiltonian prediction with many-body expansion message passing — •Chen Qian, Valdas Vitartas, James Kermode, and Reinhard J. Maurer — University of Warwick, UK

The machine learning prediction of Kohn-Sham Density Functional Theory (DFT) Hamiltonians has the potential to accelerate the prediction of electronic properties, such as electronic band structures and electron-phonon coupling, while avoiding computationally expensive self-consistent field iterations. We introduce the MACE-H graph neural network, which combines the MACE body-order expansion message passing scheme with node-degree expansion blocks to efficiently generate messages that incorporate all relevant SO(3) irreducible representations. This model achieves high accuracy and high computational efficiency in capturing the local chemical environment. We demonstrate the model performance using several open materials benchmark datasets for 2D materials, achieving sub-meV prediction errors on matrix elements. Moreover, we discuss how the many-body expansion achieves higher data efficiency and examine its effect on out-of-distribution prediction for nanostructures featuring long-range interactions. To assess prediction outputs, we analyze the correlation between errors and hermiticity. The high computational efficiency and accuracy make the model a good candidate for electronic structure prediction in large-scale systems and high-throughput material screening.

Inferring Structure-Property Relationships with Artificial Intelligence: A Lignin Case Study — •Matthias Stosiek and Patrick Rinke — Technical University Munich, Munich, Germany

The potential of lignin as an abundant, underutilized biopolymer is increasingly being realized. A key challenge for the targeted production of lignins remains the poorly understood relation between lignin properties and its complex structure. Artificial intelligence (AI) methods could reveal such structure-function relationships but remain elusive in biomaterials research.

Structurally diverse lignins are extracted from birch wood combining the Aqua Solv Omni (AqSO) biorefinery process and AI-guided data acquisition[1]. Each lignin sample is characterized with 2D nuclear magnetic resonance (NMR) spectroscopy. A total of 95 collected NMR spectra are complemented with measurements of key lignin properties such as the antioxidant activity.

To establish structure-function relationships, we first correlate regions of the NMR spectra with the corresponding property measurements. Subsequently, we use RFR feature importance analysis to identify structural features that correlate with each property and provide a chemical interpretation of our findings. For instance, we find that a higher number of β-O-4 bonds leads to a lower surface tension in water indicating a more linear lignin structure. Our structure-inference approach is designed to be general and applicable to a wide range of materials and characterization data.

MM 18.7 Wed 12:00 H23

Machine learning electrostatics: Open challenges from batteries to proteins — •Max Veit — Technische Universität Darmstadt, DE

Long-range interactions such as electrostatics have long been a concern in developing accurate, efficient machine learning potential energy surfaces (ML-PES). Such potentials have now become established as a powerful technique allowing simulations of complex structures and processes with unprecedented realism and accuracy. However, the most widespread and successful methods to date do not incorporate any interactions beyond a fixed cutoff range, typically a few coordination shells. First, we need to ask the question of how methods with such an obvious limitation can be so successful, even applied to systems where long-range electrostatic interactions are known to be relevant. Second, we need to ask what approach, among the many proposed over the last decade or so, is the most appropriate if we want to incorporate long-range interactions in an accurate, efficient, and physically appropriate way. We investigate these questions in the context of a technologically relevant, experimentally accessible test system: lithium-intercalated graphite or nearly-graphitic nanoporous carbon. We first discuss the characteristics of this system that make it uniquely suited to machine learning simulation, then turn to the difficulties involved in defining what exactly makes a "good" electrostatic model, or long-range model in general, in the context of machine learning potentials, and finally discuss the implications for other systems – such as complex biomolecules – just out of the current reach of ML-PES simulations.

MM 18.8 Wed 12:15 H23

Data driven prediction of relative stability of binary and ternary TCP phases. — •Mariano Forti, Ralf Drautz, and Thomas Hammerschmidt — Interdisciplinary centre for advanced materials simulation, Ruhr-University Bochum

The study of precipitation of topological close packed(TCP) phases is of primary importance for the performance of superalloys. However, the structural complexity of these intermetallic compounds and the chemical complexity of the superalloys with typically up to ten elements hampers the exhaustive sampling of chemical space by density-functional theory (DFT) calculations. We overcome the related computational limitations by combining machine learning (ML) techniques with descriptors of the local atomic environment of the TCP phases and the use of interatomic potentials to predict phase properties with high precision. We illustrate our methodology studying the relative stability of the complex phases R, P, M and δ in binary and ternary systems produced from the main components in Co, Ni and Fe based superalloys.

MM 18.9 Wed 12:30 H23

Inverse Materials Design with Large Language Models — •Jan Janssen and Joerg Neugebauer — MPI for Sustainable Materials, Düsseldorf, Germany

Large language models (LLM) are trained on a vast amount of scientific literature to learn the included semantic, conceptional, and statistical relationships. The LLM applies these relationships to generate responses in natural language based on the context of the conversation. This raises the question: Can a LLM replace a scientist? Or how does the thought process of a scientist differ from the statistical approach of the LLM? Can the LLM make us better scientists?

We benchmark the capabilities of current LLMs to design new materials using atomistic simulations. While the required Python programming is challenging for the LLM and suffers from hallucination, this can be addressed with an agent-based approach by providing the LLM with a series of simulation workflows for the pyiron workflow framework. With these simulation workflows the LLM is not only capable to calculate material properties but can also invert the process and leverage statistical models to identify alloying compositions which match a pre-defined materials property, enabling inverse materials design.

Our benchmarks highlight the importance of developing scientific workflows. The more a workflow reduces the technical and scientific complexity of studying a given materials property the easier it is to use for LLMs and scientists alike. In this way LLMs also help us as scientists to validate and improve our scientific workflows. https://github.com/jan-janssen/LangSim

MM 18.10 Wed 12:45 H23

Workflow Utilities within the NOMAD Infrastructure: Lowering the Barrier to FAIR Data Management for Computational Materials Science — •J.F. Rudzinski[1], E. Boydas[1], N. Daelman[1], B. Mohr[1], J.M. Pizarro[1], T. Bereau[2], C. Draxl[1], L.M. Ghiringhelli[3], M. Girard[4], D. Usvyat[5], R. Valenti[6], and S. Botti[7] — [1]CSMB, HU Berlin — [2]ITP, Heidelberg Uni. — [3]Dept. of Mater. Sci. and Eng., FAU Erlangen — [4]Max Planck Inst. for Poly. Res., Mainz — [5]Inst. für Chem., HU Berlin — [6]Inst. für Theor. Phys., GU Frankfurt/M — [7]RC-FEMS, Ruhr Uni. Bochum

NOMAD [nomad-lab.eu] [1] is an open-source, community-driven data infrastructure, focusing on materials science data. The NOMAD software can automatically extract data from the output of over 60 simulation codes, has been extensively expanded to support advanced many-body calculations and classical molecular dynamics simulations, and allows straightforward specialization via a rapidly developing plugin-based ecosystem. Both standardized and custom complex simulation workflows not only streamline data provenance and analysis but also facilitate the curation of AI-ready datasets. This contribution will focus on recently developed workflow functionalities and utilities within the NOMAD infrastructure. These advances enable highthroughput interfacing with the NOMAD repository, opening improved discovery pipelines by leveraging the benefits of NOMAD's comprehensive and FAIR-compliant data management system [2].

MM 18.11 Wed 13:00 H23

Freedom of design: towards in silico design of molecules with desired quantum-mechanical properties — •Leonardo Medrano Sandonas[1], Alessio Fallani[2], Julian Cremer[3], Alexandre Tkatchenko[2], and Gianaurelio Cuniberti[1] — [1]TUD Dresden University of Technology, Germany. — [2]University of Luxembourg, Luxembourg. — [3]Pfizer Worldwide R&D, Germany.

The rational in silico design of chemical compounds requires a deep understanding of both the structure-property and property-property relationships that exist across chemical compound space (CCS), as well as efficient methodologies for defining an inverse property-to-structure mapping. In this presentation, we will discuss these relationships in the CCS sector spanned by small [Sci. Data 8, 43 (2021)] and large [Sci. Data 11, 742 (2024)] drug-like molecules, highlighting the existence of the "Freedom of design" principle [Chem. Sci. 14, 10702 (2023)]. The insights gained are subsequently leveraged to design molecules with desired properties. To this end, we first developed a variational autoencoder (VAE) approach and demonstrated that CCS can be parameterized using a finite set of quantum-mechanical (QM) properties [Nat. Commun. 15, 6061 (2024)]. We showcased the capabilities of this method by conditionally generating de novo molecular structures, interpolating transition paths for chemical reactions, and providing insightful insights into property-structure relationships. We expect our work will contribute to the development of advanced generative frameworks that enhance the in silico design and identification of molecules for specific chemical processes.

MM 19: Invited Talk: L. Bourgois

Invited Talk MM 19.1 Wed 15:00 H10

Structure, interfacial segregation and transformations of solid-state precipitates in aluminium alloys — •Laure Bourgeois[1,2], Nikhil Medhekar[2], and Matthew Weyland[1,2] — [1]Monash Centre for Electron Microscopy, Monash University, Victoria, Australia — [2]Department of Materials Science and Engineering, Monash University, Victoria, Australia

Solid-state precipitates are key components of many materials, and none more so perhaps than of lightweight alloys such as aluminium. These precipitates are often deeply buried inside the alloy matrix due to having at least one dimension at the nanoscale or even sub-nanoscale. These precipitates are also, in most cases, metastable phases that do not exist in a monolithic state, thus constituting difficult objects to characterise at the atomic scale. In this contribution we present the structural determination of several precipitate phases in lightweight alloys, including the classic Al-Cu, Al-Au and Al-Ag systems. Using a combination of scanning transmission electron microscopy and atomistic simulations, we reveal the existence of new interfacial structures and precipitate phases, and propose atomic-scale models for the mechanisms of nucleation and growth. This includes unexpected pathways for the formation of desired strengthening precipitates. These insights are used as a starting point to predict the precipitation behaviour of other, largely unexplored, alloy systems.

MM 20: Topical Session: Thermophysical Properties of Bulk Metallic Glasses and Bulk Metallic Glass-forming Liquids

Topical Talk MM 20.1 Wed 15:45 H10

Magnetic properties of Fe-based amorphous alloys produced by melt-spinning and selective laser melting — •Paola Tiberto — INRIM, Torino, Italy

Amorphous soft-magnetic materials play an important role as core constituents in improving the energy transformation efficiency of electrical machines and passive electrical components. Although the melt-spinning process remains the main technique for obtaining amorphous soft-magnetic ribbons with remarkable soft magnetic properties, new and efficient production methods based on additive manufacturing have been developed in recent years, enabling the direct synthesis of larger elements. Ribbons were obtained by a conventional melt-spinning process while 3D-printed samples were produced by additive manufacturing via Selective Laser Melting (SLM) using powder of the same alloy as a precursor. In this study, we investigate the hysteresis properties of amorphous Fe-Si-B-based alloys in ribbon shape and 3D-printed bulk samples produced by different casting techniques. The SLM processing conditions have been observed to play a crucial role in the microstructure of the printed parts and, therefore, in their magnetic properties, due to their dependence on morphology. The effect of different printing parameters on magnetic properties, such as laser power and scan speed, has been studied. This study highlights the critical link between microstructure engineering through manufacturing techniques and the resulting magnetic performance, offering insights into optimizing both for enhanced energy efficiency in magneto-electrical applications.

MM 20.2 Wed 16:15 H10

Advancements in Developing Fe-Based Metallic Glasses for Additive Manufacturing of Soft Magnetic Components — •Amirhossein Ghavimi[1], Maryam Rahimi Chegeni[1], Purbasha Sharangi[2], Uma Rajput[2], Gabriele Barrera[2], Enzo Ferrara[2], Paola Tiberto[2], Isabella Gallino[3], and Ralf Busch[1] — [1]Saarland University, Chair of Metallic Materials, Campus C6.3, 66123 Saarbrücken, Germany — [2]INRIM, Strade delle Cacce 91, Torino, Italy — [3]Department of Materials Science and Engineering, Metallic Materials, TU-Berlin, Ernst-Reuter-Platz 1, 10587 Berlin, Germany

This research aims to create suitable Fe-based soft-magnetic amorphous alloys for the 3D printing of motor components. Since a fully amorphous structure of the 3D-printed parts is expected to improve motor efficiency, i.e. increase magnetic softness and decrease energy losses, the glass-forming ability (GFA) is enhanced through the judicious change of the alloy chemical composition while maintaining competitive soft magnetic properties. The GFA of the compositions was studied by evaluating the critical casting thickness (dc) of the samples. Subsequently, XRD, DSC and DTA were used to characterize the structure and thermal behavior of the samples. The magnetic properties were determined by means of VSM in addition to the evaluation of losses. The eutectic zone of the Fe-Si-B system was experimentally determined. Evaluation of quaternary and quinary component alloys involved studying the effects of promising elements such as phosphorous and nickel on GFA and magnetic properties.

MM 20.3 Wed 16:30 H10

Ni-Nb-(Ta)-P-Based Bulk Metallic Glasses: The Origin of Glass Formation Based on Thermodynamics, Kinetics, Structure and Crystallization Behavior — •Lucas M. Ruschel and Ralf Busch — Chair of Metallic Materials, Saarland University, 66123, Saarbrücken, Germany

Ni-Nb-based bulk glass-forming alloys are among the most promising amorphous metals for industrial applications due to their incomparable combination of strength, hardness, elasticity and plasticity. A successful approach in alloy development is so-called minor alloying, where metallic glasses with improved properties and enhanced GFA are produced, if the proper minor alloying element is chosen for the respective base alloy. Here, minor additions of P to the

binary Ni-Nb system increase the GFA up to a record value of 5 mm, which surpasses the binary $Ni_{62}Nb_{38}$ alloy by 150 %. The partial substitution of Nb by Ta further boosts the GFA up to 6 mm. To elucidate the origins of the significant improvement in GFA, key properties such as the thermodynamics and kinetics of the system are studied, including the driving force for crystallization and the kinetic slowdown of viscosity during the transition from the equilibrium liquid to the glassy state. The primary precipitating phase, critical for glass formation, is identified by high-energy synchrotron X-ray diffraction (HEXRD) under containerless electrostatic levitation conditions. Complementary low-temperature HEXRD experiments reveal the structural evolution across a wide temperature range, offering a comprehensive understanding of the mechanisms responsible for the enhanced GFA.

MM 20.4 Wed 16:45 H10

Mechanical Behavior of Phase-Separated Zr-Al-Fe-Y Metallic Glasses for Prospective Implant Applications — •Devinder Singh[1,2], Parthiban Ramasamy[1], Anna Sophie Jelinek[3], Christoph Gammer[1], Zaoli Zhang[1], and Jürgen Eckert[1,3] — [1]Erich Schmid Institute of Materials Science, Austrian Academy of Sciences, Jahnstraße 12, Leoben, Austria — [2]Amity School of Applied Sciences, Amity University Uttar Pradesh, Lucknow India — [3]Department of Materials Science, Montanuniversität Leoben, Jahnstraße 12, Leoben, Austria

Phase separation arises from the substitution of Y in Zr70-xAl12.5Fe17.5Yx (x=0-25 at.%) metallic glasses (MGs), resulting in the formation of nano-amorphous domains within a glassy matrix. The glasses with x > 10 show a typical liquid phase separation-induced two-glassy phase (Zr-rich and Y-rich) morphology with droplet-like microstructures. Atom probe tomography (APT) analysis confirms the formation of nanometer-sized Y-enriched clusters for x=15 and 20. The micro-hardness and nano-hardness are found to be in the range of 4.58-5.73 GPa and 5.22-6.11 GPa. The Zr-based MGs exhibit Young's moduli in the range of 81-91 GPa, which are lower than that of Co-Cr-Mo, 316L SS and Ti-6Al-4V commercial implant alloys. Evaluation of the cytocompatibility of the MG ribbons reveals high metabolic activity and well-spread human gingival fibroblast (HGF) cells on the surface of x=10 and 15 samples. Thus, the two glassy-phase Zr-based MGs free of toxic elements (Ni and Cu) exhibit suitable mechanical properties and biocompatibility for implant applications.

15 min. break

Topical Talk MM 20.5 Wed 17:15 H10

Diffusion and nucleation in Al-Ni melts using machine-learned MD simulations — Johannes Sandberg[1,2,3], Leon F. Granz[2,3], and •Thomas Voigtmann[2,3] — [1]Universitë Grenoble-Alpes, Grenoble, France — [2]Heinrich-Heine-Universität, Düsseldorf, Germany — [3]Deutsches Zentrum für Luft- und Raumfahrt, Köln, Germany

The microstructure that forms during solidification of metallic melts greatly influences the material properties. It depends crucially on the microscopic transport properties, and the initial phase selection in the cricial nucleus. Simulation of these phenomena faces two contradictory demands: while the relevant length and time scales match well that of classical molecular dynamics simulations, the sensitive dependence on details of the interatomic interactions is only captured in much smaller-scale quantum-mechanical simulations. In recent years, machine-learned interaction potentials have helped to reconcilce these requirements, allowing MD simulations to be performed with almost DFT-like accuracy.

I will present results that we have obtained using high-dimensional neural network potentials (HDNNP) to the case of Al-Ni melts and nucleation processes therein. Crucially, we assess the performance of the HDNNP by comparing to structural and dynamical experimental data of the liquids at different compositions. This reveals also how the level of DFT closure chosen in the quantum-mechanical simulations used to train the network influences the prediction of thermophysical quantities.

MM 20.6 Wed 17:45 H10

Study of solidification behaviour of undercooled Zr-Ni-Cu melts — •Chu Yu[1,4], Fan Yang[2], Dirk Holland-Moritz[2], Yindong Fang[1,4], Ivan Kaban[3], Stephanie Lippmann[4], and Peter K. Galenko[1] — [1]Otto Schott Institute of Material Research, Friedrich Schiller University Jena, Jena, Germany — [2]Institut für Materialphysik im Weltraum, Deutsches Zentrum für Luft- und Raumfahrt, Cologne, Germany — [3]Leibniz IFW Dresden, Institute for Complex Materials, Dresden, Germany — [4]Institute of Applied Physics, Friedrich Schiller University Jena, Jena

We investigate the solidification behaviour of the glass-forming $Zr_{50}Cu_{35}Ni_{15}$ alloy employing different levitation techniques. The primary phase solidified from the undercooled melt has been found to be independent of the degree of undercooling up to a level beyond the hypercooling limit, as observed by time-resolved X-ray diffraction. The crystal growth velocity has been measured employing electromagnetic levitation (EML), where solidification occurs under stronger fluid-flow conditions compared to previous studies employing electrostatic levitation (ESL). In both cases the observed growth velocity increases with increasing undercooling, before reaching a plateau at undercoolings between 260-320 K. However, at small undercooling the growth velocities measured with EML are slightly higher than that in ESL. The solidification kinetics is discussed in terms of different crystal growth models, taking into account the effect of fluid flow. The works is supported by DFG, DLR, ESA via MULTIPHAS-project Nr. 50WM1941, and ProChance-exchange Program of the FSU Jena.

Topical Talk MM 20.7 Wed 18:00 H10

The effect of composition on the thermodynamics, structure, mechanical properties and atomic motion of (Pd-Pt)42.5Cu27Ni9.5P21 alloys — •Ralf Busch — Saarland University, Saarbrücken, Germany

According to basic hard sphere models Pt should replace Pd in the Pd42.5Cu27Ni9.5P21 alloy. But Pt42.5Cu27Ni9.5P21 shows significant structural differences compared to the Pd based alloy. To study the differences, we prepared a series of (Pd-Pt)42.5Cu27Ni9.5P21 alloys replacing Pd with Pt. We assess the thermodynamic functions revealing that the driving force for crystallization increases with the increase of the Pt content, which is in line with the decreasing critical casting thickness. The Pt-richer alloys are thermodynamically more fragile than the Pd-rich alloys, which is revealed by a larger specific heat capacity and a faster drop of the configurational entropy in the Pt-richer alloys. High energy XRD (HEXRD) studies reveal that the structure of the Pt rich alloys is dominated by its change in medium range order whereas the Pd-rich alloy is dominated by extraordinary short range order. The mechanical properties change drastically from a ductile behavior on the Pt-rich side to an embrittlement with increasing Pd content and decreasing Pt concentration. Nano-indentation investigations together with the HEXRD studies reveal that the embrittlement with increasing Pd-content can be connected to the structural changes. We used XPCS to study the atomic dynamics of the alloys as a function of temperature and wave vector.

MM 21: Interface Controlled Properties, Nanomaterials and Microstructure Design

Time: Wednesday 15:45–18:30 Location: H22

MM 21.1 Wed 15:45 H22

Plateau-Rayleigh-type failure mode of porous films and interconnects near massive substrates: mitigation strategies — •Gideon Henkelmann[1], Xinyan Wu[2], and Jörg Weissmüller[1,3] — [1]Institute of Materials Physics and Technology, Hamburg University of Technology, Germany — [2]Institute of Optical and Electronic Materials, Hamburg University of Technology, Germany — [3]Institute of Hydrogen Technology, Helmholtz-Zentrum hereon, Geesthacht, Germany

Nanoporous thin films are under study as functional materials for actuation, photonics, catalysis, energy storage and as semiconductor interconnects. However, these thin films tend to self-detach from their substrate. The same failure mode is also observed in sintered silver paste, a widely used electronics interconnect material. In this work, we discuss the origin of the underlying instability. Based on those insights, we derive a mitigation strategy that depends on gradient in porosity. Combining experiment with kinetic Monte Carlo simulation, we validate the strategy and optimize the composition profile. An exponential gradient is found optimum, and this is rationalized by theory. Our approach greatly improves the structural stability of nanoporous thin films, enabling their more reliable use in advanced applications.

MM 21.2 Wed 16:00 H22

Compressive behavior and connecting topology of monolithic nanoporous niobium — •Seoyun Sohn[1,2], Shan Shi[3,1], Jürgen Markmann[1,2], Stefan Alexander Berger[1], and Jörg Weissmüller[2,1] — [1]Institute of Hydrogen Technology, Helmholtz-Zentrum Hereon, 21502 Geesthacht, Germany — [2]Institute of Materials Physics and Technology, Hamburg University of Technology, 21073 Hamburg, Germany — [3]Research Group of Integrated Metallic Nanomaterials Systems, Hamburg University of Technology, 21073 Hamburg, Germany

This study investigates the mechanical behavior of nanoporous (NP) Nb fabricated through liquid-metal dealloying, with an eye on the role of structure size and topology. Results from X-ray nanotomography and macro-compression tests confirm that coarsening degrades yield strength and that Young's modulus deviates from scaling laws previously developed for NP Au made by dealloying in aqueous media. Our analysis reveals that the scaled genus, a measure of network connectivity, of NP Nb observed from the tomographic reconstructions is lower than what has been reported for NP Au. This reduced connectivity provides an obvious explanation for the low modulus of NP Nb. Furthermore, the structural

dispersion implies that additional structural descriptors should be acknowledged to account for the mechanical differences between liquid-metal dealloyed materials and those synthesized via conventional aqueous dealloying.

MM 21.3 Wed 16:15 H22

Unravelling the metal-support interaction of sub-monolayer Pt thin films on manganese oxide via photoelectron spectroscopy — •Manuela Arztmann[1], Raul Garcia-Diez[1], Johannes Frisch[1], and Marcus Bär[1,2,3,4] — [1]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Germany — [2]Energy Materials In-Situ Laboratory Berlin, Germany — [3]Helmholtz-Institut Erlangen-Nürnberg für Erneuerbare Energien, Germany — [4]Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany

In heterogeneous catalysis, metal-support interactions (MSI) have been shown to greatly influence the selectivity and activity of catalysts, with reducible supports as preeminent examples. The various oxidation states accessible for manganese oxide allow to accommodate different amounts of oxygen vacancies, making it a promising support with tunable properties for catalysis. Studies show that the oxidation state of manganese is closely linked to its promoter capabilities in catalysis, though the MSI is not well understood so far. In this 'in-system' study, the chemical and electronic structure of the interface between Pt and manganese oxide was investigated by XPS/UPS as a function of Pt surface coverage. The thin film model catalysts were prepared by e-beam evaporation in a system directly connected to the XPS/UPS setup, enabling precise control of the Pt thickness from sub-monolayer levels to thick metal-like Pt layers, allowing for a systematic study of the property evolution in the near surface region without leaving vacuum conditions. Our results reveal an enhanced reduction of the manganese oxide with increasing Pt surface coverage indicating significant MSI.

MM 21.4 Wed 16:30 H22

Optical and electrical properties of borophene and borophene/silicon junction — •yaser abdi[1,2], masoud taleb[1], alireza eskandari[2], zahra alavi[2], mohsen moayedi[2], and nahid talebi[1] — [1]Institute of Experimental and Applied Physics, Kiel University, 24118 Kiel, Germany — [2]Department of Physics, University of Tehran, 1439955961 Tehran, Iran

Borophene, a 2D monolayer of boron atoms, possesses unique properties that have led scientists to conclude that it could be an excellent alternative to graphene in future electronic device applications. In this talk, which is based on our recent work on synthesis [1] and characterization [2] of optical [3] and electrical properties of borophene and borophene/silicon Schottky junction, I will discuss about the growth of borophene using a chemical vapor deposition approach and investigation of its optical and electrical behaviors. Leveraging advanced deep-subwavelength cathodoluminescence spectroscopy, we reveal the extreme anisotropic optical response of borophene in the visible range[3]. Finally, direct growth of borophene on silicon to make Schottky junction will be explained and some opto-electrical measurements will be presented. The optoelectronic response of a borophene/silicon-based detector is approximately ten times higher than that of detectors fabricated by transferring 2D materials onto silicon, due to the excellent junction formed by the direct growth of borophene on silicon.

[1] ACS Applied Materials & Interfaces 2021 13 (7), 8844-8850 [2] ACS Applied Nano Materials 2024 7 (11), 13712-13719 [3] arXiv preprint arXiv:2404.13609v2

MM 21.5 Wed 16:45 H22

Atomistic computer simulations of the influence of grain boundary phases on segregation — •Tobias Brink, Dongjin Kim, and Gerhard Dehm — Max Planck Institute for Sustainable Materials, Düsseldorf, Germany

The properties of polycrystalline materials are often strongly affected by grain boundary (GB) segregation. Segregation energies, in turn, strongly depend on the available segregation sites and their atomic environments in the GB. At the atomic level, however, GBs are not only distinguished by their macroscopic, crystallographic parameters: different GB phases (or "complexions") can coexist even along the same GB and consequently affect available segregation sites. Similar as for bulk phases, the equilibrium atomic structure and chemistry of GBs changes based on temperature, pressure, concentration, chemical potential, etc.

Here, we investigate Ag segregation to [111] tilt GBs in Cu with hybrid molecular dynamics/Monte Carlo computer simulations using EAM potentials. These GBs are of interest because they exhibit two GB phases, "pearl" and "domino". Depending on the misorientation, either the pearl or the domino phase can more easily accommodate Ag segregants. As a consequence, the GB phases not only display distinct segregation behavior, but the stability of the GB phases is now also a function of the Ag excess concentration. An outlook on the effects of other segregants will be given and comparisons to experimental results will be discussed.

MM 21.6 Wed 17:00 H22

Characterizing the strength and stability of grain boundaries in Ni alloys by atomistic simulations — Reyhaneh Ghassemizadeh, •Daniel F. Urban, and Christian Elsässer — Fraunhofer Institute for Mechanics of Materials IWM, Freiburg, Germany

When increasing the in-service performance of engineering metallic materials, interfaces such as phase or grain boundaries (GB) may act as the weakest links. For the nickel-base superalloy Alloy 718 intergranular cracking can be a relevant damage mechanism as result of high-temperature fatigue in an oxygen-rich environment. The reliable prediction of the adhesion and mechanical stability of interfaces between two grains in a microstructure of a material from atomistic calculations remains a challenge. A possible approach to systematically address this issue is an idealized cleavage simulation analyzed in terms of the Rose-Ferrante-Smith universal binding energy relationship (UBER) which results in a measure for the ideal work of separation and the maximum tolerable normal strain. With this approach, we analyze the stability of GBs in Alloy 718 using density functional theory calculations and thereby distinguish the influence of the different alloying elements on the strength of these interfaces. Furthermore, we systematically examine the influence of oxygen at the GBs and thereby shed light on the respective segregation-induced embrittlement in polycrystalline Ni systems. Our results can be used to parametrize traction separation laws used in finite element modelling, allowing for microstructure-sensitive modelling of fatigue crack formation and growth.

MM 21.7 Wed 17:15 H22

Ce-doped Ni-based nanocrystal ribbons for Near-Perfect Infrared Absorbers — •Timuçin Emre Tabaru[1], Ali Karatutlu[2], Iremnur Duru[1], and M. Fatih Kilicaslan[3] — [1]Department of Electrical Electronics Engineering, Sivas University of Science and Technology, 58000 Sivas, Turkey — [2]Institute of Materials Science Nanotechnology and National Nanotechnology Research Center (UNAM) Bilkent University Ankara 06800, Türkiye — [3]Department of Engineering Fundamental Sciences, Sivas University of Science and Technology, 58000 Sivas, Turkey

Absorption properties of Ni-based ribbons prepared with a composition of 75 % Ni, 10 % Cr, 8 % Si, 5 % Fe, 2 % B, and %1 Ce-doped were investigated in the infrared region. The ribbons were prepared by melt spinning, and the samples exhibited a nanocrystalline structure due to rapid solidification. The total absorbing effectiveness of the Ni-based ribbons reached a maximum of about %93 at 3-5 *m mid-wave infrared (mid-IR) window when the ribbons were doped with Ce causing an approximate 5% improvement in the mid-IR absorption. Overall, the composite films provide over 80% IR absorption at the wavelengths from 3 *m to 25 *m. Due to the superparamagnetic behavior of the Ni-based composite film suggesting a decrease in electrical conductivity, a high impedance allows such high IR absorption over a large EM spectrum. This indicates that Ce-doped Ni composite film can be a good candidate for thermal emitters and infrared imaging, and for integrating into small-pixel uncooled infrared detectors.

MM 21.8 Wed 17:30 H22

Tracking the emergence and persistence of abnormal grain growth in the commercial aluminum alloy AA5252 using 3D X-ray microscopy — •Helmuth-André Schulz-Harder[1], Jules M. Dake[1], Wolfgang Ludwig[2], Haixing Fang[2], Pierre-Olivier Autran[2], Karolína Gutbrod[1], Markus Ziehmer[1], Madlen Atzen[1], Thomas Wilhelm[3], Volker Schmidt[3], and Carl E. Krill III[1] — [1]Institute of Functional Nanosystems, Ulm University, Germany — [2]The European Synchrotron (ESRF), Grenoble, France — [3]Institute of Stochastics, Ulm University, Germany

The origin of abnormal grain growth (AGG) remains unclear despite decades of investigation, even though this phenomenon has far-reaching implications for a wide range of industrial applications. A significant challenge lies in the scarcity of time-resolved 3D data on AGG. To address this, we acquired a time series of 3D maps of the commercially available aluminum alloy AA5252 using synchrotron-based diffraction-contrast tomography (DCT). The reconstructed grain maps reveal the presence of extreme abnormal grains, the evolution of which could be observed over time and traced back nearly to the point of emergence. To further explore the influence of second-phase particles (known to be present in AA5252) on the growth of abnormal grains, we conducted complementary phase-contrast tomography (PCT) measurements. The combination of these datasets provides new insight into the locations where abnormal grains emerge and the mechanism(s) driving their persistent growth advantage.

MM 21.9 Wed 17:45 H22

Direct Laser Writing of metallic material utilizing the principle of sensitized triplet-triplet upconversion — •Kristin E. J. Kühl[1] and Georg von Freymann[1,2] — [1]University of Kaiserslautern-Landau, 67663 Kaiserslautern — [2]Fraunhofer Institute for Industrial Mathematics ITWM, 67663 Kaiserslautern

Direct Laser Writing (DLW) is a versatile technique for fabrication of microstructures, which is constantly evolving. Conventional DLW uses two photon absorption to form polymers from monomers via a photochemical reaction. Current research is leaning towards new materials, such as different kinds of metal which satisfy different demands on the physical properties of structures like electric conductivity or ferromagnetism, as well as the application of different photochemical reactions to provide more opportunities in the implementation of the printing process.

In this talk a novel approach to Direct Laser Writing of metallic materials is presented. For this purpose, photochemical compounds and principles were investigated via different methods and applied in a home built setup for Direct Laser Writing. A sensitized triplet-triplet annihilation upconversion process (sTTA-UC) is used to generate the energy required for the photochemical reduction of nickel. Since efficient sTTA-UC is usually limited to deoxygenated materials, a solvent is used that has the property of generating a local deoxygenated area upon excitation by a sensitizer. These three processes are combined to enable Direct Laser Writing of 2D nickel structures.

MM 21.10 Wed 18:00 H22

Friction coefficient and work function investigation of transition-metal dichalcogenide — •Malik Al naabi, Shuyu Huang, Antoine Hinaut, Ernst Meyer, and Thilo Glatzel — University of Basel, Basel, Switzerland

Despite extensive research on the tribological properties of MoS2,the frictional characteristics and electronic properties of other members of the transition-metal dichalcogenide (TMD) family have remained relatively unexplored. To understand the effect of the chalcogen on the tribological behavior of these materials and gain broader general insights into the factors controlling friction at the nanoscale, we compared the friction force behavior for a nanoscale single asperity sliding on MoS2, MoSe2, WS2, and WSe2, in bulk using friction force microscopy (FFM). Additionally, we used Kelvin probe force microscopy (KPFM) to investigate the work function. All the materials were cleaved in the nitrogen glovebox.

MM 21.11 Wed 18:15 H22

Nano-scale precipitations in NiTi-based alloys after laser powder bed fusion: FIB/STEM and APT analyses — •Farzad Khodabakhshi[1], Raphael Freundl[2], Eric A. Jägle[2], and Gerhard Wilde[1] — [1]University of Muenster — [2]Universität der Bundeswehr München

Phase formation and nano-scale precipitation during laser powder bed fusion (LPBF) of a NiTi/Nb powder mixture were characterized throughout the matrix of NiTi using advanced microscopy techniques. The study employed focused ion beam (FIB) preparation combined with scanning transmission electron microscopy (STEM) and atom probe tomography (APT). Different nano-scale phases formed through in situ alloying and their interfacial coherence with the NiTi-based alloy were examined using atomic-scale high-resolution microscopy. Subsequent nano-scale elemental mapping and chemical analysis were performed by APT. The results indicated significant changes in the contributions of in situ formed phases when altering the fraction of niobium. Low fractions of Nb can modify the intrinsic structure of NiTi precipitates. Changing the grain boundary energy helps shift these precipitates toward the interiors of grains rather than remaining at the boundaries. Conversely, increasing the niobium fraction towards the eutectic composition results in the formation of a new structure comprised of precipitates with a specific ternary composition within the NiTi alloy matrix due to LPBF deposition.

MM 22: Materials for the Storage and Conversion of Energy

Time: Wednesday 15:45–16:45 Location: H23

MM 22.1 Wed 15:45 H23

Understanding Stability of Ni-rich NMC cathodes using beyond DFT many-body calculatations — •Hrishit Banerjee[1,2,3,4], Clare Grey[2,4], and Andrew Morris[3,4] — [1]University of Dundee — [2]University of Cambridge — [3]University of Birmingham — [4]The Faraday Institution

High energy density Ni-rich $LiNi_aMn_bCo_cO_2$ (NMC) cathodes undergo degradation in the form of O loss from the surface of NMC particles. O loss increases with Ni content and higher voltages. Our first-principles study examines the redox behavior of transition metals and O in NMC cathodes as a function of (de)lithiation. Despite Ni, Mn, and Co K-edges calculated using GW Approximation showing an excellent match with experimentally obtained XANES, we demonstrate that the ionic model of ascribing shifts in the XANES to changes in metal oxidation states is inappropriate. In these cases, which are characterised by strong covalency between the strongly correlated transition metal and oxygen, Dynamical Mean-Field Theory calculations are essential to calculate charges and hence assign oxidation states accurately. Due to a charge transfer from O p to Ni d, a ligand hole forms on O in Ni-rich regions. The individual Ni charge remains fairly constant throughout the charging/discharging process. In contrast, O has dual redox behavior, showing greater involvement in redox in Ni-rich regions while showing negligible redox involvement in Ni-poor regions. The dual behaviour of O in terms of participation in the redox process explains the overall higher relative stability of lower Ni content NMCs compared to Ni-rich NMCs or $LiNiO_2$ in terms of O loss.

MM 22.2 Wed 16:00 H23

Splitting Water Without Falling Apart: Accelerating the Understanding of NiFeV LDH via Design of Experiments and Machine Learning — •Juan Manuel Lombardi, Charles Pare, Karsten Reuter, and Christoph Scheurer — Fritz-Haber-Institut der MPG, Berlin

The development of sustainable energy technologies requires efficient, affordable, and durable electrocatalysts. Ni-based layered double hydroxides (LDHs) doped with Fe and V are promising candidates for the oxygen evolution reaction in anion exchange membrane water electrolyzers (AEMWE) due to their tunable structure and exceptional redox properties. However, the mechanisms by which dopants influence catalytic and structural properties are not fully understood, mainly due to the challenges posed by their humongous configurational space. In this study, we efficiently explore the thermally accessible configurations within the complex configurational space of γ-phase Ni LDHs doped with Fe and V. To maximize information gain, we sample the composition space using Design of Experiments (DoE), leverage machine learning interatomic potentials (MLIPs) to sample these configurations, and refine the results with Density Functional Theory (DFT) calculations for first-principles quality predictions. By combining these tools, we develop an optimal protocol to elucidate how the dopants influence material properties. This integrated methodology reveals pathways for optimizing NiFeV LDH compositions, enhancing energy conversion efficiencies while ensuring long-term stability.

MM 22.3 Wed 16:15 H23

Benchmarking exchange-correlation functionals for accurate computational predictions of metal organic frameworks — •Julia Santana Andreo, Joshua Edzards, Holger-Dietrich Sassnick, and Caterina Cocchi — Carl von Ossietzky Universität Oldenburg, Institute of Physics

Metal-organic frameworks (MOFs) have attracted significant attention due to their structural and chemical flexibility which makes them relevant for a wide range of technological applications, from gas storage to photocatalysis. The substitution of metal nodes and the functionalization of organic linkers can significantly expand the range of available MOFs, enabling the design of tailored properties for specific applications. While atomistic ab initio simulations can significantly contribute to explore this vast configurational space, it is mandatory to assess whether and how common approximations of density-functional-theory calculations affect the description of the structural, electronic, and vibrational properties of computationally predicted compounds. With the example of MOF-5 and its recently predicted functionalized variants [1] , we find that R2SCAN offers the optimal trade-off between accuracy and computational costs to describe electronic and vibrational properties in these materials.

MM 22.4 Wed 16:30 H23

Assessing the Bulk Stability of Oxygen Evolution Reaction Catalysts using Crystal Field Theory and Orbital Analysis — •Katarina Kretschmer[1], Michael Eikerling[1,2], and Tobias Binninger[1] — [1]Theory and Computation of Energy Materials (IET-3), Institute of Energy Technologies, Forschungszentrum Jülich GmbH, 52425 Jülich, Germany — [2]Chair of Theory and Computation of Energy Materials, Faculty of Georesources and Materials Engineering, RWTH Aachen University, 52072 Aachen, Germany

Proton exchange membrane water electrolysis (PEMWE) is an effective method for producing green, i.e. carbon-neutral hydrogen. At the PEMWE anode catalyst, water molecules are split to form oxygen molecules in the so-called oxygen evolution reaction (OER). Iridium oxide (IrO2) and ruthenium oxide (RuO2) are recognized as highly effective catalysts for the OER.

In this talk, I will discuss the electronic properties governing the bulk stability if IrO2 and RuO2. Utilizing density functional theory (DFT) calculations, the stability of both oxide materials is assessed from the perspective of crystal field theory and bond orbital analysis. The orbital overlap between the metal (iridium or ruthenium) and oxygen atoms in the lattice and the population of the emerging bonding or antibonding orbitals is analyzed, which can either contribute to or counteract the stability of the IrO2 and RuO2 lattices. This analysis will lead to the definition of electronic descriptors for predicting the bulk stability of transition metal oxide catalysts.

MM 23: Phase Transformations

Time: Wednesday 17:15–18:30 Location: H23

MM 23.1 Wed 17:15 H23

study on solid/liquid interfacial energy of Al-Cu alloys and its anisotropy under a static magnetic fields — •Chenglin Huang[1], Peter Galenko[2], Rainer Backofen[3], Ken Elder[4], Sansan Shuai[1], Jiang Wang[1], and Zhongming Ren[1] — [1]State Key Laboratory of Advanced Special Steel, School of Materials Science and Engineering, Shanghai University, 200444, P. R. C — [2]Department of Physics and Astronomy, Friedrich Schiller University of Jena, 07743, Germany — [3]Institute of Scientific Computing, Technische Universität Dresden, 01062 , Germany — [4]Department of Physics, Oakland University, Rochester, MI, 48309-4487, USA

In recent decades, external magnetic fields have been widely used in materials processing to control microstructure and optimize properties. Key phenomena include magnetic levitation, crystallographic orientation changes, magnetically induced phase transitions, and TEMHD. External magnetic fields also impact thermophysical properties such as phase transition temperatures, resistivity, viscosity, diffusion, and surface tension. These effects are closely linked to interface changes, where properties differ from the bulk. Despite their importance, quantitative studies on solid/liquid interfaces under magnetic fields remain limited. Accurately measuring interfacial energy and anisotropy, and exploring atomic-scale behavior under magnetic fields, are key challenges. This research systematically investigates the effects of external magnetic fields on interfacial energy and its anisotropy in Al-Cu alloys, offering theoretical and practical insights for controlling solidification under such fields.

MM 23.2 Wed 17:30 H23

From electronic structure to thermodynamic phase diagrams with automated workflows — •Sarath Menon[1], Marvin Poul[1], Tilmann Hickel[2], Ralf Drautz[3], and Jörg Neugebauer[1] — [1]Max Planck Institute for Sustainable Materials — [2]Bundesanstalt für Materialforschung und -prüfung — [3]Ruhr University Bochum

Phase diagrams are useful for understanding coexistence lines, phase stability, and phase transitions under varying thermodynamic conditions. Calculating phase diagrams involves determining the Helmholtz and Gibbs free energies of different phases and their dependence on thermodynamic state variables - a task that is both intricate and computationally demanding.

In this work, we introduce automated workflows for the calculation of Helmholtz and Gibbs free energies, incorporating configurational entropy, and provide accompanying computational tools. A key component of our approach is the alchemical transformation method, where atomic species are systematically altered along a thermodynamic path to evaluate free energy changes with composition.

We demonstrate the effectiveness of this methodology using an Atomic Cluster Expansion (ACE) machine-learning interatomic potential, parametrized using the ASSYST method, to generate unbiased *ab initio* structure datasets, and compute the phase diagram of the Au-Cu system. Our workflows are independent of the interatomic potential and the material system, making them readily transferable and paving the way for making the computation of thermodynamic phase diagrams a routine task in the field of atomistic simulations.

MM 23.3 Wed 17:45 H23

Phase formation at an interface between Ni and Sn layers during a soldering process — •Sandra Gaertner, Sergiy V. Divinski, Harald Rösner, and Gehard Wilde — Institute of Materials Physics, University of Münster, Münster, Germany

Soldering is a method for creating permanent bonds between metal parts, often resulting in the formation of intermetallic compounds. The transition to lead-free solder, driven by environmental regulations, has increased the interest in Sn-based solder alloys. However, the soldering process for interconnects involves complex processes related to material transport, phase stability, phase formation, and kinetic aspects of phase transformation. In this study, we investigated the interdiffusion and diffusion-controlled phase formation in a SnSb-solder alloy between a Ni-based layer with a small amount of Si and a Cu substrate, employing SEM and TEM. Analysis of the untreated states revealed a lamellar-type structure of the Ni-based layer, characterized by a uniform distribution of elements, while the solder alloy exhibited a β-Sn matrix and a SbSn phase. Following the soldering process, we observed the formation of various intermetallic compounds like CuSnNi and SnCu, encased within the β-Sn matrix. The SbSn phase remained as small inclusions. Moreover, the Ni-based layer initially shrank, resulting in a residual thin film that displayed an increased Si content compared to its untreated counterpart. This study highlights the intricate mechanisms involved in Cu transport from the substrate through the solder material. Alongside Sn, Cu drives the transformation of the Ni-based layer, ultimately leading to its complete consumption.

MM 23.4 Wed 18:00 H23

Temperature-modulated dilatometry as a tool for studying precipitation kinetics in alloys — •Marcel Simhofer[1], Philipp Brunner[1], Jiehua Li[2], Wolfgang Sprengel[1], and Roland Würschum[1] — [1]Inst. of Mater. Phys., NAWI Graz, Graz Univ. of Technol., Graz 8010, Austria — [2]Inst. of Casting Res., Montanuniv. Leoben, Leoben 8700, Austria

Temperature-modulated dilatometry is implemented as a tool for studying phase equilibration processes in alloys. As a case example, the phase equilibration between the saturated solid solution Al(Mg) and intermetallic Al_3Mg_2 in the Al(Mg) binary alloy is studied. The varying solubility of Mg in Al upon temperature modulation causes a modulation of the relative fractions of the two phases, which can be in-situ monitored by dilatometry owing to their different atomic volumes. The phase shift between the length change caused by phase equilibration and the applied sinusoidal temperature variation yields access to equilibration kinetics. The observed variation of the phase shift with the modulation frequency is quantitatively analyzed in the framework of a simple kinetic model, revealing that the equilibration process is controlled by the diffusion of Mg in Al.

MM 23.5 Wed 18:15 H23

Formation mechanism of bicontinuous structure during peritectic melting of TiAg — •Zhongyang Li[1], Lukas Lührs[1], Tobias Krekeler[2], and Jörg Weissmüller[1,3] — [1]Institute of Materials Physics and Technology, Hamburg University of Technology, Hamburg, Germany — [2]Electron Microscopy Unit, Hamburg University of Technology, Hamburg, Germany — [3]Institute of Hydrogen Technology, Helmholtz-Zentrum Hereon, Geesthacht, Germany

Reverse peritectic reactions, and specifically the peritectic melting of TiAg, have been proposed as dealloying-like processes that produce quite similar microstructures but avoid the restrictions on sample size inherent in liquid-metal dealloying (LMD). Here, studies of the microstructure evolution during peritectic melting of TiAg suggest a formation mechanism that is not LMD-like but rather relies on liquid film migration. The process starts with wetting of the TiAg grain boundaries by the alloy melt. Successively, both Ti and Ag continue to dissolve from one side of, while β-Ti deposits on the other side and the liquid film sweeps the pristine TiAg crystal. TiAg-Ti interfaces with well-defined orientation relationship and with concentration gradients support this picture, as does the phase morphology in partly decomposed samples. The process generates a bicontinuous structure with a solid Ti skeleton, interpenetrated by the Ag-rich melt, which is conserved even after coarsening. This study clarifies the mechanism of peritectic melting in TiAg, and it may provide a basis for identifying other alloy systems suitable for producing bicontinuous microstructures by that process.

MM 24: Members' Assembly

Welcome to this general meeting of the DPG-SKM division MM! All of you, presenters of MM talks or posters and other interested participants of this conference, are cordially invited to this meeting. We will come together in a relaxed atmosphere, supported by drinks and pretzels (at least) for personal exchange. The poster prizes will be awarded during the Members Assembly. The current conference will be discussed and your feedback is very welcome. We will ask for your suggestions for future topical sessions in MM and symposia as well as for invited speakers. Take this opportunity to share your ideas regarding our MM program for our next DPG spring meeting.

Time: Wednesday 18:45–20:45 Location: H10

All members of the Metal and Material Physics Division are invited to participate.

MM 25: Invited Talk: D. Rodney

Time: Thursday 9:30–10:00 Location: H10

Invited Talk MM 25.1 Thu 9:30 H10

Transformation-induced plasticity in zirconia ceramics: neural network simulations and in-situ experiments — •David Rodney — Institut Lumière Matière, Université de Lyon, France

Brittleness limits the structural use of ceramics, but zirconia stands out due to transformation-induced plasticity (TRIP) between tetragonal and monoclinic phases. This stress-driven transformation enables up to 7% plastic deformation in single-crystalline ceria-doped zirconia, offering potential for high ductility. However, understanding the TRIP effect remains incomplete.

To address this, we combined in situ Laue micro-diffraction experiments at synchrotron facilities with atomistic simulations. Existing interatomic potentials fail to capture zirconia's complex polymorphism. We thus developed neural network interatomic potentials (NNIP) using DeepMD-kit for pure and ceria-doped zirconia. These NNIPs align well with ab initio data on thermodynamic, mechanical, and dynamical properties, accurately modeling phase stability, elastic properties, and energy barriers.

Using the NNIPs, we simulated the uniaxial compression of tetragonal ceramics, exploring stress-strain behavior, phase transformations, and deformation mechanisms across various compression directions. Simulations are confronted with the in situ experiments and the phenomenological theory of martensitic transformation. Key factors, including size, temperature, strain rate, and pre-existing defects, are critically analyzed, providing a comprehensive understanding of stress-induced phase transformations in zirconia ceramics.

MM 26: Topical Session: Thermophysical Properties of Bulk Metallic Glasses and Bulk Metallic Glass-forming Liquids

Time: Thursday 10:15–11:45 Location: H10

MM 26.1 Thu 10:15 H10

Influence of sulfur on the amorphous structure, high temperature viscosity and solidification of Zr-based bulk metallic glass formers — •Bastian Adam, Oliver Kruse, Lucas Mathias Ruschel, Maximillian Frey, Nico Neuber, and Ralf Busch — Chair of Metallic materials (LMW), Saarbrücken, Germany

The usage of the element sulfur in Bulk Metallic Glass (BMG) synthesis was recently introduced by Kuball et al. and lead to increased research interest into these new family of BMG [1]. Here we report on the influence of sulfur on the A2B type intermetallic composition (Zr50Ti16.6Ni18.3Cu15) that was characterized by container-less electromagnetic melting under microgravity within the 43rd & 44th TEMPUS parabolic flight campaigns by the German aerospace center (DLR). The investigation is accompanied by structural investigations of the amorphous solid and liquid that were conducted with the help of an electrostatic levitation device to observe the structure and solidification in an in-situ wide-angle scattering diffraction experiment at the German electron synchrotron (DESY) in Hamburg.

[1]A. Kuball, O. Gross, B. Bochtler, and R. Busch, Sulfur-bearing metallic glasses: A new family of bulk glass-forming alloys, Scr. Mater., 2018.

MM 26.2 Thu 10:30 H10

Structure and dynamics of Ni-Nb alloy melts upon sulfur addition — Nicolai Grund[1], Dirk Holland-Moritz[1], Saba Khademorezaian[2], Lucas P. Kreuzer[1,3], Nico Neuber[4], Lucas M. Ruschel[4], Hendrik Voigt[2], Johanna Wilden[1], •Fan Yang[1], Sergiy Divinski[2], Ralf Busch[4], Andreas Meyer[1], and Gerhard Wilde[2] — [1]Institut für Materialphysik im Weltraum, Deutsches Zentrum für Luft- und Raumfahrt (DLR), Köln, Germany — [2]Institute of Materials Physics, University of Münster, Münster, Germany — [3]Heinz Maier-Leibnitz-Zentrum, Technische Universität München, Garching, Germany — [4]Chair of Metallic Materials, Saarland University, Saarbrücken, Germany

We investigated the change in the structure and dynamics of a Ni-Nb bulk metallic glass upon sulfur addition on microscopic and macroscopic scales. With the sulfur concentration of 3 at.%, where the composition $Ni_{58}Nb_{39}S_3$ exhibits the best glass forming ability in the investigated sulfur concentration range, both the equilibrium and undercooled melt dynamics remain almost unchanged. Only in the glassy state sulfur seems to result in less decoupled mass transport to the viscosity of the undercooled liquid, where the Ag tracer diffusion coefficient is slower in the ternary alloy. With the structural disorder introduced by alloying sulfur, the improved glass forming ability is attributed to geometrical frustration, where crystal nucleation requires a depletion of sulfur and hence long range diffusion, as long as no primary sulfur-containing crystalline phase is involved.

MM 26.3 Thu 10:45 H10

Probing Medium-Range Order in Metallic Glasses with 4D-STEM — •Birte Riechers[1] and Robert Maass[1,2,3] — [1]Federal Institute of Materials Research and Testing (BAM), Germany — [2]University of Illinois at Urbana-Champaign, USA — [3]Technical University of Munich, Germany

Medium-range order (MRO) in metallic glasses (MGs) plays a crucial role for their applicability, as it significantly affects their mechanical properties. Important details of the MRO were revealed by micro-second long atomistic simulations, that have shed light on the temperature- and time-dependent evolution of MRO, especially in connection to the emergence of a network of specific structural motifs (JALCOM 821, 153209, 2020; Acta Mater. 267, 119730, 2024).

While these insights help to understand the effect of MRO evolution, the experimental validation remains challenging. To test these findings, we employ 4-dimensional scanning transmission electron microscopy (4D-STEM) (Ultramicroscopy 232, 113405, 2022) to analyze both the first and second diffraction shells of MGs. By examining the diffraction symmetries at these length scales, we aim to uncover the dominant structural features associated with MRO.

MM 26.4 Thu 11:00 H10

Structural evolution during annealing in a Zr-Cu-Al bulk metallic glass by X-ray absorption spectroscopy — •Andrea Fantin, Reza Rashidi, Birte Riechers, and Robert Maass — Bundesanstalt fuer Materialforschung und -pruefung, Unter den Eichen 87, 12205 Berlin, Germany

Understanding structural evolution in the time-temperature-transformation diagrams of bulk metallic glasses (BMGs) is crucial to tackle common challenges in glass science such as embrittlement and mechanical failure. Preliminary extended X-ray absorption spectroscopy fine structure (EXAFS) measurements carried out at the Zr and Cu K-edges on a typical Zr-Cu-Al system allowed following the evolution of element-specific bond lengths, static and dynamic disorder, and nearest-neighbor numbers as a function of temperature and time. Data on the as-cast BMG, on further annealed BMG at two different temperatures (0.9Tg and 1.02Tg) and at different holding times was collected (ex-situ) at the BM-08 beamline, ESRF, finally showing two different behaviors depending on the temperature used, which will be described in terms of EXAFS fitting parameters during the presentation.

MM 26.5 Thu 11:15 H10

Thermodynamic, kinetic and structural study of Pt42.5CuxNi36.5-xP21 alloy variations — •Ziyu Ling[1], Maryam Rahimi Chegeni[1], Nico Neuber[1], Sergey Kasatikov[2], Amirhossein Ghavimi[1], Andrea Fantin[3], Isabella Gallino[4], and Ralf Busch[1] — [1]Lehrstuhl für Metallische Werkstoffe, Universität des Saarlandes — [2]Helmholtz-Zentrum Berlin für Materialien und Energie Elektrochemische Energiespeicherung — [3]Bundesanstalt für Materialforschung und -prüfung, Berlin — [4]Lehrstuhl für Metallische Werkstoffe,TU Berlin

The thermodynamic and kinetic properties of Pt42.5CuxNi36.5-xP21 glass-forming liquids are studied via differential scanning calorimetry and Flash DSC (Mettler Toledo). The kinetic fragilities of the alloys are determined from relaxation times measured in a broad heating rates range using a Tg shift method and the relaxation time of the deeply undercooled liquids determined via a step-response method. Furthermore, the specific capacity heat (Cp) as a function of temperature for the glassy, liquid and crystalline state of the chosen alloys are determined. The thermodynamic fragility is assessed from the 'Cp jump' at Tg and the driving force for crystallization is calculated using fitting parameters of thermodynamic functions derived from Cp data. Then the glass forming ability of the alloy liquids is evaluated based on their critical cooling rates and TTT-diagrams. The interfacial energy is obtained by JMAK fitting with TTT-diagrams. Moreover, the alloy ribbons were investigated by synchrotron X-ray scattering experiments at DESY for structural study and by XPS and NEXAFS at BESSY for energy state information of each elements.

MM 26.6 Thu 11:30 H10

Temperature dependence of cooperativ fluctuations in supercooled glass-forming metallic melts — •Jürgen Schawe[1], Min Kyung Kwak[2], Mihai Stoica[1], Eun Soo Park[2], and Jörg Löffler[1] — [1]ETH Zürich, Laboratory of Metal Physics and Technology, Zurich, Switzerland — [2]Seoul National University, Department of Materials Science and Engineering, Seoul, Republic of Korea

The behavior of a supercooled glass-forming metal alloy depends on the cooperative atomic fluctuations caused by the dynamic heterogeneities in the melt. These spatial and temporal heterogeneities form dynamic clusters, which are re-

gions of cooperative rearrangement (CRR). The time and temperature dependence of the CRR characterizes the α-relaxation. In this study, the correlation length ξ, characteristic of the CRR, is derived for Pt57.4Cu14.7Ni5.3P22.6 and Pd43Cu27Ni10P20 bulk metallic glasses by fast differential scanning calorimetry in a temperature range between the glass transition temperature Tg and Tg + 50K. It appears that while the composition of the alloy influences the macroscopic α-relaxation and vitrification kinetics, typically defined by Tg, as well as the limiting temperature of the Vogel-Fulcher-Tammann-Hesse equation and the fragility index, it has no significant influence on the correlation length of the cooperative atomic motions. In agreement with many other materials, ξ at Tg is about 3 nm for both metallic glasses. The temperature dependence of ξ correlates with the apparent activation energy of the α-relaxation and is the reason for their non-Arrhenius behavior.

MM 27: Transport in Materials: Diffusion, Charge or Heat Conduction

Machine Learning, Quantum Theory

Time: Thursday 10:15–13:00 Location: H22

MM 27.1 Thu 10:15 H22

Modelling Heat Transport in Metal-Organic Frameworks with Machine Learned Potentials — •Martin Klotz[1], Florian Lindner[1], Sandro Wieser[2], and Egbert Zojer[1] — [1]Institute of Solid State Physics, Graz University of Technology, Austria — [2]Institute of Materials Chemistry, TU Wien, Austria

Many of the envisioned applications of porous metal-organic frameworks (MOFs), like gas storage or catalysis, involve exothermal processes. This requires the materials to efficiently dissipate heat. It is, thus, vital to gain a fundamental understanding of how structural and chemical modifications impact heat-transport in such systems. Here, we chose MOF-74/Zn as parent system for which we calculated the anisotropic thermal conductivity using approach to equilibrium molecular dynamics simulations. For these, we applied machine-learned force field potentials, as they surpass DFT simulations by orders of magnitudes in terms of speed and classically parametrized force field potentials in terms of accuracy. Subsequent to thoroughly benchmarking and testing the employed methodology, we studied structure-to-property relationships for MOF-74 derivatives, systematically varying the node metal and the linker structure.

MM 27.2 Thu 10:30 H22

Predicting 2D conventional superconductors — Thalis H. B. da Silva[1], Théo Cavignac[2], Tiago F. T. Cerqueira[1], •Hai-Chen Wang[2], and Miguel A. L. Marques[2] — [1]CFisUC, Department of Physics, University of Coimbra, Rua Larga, 3004-516 Coimbra, Portugal — [2]Universitätsstr. 150

We perform a large-scale search for two-dimensional (2D) superconductors by using electron-phonon calculations with density-functional perturbation theory combined with machine learning models. In total, we screened over 140k 2D compounds from the Alexandria database. Our high-throughput approach revealed a multitude of 2D superconductors with diverse chemistries and crystal structures. Moreover, we find that 2D materials generally exhibit stronger electron-phonon coupling than their 3D counterparts, although their average phonon frequencies are lower, leading to an overall lower transition temperature (T_c). Despite this, we discovered several out-of-distribution materials with relatively high T_c. In total, 105 2D systems were found with $T_c > 5$ K. Some interesting compounds, such as CuH_2, NbN, and V_2NS_2, demonstrate high T_c values and good thermodynamic stability, making them strong candidates for experimental synthesis and practical applications. Our findings highlight the critical role of computational databases and machine learning in accelerating the discovery of novel superconductors.

MM 27.3 Thu 10:45 H22

Modelling complex proton transport phenomena - Exploring the limits of fine-tuning and transferability of foundational machine-learned force fields — •Christian Dressler[1], Malte Grunert[2], Jonas Hänseroth[1], Max Grossmann[2], and Erich Runge[2] — [1]TU Ilmenau, Institute of Physics, Theoretical Solid State Physics — [2]TU Ilmenau, Institute of Physics, Group of Theoretical Physics 1

The solid acids CsH_2PO_4 and $Cs_7(H_4PO_4)(H_2PO_4)_8$ pose significant challenges for the simulation of proton transport phenomena. In this talk, we present the use of the recently developed machine-learned force field MACE to model proton dynamics on nanosecond timescales for these systems and compare its performance with long-term ab initio molecular dynamics (AIMD) simulations. The MACE-MP-0 foundation model shows remarkable performance for all observables derived from molecular dynamics simulations, but minor quantitative discrepancies remain compared to the AIMD reference data. However, we show that minimal fine-tuning - fitting to as little as 1 ps of AIMD data - leads to full quantitative agreement between the radial distribution and autocorrelation functions of MACE force field and AIMD simulations. Long-time AIMD simulations are unable to capture the correct qualitative trends in diffusion coefficients due to their inherent time scale limitations. In contrast, we demonstrate that accurate and convergent diffusion coefficients, consistent with experimental data, can only be reliably achieved through multi-nanosecond molecular dynamics simulations utilizing machine-learned force fields.

MM 27.4 Thu 11:00 H22

Understanding thermal transport in organic semiconductors using machine learned force fields — •Florian Unterkofler[1], Lukas Reicht[1], Lukas Legenstein[1], Sandro Wieser[2], Michele Simoncelli[3], and Egbert Zojer[1] — [1]Graz University of Technology, Austria — [2]TU Wien, Austria — [3]Columbia University, New York (USA)

Organic semiconductors (OSCs) are key materials for optoelectronic devices such as solar cells and organic light-emitting diodes (OLEDs). While the properties related to charge transport of OSCs are relatively well understood, we still lack an understanding of the fundamentals of the heat transport in those materials. To study the atomistic origins of heat transport, we developed a strategy for calculating the thermal conductivity of complex organic crystals employing non-equilibrium molecular dynamics (NEMD) simulations with highly accurate, system-specific, machine-learned Moment Tensor Potentials (MTPs). These MTPs are trained on ab initio data obtained from on-the-fly active-learning molecular dynamics simulations.[1]

We then simulated the thermal transport in pentacene with NEMD to analyze the heat conduction in real space at an atomistic level and to identify heat-transport bottlenecks. Alternatively, we also use the MTPs to accurately calculate thermal conductivities arising from the particle-like propagation and the wave-like tunneling of phonons in reciprocal space. Both approaches are consistent and agree with available experiments.

MM 27.5 Thu 11:15 H22

Influence of Defects and Layer Twisting on Phonon Dynamics in Bilayer Graphene and MoS_2 Using Machine Learned-Force Field Calculations — •Sabuhi Badalov[1,2] and Harald Oberhofer[1,2] — [1]Department of Physics, University of Bayreuth — [2]Bavarian Center for Battery Technology, Bayreuth, Germany

In crystalline materials, thermal, mechanical and even electronic properties are often described in terms phonon spectra and dynamics. These, can, to a large degree be influenced by even minute structural changes, such as through defects or by altering the relative alignment of a material's layers. By means of a state-of-the-art machine learning-augmented force field approach, we carry out extensive phonon calculations to understand how the defect density and layer configurations influence the phonon spectra in bilayer graphene and MoS_2. Our results highlight an interplay of phononic phenomena with the materials' Moiré patterns with major consequences on the transport properties of these materials. Moreover, we explore the possibility of phonon-mediated superconductivity through the electron-phonon coupling in topologically nontrivial phonon states. While this is still ongoing research, our results so far not only further the understanding of phonon dynamics in 2D materials, but also offer a solid foundation for future investigations into harnessing topological phonons for advanced electronic and thermal control technologies.

15 min. break

MM 27.6 Thu 11:45 H22

Thermoelectric quantum transport simulations via the time-linear nonequilibrium Green's function method — •Riku Tuovinen[1] and Yaroslav Pavlyukh[2] — [1]Department of Physics, University of Jyväskylä, Finland — [2]Institute of Theoretical Physics, Wroclaw University of Science and Technology, Poland

Thermoelectric transport focuses on understanding charge and heat flow in quantum systems. While measuring electron current is relatively straightforward, nanoscale heat flux remains challenging to quantify [1]. Heat and charge exhibit fundamental differences, as highlighted by electron transport analysis within the nonequilibrium Green's function theory [2]. In the time-linear formulation, based on the generalized Kadanoff-Baym ansatz (GKBA), open system dynamics are described using an embedding correlator, enabling the calculation of time-dependent currents via the Meir-Wingreen formula [3]. However, calculating heat currents presents challenges, particularly within the wide-band limit

approximation (WBLA), which can result in divergent energy integrals. Besides the mathematical issues, the WBLA's reliability depends on the physical properties of the leads. To address these limitations, we present thermoelectric quantum transport simulations using the time-linear GKBA method without relying on the WBLA [4].

MM 27.7 Thu 12:00 H22

Sublinear in temperature transport in kagome metals: interplay of Dirac cones and Van Hove singularities — •Nikolai Peshcherenko[1], Ning Mao[1], Claudia Felser[1], and Yang Zhang[2,3] — [1]Max Planck Institute for Chemical Physics of Solids, 01187, Dresden, Germany — [2]Department of Physics and Astronomy, University of Tennessee, Knoxville, TN 37996, USA — [3]Min H. Kao Department of Electrical Engineering and Computer Science, University of Tennessee, Knoxville, Tennessee 37996, USA

Kagome metals are known to host Dirac fermions and saddle point Van Hove singularities near Fermi level. With the minimal two-pocket model (Dirac cone + Van Hove singularity), we propose a semiclassical theory to explain the experimentally observed sublinear resistivity in Ni_3In and other Kagome metals. We derive the full semiclassical description of kinetic phenomena using Boltzmann equation, and demonstrate that internode electron-electron interaction leads to sublinear in T scaling for both electrical and thermal transport at low temperatures. At higher temperatures above the Dirac node chemical potential, thermal and electric currents dissipate through distinct scattering channels, making a ground for Wiedemann-Franz law violation.

MM 27.8 Thu 12:15 H22

Phonon induced heat transfer between gold nanogap electrodes — •Yuki Hanamura, Kazuma Kishimoto, Mizuki Tada, Ryo Yamada, and Hirokazu Tada — Graduate School of Engineering Science, Osaka University, Japan

Recent studies have observed anomalous increases in thermal conductance in nanogaps narrower than a few nanometers [1]. Theoretical models attribute this phenomenon to electron tunneling effects and propagation of lattice vibrations due to mechanical interactions between the electrodes, i.e., phonon transport [2]. Experimental difficulties in the nanoscale have prevented us from sufficiently understanding the heat transfer mechanisms.

We have developed a device to measure both thermal and electrical conductance across nanogap electrodes. The device comprises a suspended structure with Micro Electro Mechanical System (MEMS) based actuators to tune the gap distance. We observed increased thermal conductances in sufficiently separated nanogaps, even in the absence of electron tunneling, suggesting phonon transport as the dominant mechanism [3]. We will show the effects of electrode gap distance and temperature on heat transfer across the nanogap.

MM 27.9 Thu 12:30 H22

Hydrodynamics of Lorentz symmetric systems: a quantum Monte Carlo study — •Adrien Reingruber[1], Kitinan Pongsangangan[2], Fakher Assaad[1], and Maksim Ulybyshev[1] — [1]Universität Würzburg, Würzburg, Germany — [2]Mahidol University, Bangkok, Thailand

We present a study on the hydrodynamic behavior of charge current in a Lorentz symmetric sys- tem: graphene at charge-neutrality. The momentum flow is completely decoupled from the charge current in this regime, since the electrons and holes propagate in opposite directions with exactly equal distribution functions. Instead of Navier-Stokes equations for the velocity field, we derive sim- ilar equations directly for the charge current. This eliminates the need for any coupling between the velocity field and charge current to explain the experimentally observed hydrodynamic flow profiles in graphene at half-filling. In this framework, the current diffusion coefficient replaces viscosity. To support this, we performed an extensive quantum Monte Carlo study, directly simulating samples with disordered edges using the underlying microscopic interacting quantum Hamiltonian. For the first time, we observe hydrodynamic behavior of the charge current in such simulations, extract- ing current profiles and a current diffusion coefficient whose temperature dependence qualitatively agrees with predictions from Boltzmann transport theory.

MM 27.10 Thu 12:45 H22

Transport coefficients of Weyl semimetals: the contribution of plasmons — •Kitinan Pongsangangan — Mahidol University, Bangkok, Thailand

This work investigates the contribution of plasmon, a collective mode arising from the dynamical screening of the long-range coulomb interaction, to thermoelectric responses as well as shear viscosity of Weyl semimetals using Boltzmann-equation approach. We find that plasmons make a noticeable contribution to the thermal conductivity and shear viscosity in an appropriate temperature window. We propose that this effect could be potentially observed in, for example, TaAs and NbAs.

Parameterising edge dislocation trajectories in Ni-based superalloys with uncertainty quantification — •Geraldine Anis, Thomas Hudson, and Peter Brommer — University of Warwick, Coventry, United Kingdom

The extraordinary strength exhibited by Ni-based superalloys at high temperatures is attributed to the presence of nanoscale precipitates in their microstructure, which hinder dislocation motion. In our work, we study edge dislocation-precipitate interactions using Molecular Dynamics (MD) simulations with classical effective potentials. The motion of a pair of edge dislocations moving under shear between pure Face-Centred Cubic (FCC) Ni into Ni3Al with an L12 structure is simulated using MD, where Ni is used to represent an idealised γ solid solution phase and Ni3Al for the γ' precipitate phase. The obtained trajectories are parameterised and Differential Evolution Monte Carlo (DE-MC) is used to determine parameter distributions. These distributions are then used to quantify the uncertainty in the model outputs, namely the dislocations' positions and velocities. The present approach yields physically meaningful parameters and accordingly, offers a means of extracting quantitative information from the atomistic scale that can be used to inform larger length scale simulations of dislocations. Using DE-MC as a sampling approach also means that parameter uncertainties can be propagated through a hierarchy of multiscale models. We illustrate how such uncertainty propagation can be achieved by considering a dislocation mobility law with quantified uncertainties.

MM 28.2 Thu 10:30 H23

Atomistic Modelling of Solid Solution Strengthening in the Mg-Al-Ca System — •Erik Bitzek and Marvin Poul — MPI SusMat, Düsseldorf, Germany

Solid solution strengthening is one of the most important strengthening mechanisms for engineering alloys. It is caused by solutes impeding the glide of dislocations and is therefore best studied using atomistic simulations. While the interaction strength of individual solute atoms with dislocations in Mg has been well-studied with density functional density (DFT) calculations, the combined impact of multiple solute species on dislocation glide has not been extensively investigated. Furthermore, the prediction of the critical resolved shear stress requires additionally a statistical treatment and a continuum elastic model for the dislocation line.

Here we present atomistic simulations of basal dislocations gliding in Mg with different concentrations of Al, Ca, and mixtures of Al and Ca. These large-scale simulations were enabled by a newly-developed machine learning interatomic potential that allows for near-DFT accuracy. Using MD/MC simulations of different heat treatments, we show that Al-Ca clusters can form, which influence the solid solution strengthening by reducing the concentrations of individual solutes and through an antagonistic effect of Al and Ca on the stress field of these clusters.

MM 28.3 Thu 10:45 H23

Normal stress effect on the slip system of Mg alloys with long-period stacking ordered structures — •Naoki Uemura[1] and Ryosuke Matsumoto[2] — [1]Nagamori Institute of Actuators, Kyoto University of Advanced Science, Kyoto, Japan — [2]Department of Mechanical and Electrical Systems Engineering, Faculty of Engineering, Kyoto University of Advanced Science, Kyoto, Japan

Mg alloys with long-period stacking, which have a unique structure with synchronized concentration modulation and structural modulation are attracting attention for their high strength. Various studies are currently being conducted to understand their high mechanical properties and plastic deformation behaviors. We investigated the tensile and compressive dependence of the stacking fault energy (SFE) by using first-principles calculations for the Mg-Y-Zn system, which is a typical LPSO-Mg alloy. As with hcp-Mg, the change in SFE due to tensile and compressive loading was greater on the basal plane than on the prismatic

plane. This work was supported by JST, CREST Grant Number JPMJCR2094, Japan.

MM 28.4 Thu 11:00 H23

Understanding crystal defects mechanisms with atomistic simulations and knowledge engineering — •Abril Azocar Guzman, Guojing Huang, and Stefan Sandfeld — Institute for Advanced Simulations, Materials Data Science and Informatics (IAS-9), Forschungszentrum Jülich GmbH, Aachen, Germany

Crystallographic defects play a key role for determining the physical properties of materials. Computational methods, such as density functional theory and molecular dynamics, have been widely used to investigate these defects and their mechanisms at the atomic scale. However, the application of these methods require increasingly complex workflows. To enable workflow and data reusability, as well as meaningful interpretation, it is crucial to ensure well-described (meta)data at each step of the workflow, from atomic structure to computed material properties. Our aim is to facilitate data-driven approaches in materials science by establishing semantic standards for representing material structures, including defects, simulation workflows, and calculated properties. Using this framework, datasets of crystal defects simulations can be generated in the form of a materials knowledge graph. We showcase the application for the study of hydrogen segregation at grain boundaries in iron and nickel, quantifying the influence of the local atomic environment on the energetics of the system. The resulting knowledge graph incorporates structure-property relationships and serves as a tool to understand defect mechanisms at the atomic scale. Additionally, it provides a robust data foundation for exploring the potential of emerging methods in the field of knowledge engineering.

MM 28.5 Thu 11:15 H23

Effect of Cold Work on the Microstructure and Properties of Hierarchical Nanoporous Metals — •Weiche Chang[1] and Shan Shi[2,1] — [1]Institute of Hydrogen Technology, Helmholtz-Zentrum Hereon, Geesthacht, Germany — [2]Research Group of Integrated Metallic Nanomaterials Systems, Hamburg University of Technology, Hamburg, Germany,

Nanoporous metals with bicontinuous porous network, high specific surface area, and low density have shown promising applications as light-weight structural materials and high-performance functional materials in actuators, sensors, and various energy devices. Recently, monolithic hierarchical nanoporous gold (HNPG) has been tailor-made via a two-step dealloying method and has shown improved mechanical properties and much lower density than non-hierarchical nanoporous gold. The effects of ligament size and structural hierarchy on the strength of HNPG have also been well studied via macro- or micro-compression approaches. In this work, we further explore the role of cold working treatments before and after second step dealloying on the mechanical properties of HNPG using micropillar compression tests. Furthermore, HNPG with a controllable degree of anisotropy and a much wider range of solid fractions are obtained.

Molecular Feuds and Fragment Tales: Exploring Cyanobiphenyl Liquid Crystals with Cryo Atom Probe Tomography — •Kuan Meng, Kang'an Wang, Sebastian Eich, and Guido Schmitz — Stuttgart University,Institute for Materials Science, Heisenbergstr. 3, 70569, Stuttgart, Germany

Liquid crystals exhibit the fascinating duality of liquid-like fluidity and solid-like long-range order, requiring nanoscale characterization techniques with high spatial resolution and chemical sensitivity. Atom probe tomography (APT) uniquely meets these requirements, offering unprecedented insights into the behavior of anisotropic organic molecules. This talk bridges liquid crystal science and APT by exploring cyanobiphenyl systems (5CB, 8CB, and 8OCB).

We investigated the field evaporation behaviors of these molecules, observing remarkable stability under high electric fields. Molecular signals dominated (90% for 5CB and 8CB, 70% for 8OCB), with fragmentation patterns influenced by oxygen atoms. The fragments were classified as alkyl chains, single phenyl derivatives, cyanobiphenyl residues, and cyano-hydrogen substitution pairs. Spatially, both molecular and fragment signals correlate strongly with laser orientation: fragmentation decreases from illuminated to shadowed regions, reflecting cleavage behavior under thermal gradient-induced field variations. Additionally, APT revealed the uniform mixing of 5CB and 8CB across various ratios, as well as the lattice plane of the crystal structure of pure 8CB. In the crystalline regions, we will discuss how the molecules field evaporate at specific angles relative to their intrinsic orientations.

MM 29.2 Thu 12:15 H10

Peptide Analysis at Atomic Resolution with Atom Probe Tomography — •Sakshi Sinha and Guido Schmitz — Department of Materials Physics, Institute of Material Science, University of Stuttgart, Heisenbergstr. 3, 70569 Stuttgart

Atom Probe Tomography (APT) promise decisive advancements in nanoscale characterization of biomolecules, since it offers in principle single atom sensitivity in the study of organic molecular structures. In our experiments, we test the analysis of carnosine (β-alanylhistidine), in aqueous solution since water provides a natural biological environment. The investigated dipeptide is for example essential for brain and muscle function. By combining cryogenic sample preparation with advanced laser-pulsing techniques, APT enables three-dimensional mapping of carnosine's atomic composition and the distribution of various molecule fragments in the water matrix. Remarkably, the concentration of the solution controls the detected fragmentation behavior in the full range from single atoms to the full peptide molecule. So, the measurement conditions can be optimized to preferentially address the questions regarding the local stoichiometry or the different subunits of the molecule.

MM 29.3 Thu 12:30 H10

Fe self-diffusion in Fe-Al-Si melts - A combined ab initio molecular dynamics and experimental study — •Katharina Dammer[1], Fan Yang[1], Elke Sondermann[1], Florian Kargl[1], Andreas Meyer[1,2], and Noel Jakse[3] — [1]Institut für Materialphysik im Weltraum, Deutsches Zentrum für Luft- und Raumfahrt (DLR), 51170 Köln, Germany — [2]Institut Laue-Langevin (ILL), 38042 Grenoble, France — [3]Université Grenoble Alpes, CNRS, Grenoble INP, SIMaP, 38000 Grenoble, France

Understanding the structural, dynamic and thermophysical properties of binary and ternary Al-Fe-Si alloys in the liquid and supercooled state before solidification is crucial to ensure the desired microstructure and therefore ideal product properties. With an increasing iron content in the alloy, the liquidus temperature increases and exceeds 1000°C for most ternary Al-Si-Fe alloys. At these high temperatures, experiments are more delicate to perform, making it challenging to obtain information on transport coefficients and (partial) structure factors.

We present a combined first principle-based molecular dynamics (AIMD) simulations and experimental study of Al-Fe melts. Measurements were performed using quasi elastic neutron scatting (QENS) to obtain the self-diffusion coefficients of Fe at different Al-Fe compositions as a function of temperature. We intend to achieve in the future an improved simulation scheme using machine learning that realistically covers a larger range of the phase diagram, which cannot be easily assessed with experiments.

MM 30: Functional Materials: Performance, Reliability and Degradation; and Complex Materials (joint session MM/KFM)

Untersuchungen des Bruchverhaltens im Bereich der Ultra-Langzeitfestigkeit von Federstählen — •Jörg Gollnick — THM, FB ME, Wiesenstr. 14, 35390 Gießen

In einer hochfrequenten resonanten Anwendung als Spiegel für Laserscanner werden Federstähle des Typs Ck101 im Grenzbereich belastet. Im Rahmen eines Forschungsvorhabens wurden die spezifischen Möglichkeiten untersucht, die Lebensdauer dieser Bauteile zu steigern. Bislang wurden nur unzureichende Lebensdauern erreicht.

Bemerkenswert war die Ausprägung des Versagensverhaltens, dass in Zusammenhang mit der Fertigungstechnologie einem Sprödbruch unter Mode III nach den bruchmechanischen Ansätzen gemäß Griffith entspricht. Aus der Erklärung der Schädigungen wurden weitere Möglichkeiten untersucht, die Lebensdauer nicht nur zu steigern sondern weiterhin die nach Paris-Erdogan zu erwartende

Dauerfestigkeit genau zu bestimmen.

Mit hohen Frequenzen im Bereich bis zu 10000kHz werden Bauteile bis zu 10 Milliarden Schwingungen im Grenzbereich betrieben. Eine mehrstufige Auswertung nach dem Treppenstufenverfahren zeigt, dass eine Auswertung in diesem Segment nicht nur möglich ist, sondern als geeignete Strategie angesehen werden darf, die Erkenntnisse der Ultra-Langzeitfestigkeit diesbezüglich zu erweitern.

Weitergehende Versuche werden vorgestellt.

Falls gewünscht kann der Vortrag und Beitrag gerne auch auf englisch abgefasst werden.

MM 30.2 Thu 12:00 H23

Searching for ferroelectric porous metal organic frameworks using machine-learning and Monte-Carlo-simulations — •Thomas Bergler[1,2], Harald Oberhofer[1,2], and Dirk Volkmer[3] — [1]University of Bayreuth, Germany — [2]Bavarian Center for Battery Technologies — [3]University of Augsburg, Germany

Metal organic frameworks (MOFs) have so far found a number of successful applications, among them as storage for gasses and filter for gas mixtures. So far these mostly incorporated them as passive materials, but recent research points the way towards a more active role, possibly through the external manipulation of the materials' internal properties. One recent example for such a property is the susceptibility of the lattice parameters of a number of MOFs towards electric fields. Inspired by this, the aim of our project is to further investigate this behavior and potentially design ferroelectric MOFs. Using a hierarchy of Monte-Carlo-simulations aided by Machine-Learning (ML) we sample the design space MOFs augmented by rotatable polar groups. In succession, we first sample a huge space of rotors in a simplified point-dipole model. A selection of thus uncovered MOF geometries is then investigated with a specially parameterized atomistic model to confirm earlier predictions. Using this data, an ML model is trained to predict the dielectric properties of such polar rotor-augmented MOFs. The best candidates extracted with this procedure are finally evaluated with density functional theory. MOF geometries surviving this funnel-like approach can finally be checked experimentally for a variety of applications, ranging from data-storage to gas nano-funnelling.

MM 30.3 Thu 12:15 H23

Atomic Scale Insights into A-site Deficient Perovskite Catalysts: $La_{0.7}Fe_{0.7}Mn_{0.3}O_3$ — •Roham Talei Jeid — Institute for Material Physics, University of Stuttgart, Deutschland

This study investigates the atomic-scale properties of the A-site-deficient perovskite catalyst $La_{0.7}Fe_{0.7}Mn_{0.3}O_3$ (La07FM), emphasizing the role of iron oxide (FeO) in redox reactions. Advanced techniques, including scanning transmission electron microscopy (STEM), energy-dispersive X-ray spectroscopy (EDXS), and a custom Python-based strain mapping tool linked to chemical analysis reveal nanoscale La deficiencies and Fe enrichments at grain boundaries as key for catalytic activity. Post-catalysis studies identify Fe-rich, FeO-like nanoparticles at strained, defective grain boundaries, underscoring the impact of A-site deficiencies on performance in NOx denitrification (DeNOx). These findings highlight how A-site deficiencies and Fe-rich nanostructures enhance catalytic efficiency, offering broader insights into electrochemistry and heterogeneous catalysis.

MM 30.4 Thu 12:30 H23

Use of LiMn2O4 for switching applications in silicon waveguide circuits — •Vinit Agarwalla[1], Yug Joshi[2], and Guido Schmitz[1] — [1]Insitut für Materialwissenschaft, Universität Stuttgart, Heisenbergstr.3, 70569 Stuttgart — [2]Max-Planck-Institut für Nachhaltige Materialien, Max-Planck-Straße 1, 40237, Düsseldorf

Lithium ion intercalation and deintercalation play an important role in determining the storage performance of cathode materials for lithium ion batteries. However, intercalation of ions also regularly modifies electron structure and optical properties of the materials. This study explores the possibility of exploiting the optical properties of the cathode material LiMn2O4 (LMO) for optical switching applications in silicon waveguide circuits. For this, LMO is coated as a cladding around Si waveguides suitable for the 1550 nm wavelength of optical telecommunication. To stabilize the interface a thin intermediate Si oxide film is tested as an optical transparent reaction barrier. Our TEM images and the EDX mapping show that the Si does not react with LMO for oxide layer thickness as low as 10 nm. Previous work has explored the change in resonance wavelength of reflectance spectra with lithiation/ delithiation in the visible region[1]. In extension, we have measured FTIR reflectance spectra in the near IR region. They show a fairly continuous spectrum between visible and IR region with reflectance going to 100 % and a gradual shift in resonance wavelength in the IR region with Li intercalation. The optical response on light transmission along the wave guides has been determined in dependence on the degree of lithiation.

MM 30.5 Thu 12:45 H23

Chemical short-range order and local lattice distortions in High-Entropy Alloys: state of the art — •Andrea Fantin, Anna Maria Manzoni, Reza Darvishi Kamachali, and Robert Maass — Bundesanstalt fuer Materialforschung und -pruefung, Unter den Eichen 87, 12205 Berlin, Germany

Understanding the intricate atomic-scale structures within High-Entropy Alloys (HEAs) is crucial for tailoring their properties for diverse applications. This contribution tries to provide a brief overview of the state-of-the-art experimental techniques employed to probe local lattice distortions and chemical short-range order in HEAs, with specific focus on X-ray absorption spectroscopy and total scattering. The main problem to overcome in multi-component alloys is the intrinsic reduced scattering contrast between nearest neighbors in the periodic table, which limits the amount of information that can be extracted from the data. This statement remains valid when employing transmission electron microscopy, as well. Specific examples such as the Al-Co-Cr-Cu-Fe-Ni fcc system [Small Science 4(2), 2300225 (2024); Nature Communications 15(1), 7815 (2024)] and the MoNbTaW bcc system [Materials Research Letters 12(5), 346-354 (2024)] will be outlined. It comes clear that rather than specific techniques, it is only the combination of several experiments, supported by simulations and multi-technique simultaneous structural refinements, that can help in disentangling the different contributions to performances of each element within the alloy solid solution, with strength and weaknesses depending on the specific experimental measurements.

MM 31: Data-driven Materials Science: Big Data and Worksflows

Materials Properties and more

MM 31.1 Thu 15:00 H10

Thermodynamic stability of the materials in the Materials Cloud three-dimensional crystals database (MC3D) — •Timo Reents[1,2], Marnik Bercx[1], and Giovanni Pizzi[1,2] — [1]Laboratory for Materials Simulations (LMS) and National Centre for Computational Design and Discovery of Novel Materials (MARVEL), Paul Scherrer Institut (PSI), CH-5232 Villigen PSI, Switzerland — [2]École Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland

High-throughput studies based on ab initio methods such as Density Functional Theory (DFT) enable the analysis of physical properties across a broad chemical space. Here, we present the Materials Cloud three-dimensional crystals database (MC3D), a DFT optimized and curated structural database of experimentally known inorganic crystals. All calculations are managed and driven by the AiiDA [1, 2] workflow engine, allowing to browse the full provenance graph and to share the results in the Materials Cloud [3]. We introduce the protocols behind MC3D, the new frontend, and we then focus on the thermodynamic stability. To improve the agreement between the theoretical and experimental thermodynamic stability, we apply empirical [4] and machine-learning [5] based corrections, and improve upon them, discussing the agreement with experimental data on stability.

high-throughput computation and machine learning modeling of magnetic moments and Mössbauer spectroscopy for Fe-based intermetallics — •Bo Zhao, Xiankang Tang, and Hongbin Zhang — Institute of Materials Science, Technische Universität Darmstadt, Otto-Berndt-Str. 3, 64287 Darmstadt, Germany

Understanding the relationship between the local crystalline environment and magnetic properties is a fundamental challenge in condensed matter physics and materials science. This study explores this relationship in Fe-based intermetallic compounds, focusing on the magnetic moments and Mössbauer parameters of iron atoms, including the isomer shift, electric field gradient, and magnetic hyperfine field. High-throughput calculations and machine learning techniques are employed to predict magnetic properties based on local atomic structures, using smooth overlap of atomic positions (SOAP) as local descriptors. The results first reveal the sparsity of relevant materials in the Materials Project database. Lever-

aging high-throughput, system-specific data, the study demonstrates strong correlations between local atomic environments and magnetic properties, achieved through machine learning models. Furthermore, the limitations of symmetry-invariant descriptors in predicting tensor-like properties, such as the electric field gradient, are highlighted. By incorporating a graph-based equivariant autoencoder, the model achieves improved predictions by effectively capturing the symmetry of local environments.

MM 31.3 Thu 15:30 H10

Advanced Machine Learning of ^{17}O NMR in Non-Magnetic Oxides: High-Throughput Calculation, Prototype Compound Analysis, and Transfer Learning — •Zhiyuan Li, Bo Zhao, Hongbin Zhang, and Yixuan Zhang — Institute of Materials Science, TU Darmstadt, 64287 Darmstadt Germany

The study of ^{17}O NMR spectroscopy is crucial for understanding the local structure of oxides, where the naturally occurring NMR-active oxygen isotope, ^{17}O, provides unique insights into local environments due to its large chemical shift range and quadrupolar nature. In this work, we present a high-throughput workflow integrating AiiDa and CASTEP to calculate the NMR parameters of over 7100 compounds from the Materials Pro ject database, followed by utilizing machine learning models to predict ^{17}O NMR parameters. Furthermore, taking $BaTiO_3$ as an example, we identify prototypical ABO_3 crystal structures, construct $BaTiO_3$ analogs via substitution, perform ab initio molecular dynamics simulations to generate 3000 perturbated structures, and evaluate the NMR parameters. The results of our machine learning modeling with such additional dataset reveal that incorporating perturbated structures enhances the accuracy of the machine learning model. Moreover, by leveraging transfer learning, using previously trained model from our high-throughput dataset, the predictivity for the newly generated $BaTiO_3$ analogs can be further improved.

MM 31.4 Thu 15:45 H10

Advancing chemical shielding predictions in organic solids — •Matthias Kellner and Michele Ceriotti — École Polytech- nique Fédérale de Lausanne, 1015 Lausanne, Switzerland

In this presentation, we showcase our recent advancements in machine learning for predicting chemical shieldings in organic solids. Leveraging symmetry-adapted machine learning models, our updated infrastructure facilitates the accurate prediction of chemical shielding anisotropy and enables structure optimization driven by chemical shielding gradients. We will highlight how integrating machine learning potentials with property prediction models provides unique insights into atomistic processes, offering a powerful framework for exploring the complex behavior of organic materials.

MM 31.5 Thu 16:00 H10

Active learning workflow for mixed-halide perovskite stability and electronic band-structure — •Tim Bechtel[1,2], Santiago Rigamonti[1], and Claudia Draxl[1,2] — [1]Humboldt-Universität zu Berlin, Germany — [2]Max Planck Institute for Solid-State Research, Stuttgart, Germany

Mixed-halide perovskites are promising materials for stable and efficient light harvesting and emission applications, and their composition can be tailored to match relevant regions of the light spectrum [1]. Theoretical predictions from first-principles calculations can provide insight into stability, ground-state properties, and electronic structure [2,3]. Comparison with experimental results for "real" materials is, however, challenging. For example, the consideration of chemical (dis)order requires huge supercells, which is computationally out of reach with state-of-the-art methodology. For the family of $CsPb(Cl_xBr_yI_{1-x-y})_3$ compounds, we bridge this gap with an active learning workflow. It is based on a fine-tuned machine learning interatomic potential [4] that interpolates between already seen compositions, and actively explores new composition ranges. This approach allows for data-efficient predictions of stability through finite-temperature phase diagrams and optical properties for a wide range of compositions.

Towards Multi-Fidelity Machine Learning Using Robust Density Functional Tight Binding Models — •Mengnan Cui[1,2], Karsten Reuter[1], and Johannes T. Margraf[2] — [1]Fritz-Haber-Institut der MPG, Berlin, Germany — [2]University of Bayreuth, Physical Chemistry V: Theory and Machine Learning

Machine learning has revolutionized the atomistic simulation of molecules and materials, offering unparalleled computational speed with high accuracy. However, its performance depends heavily on the quality and quantity of training data, presenting challenges due to the scarcity of high-fidelity datasets (beyond semilocal DFT). This study investigates transfer learning (TL) across multiple fidelities for molecules and solids, examining the role of fidelity levels and configuration/chemical space overlap in pre-training and fine-tuning. This reveals negative transfer driven by noise from low-fidelity methods like DFTB, which can significantly impact fine-tuned models. Despite this, multi-fidelity approaches consistently outperform single-fidelity learning and, in some cases, even surpass TL based on foundation models by leveraging an optimal overlap of pre-training and fine-tuning chemical spaces.

MM 31.7 Thu 16:45 H10

Enhancing FAIR Data Management with Automated Visualization of Calculations — •N. Daelman[1], E. Boydas[1], B. Mohr[1], J.M. Pizarro[1], T. Bereau[2], C. Draxl[1], L.M. Ghiringhelli[3], M. Girard[4], D. Usvyat[5], R. Valenti[6], S. Botti[7], and J.F. Rudzinski[1] — [1]CSMB, HU Berlin — [2]ITP, Heidelberg Uni. — [3]Dept. of Mater. Sci. and Eng., FAU Erlangen — [4]Max Planck Inst. for Poly. Res., Mainz — [5]Inst. für Chem., HU Berlin — [6]Inst. für Theor. Phys., GU Frankfurt/M — [7]RC-FEMS, Ruhr Uni. Bochum

In contrast to data science packages, first-degree data post-processing tends to lock people into silos built around a particular simulation software. NOMAD [nomad-lab.eu][1] is an open-source and community-driven data infrastructure that breaks open these silos by extracting scientific data from over 60 code packages into a code-agnostic schema within a research data management (RDM) ecosystem [2]. This talk showcases NOMAD*s new visualization features at various levels of RDM. At the level of individual calculations, NOMAD provides now more detailed electronic structure visualizations and fast, dynamic rendering of heavy files. Automated visualization does not imply, however, a lack of customizability. NOMAD provides support for tailored figures and larger-scale specialization via an accessible plugin-based system. At the level of research projects, NOMAD allows for quick monitoring of the data coverage via a fully customizable dashboard.

MM 31.8 Thu 17:00 H10

NOMAD CAMELS: An Open-Source Solution for Creating FAIR Data from Experiments — •Alexander Fuchs[1,2], Johannes Lehmeyer[1,2], Michael Krieger[1,2], and Heiko Weber[1,2] — [1]Lehrstuhl für Angewandte Physik, Friedrich-Alexander-Universität Erlangen-Nürnberg — [2]FAIRmat Consortium

NOMAD CAMELS is a configurable open-source measurement software. It is suited to control experiments and records fully self-describing experimental data. It has its origins in the field of experimental physics where a wide variety of measurement instruments are used in frequently changing experimental setups and measurement protocols. CAMELS provides a graphical user interface (GUI) which allows the user to configure experiments without the need of programming skills or deep understanding of instrument communication. CAMELS translates user-defined measurement protocols into stand-alone executable Python code for full transparency of the actual measurement sequences. Metadata inflow from Electronic Lab Notebooks (ELNs) and data output into such is well supported for a seamless workflow. CAMELS is designed with a focus on full recording of data and metadata aligned with the NeXus ontology. When shared with others, data produced with CAMELS allow full understanding of the measurement and the resulting data in accordance with the FAIR principles.

MM 31.9 Thu 17:15 H10

Databases of Fermi surfaces and de Haas-van Alphen oscillation frequencies from first principles simulations — •Nataliya Paulish[1], Junfeng Qiao[2], and Giovanni Pizzi[1] — [1]PSI Center for Scientific Computing, Theory and Data, 5232 Villigen PSI, Switzerland — [2]Theory and Simulation of Materials (THEOS), and National Centre for Computational Design and Discovery of Novel Materials (MARVEL), École Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland

The Fermi surface (FS) of a metal separates occupied from unoccupied electronic states. Knowing its shape is crucial to understanding the electronic properties of the material. Accurate simulation of the FS requires a very dense sampling of the Brillouin zone, and thus direct density functional theory (DFT) calculations are limited by their computational cost. To overcome this difficulty, we use interpolation from a basis of spatially localized projectability disentangled Wannier functions (PDWFs) - a recently developed algorithm for automated Wannierization [1]. Using this algorithm, FSs were generated for over 7'000 inorganic metals. We also computed de Haas-van Alphen frequencies associated with each FS, enabling direct comparison of our simulations with experiments. The procedure is fully automated using the AiiDA workflow engine [2]. Our database will be published openly online and browsable on the Materials Cloud MC3D section (https://mc3d.materialscloud.org).

MM 31.10 Thu 17:30 H10

A systematic benchmark of G_0W_0 calculations — •Marc Thieme, Max Grossmann, Malte Grunert, and Erich Runge — Technische Universität Ilmenau, Ilmenau, Germany

Accurate and efficient ab initio electronic structure calculations of semiconductors and insulators are a prerequisite for building large, high-quality databases for machine learning (ML). However, the "optimal" choice (speed vs. accuracy) of the approximations used, i.e. the exchange-correlation (XC) functional for density functional theory (DFT) calculations or a particular many-body perturbation theory, remains unclear. A systematic benchmark of band gaps of solids using several different DFT XC functionals by Borlido et al [1,2] showed that hybrid functionals perform exceptionally well and seem to be the functionals of choice. The present study addresses the question of whether G_0W_0 calculations provide a sufficient increase in accuracy to justify their increased computational cost compared to simpler DFT calculations with hybrid functionals. We calculate the band gaps for about 300 materials using the G_0W_0 method starting from LDA/PBE DFT calculations. The deviations between G_0W_0 and experimental band gaps are systematically compared with those of the best hybrid functionals

MM 31.11 Thu 17:45 H10

Machine Learning-Assisted Design of Magnetic Materials: Predicting Properties for not purely ternary $Nd_2Fe_{14}B$ — •Manuel Enns, Daniel Urban, Wolfgang Körner, and Christian Elsässer — Fraunhofer IWM, Wöhlerstraße 11, 79108 Freiburg, Germany

$Nd_2Fe_{14}B$-based hard-magnetic materials are widely used for strong permanent magnets. Their re-use and recycling after the end of the magnet's life cycle opens the question of the degradation of the magnetic properties due to the incorporation of unintentional impurity elements originating from the recycling procedures. In this talk, we present a data-mining and machine-learning (ML) approach using kernel-based learning methods to predict the influence of impurity atoms in $Nd_2Fe_{14}B$-based materials. The magnetic-property data used for training and testing the ML model were obtained by a combinatorial high-throughput screening (HTS) using density-functional theory calculations. We demonstrate that our ML approach can accurately predict the saturation magnetization, the uniaxial anisotropy constant, and the formation energy for $Nd_2Fe_{14}B$ with impurities added by recycling.

MM 32: Transport in Materials: Diffusion, Charge or Heat Conduction

Battery Materials, Effects of Defects

Time: Thursday 15:00–17:45 Location: H22

MM 32.1 Thu 15:00 H22

Kinetic analysis of lithium transport in silicon anode using operando optical microscopy — •Shihao Wei, Monica Mead, Yug Joshi, and Guido Schmitz — Institute of Materials Science, University of Stuttgart, Germany

The performance of silicon(Si) anodes in lithium(Li)-ion batteries is significantly influenced by the kinetics of Li insertion and migration, particularly at the phase boundaries formed during cycling. Traditional techniques, such as EIS, SIMS, and NMR, are limited in providing detailed kinetic information at internal phase boundaries. This study proposes a novel approach to measure Li migration across phase boundaries in Si-based anodes. First, reflectance spectroscopy is employed to examine the optical response of Si thin films sputtered onto copper current collectors at various charge states, revealing reversible electrochromic behavior and the effect of Li content on spectral characteristics. Based on this, operando optical microscopy is developed to track the lithiation front, by using SU-8 photoresist as a patterning tool. The lithiation process is predominantly governed by diffusion-controlled parabolic growth, with minimal evidence of interface-controlled linear growth. Interestingly, applying the same method during delithiation, a significant slow-down of delithiation front appears. In addition, temperature-dependent diffusion behaviors are explored, quantified with an Arrhenius-like model. By altering the geometry of the photoresist patterns, the transport dynamics are analyzed under two distinct scenarios: a 1D semi-infinite planar configuration and a 2D finite circular configuration.

MM 32.2 Thu 15:15 H22

Crossing Boundaries? Probing Ion Conduction across Interfaces in Solid Electrolytes using Computational NMR Spectroscopy — •Tabea Huss[1], Federico Civaia[1], Simone Köcher[2,1], Karsten Reuter[1], and Christoph Scheurer[1,2] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Institute of Energy Technologies (IET-1), Forschungszentrum Jülich GmbH

Grain boundaries are critical, yet poorly understood factors affecting ion transport in solid-state electrolytes. The spin-alignment echo (SAE) nuclear magnetic resonance (NMR) experiment is a versatile tool to study the manifold transport processes of quadrupolar ions in these solid state materials. However, assigning the measured decay coefficients to physical transport phenomena often proves to be challenging. We have previously demonstrated that we can replicate the SAE experiment for bulk materials using a multi-scale machine learning framework.[1] This framework simulates both the atomic structure and dynamics of solid-state systems, along with generating solid state NMR observables. Our approach has already allowed us to predict electric field gradients over molecular dynamics trajectories and use them to compute decay constants that align with ion hopping times in bulk lithium thiophosphates. In this work, we extend our methodology to explore ion transport in grain boundary structures of the solid-state electrolyte $Li_{10}GeP_2S_{12}$. We extract SAE time constants and differentiate among various decay processes, advancing another step towards direct comparability with experimental results.

MM 32.3 Thu 15:30 H22

Theoretical Investigation of Electron Transport in the $LiMnPO_4$ Battery Material — •Franz Winkler[1,2] and Harald Oberhofer[1,2] — [1]University of Bayreuth — [2]Bavarian Center for Battery Technologies

Developing better batteries and thus battery materials is a crucial step in humanity's urgent energy transition. Thereby, theory can play an important role in characterizing and understanding the properties of the involved materials. In this contribution we present our work on $LiMnPO_4$ which exhibits some desirable properties such as a high energy density and a high potential and thus operating voltage. However, its adoption is hampered by a bad electronic conductivity.

Using electronic density functional theory (DFT), we compute the parameters of conductivity for both band- and polaronic hopping transport, to identify possible bottlenecks and thus possible future improvements of the material. For this we consider both the paramagnetic and antiferromagnetic configuration of $LiMnPO_4$. Due to the well known failures of plain semi-local DFT to represent both localized polaronic configurations and complex spin structures, we thereby use Hubbard-corrected DFT for the bulk of our calculations and range-separated hybrid DFT as a reference. Improvements suggested by our theoretical results can then help experimental collaborators to establish synthetic routes towards more efficient battery materials.

MM 32.4 Thu 15:45 H22

Lithium transport in Lithium Manganese Oxide as a function of temperature, concentration and grain size measured by operando optical microscopy — •Monica Mead[1], Yug Joshi[2], and Guido Schmitz[1] — [1]Institut für Materialwissenschaft, Universität Stuttgart, Heisenbergstr.3, 70569 Stuttgart — [2]Max-Planck-Institut für Nachhaltige Materialien, Max-Planck-Straße 1, 40237 Düsseldorf

Common methods for the determination of diffusion coefficients in electrode materials require critical interpretation, as their formal derivations rely on restrictive assumptions (e.g. galvanostatic/potentiostatic intermittent titration technique (G/PITT), electrochemical impedance spectroscopy (EIS), cyclic voltammetry (CV)). Alternatively, an optical method for studying ion transport in battery electrodes through operando microscopy can be applied. Here, the measurement of diffusion coefficients is done on thin films in lateral diffusion geometry and is based on an optical response upon ion intercalation. This allows measuring the diffusion coefficient as a function of temperature, concentration and grain size. In this work, diffusion of Li ions in Lithium Manganese Oxide (LMO) is studied by operando microscopy. The temperature dependence of the diffusion coefficient, providing the activation energy via the Arrhenius relation, and the diffusion coefficients for the bulk/grain boundaries of LMO can be determined. Additionally, it is possible to find the concentration dependence by an inverse Boltzmann-Matano method on concentration profiles derived from the intensity profiles along the diffusion direction.

MM 32.5 Thu 16:00 H22

Charge Transport Simulation in the High State-Of-Charge using Kinetic Monte Carlo — •Roya Ebrahimi Viand, Chiara Panosetti, Christoph Scheurer, Karsten Reuter, and Sebastian Matera — Fritz-Haber-Institut der MPG, Berlin

Understanding charge transport in solids is crucial for improving energy storage systems such as lithium-ion batteries. The diffusion of particles in solid materials typically involves rare transitions between low-energy sites, making kinetic Monte Carlo (kMC) an effective tool for studying the long-time dynamics. To address the computational challenges posed by long-range Coulomb interactions, we utilize fast rules for updating the process rates at each kMC step. We investigate ion transport on an isotropic rectangular lattice as well as in lithium graphite structures at high states of charge. We find that small changes in the ion

concentration can significantly influence ion mobility, depending on temperature and dielectric response. This happens near stoichiometric concentrations, where the ions freeze in a Coulomb superlattice where effective motion is energetically uphill. Introducing defects or excess ions then opens effective pathways for diffusion. Finally, we discuss the possibility of multiple quasi-stationary states manifesting in different mobilities under the same applied conditions and concentrations.

MM 32.6 Thu 16:30 H22

Electrical characterization of the gate length dependence in graphene field-effect transistors — •Daniel Nickel[1], Daniele Capista[1], Rasuole Lukose[1], Christian Wenger[1,2], and Mindaugas Lukosius[1] — [1]IHP - Leibnitz Institute for High Performance Microelectronics, Im Technologiepark 25, 15236 Frankfurt (Oder), Germany — [2]BTU Cottbus Senftenberg, Platz der Deutschen Einheit 1, 03046 Cottbus, Germany

Integrating graphene into silicon complementary metal-oxide semiconductor technology for electronic and optoelectronic applications holds great promise but faces challenges such as limited graphene mobility. This work addresses this limitation by using graphene field-effect transistors (GFETs) to analyze the influence of fabrication parameters on the electrical properties of graphene and to investigate the gate length dependence of sheet mobilities at T = 300 K. The GFET devices are fabricated with a wolfram back-gate on a 200 mm SiO_2/Si wafer, transferring chemical vapor deposition-grown graphene, patterning it, and forming graphene channel contacts with Pd/Au and Ni. The Dirac point is well detected in electrical measurements, indicating the transition between p- and n-type conduction. Graphene mobility is evaluated using the transconductance method and total resistance fit, revealing peak mobilities of μ_p = 715 cm^2/Vs for the p-branch and μ_n = 986 cm^2/Vs for the n-branch, with dependencies on channel length and contact metals used. Funding was provided by the EU's Horizon 2020 research and innovation program under the Graphene Flagship grant agreement no. 101189797.

MM 32.7 Thu 16:45 H22

Structural and electronic impact of defective sites and their effects on the thermoelectric properties of scandium nitride thin films — •Luigi Cigarini, Urszula Danuta Wdowik, and Dominik Legut — IT4Innovations, VŠB Technical University of Ostrava, 17. listopadu 2172/15, 708 00 Ostrava-Poruba, Czech Republic

The Landauer model provides a theoretical tool to understand the electronic transport mechanisms that deeply govern at the atomic scale the thermoelectric conversion of interesting materials. Transition metals nitrides are currently studied for potential applications in energy conversion. Modeling the effects on electronic transport that result from the electronic and structural modifications produced by oxygen impurities and spatial vacancies in scandium nitride (ScN), we propose a theoretical interpretation for new experimental results revealing a strong dependence of the thermoelectric properties of ScN thin films on procedural changes during their fabrication. We find that the thermoelectric properties of ScN are actually decisively determined by the structural and electronic factors caused by the presence of these defects or impurities. Evaluating to what extent these material's overall properties are influenced by these features necessarily requires a theoretical approach. This is particularly true as the presence of oxygen, which proves to be a decisive factor, is extremely difficult to control in standard fabrication processes and experimental conditions. The results presented in this contribution demonstrate the potential of this theoretical approach in studying the thermoelectric properties of these materials uncovering future strategies for improvement.

MM 32.8 Thu 17:00 H22

Helium Interaction with Atomic Level Defects in TungstenStudied by Positron Annihilation Spectroscopy — •Vassily Vadimovitch Burwitz[1,2], Annemarie Kärcher[1,3], Maik Butterling[4], Eric Hirschmann[4], Emma Huntley[2], Adrian Langrehr[1,2], Maciej Oskar Liedke[4], Lucian Mathes[1,2], Thomas Schwarz-Selinger[3], Christoph Springl[1,2], Monia Vadrucci[5,6], Andreas Wagner[4], and Christoph Hugenschmidt[2] — [1]TU München, School of Natural Sciences, Physikdepartment — [2]TU München, MLZ — [3]MPI für Plasmaphysik, Garching — [4]HZDR, Institute of Radiation Physics — [5]ENEA, Development of Particle Accelerators and Medical Applications, Frascati (RM), Italy — [6]Italian Space Agency, Science and Innovation Directorate, Rome

Understanding the type and evolution of lattice defects in tungsten (W) is of interest in nuclear fusion materials research. We therefore investigated W(111) mono-crystals by positron annihilation Doppler-broadening spectroscopy (DBS) and positron annihilation lifetime spectroscopy (PALS). Both complementary methods are sensitive tools for the examination of the defect type and concentration. The literature currently lacks conclusive experimental work regarding the influence of He decoration of vacancies on PAS. We therefore irradiated samples by 4.5 MeV electrons to different damage levels in order to specifically produce mono-vacancies in W. We will present DBS and PALS measurements, both performed with a slow positron beam, before and after plasma loading with 50 eV He ions. The implantation energy is chosen low enough to prevent displacement damage.

MM 32.9 Thu 17:15 H22

Formation energies and charge transition levels of charged point defects in Hematite — •Hao Chen, Christoph Freysoldt, Mira Todorova, and Jörg Neugebauer — Max-Planck-Institut für Nachhaltige Materialien GmbH, Düsseldorf, Germany

Hematite (Fe_2O_3), an iron oxide fundamental to the process of iron ore reduction, exhibits rich defect physics and off-stoichiometric features, as iron can occur as either Fe^{3+} and Fe^{2+}. Charged point defects and the associated Fe^{2+}/Fe^{3+} transitions play an important role in phenomena such as thermodynamic stability, phase transitions between iron oxides, and electronic structure modulation. In order to correctly account for these effects in the prediction of defect equilibria, phase diagrams, diffusion, and related properties, a robust framework for understanding defect thermodynamics and constructing a comprehensive defect model at the ab initio level is essential. Here, we employ DFT+U as an efficient tool for studying strongly correlated systems. In view of the delocalization error of standard functionals, DFT+U is crucial to investigate Fe^{2+} ions as distinct species. Moreover, it systematically opens the band gap of the bulk iron oxides. Since Hubbard U parameter has a direct influence on the band structure and Fe-related defect states in the band gap, we investigate the impact of U values on the computed formation energies of vacancies and interstitials. Our results show that the defect formation energies have a surprisingly weak dependence on U, thus allowing reliable predictions. We analyze the electronic structures of the defects in detail to uncover the underlying physical mechanisms.

MM 32.10 Thu 17:30 H22

Contribution of damped collective modes to thermopower in the strange metal phase of cuprates — •Giovanni Mirarchi[1], Sergio Caprara[2,3], Carlo Di Castro[2], Götz Seibold[4], and Marco Grilli[2,3] — [1]Institute of Theoretical Physics and Astrophysics, University of Würzburg, Am Hubland, 97074 Würzburg, Germany — [2]Dipartimento di Fisica, Sapienza Università di Roma, P. le Aldo Moro 5, 00185 Roma, Italy — [3]ISC-CNR, Unità di Roma Sapienza, P. le Aldo Moro 5, 00185 Roma, Italy — [4]Institut für Physik, BTU Cottbus-Senftenberg - PBox 101344, D-03013 Cottbus, Germany

The strange-metal behavior, which is still an unsolved problem in condensed matter physics, is typically signaled by anomalies in thermodynamic and transport properties, including the famous linear-in-temperature resistivity [1]. The best-known case of strange-metal behavior in literature is that of high-temperature superconducting cuprates, whose strange-metal phase seems to always be accompanied by some kind of dynamical charge order [2]. Based on the experimental evidence of damped short-ranged charge density collective modes in the strange-metal phase of cuprates [3], we propose a scenario in which these collective modes can affect the phenomenology of this phase by interacting with electrons and by directly contributing to thermodynamics and transport [4]. In this talk, the concept of heat current in the presence of damping is discussed and used to describe the Seebeck effect in cuprates through a mechanism analogous to phonon drag. [1] Nat. Phys. 15, 142-147 (2019). [2] Science 337, 821 (2012). [3] Science 365, 906-910 (2019). [4] Commun. Phys. 5, 10 (2022).

MM 33: Invited Talk: P. Sonnweber-Ribic

Invited Talk MM 33.1 Fri 9:30 H10

Fatigue in steels: Micromechanical modelling of cyclic damage — •Petra Sonnweber-Ribic[1], Alexandra Stark[1], and Christian Elsässer[2] — [1]Robert Bosch GmbH, Renningen — [2]Fraunhofer-Institut für Werkstoffmechanik IWM, Freiburg

Fatigue is a common phenomenon in engineering structures and can lead to unexpected failures, especially in critical components such as aircrafts, trains, and automotive parts. Understanding the mechanisms behind fatigue is crucial for ensuring the safety and reliability of these structures. A specific challenge of fatigue lies in the difficulty of external detection, as the initial stages of fatigue

damage manifest as highly localized processes within specific microstructural domains.

The micromechanical modelling offers a method for predicting fatigue properties and achieving a more profound comprehension of damage and relevant micromechanical parameters. Initially, this is based on the representation of the underlying microstructure of the material and the description of local plastic deformation using the crystal plasticity method. This approach has been successfully employed in industrial environment to assess the role of different metallographic phases in relation to local cyclic damage, among other applications.

Subsequently, this methodology can be enhanced by integrating a hydrogen diffusion approach and advanced damage models to consider the influence of hydrogen on fatigue damage mechanisms. The relevance of different influencing factors is analyzed based on selected examples.

MM 34: Development of Calculation Methods

Atomic Structure, Quantum Effects

Time: Friday 10:15–12:15 Location: H10

MM 34.1 Fri 10:15 H10

Enhancing 3D Volume Reconstruction in Atom Probe Tomography through Curvature-Based Tip Shape Analysis — Sebastian Eich and •Guido Schmitz — Department for Materials Physics, Institute for Materials Science, University of Stuttgart

Atom Probe Tomography (APT) provides chemical analysis of nanometric volumes with single-atom sensitivity in 3D. Traditionally, reconstruction assumes a hemispherical tip shape, which can lead to significant distortions, especially due to local magnification effects.

Instead of relying on in-situ correlative microscopy, we propose a numerical method to extract the emitter shape from the event density statistics on the 2D detector plane. This method is based on the fundamental relationship between event density and the local Gaussian curvature of the tip surface, with no mathematical restrictions other than convexity. By knowing the curvature and assuming suitable boundary conditions, the surface profile can be uniquely reconstructed, bypassing the need for a hemispherical assumption.

The method is implemented as an easy-to-use Python module, which will be demonstrated using various simulated and experimental datasets involving complex tip shapes. This approach significantly reduces the local magnification effects at material interfaces with contrasting evaporation thresholds and is expected to improve the accuracy of atom probe reconstructions.

MM 34.2 Fri 10:30 H10

Sum frequency generation from real-time simulation in 2D crystals — •Mike Nico Pionteck[1], Myrta Grüning[2,3], Simone Sanna[1], and Claudio Attaccalite[3,4] — [1]Institut für Theoretische Physik and Center for Materials Research (LaMa), Justus-Liebig-Universität Gießen, Germany — [2]School of Mathematics and Physics, Queen's University Belfast, United Kingdom — [3]European Theoretical Spectroscopy Facilities (ETSF) — [4]CNRS/Aix-Marseille Université, Centre Interdisciplinaire de Nanoscience de Marseille UMR 7325 Campus de Luminy, France

Sum and difference frequency generation (SFG, DFG) are powerful experimental techniques which involve the interaction of two laser with frequency ω_1 and ω_2, generating an output beam with frequency $\omega = \omega_1 \pm \omega_2$ as second-order nonlinear response. These techniques are widely used to study 2D materials, providing complementary insights to those obtained from infrared and Raman spectroscopy.

We present an implementation of SFG and DFG within the Yambo code [1], based on real-time time-dependent adiabatic GW (TD-aGW). To account for local field effects and electron-hole interactions, our approach reduces to the Bethe-Salpeter equation (BSE) in the linear limit regime. We demonstrate this framework by calculating SFG and DFG signatures in h-BN and MoS_2. Furthermore, the method enables the extraction of higher-order response functions (e.g. TPA). This work establishes a first-principles approach to nonlinear optics, enabling investigations of optical responses of bulk materials with high versatility.

MM 34.3 Fri 10:45 H10

Ab initio calculations of longitudinal electrical conductivity using a Wannier-based coherent potential approximation — •Shota Namerikawa and Takashi Koretsune — Department of Physics, Tohoku University, Sendai, Japan

We present a longitudinal electrical conductivity calculation method for disordered alloys applicable from a wide range of density functional theory (DFT) codes based on the first-principles Wannier-based coherent potential approximation (Wannier-CPA). For evaluation of electrical conductivity, we employ two complementary methods; the Kubo-Greenwood formula and numerical analytic continuation of the current-current correlation function. We apply the developed method to Ag-Pd alloys and find that the results obtained by the Wannier-CPA reasonably reproduce previous studies by the well-established CPA implementation based on the Korringa-Kohn-Rostoker Green*s function method (KKR-CPA).

MM 34.4 Fri 11:00 H10

Ab-initio-based analysis of phonon contributions to negative thermal expansion of *a*-tin — •Petr Čípek[1,2], Jana Pavlů[2], Martin Friák[1], and Alena Michalcová[3] — [1]Inst. Phys. Mater., Czech Acad. Sci., Brno, Czech Rep. — [2]Dept. Chem., Masaryk Uni., Brno, Czech Rep. — [3]Dept. Met. Corr. Eng., Uni. Chem. Technol. Prague, Czech Rep.

We applied quantum-mechanical calculations to investigate tin's thermodynamic and dynamic stability in its various allotropic forms. Focusing specifically on the *a*-Sn, our results showed a negative thermal expansion within the temperature range from T = 0 K to T = 45 K. No similar phenomenon appears in spectra of other allotropic modifications of tin. That means that the origin of this behaviour is connected to the diamond structure of alpha tin. We investigated the behaviour of the Grüneisen constant of *a*-tin in reciprocal space to explain the causes of this phenomenon. There are interesting temperature-dependent contributions of individual phonon modes from different k-points in the reciprocal space. In particular, these contributions are negative at all studied temperatures for the k-points around k-point X (0, 0, 0.5) and positive around k-point Γ (0, 0, 0). Negative thermal expansion of *a*-Sn at low temperatures is thus related to the behaviour of phonons around k-points X, M and N.

MM 34.5 Fri 11:15 H10

Bayesian Uncertainty Estimates for Spin-Component-Scaled Second-Order Møller-Plesset Perturbation Theory — •Elisabeth Keller and Johannes Margraf — Universität Bayreuth, Bayreuth, Germany

Spin-component-scaled second-order Møller-Plesset perturbation theory (SCS-MP2) improves upon MP2 by separately scaling the same-spin and opposite-spin MP2 contributions, achieving near coupled cluster (CCSD(T)) accuracy in some applications. However, the optimal scaling parameters vary by target domain, limiting the transferability of any given SCS-MP2 parameterization. To address this limitation, we employ a Bayesian multilevel linear regression model to obtain a robust parameterization for SCS-MP2, termed BSCS-MP2, predicting various energetic properties, including total, atomization, reaction, and non-covalent interaction energies. Additionally, the Bayesian model provides credible intervals to quantify the uncertainty of the BSCS-MP2 energy predictions. We evaluate how these uncertainty estimates adjust to data quality and model complexity, and assess their robustness for out-of-sample inference.

pyTTN, an open source toolbox for Quantum Dynamics simulations using Tree Tensor Network states — Lachlan Lindoy, •Daniel Rodrigo-Albert, Yannic Rath, and Ivan Rungger — National Physical Laboratory, Teddington, TW11 0LW, United Kingdom

The simulation of large-scale dissipative quantum systems is a significant challenge arising in several areas of physics and chemistry. In this talk we will discuss pyTTN, our recently developed software package for simulating dynamical properties of open quantum systems. This package makes use of Tree Tensor Network (or equivalently, Multi-Layer Multi-Configuration Time-Dependent Hartree) based representations of the state vector, and features both single- and multi-set ansätze, as well as adaptive bond dimension through subspace expansion techniques. The software has been designed with a focus on performance and ease of setup of new models and wavefunction topologies, including simple preparation of zero- and finite-temperature calculations with general bosonic, fermionic, and spin Hamiltonians. We will demonstrate the capabilities of the package with both unitary dynamics and non-unitary pseudomode-based approaches for the simulation of Anderson impurity models.

MM 34.7 Fri 12:00 H10

Spectral properties from an efficient analytical representation of the GW self-energy within a multipole approximation — •Dario Alejandro Leon[1], Kristian Berland[1], and Claudia Cardoso[2] — [1]Norwegian University of Life Sciences, As, Norway — [2]S3 Centre, Istituto Nanoscienze, CNR, Modena, Italy

We propose an efficient analytical representation of the frequency-dependent GW self-energy via a multipole approximation (MPA-Σ). Similar to the earlier developed multipole approach for the screening interaction W (MPA-W) [Phys. Rev. B 104, 115157 (2021)], the multipole-Padé model for the self-energy is interpolated from a small set of values evaluated numerically in the complex frequency plane. As for MPA-W , we show that an appropriate choice of the frequency sampling is paramount to guarantee computational efficiency and high level of accuracy in the description of the self-energy. Crucially, MPA-Σ enables a multipole representation for the interacting Green's function G (MPA-G), providing straightforward evaluation of all the spectral properties. Combining the MPA-W and MPA-Σ schemes considerably reduces the cost of full-frequency self-energy calculations, especially when targeting spectral band structures in a wide energy range. We validate the MPA-Σ approach in bulk Si, Na and Cu, monolayer MoS2, the NaCl ion-pair and the F2 molecule, as prototypical semiconducting and metallic materials of different dimensionality. Moreover, toy MPA-Σ models with one and two poles and their corresponding MPA-G solutions, are used to examine the quasiparticle picture in different situations.

MM 35: Transport in Materials: Diffusion, Charge or Heat Conduction

Diffusion

Time: Friday 10:15–11:45 Location: H22

MM 35.1 Fri 10:15 H22

Influence of second phase precipitation on bulk diffusion of Ni in the CoFeMnNiV high-entropy alloy — •Aditya Burla[1], Mohan Muralikrishna Garlapati[1], Aditya Srinivasan Tirunilai[2], Guillaume Laplanche[2], Gerhard Wilde[1], and Sergiy V Divinski[1] — [1]Institut für Materialphysik, Universität Münster, 48149 Münster, Germany — [2]Institut für Werkstoffe, Ruhr-Universität Bochum, 44780 Bochum, Germany

High-entropy alloys (HEAs), or multi-principal element alloys represent a new class of metallic materials that offer tremendous opportunities for advancing materials science due to their vast compositional space and exceptional properties. While tracer diffusion and sigma phase precipitation kinetics in the Co-Cr-Fe-Mn-Ni system have been widely studied, the interaction between the two has received limited attention. The present work focuses on an equiatomic CoFeMnNiV HEA, in which Vanadium is known to have a strong tendency to stabilize the sigma phase. Therefore, this element promotes its precipitation in the CoFeMnNiV alloy, particularly at temperatures below ~1080°C, even after short anneal times of just 1 h in the fully recrystallized state. In this study, bulk diffusion of Ni is investigated using the radiotracer technique. A strong impact of sigma phase precipitation on the self-diffusion kinetics was discovered and analyzed. The obtained tracer diffusivities follow an Arrhenius-type relationship when estimated in the stable microstructures, whereas concurrent precipitation enhances the tracer diffusion rates.

MM 35.2 Fri 10:30 H22

Investigation of lateral hydrogen diffusion in polycrystalline molybdenum trioxide thin films — •Tim K. Hecker, Martin Becker, and Peter J. Klar — Institute of Experimental Physics I and Center for Materials Research, Justus Liebig University Giessen, Giessen, Germany

Molybdenum trioxide thin films were prepared by RF sputter deposition exploring a wide range of growth parameters. To characterise the thin films, electrochemical, Raman, and XRD experiments were conducted. In order to gain a deeper understanding of the diffusion of hydrogen in these thin films, the samples were microstructured with a PMMA film in a way that restricts the contact surface with the electrolyte to a narrow stripe-like gap. This enables the lateral diffusion of hydrogen beneath the PMMA film to be studied using a transmission experiment, making use of the electrochromic properties of molybdenum trioxide. This increases the accessible spatial and temporal scale by several orders of magnitude, significantly improving the spatial and temporal resolution of the in-situ transmission measurement. Spatially resolved transmission measurements in the wavelength range of 633±55 nm demonstrate that the investigated diffusion is dependent on the hydrogen concentration. The results are also supported by a spatially and temporally resolved diffusion simulation. Furthermore, the measurement method presented here is universally applicable to electrochromic thin film samples.

MM 35.3 Fri 10:45 H22

Diffusion and activation energies of hydrogen and its isotopes in boron structure — •Bianca Solomonea[1,2], Calin Pantis-Simut[2,3], Mihaela Cosinschi[2,3], Paul Dinca[1], Corneliu Porosnicu[1], and George Nemnes[2,3] — [1]National Institute for Laser, Plasma and Radiation Physics (INFLPR), Atomiştilor Street 409, 077125 Măgurele, Ilfov, Romania — [2]Faculty of Physics, Univer- sity of Bucharest, Atomistilor 405, Magurele-Ilfov 077125, Romania — [3]Horia Hulubei National Institute for Physics and Nuclear Engineer- ing, Reactorului 30, Magurele-Ilfov 077125, Romania

The retention and release of hydrogen isotopes in plasma-facing materials (PFM) is a critical concern for the ITER project. The decision to construct the Tokamak reactor as a fully tungsten-based machine presents challenges regarding plasma ignition and stability, particularly due to impurities in the working gases. Boronization is applied to retain impurities by forming covalent bonds with oxygen and nitrogen. This study uses ab initio calculations via Density Functional Theory (DFT), molecular dynamics (MD), and the nudged elastic band (NEB) method in the SIESTA code to examine boron structures in crystalline and amorphous forms. Activation energies for trapping, detrapping, and diffusion processes are determined. Given the difficulty of defining hydrogen-isotope diffusion in boron structures, and its importance for retention and desorption in redeposited or co-deposited layers of the PFM, we focus on identifying the potential diffusion trajectories of hydrogen within the boron structure. This includes mapping a potential landscape and locating local minima and saddle points.

MM 35.4 Fri 11:00 H22

Diffusion behavior of Li ions in crystalline and amorphous Li-Zr-O and Li-Nb-O phases — •Daniel Mutter[1], Diego A. Pantano[2], Christian Elsässer[1], and Daniel F. Urban[1] — [1]Fraunhofer IWM, Wöhlerstraße 11, 79108 Freiburg, Germany — [2]TotalEnergies OneTech, 2 place Jean Millier, 92400 Courbevoie, France

Li containing transition metal oxides are known as good ionic conductors. Performing classical molecular dynamics simulations with a Morse potential model based on the Bond Valence method, the diffusion behavior of Li ions is investigated in crystalline and amorphous phases with the stoichiometries Li_2ZrO_3 and $LiNbO_3$. The diffusivities are obtained from a statistical Arrhenius analysis of mean square displacement curves at different temperatures. The crystalline phase of Li_2ZrO_3 exhibits two well-defined migration mechanisms: vacancy-mediated migration is dominant below and a collective site exchange of Li ions above a crossover region between about 1700 and 1800 K. The latter mechanism, which is related to the formation of Frenkel pair defects and subsequent rotation of Li-Li pairs, also prevails in the amorphous phases with a strongly reduced activation energy. This is explained by a smaller equilibrium separation of Li ions in the amorphous phase than in the crystal structure. The demonstrated methodology and the discussed results shed light on a hitherto rarely described diffusion mechanism in ionic metal-oxide materials relevant for ion-battery applications.

MM 35.5 Fri 11:15 H22

Ag bulk and grain boundary diffusion in AlCoCrFeNi2.1 compositionally complex alloy — •Heng Zhang, Mohan Muralikrishna Garlapati, Sergiy V Divinski, and Gerhard Wilde — Institute of Materials Physics, University of Munster, Wilhelm-Klemm-Str. 10

Bulk and grain boundary diffusion of Ag in a eutectic Al-Co-Cr-Fe-Ni multi-principal element system is measured using the radiotracer technique and applying the 110Ag radioisotope. An equilibrium microstructure was produced by rotary forging and annealing of cast and homogenized initial casting ingot material. Ag diffusion is measured in the temperature interval from 673K to 1373K accounting for volume (at high temperatures) and short-circuit (at moderate and low temperatures) diffusion contributions. In the present case, interphase boundaries can potentially contribute in addition to grain boundaries to the short-circuit diffusion. The grain- and interphase-boundary diffusion experiments were performed in the B-type kinetic regime based on Harrison's classification. The results are analyzed with respect to constituent phases (FCC and B2) and different interface types. The contribution of interphase boundary diffusion is analyzed in detail.

MM 35.6 Fri 11:30 H22

Mechano-chemical coupling induced by Co grain boundary diffusion in SIGMA5(310) Cu bicrystals — •Esakkiraja Neelamegan[1], Anoosheh Akbari[1], Hui Ding[2], Harald Rösner[1], Daniel Gaertner[1], Christian Liebscher[2,3], Gerhard Wilde[1], and Sergiy Divinski[1] — [1]Institute of Materials Physics, University of Münster, Münster-48149 Germany — [2]Max-Planck-Institut für Sustainable Materials, Düsseldorf, Germany — [3]Faculty of Physics and Astronomy, Ruhr University Bochum, Bochum, Germany

Grain boundary diffusion of 57Co in pure copper SIGMA-5(310)[001] bicrystals is investigated using the radiotracer technique. Experiments are conducted under both the type-B and type-C kinetics regimes, as classified by Harrison. By varying the amount of applied 57Co tracer solution, characteristic changes in

the shape of the penetration profiles are observed and attributed to Co segregation induced changes of the grain boundary structure. The structural changes due to the Co addition are examined by scanning transmission electron microscopy. The elastic strains near the grain boundary are measured using nano-beam diffractions with a nanometer resolution. The Co-induced variations of the GB structure provide an intriguing picture, particularly when considering their influence on the diffusion behaviour in the presence of deliberately introduced solute atoms.

MM 36: Mechanical Properties

Nanomaterials and Alloys

Time: Friday 10:15–13:00 Location: H23

MM 36.1 Fri 10:15 H23

STEM investigation of early precipitation reactions in Al-Cu alloys — •Johannes Berlin and Ferdinand Haider — Chair for Experimental Physics I, University of Augsburg, Universitätsstraße 1, 86159 Augsbur

Due to their excellent strength-to-weight ratio, heat-treatable Al-Cu alloys have been widely used since their invention. Although the occurring precipitates in naturally aging aluminium alloys are well known, the very early stages of formation mechanisms still are a topic of ongoing research. Scanning transmission electron microscopy is used to investigate the influence of different parameters, such as thermal history and effects of microalloying, on early-stage precipitate formation and transformation in Al. Due to their strong binding potential to quenched in vacancies even a few hundred ppm of trace elements such as tin and indium can alter the natural aging process drastically. Even after prolonged natural ageing, a slight increase in temperature can lead to drastic changes in precipitation size and densitiy inthese materials. This proves a long-lasting supersaturation of the material with vacancies. Additionally, these results are compared to the measurements of hardness, DSC and electrical resistance.

MM 36.2 Fri 10:30 H23

Surface structure and reactivity of Aluminium alloys studied by DFT — •Zhengqing Wei[1], Inna V. Plyushchay[2], Nebahat Bulut[1], Florian Lehmann[3], Maik Gude[3], Julia Hufenbach[4,5], and Sibylle Gemming[1,6] — [1]Inst. Physics, TU Chemnitz, Germany — [2]Natl. Taras Shevchenko University of Kyiv, Ukraine — [3]ILK, TU Dresden, Germany — [4]IFW Dresden, Germany — [5]Inst. Materials Science, TU-BA Freiberg, Germany — [6]MAIN Center, TU Chemnitz, Germany.

Classically, the mechanical properties of alloys are attributed to the action of stress fields around defect sites and to their combined influence on the overall elastic moduli. The present study employs first-principles modeling to include also changes of the electronic structure and investigate the bonding, stability, and reactivity changes around impurities in the bulk and at surfaces. We focus on Al alloys with low amounts of substitutional Mg, Zr, and Si atoms. The results indicate that the electron density changes mostly within the first coordination sphere around the impurity, the bond lengths vary locally within few percent, and there exists a thermodynamic driving force for most elements to diffuse to or near surfaces or interfaces. Stable 2D surface alloy compositions in part differ from the bulk phase and exhibit an element-specific reactivity with air and polymer coatings. Modeling the adsorption of oxygen, nitrogen and the PEEK polymer from first principles gives access to modified local potentials for the classical modeling of large-scale surface and interface areas (tu-dresden.de/ing/forschung/Graduiertenkollegs/grk2868#intro).

MM 36.3 Fri 10:45 H23

Active learning-based interatomic potential for investigating mechanical properties of Al-Mg-Zr alloys — •Lukas Volkmer, Leonardo M. Sandonas, Gianaurelio Cuniberti, and Markus Kästner — TU Dresden

The unique properties of aluminum-based alloys, such as low density, high specific strength, and excellent resistance to oxidation and corrosion, enable the design of advanced metamaterials. In this work, we theoretically investigate the effect of alloying aluminum with magnesium and zirconium on its thermodynamic and mechanical properties. Since exploring the vast chemical compound space of these alloys through Density Functional Theory (DFT) calculations is computationally prohibitive, we developed a scalable and transferable machine learning interatomic potential (MLIP) capable of accurately calculating diverse properties of Al-Mg-Zr alloys. The MLIP was trained using an active learning technique based on ab initio molecular dynamics simulations, Bayesian statistics, and kernel ridge regression. This methodology ensures that the MLIP captures the effects of alloying concentration and atomic configurations up to the solubility limit, providing access to highly accurate physicochemical properties of a wide range of Al-based alloys at a reasonable computational cost. We expect this approach to enable efficient phase space exploration, offering a robust tool for designing advanced Al-based alloys with optimized properties.

MM 36.4 Fri 11:00 H23

Phase identification by Raman Spectroscopy on pre-oxidized AISI 316L-MgO composite produced by Spark Plasma Sintering — •Julia Richter[1], Mahnaz Mehdizadehlima[2], Cameliu Himcinschi[1], and Jens Kortus[1] — [1]TU Bergakademie Freiberg, Institut für Theoretische Physik, Leipziger Straße 23, D-09599 Freiberg — [2]TU Bergakademie Freiberg, Institut für Werkstoffwissenschaft, Gustav-Zeuner-Straße 5, D-09599 Freiberg

Re-usage, recycling and upcycling of MgO-C refractories as they are widely used in the steel industry are crucial for resource efficiency. Our upcycling concept is aimed at steel-MgO composite anodes for application in the extraction of aluminum by fused-salt electrolysis. The composite anode material is produced by Spark Plasma Sintering based on 60 vol.% AISI 316L steel powder and 40 vol.% MgO. In this stage of development, the raw material is fused fresh MgO instead of recyclate as a proof of concept. Pre-oxidation treatment of the developed composite is intended to enhance the material's corrosion resistance in the aggressive environment of molten cryolite during application. In order to gain a better understanding of the oxidation behavior at different temperatures, phase identification is required. For this purpose, Raman spectroscopy as a sensitive, non-destructive, non-contact method is employed complementary to other investigative techniques; e.g., Scanning Electron Microscopy.

MM 36.5 Fri 11:15 H23

Atomic Cluster Expansion for Ag-Au-Pd alloys — •Yanyan Liang, Matous Mrovec, Yury Lysoroskiy, and Ralf Drautz — ICAMS, Ruhr-Universität Bochum, Germay

Ternary alloys of Ag-Au-Pd are of technological importance in catalysis and electrical applications. However, the system lacks reliable and efficient interatomic potentials capable of accurately describing structural and thermodynamic properties, particularly for investigating complex segregation and ordering phenomena in bulk systems and nanoclusters. In this work, we present an atomic cluster expansion (ACE) model parameterized for the Ag-Au-Pd system with quantum-level accuracy. We demonstrate that the ACE model provides an accurate description of fundamental properties, including structural stability and thermodynamics, not only for the elemental metals but also for their binary and ternary compounds. Furthermore, we highlight the wide applicability of the ACE model for large-scale atomistic simulations, enabling predictive modeling of complex phenomena.

MM 36.6 Fri 11:45 H23

Scalable fabrication and mechanical behavior of hierarchical nanoscale network nickel — •Ulrike Dette[1,2], Lukas Lührs[2], and Shan Shi[1,3] — [1]Research Group of Integrated Metallic Nanomaterials Systems, Hamburg University of Technology, 21073 Hamburg, Germany — [2]Institute of Materials Physics and Technology, Hamburg University of Technology, 21073 Hamburg, Germany — [3]Institute of Hydrogen Technology, Helmholtz-Zentrum Hereon, 21502 Geesthacht, Germany

The recent fabrication of mechanically robust two-level hierarchical nanoporous gold by two-step electrochemical dealloying has enabled the demonstration of enhanced mechanical properties and reduced density attributed to the structural hierarchy in the nanoscale network materials. This work aims to develop a new method for the scalable fabrication of low-cost hierarchical nanoscale network metals. Here, two- and three-level hierarchical network (HN) Ni samples are successfully prepared from Ni foams by a novel and simple alloying-dealloying method. Bulk three-level HN Ni samples are characterized by three well-defined strut/ligament sizes (160 μm, <10 μm and <10 nm) and a low density down to 0.06. In addition, we systematically perform mechanical studies on both two- and three-level HN Ni via macroscopic compression tests. We propose general scaling equations between mechanical properties and relative density for HN materials.

MM 36.7 Fri 12:00 H23

Transferable machine learning interatomic potential for Au nanoparticles — •Jovana Vlahović, Cem Sevik, and Milorad V. Milošević — University of Antwerp, Groenenborgerlaan 171, Antwerp, Belgium

Effective molecular dynamics and Monte Carlo simulations fundamentally depend on the accuracy of interatomic potentials, which define the potential energy surface as a function of atomic positions. This precision is essential for metallic nanoparticles (NPs), whose small size and diverse morphologies demand robust modelling. While classical empirical potentials offer computational efficiency,

they often lack the necessary accuracy and density functional theory (DFT) calculations, though highly accurate, are computationally prohibitive for NPs with thousands of atoms. This work introduces a machine learning-based interatomic potential for Au NPs, trained on a compact dataset of bulk structures, surface slabs and NPs containing up to 55 atoms. Our training dataset includes a diverse set of atomic configurations with corresponding properties obtained from ab initio molecular dynamics calculations, which we use to train a Gaussian Approximation Potential (GAP) via Gaussian Process Regression. Parameter optimization was performed to maximize model accuracy, and LAMMPS validation tests demonstrated GAP performance against DFT benchmarks. In addition, transferability tests on larger NPs of various shapes reveal our GAP's robustness beyond the training set. Comparisons with an existing GAP model and the universal MACE potential underscore our model's improved accuracy and generalizability for Au NPs.

MM 36.8 Fri 12:15 H23

Scaling behavior of Poisson's ratio in hierarchical nanoporous materials — •Haonan Sun[1,2], Lukas Lührs[2], Wei-che Chang[3], and Shan Shi[1,3] — [1]Research Group of Integrated Metallic Nanomaterials Systems, Hamburg University of Technology, 21073 Hamburg, Germany — [2]Institute of Materials Physics and Technology, Hamburg University of Technology, 21073 Hamburg, Germany — [3]Institute of Hydrogen Technology, Helmholtz-Zentrum Hereon, 21502 Geesthacht, Germany

The recent fabrication of crack-free monolithic hierarchical nested network nanoporous gold allows the investigation of the benefits of hierarchy in the aspect of mechanical properties at the nanoscale. It has been demonstrated that hierarchical nanoporous gold (HNPG) can achieve a substantially reduced solid fraction and enhanced specific stiffness and strength compared with non-hierarchical nanoporous gold. However, the role of hierarchical structure on Poisson's ratio has not been investigated yet. In this work, mm-sized HNPG samples are made out of an Ag93Au7 master alloy by a dealloying-coarsening-dealloying method. We then explore the elastic and plastic Poisson*s ratios of HNPG by using digital image correlation during compression tests. Remarkably, a scaling law of the elastic Poisson's ratio in hierarchical nanoporous materials with respect to the solid volume fraction is proposed and excellently supported by our experiments. This work enriches the understanding on the relationship between mechanical properties and microstructure in hierarchical network materials at the nanometer scale.

MM 36.9 Fri 12:30 H23

Frenkel pair energetics in disordered solid solutions and implications for alkali feldspar diffusivity — •Alexander Gorfer, Rainer Abart, and Christoph Dellago — University of Vienna, Vienna, Austria

Predicting defect concentrations from the density of states (DOS) of formation energies in disordered materials has recently been formulated for vacancies in high entropy alloys. That methodology however does not translate to disordered ionic crystals as charged defects need to be paired up to ensure charge neutrality. Here, we present a general expression to predict the defect concentrations of Frenkel pairs in disordered ionic crystals out of the DOS of formation energies of both positively and negatively charged defects. To demonstrate its applicability we use a recently developed machine learning force field to calculate the DOS of formation energies for different states of (dis)ordering in alkali feldspar (Na, K)$AlSi_3O_8$, an abundant mineral in the Earth's crust. Applying our expression to these DOS reveals a significant increase in the concentration of point defects in disordered ionic crystals as pairs of low formation energy defect states between the positively and negatively charged DOS can be identified. Implications for the diffusivity that controls the exsolution of alkali feldspars which is an important phenomenon in the formation of magmatic and metamorphic rocks are discussed.

MM 36.10 Fri 12:45 H23

Ferromagnetism at ambient temperature in Cantor and nanocomposite high-entropy alloys induced by severe plastic deformation — •Shabnam Taheriniya, Harald Rösner, and Gerhard Wilde — Universität Münster, Institut für Materialphysik, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany

In this study, single phase Cantor (CoCrFeMnNi) and nanocomposite high-entropy alloys (HEAs) (CoCrFeMnNi and HfNbTaTiZr) were processed using high-pressure torsion (HPT), subjecting the samples to a constant pressure of 9 GPa either as a single disk or stacked disks, with the top anvil rotating at 1 rpm at ambient temperature for up to 15 revolutions. Vibrating sample magnetometry (VSM) confirmed that HPT processing induces the development of ferromagnetic properties. The distribution and orientation of magnetic domains post-deformation were examined in detail using differential phase contrast scanning transmission electron microscopy (DPC STEM), analytical TEM and atom probe tomography (APT) analysis. Our study demonstrates that HPT processing of HEAs induces a transition from paramagnetic to ferromagnetic states at ambient conditions. This deformation-induced ferromagnetism can be explained by the cocktail effect in HEAs, where the formation of ferromagnetic particles is linked to deformation-induced element-selective atomic migration and local enrichment of ferromagnetic elements.

MM 37: Functional and Complex Materials

Time: Friday 12:00–12:45 Location: H22

MM 37.1 Fri 12:00 H22

Unveiling Material Dynamics with Machine-Learned Interatomic Potentials — •Ferenc Tasnadi, Bobur Mukhamedov, Amanda Ehn, Florian Trybel, and Igor A. Abrikosov — IFM Linköping University

Machine-learned interatomic potentials (MLIPs) have revolutionized our ability to understand the properties of materials with complex dynamical processes. In this work, we present an active learning MLIP strategy to: (i) investigate the elasticity of alloys near dynamical instability [1] and (ii) explore dynamical bond disorder in high-pressure synthesized PN2 [2]. bcc-Ti-based alloys have wide industrial applicability, ranging from low-modulus biomedical implants to high-strength GUM metals. The low-temperature dynamical instability of bcc-Ti can be tailored through the addition of bcc stabilizers (Nb, Ta, Zr, V), resulting in anomalous mechanical properties such as elinvar behavior or high anisotropy with low modulus in Ti-Nb-Zr and Ti-Zr-Sn alloys. Pnictogen compounds (Group 15 elements) exhibit fascinating chemistry due to the variety of bonding configurations, as demonstrated in the recently studied P-N system [2]. Long-timescale MLIP-driven simulations reveal that N-N distances connecting the P-N octahedra vary dynamically between single-bonded and non-bonding configurations. The results are compared with experimental observations. If time permits, we will demonstrate how MLIP-driven molecular dynamics simulations can offer deeper insights into materials exhibiting Peierls instability. [1] New J. Phys. 22 113005 (2020); J. Vac. Sci. Technol. A 42, 013412 (2024). [2] Chem. Eur. J. 2022, 28, e202201998.

MM 37.2 Fri 12:15 H22

Decoding Molecular Ion Dissociation Effects in Atom Probe Tomography of Iron Oxides — •Shyam Katnagallu[1], SeHo Kim[1], Shalini Bhatt[1], Daniel K Schreiber[2], Jörg Neugebauer[1], Baptiste Gault[1], and Christoph Freysoldt[1] — [1]Max Planck Institute for Sustainable Materials, Düsseldorf, Germany — [2]Energy and Environment Directorate, PNNL, Richland, USA.

To mitigate CO2 emissions, we require efficient carbon-free reduction processes for iron ores. Atom probe tomography (APT) can elucidate the gradual reduction of FexO at the nanometer length scale, but it is hindered by compositional bias. We investigated the changes in the measured composition of FeO, Fe2O3, and Fe3O4 across a range of analysis conditions. However, APT of ionic or covalently bonded materials often results in molecular ions. The metastability of these molecular ions, under an intense electrostatic field, makes them vulnerable to dissociation. These processes can significantly impact the analytical performance of APT. For instance, neutral molecules formed through dissociation may not be detected or may have a time-of-flight no longer associated with their actual mass, leading to their loss from the analysis. To predict possible dissociation reactions of molecular ions, we employed density-functional theory that considered the spin states of the molecules. The energetically favoured reactions were traced onto multi-hit correlation histograms to validate their existence within APT data. These detected reactions were carefully analysed to assess the impact of neutrals resulting from dissociation reactions on the performance of APT for analysing iron oxides.

MM 37.3 Fri 12:30 H22

Entropy Decoupling in Vacancy Formation of BCC High-Entropy Alloys — •Xiang Xu, Xi Zhang, and Blazej Grabowski — University of Stuttgart, Stuttgart, Germany

The temperature-dependent vacancy formation energies in MoTaNbW systems have been calculated using a machine-learning-based interatomic potential that accurately captures the simultaneous effects of configurational and vibrational entropies, along with their coupling. Our results indicate that at elevated temperatures, careful treatment of the chemical potential is essential. We computed the distributions of vacancy formation energies up to the melting point, explicitly accounting for anharmonic vibrational effects. The findings demonstrate that, in this system, the local atomic environment around a vacancy exerts minimal influence on the vibrational entropy contributions.

O 15.2	Mon	15:30–16:00	H24	**Electron delocalization in a 2D Mott insulator** — •Amadeo L. Vazquez de Parga, Cosme G. Ayani, Michele Pisarra, Iván M. Ibarburu, Clara Rebanal, Manuela Garnica, Fabián Calleja, Fernando Martín
O 15.3	Mon	16:00–16:30	H24	**Kondo or no Kondo, that is the question** — •Alexander Weismann, Neda Noei, Niklas Ide, Richard Berndt
O 15.4	Mon	16:30–17:00	H24	**Evidence for spinarons in Co atoms on noble metal (111) surfaces** — •Artem Odobesko
O 15.5	Mon	17:00–17:30	H24	**Spinarons: A new view on emerging spin-driven many-body phenomena in nanostructures** — •Samir Lounis
O 26.1	Tue	10:30–11:00	H2	**Attosecond Electron Microscopy** — •Peter Baum
O 27.7	Tue	12:00–12:30	H4	**Ultrafast electrochemistry beyond the RC time constant** — •Yujin Tong
O 30.5	Tue	11:30–12:00	H11	**Resonant molecular transitions in femtosecond second harmonic generation spectroscopy of Fe-porphyrin/Cu(001)** — •Andrea Eschenlohr, Rui Shi, Jinghao Chen, Ping Zhou, Uwe Bovensiepen, Wolfgang Hübner, Georg Lefkidis
O 31.3	Tue	11:00–11:30	H24	**Single molecule machines on surface** — •Francesca Moresco
O 57.3	Wed	11:00–11:30	H2	**Floquet engineering in black phosphorus** — •Changhua Bao, Shaohua Zhou, Benshu Fan, Michael Schüler, Teng Xiao, Hui Zhou, Zhiyuan Sun, Peizhe Tang, Sheng Meng, Wenhui Duan, Shuyun Zhou
O 61.3	Wed	11:00–11:30	H11	**Polaritons in two-dimensional materials and hybrids probed by electron beams** — •Nahid Talebi
O 62.5	Wed	11:30–12:00	H24	**On-Surface Synthesis with Hydrogen Atoms** — •Szymon Godlewski
O 64.1	Wed	15:00–15:30	H2	**Topological spin structures in two-dimensional van der Waals magnets and heterostructures** — •Stefan Heinze
O 64.2	Wed	15:30–16:00	H2	**Ferromagnetic Order in 2D Layers of Transition Metal Dichlorides** — Andrea Aguirre, Andres Pinar, Diego Soler, Carmen Gonzalez-Orellana, Jon Ortuzar, Oleksandr Stesovych, Celia Rogero, Jose Ignacio Pascual, Pavel Jelinek, Maxim Ilyn, •Martina Corso
O 64.3	Wed	16:00–16:30	H2	**Tailoring spin lattice in van der Waals monolayer crystals** — •Ying-Shuang Fu
O 64.4	Wed	16:30–17:00	H2	**Spin excitations in 2D heterostructures from realistic fermionic models** — •António Costa

O 66.1	Wed	15:00–15:30	H8	**Unveiling the crucial role of kinetic modeling of gas flows in vacuum and fusion technologies** — •Christos Tantos, Thomas Giegerich
O 66.2	Wed	15:30–16:00	H8	**Advances in traceable vacuum and outgassing rate measurements** — •Matthias Bernien, Annas Bin Ali, Thomas Bock, Tom Rubin, Janez Setina, Perrin Waldock, Kirk Madison, Karl Jousten
O 68.9	Wed	17:00–17:30	H24	**On-Surface Synthesis of Porphyrins and BN-Substituted Carbon Scaffolds** — •Willi Auwärter
O 91.1	Thu	15:00–15:30	H24	**Infrared Nanoscopy and Tomography of Intracellular Structures** — Joachim Heberle, Katerina Kanevche, •Emmanuel Pfitzner, David Burr, Janina Drauschke, Andreas Elsaesser, Jacek Kozuch
O 91.2	Thu	15:30–16:00	H24	**Coherent Raman Imaging** — •Michael Schmitt, Juergen Popp
O 91.3	Thu	16:00–16:30	H24	**Sum Frequency Generation Microscopy of Electrochemical Interfaces** — •Steven Baldelli
O 100.1	Fri	10:30–11:00	H24	**Multidimensional Super-resolution Imaging: Wasting Light to Learn New Things** — •Steven Lee
O 100.2	Fri	11:00–11:30	H24	**MALDI mass spectrometry imaging: application examples ranging from food analysis to pharmaceutical research** — •Andreas Römpp

Invited Talks of the joint SKM Dissertationspreis 2025 (SYSD)

See SYSD for the full program of the symposium.

SYSD 1.1	Mon	9:30–10:00	H2	**Nanoscale Chemical Analysis of Ferroic Materials and Phenomena** — •Kasper Aas Hunnestad
SYSD 1.2	Mon	10:00–10:30	H2	**Advanced Excitation Schemes for Semiconductor Quantum Dots** — •Yusuf Karli
SYSD 1.3	Mon	10:30–11:00	H2	**Aspects and Probes of Strongly Correlated Electrons in Two-Dimensional Semiconductors** — •Clemens Kuhlenkamp
SYSD 1.4	Mon	11:00–11:30	H2	**Mean back relaxation and mechanical fingerprints: simplifying the study of active intracellular mechanics** — •Till Münker
SYSD 1.5	Mon	11:30–12:00	H2	**Coherent Dynamics of Atomic Spins on a Surface** — •Lukas Veldman

Invited Talks of the joint Symposium AI-driven Materials Design: Recent Developments, Challenges and Perspectives (SYMD)

See SYMD for the full program of the symposium.

SYMD 1.1	Mon	15:00–15:30	H1	**Learning physically constrained microscopic interaction models of functional materials** — •Boris Kozinsky
SYMD 1.2	Mon	15:30–16:00	H1	**GRACE universal interatomic potential for materials discovery and design** — •Ralf Drautz
SYMD 1.3	Mon	16:00–16:30	H1	**Multiscale Modelling & Machine Learning Algorithms for Catalyst Materials: Insights from the Oxygen Evolution Reaction** — •Nong Artrith
SYMD 1.4	Mon	16:45–17:15	H1	**Inverse Design of Materials** — •Hongbin Zhang
SYMD 1.5	Mon	17:15–17:45	H1	**Data-Driven Materials Science** — •Miguel Marques

Invited Talks of the joint Symposium Progress and Challenges in Modelling Electron-Phonon Interaction in Solids (SYIS)

See SYIS for the full program of the symposium.

SYIS 1.1	Tue	9:30–10:00	H1	**Electron-phonon and exciton-phonon coupling in advanced materials** — •Claudia Draxl
SYIS 1.2	Tue	10:00–10:30	H1	**Exciton-phonon dynamics from first principles** — •Enrico Perfetto
SYIS 1.3	Tue	10:30–11:00	H1	**Polarons and exciton polarons from first principles** — •Feliciano Giustino
SYIS 1.4	Tue	11:15–11:45	H1	**Wannier-Function-Based First-principle Approach to Coupled Exciton-Phonon-Photon Dynamics in Two-Dimensional Semiconductors** — •Alexander Steinhoff, Matthias Florian, Frank Jahnke
SYIS 1.5	Tue	11:45–12:15	H1	**Phonon influence on (cooperative) photon emission from quantum dots** — •Erik Gauger, Julian Wiercinski, Moritz Cygorek

Invited Talks of the joint Symposium Pushing the Boundaries of Fair Data Practices for Condensed Matter Insights: From Workflows to Machine Learning (SYFD)

See SYFD for the full program of the symposium.

SYFD 1.1	Wed	9:30–10:00	H1	**Pushing the Boundaries of Fair Data Practices for Condensed Matter Insight** — •Astrid Schneidwind
SYFD 1.2	Wed	10:00–10:30	H1	**Establishing Workflows of Experimental Solar Cell Data into NOMAD** — Edgar Nandayapa, Paolo Graniero, Jose Marquez, Michael Götte, •Eva Unger
SYFD 1.3	Wed	10:30–11:00	H1	**Building up the EOSC Federation** — •Ute Gunsenheimer
SYFD 1.4	Wed	11:15–11:45	H1	**Data-Driven Materials Science for Energy-Sustainable Applications** — •Jacqueline Cole
SYFD 1.5	Wed	11:45–12:15	H1	**Machine Learning and FAIR Data in X-ray Surface Science** — •Stefan Kowarik

Invited Talks of the joint Symposium Spins in Molecular Systems: Strategies and Effects of Hyperpolarization (SYMS)

See SYMS for the full program of the symposium.

SYMS 1.1	Wed	15:00–15:30	H1	**Exploring the Non-Perturbative Magnetic Resonance Drive Regime with spin selection rules in a π-Conjugated Polymer** — •Christoph Boehme
SYMS 1.2	Wed	15:30–16:00	H1	**The puzzle of spin and charge transport in the chirality induced spin selectivity effect** — •Bart van Wees
SYMS 1.3	Wed	16:00–16:30	H1	**Nano- and Microscale NMR spectroscopy with spin qubits in diamond** — •Nabeel Aslam
SYMS 1.4	Wed	16:45–17:15	H1	**Spin effects in adsorbed organometallic complexes** — •Richard Berndt
SYMS 1.5	Wed	17:15–17:45	H1	**Quantum Computing with Molecules** — •Mario Ruben

Invited Talks of the joint Symposium Electronic Structure Theory for Quantum Technology: From Complex Magnetism to Topological Superconductors and Spintronics (SYES)

See SYES for the full program of the symposium.

SYES 1.1	Fri	9:30–10:00	H1	**Ab-initio Design of superconductors** — •Lilia Boeri
SYES 1.2	Fri	10:00–10:30	H1	**Topological superconductivity from first principles** — Bendegúz Nyári, András Lászlóffy, Levente Rózsa, Gábor Csire, Balázs Újfalussy, •László Szunyogh
SYES 1.3	Fri	10:30–11:00	H1	**First-principles study and mesoscopic modeling of two-dimensional spin and orbital fluctuations in FeSe** — •Myrta Grüning, Abyay Ghosh, Piotr Chudzinski
SYES 1.4	Fri	11:15–11:45	H1	**Non-collinear magnetism in 2D materials from first principles: Multiferroic order and magnetoelectric effects.** — •Thomas Olsen
SYES 1.5	Fri	11:45–12:15	H1	**Spin-phonon and magnon-phonon interactions from first principles** — •Marco Bernardi

Sessions

O 1.1–1.4	Sun	16:00–18:00	H3	**Tutorial: How to Use NOMAD's Workflow Utilities to Improve Data Management and Facilitate Discovery in Materials Science (joint session O/TUT)**
O 2.1–2.3	Sun	16:00–18:15	H10	**Tutorial: Do it Yourself Guide for Simulating Complex Magnetism: From Theoretical Foundations to Hands-on Spin-dynamics (joint session O/TUT)**
O 3.1–3.1	Mon	9:30–10:15	H24	**Overview Talk Kerstin Volz**
O 4.1–4.10	Mon	10:30–13:00	H4	**Solid-Liquid Interfaces: Structure**
O 5.1–5.10	Mon	10:30–13:00	H6	**Scanning Probe Microscopy: Light-Matter Interactions at the Atomic Scale I**
O 6.1–6.9	Mon	10:30–12:45	H8	**Oxides and Insulator Surfaces: Structure, Epitaxy and Growth**
O 7.1–7.8	Mon	10:30–12:45	H11	**Focus Session Ultrafast Electron Microscopy at the Space-Time Limit I**
O 8.1–8.9	Mon	10:30–13:00	H24	**Focus Session Molecular Nanostructures on Surfaces: On-Surface Synthesis and Single-Molecule Manipulation I**
O 9.1–9.8	Mon	10:30–12:30	H25	**Surface Reactions**
O 10.1–10.9	Mon	15:00–17:45	H2	**Focus Session Ultrafast Electron Microscopy at the Space-Time Limit II**
O 11.1–11.12	Mon	15:00–18:00	H4	**Electronic Structure of Surfaces: Spectroscopy, Surface States I**
O 12.1–12.11	Mon	15:00–17:45	H6	**Nanostructures at Surfaces I**
O 13.1–13.10	Mon	15:00–17:30	H8	**Organic Molecules on Inorganic Substrates: Adsorption and Growth**

O 14.1–14.12	Mon	15:00–18:00	H11	**2D Materials Beyond Graphene: Growth, Structure and Substrate Interaction (joint session O/HL)**
O 15.1–15.8	Mon	15:00–18:15	H24	**Focus Session Many-Body Phenomena in Nanomagnets: Kondo, Spinons, Spinarons and Beyond (joint session O/TT)**
O 16.1–16.12	Mon	15:00–18:00	H25	**Scanning Probe Techniques: Method Development**
O 17.1–17.12	Mon	18:00–20:00	P2	**Poster Focus Session Molecular Nanostructures on Surfaces: On-Surface Synthesis and Single-Molecule Manipulation**
O 18.1–18.7	Mon	18:00–20:00	P2	**Poster Focus Session Ultrafast Electron Microscopy at the Space-Time Limit**
O 19.1–19.2	Mon	18:00–20:00	P2	**Poster Surface Magnetism**
O 20.1–20.11	Mon	18:00–20:00	P2	**Poster Scanning Probe Microscopy: Light-Matter Interactions at the Atomic Scale**
O 21.1–21.8	Mon	18:00–20:00	P2	**Poster Heterogeneous Catalysis**
O 22.1–22.6	Mon	18:00–20:00	P2	**Poster Surface Reactions**
O 23.1–23.21	Mon	18:00–20:00	P2	**Poster Ultrafast Electron Dynamics**
O 24.1–24.11	Mon	18:00–20:00	P2	**Poster Scanning Probe Techniques: Method Development**
O 25.1–25.1	Tue	9:30–10:15	H24	**Overview Talk Jörg Kröger**
O 26.1–26.9	Tue	10:30–13:00	H2	**Focus Session Ultrafast Electron Microscopy at the Space-Time Limit III**
O 27.1–27.9	Tue	10:30–13:00	H4	**Solid-Liquid Interfaces: Reactions and Electrochemistry I**
O 28.1–28.7	Tue	10:30–12:15	H6	**Graphene: Electronic Structure and Excitations (joint session O/HL)**
O 29.1–29.10	Tue	10:30–13:00	H8	**2D Materials: Electronic Structure and Exitations I (joint session O/HL/TT)**
O 30.1–30.8	Tue	10:30–12:45	H11	**Surface Magnetism**
O 31.1–31.9	Tue	10:30–13:00	H24	**Focus Session Molecular Nanostructures on Surfaces: On-Surface Synthesis and Single-Molecule Manipulation II**
O 32.1–32.9	Tue	10:30–12:45	H25	**Heterogeneous Catalysis I**
O 33.1–33.21	Tue	13:30–15:30	P3	**Poster Graphene: Electronic Structure and Excitations**
O 34.1–34.6	Tue	13:30–15:30	P3	**Poster Solid-Liquid Interfaces: Reactions and Electrochemistry**
O 35.1–35.4	Tue	13:30–15:30	P3	**Poster Solid-Liquid Interfaces: Structure**
O 36.1–36.8	Tue	13:30–15:30	P3	**Poster 2D Materials: Electronic Structure and Exitations (joint session O/HL)**
O 37.1–37.5	Tue	13:30–15:30	P3	**Poster 2D Materials Beyond Graphene: Growth, Structure and Substrate Interaction (joint session O/HL)**
O 38.1–38.5	Tue	13:30–15:30	P3	**Poster 2D Materials: Stacking and Heterostructures (joint session O/HL)**
O 39.1–39.6	Tue	14:00–15:30	H4	**Oxides and Insulator Surfaces: Adsorption and Reaction of Small Molecules I**
O 40.1–40.6	Tue	14:00–15:30	H6	**Surface Dynamics**
O 41.1–41.5	Tue	14:00–15:15	H8	**Heterogeneous Catalysis II**
O 42.1–42.6	Tue	14:00–15:30	H11	**Electron-driven Processes**
O 43.1–43.7	Tue	14:00–15:45	H24	**Scanning Probe Microscopy: Light-Matter Interactions at the Atomic Scale II**
O 44.1–44.3	Tue	18:00–20:00	P2	**Poster Oxides and Insulator Surfaces: Structure, Epitaxy and Growth**
O 45.1–45.18	Tue	18:00–20:00	P2	**Poster Spins on Surfaces at the Atomic Scale**
O 46.1–46.13	Tue	18:00–20:00	P2	**Poster Organic Molecules on Inorganic Substrates: Electronic, Optical and Other Properties**
O 47.1–47.5	Tue	18:00–20:00	P2	**Poster Electron-driven Processes**
O 48.1–48.4	Tue	18:00–20:00	P2	**Poster Surface Dynamics**
O 49.1–49.11	Tue	18:00–20:00	P2	**Poster Nanostructures at Surfaces**
O 50.1–50.9	Tue	18:00–20:00	P2	**Poster Organic Molecules on Inorganic Substrates: Adsorption and Growth**
O 51.1–51.5	Tue	18:00–20:00	P2	**Poster Electronic Structure of Surfaces: Spectroscopy, Surface States**
O 52.1–52.5	Tue	18:00–20:00	P2	**New Methods: Experiment**
O 53.1–53.2	Tue	18:00–20:00	P2	**Poster Electronic Structure Theory**
O 54.1–54.1	Tue	18:00–20:00	P2	**Poster New Methods: Theory**
O 55.1–55.3	Tue	18:00–20:00	P2	**Poster Topology and Symmetry-protected Materials**
O 56.1–56.1	Wed	9:30–10:15	H24	**Overview Talk Pavel Jelinek**
O 57.1–57.9	Wed	10:30–13:00	H2	**Ultrafast Electron Dynamics I**
O 58.1–58.10	Wed	10:30–13:00	H4	**Solid-Liquid Interfaces: Reactions and Electrochemistry II**
O 59.1–59.10	Wed	10:30–13:00	H6	**Spins on Surfaces at the Atomic Scale I**
O 60.1–60.9	Wed	10:30–12:45	H8	**Plasmonics and Nanooptics: Fabrication, Characterization and Applications I**
O 61.1–61.8	Wed	10:30–12:45	H11	**2D Materials: Electronic Structure and Exitations II (joint session O/HL/TT)**
O 62.1–62.9	Wed	10:30–13:00	H24	**Focus Session Molecular Nanostructures on Surfaces: On-Surface Synthesis and Single-Molecule Manipulation III**
O 63.1–63.8	Wed	10:30–12:30	H25	**Oxides and Insulator Surfaces: Adsorption and Reaction of Small Molecules II**
O 64.1–64.8	Wed	15:00–18:00	H2	**Focus Session Atomic Scale Investigation of Magnetic 2D Materials**
O 65.1–65.11	Wed	15:00–17:45	H6	**Solid-Liquid Interfaces: Reactions and Electrochemistry III**
O 66.1–66.10	Wed	15:00–18:00	H8	**Vacuum Science Technology: Theory and Applications**
O 67.1–67.11	Wed	15:00–17:45	H11	**Ultrafast Electron Dynamics II**
O 68.1–68.10	Wed	15:00–17:45	H24	**Focus Session Molecular Nanostructures on Surfaces: On-Surface Synthesis and Single-Molecule Manipulation IV**

O 69.1–69.10	Wed	15:00–17:30	H25	**Nanostructures at Surfaces II**
O 70.1–70.1	Wed	18:00–20:00	P2	**Poster Oxides and Insulator Surfaces: Adsorption and Reaction of Small Molecules**
O 71.1–71.5	Wed	18:00–20:00	P2	**Poster Plasmonics and Nanooptics: Fabrication, Characterization and Applications**
O 72.1–72.13	Wed	18:00–20:00	P2	**Poster Plasmonics and Nanooptics: Light-Matter Interaction, Spectroscopy**
O 73.1–73.10	Wed	18:00–20:00	P2	**Poster Metal and Semiconductor Substrates: Adsorption and Reactions of Small Molecules**
O 74.1–74.7	Wed	18:00–20:00	P2	**Poster Metal and Semiconductor Substrates: Structure, Epitaxy and Growth**
O 75.1–75.1	Wed	18:00–20:00	P2	**Poster Focus Session Chemical Imaging for the Elucidation of Molecular Structure (joint session O/BP)**
O 76.1–76.3	Wed	18:00–20:00	P2	**Poster Focus Session Atomic Scale Investigation of Magnetic 2D Materials**
O 77.1–77.3	Wed	18:00–20:00	P2	**Poster Vacuum Science Technology: Theory and Applications**
O 78.1–78.1	Thu	9:30–10:15	H24	**Overview Talk Manish Garg**
O 79.1–79.8	Thu	10:30–12:30	H2	**Ultrafast Electron Dynamics III**
O 80.1–80.8	Thu	10:30–12:30	H4	**Organic Molecules on Inorganic Substrates: Electronic, Optical and Other Properties I**
O 81.1–81.8	Thu	10:30–12:30	H6	**Heterogeneous Catalysis III**
O 82.1–82.8	Thu	10:30–12:30	H8	**Plasmonics and Nanooptics: Fabrication, Characterization and Applications II**
O 83.1–83.8	Thu	10:30–12:30	H11	**2D Materials: Electronic Structure and Exitations III (joint session O/HL/TT)**
O 84.1–84.5	Thu	10:30–13:00	H24	**Gerhard Ertl Young Investigator Award Competition**
O 85.1–85.9	Thu	10:30–12:45	H25	**New Methods: Theory**
O 86.1–86.10	Thu	15:00–17:30	H2	**Electronic Structure of Surfaces: Spectroscopy, Surface States II**
O 87.1–87.10	Thu	15:00–17:30	H4	**Plasmonics and Nanooptics: Light-Matter Interaction, Spectroscopy I**
O 88.1–88.11	Thu	15:00–17:45	H6	**2D Materials: Stacking and Heterostructures (joint session O/HL)**
O 89.1–89.11	Thu	15:00–17:45	H8	**Metal and Semiconductor Substrates: Structure, Epitaxy and Growth**
O 90.1–90.10	Thu	15:00–17:30	H11	**Spins on Surfaces at the Atomic Scale II**
O 91.1–91.7	Thu	15:00–17:30	H24	**Focus Session Chemical Imaging for the Elucidation of Molecular Structure I (joint session O/BP)**
O 92.1–92.13	Thu	15:00–18:15	H25	**Electronic Structure Theory**
O 93	Thu	19:00–19:30	H1	**Members' Assembly**
O 94	Thu	19:30–20:30	H1	**Post Deadline Session**
O 95.1–95.1	Fri	9:30–10:15	H24	**Overview Talk Kai Rossnagel**
O 96.1–96.10	Fri	10:30–13:00	H4	**Plasmonics and Nanooptics: Light-Matter Interaction, Spectroscopy II**
O 97.1–97.8	Fri	10:30–12:30	H6	**Organic Molecules on Inorganic Substrates: Electronic, Optical and Other Properties II**
O 98.1–98.8	Fri	10:30–12:30	H8	**Metal and Semiconductor Substrates: Adsorption and Reactions of Small Molecules**
O 99.1–99.10	Fri	10:30–13:00	H11	**Ultrafast Electron Dynamics IV**
O 100.1–100.7	Fri	10:30–12:45	H24	**Focus Session Chemical Imaging for the Elucidation of Molecular Structure II (joint session O/BP)**
O 101.1–101.7	Fri	10:30–12:15	H25	**Topology and Symmetry-protected Materials (joint session O/TT)**
O 102.1–102.1	Fri	13:15–14:00	H1	**Closing Talk Andreas Heinrich**

Members' Assembly of the Surface Science Division

Thursday 19:00–19:30 H1

Sessions

– Invited Talks, Topical Talks, Tutorials, Contributed Talks, and Posters –

O 1: Tutorial: How to Use NOMAD's Workflow Utilities to Improve Data Management and Facilitate Discovery in Materials Science (joint session O/TUT)

NOMAD (nomad-lab.eu) [1] is an open-source, community-driven data infrastructure, that supports automated (meta)data extraction from a wide range of simulations, including ab initio and advanced many-body calculations as well as molecular dynamics simulations. NOMAD allows users to store both standardized and custom complex simulation workflows, which not only streamlines data provenance and analysis but also facilitates the curation of AI-ready datasets. This tutorial will focus on recently developed workflow functionalities and utilities within the NOMAD infrastructure. These advances enable high-throughput interfacing with the NOMAD repository, opening improved discovery pipelines by leveraging the benefits of NOMAD's comprehensive and FAIR-compliant data management system [2].

[1] Scheidgen, M. et al., JOSS 8, 5388 (2023).

[2] Scheffler, M. et al., Nature 604, 635-642 (2022).

Time: Sunday 16:00–18:00 Location: H3

Tutorial O 1.1 Sun 16:00 H3

FAIR-data management with the NOMAD infrastructure: Core functionalities — •Joseph F. Rudzinski — Physics Department and CSMB Adlershof, Humboldt-Universität zu Berlin, Germany

In this first part of the tutorial series, an overview of the NOMAD infrastructure will be provided. Attendees will learn how NOMAD processes raw data and stores it within a generalized data structure, and the corresponding GUI features that allow users to comfortably browse data. An example scenario will also be set up for use throughout the remainder of the tutorial series: *A researcher with a variety of data obtained within a project workflow would like to upload this data to NOMAD in order to link it to their manuscript while exposing the details of their (meta)data and retaining the scientifically relevant connections between the individual project tasks.*

Tutorial O 1.2 Sun 16:30 H3

Using NOMAD's API for project management — •Nathan Daelman — Physics Department and CSMB Adlershof, Humboldt-Universität zu Berlin, Germany

In this part of the tutorial series, you will learn how to interface with NOMAD programmatically using a Python module built to simplify the API (application programming interface). Functionalities for uploading data, editing metadata of uploads, creating datasets with multiple uploads, and publishing data will be covered. Attendees will use these functionalities to manage a portion of the data from the example project workflow, in particular, the subset of data that is automatically recognized and processed by one of NOMAD's existing parsers. *(For attendees without any Python experience, an alternative route to upload via the GUI will also be demonstrated!)*

Tutorial O 1.3 Sun 17:00 H3

Creating custom entries in NOMAD using yaml schema and ELN integration — •Andrea Albino — Physics Department and CSMB Adlershof, Humboldt-Universität zu Berlin, Germany

In this part of the tutorial series, attendees will learn how to create custom entries to store data that is not already supported by one of NOMAD's parsers. The basics of writing a schema, using NOMAD's ELN (electronic lab notebook) integration, and how to create simple plots of your data to visualize in the GUI will be covered. Attendees will then use this knowledge to manage the remainder of the data from the example project workflow, which is not automatically recognized by NOMAD.

Tutorial O 1.4 Sun 17:30 H3

Creating custom workflow entries in NOMAD to link multiple uploads — •Bernadette Mohr — Physics Department and CSMB Adlershof, Humboldt-Universität zu Berlin, Germany

In this last part of the tutorial series, attendees will complete the example project workflow storage by creating a custom workflow entry in NOMAD that connects all the uploaded tasks. The basics of the schema for defining custom workflows will be covered, followed by a demonstration of the straightforward creation of the required workflow file using the same workflow utility Python module as in the first part of the tutorial series. Finally, attendees will navigate NOMAD's interactive workflow graph visualizations to investigate the uploaded data, and learn how to obtain a DOI for their workflow.

O 2: Tutorial: Do it Yourself Guide for Simulating Complex Magnetism: From Theoretical Foundations to Hands-on Spin-dynamics (joint session O/TUT)

This tutorial is designed for students, early-career researchers, and anyone interested in the foundational principles and practical methods for simulating magnetic materials. The journey begins with an introduction to the fundamentals of spin lattice Hamiltonians and their various forms, including a detailed discussion of their derivation (Lecture 1). Next, we explore state-of-the-art techniques for extracting magnetic exchange interactions from first-principles calculations through an engaging overview (Lecture 2). The final session (Lecture 3) delves into atomistic spin-dynamics simulations using the SPIRIT code, a versatile tool compatible with both smartphones and laptops. Throughout, we will emphasize the theoretical framework underpinning these approaches. The participants will have the freedom to explore a large range of phenomena, such as domain walls, skyrmions, and their dynamics under applied currents or torques.

Time: Sunday 16:00–18:15 Location: H10

Tutorial O 2.1 Sun 16:00 H10

Derivation of the spin-lattice Hamiltonian: Heisenberg, beyond Heisenberg, DMI, nematic exchange — •Hiroshi Katsumoto — Peter Grünberg Institut, Forschungszentrum Jülich and JARA, 52428 Jülich, Germany

Magnetization textures, such as domain walls, skyrmions, or hopfions, are very active areas of condensed matter physics. These magnetic textures are usually explained based on the Heisenberg and the relativistic Dzyaloshinskii-Moriya interaction (DMI). Comparisons with experiments have shown that, in many cases, these interactions are insufficient, and a whole range (sometimes called a zoo) of higher-order symmetric and antisymmetric interactions have been proposed. In this tutorial, based on four elemental ingredients: Coulomb interaction, indistinguishability of electrons, spin, and spin-orbit interaction (SOI),

I present a framework for systematically constructing exact spin-lattice models containing all spin Hamiltonians, including higher-order terms dependent on spin quantum numbers and lattice size. Examples of spin Hamiltonians for spin-1/2 and spin-1 systems up to four lattice sites are discussed. The tutorial also explores higher-order relativistic exchange interactions derived from SOI. I consider perturbations up to the 2nd order of SOI and organize (anti)symmetric interactions. Finally, the classicalization of quantum spin relevant to magnetism in solids is discussed, culminating in a spin-lattice model that provides a theoretical framework for extracting material-dependent exchange interactions via numerical calculations and enables the modeling of magnetic textures. – DFG supports the work through SPP-2137 Skyrmionics.

Tutorial O 2.2 Sun 16:45 H10

Computing magnetic exchange interactions using DFT — •Manuel dos Santos Dias — Scientific Computing Department, STFC Daresbury Laboratory, United Kingdom

Magnetic materials are an unending source of fascinating physical behaviour which have fundamental appeal but also important technological applications. In order to understand, quantify and predict the properties of magnetic materials, we need information about the magnetic exchange interactions (introduced in the preceding tutorial), which control how the different magnetic atoms interact with each other and respond to external stimuli. This tutorial will give an overview on first-principles approaches to the calculation of magnetic exchange interactions using density functional theory (DFT). First I will outline how the properties of magnetic materials can be computed with and what capabilities are offered by different DFT codes. Next I will discuss how to map DFT calculations to spin models and when such a mapping is expected to work, followed by a discussion of the two main approaches to compute magnetic exchange interactions: the infinitesimal rotation method and the spin cluster expansion. Lastly, I will explain how to obtain simple information from the computed magnetic exchange interactions, such as the magnetic ground state and the spin wave spectrum, and how to connect to atomistic spin dynamics (for instance using the Spirit code covered in the next tutorial), Monte Carlo and micromagnetic simulations.

Tutorial O 2.3 Sun 17:30 H10

Hands-on atomistic spin-dynamics simulations with Spirit — •Thorben Pürling[1,2] and Moritz Sallermann[1,2,3] — [1]Peter Grünberg Institute, Forschungszentrum Jülich, D-52425 Jülich — [2]Physics Department, RWTH-Aachen University, D-52062 Aachen — [3]University of Iceland

Atomistic spin-dynamics is a powerful, fascinating and educational simulation approach to studying the stability and dynamics of mesoscopic spin-textures such as skyrmions on the basis of atomistic spin-models. It can be used as digital twin to experiments.In this tutorial, participants will be introduced to the atomistic spin model and learn interactively how to perform atomistic spin simulations using the Spirit code [1]. We will cover common computational methods employed in atomistic spin simulations, emphasizing their practical application through the Spirit software framework [2]. The majority of the session will be dedicated to engaging exercises, where participants will work through example problems using Jupyter notebooks that interface directly with Spirit. Participants are encouraged to come with basic knowledge of Python and bring their charged laptops to fully engage in the tutorial. We provide a website [3] to keep you updated such that you arrive at the tutorial prepared for a hands-on experience.

We acknowledge funding from the ERC grant 856538 (project "3D MAGIC").

O 3: Overview Talk Kerstin Volz

Time: Monday 9:30–10:15 Location: H24

Topical Talk O 3.1 Mon 9:30 H24

Insights in real and electronic structure of interfaces by electron microscopy — •Kerstin Volz — Philipps-Universität Marburg, Center for Quantum Materials and Sustainable Technology (mar.quest) and Department of Physics, Hans Meerwein Str., 35032 Marburg, Germany

Internal interfaces between materials are decisive for the functionality of many devices. Hence, an understanding of the atomic as well as electronic structure across interfaces is essential. Electron microscopy can give insights into these properties from Angstrom to several micrometer length scales. With examples from semiconductors, batteries and 2D materials I will show, how Scanning Transmission Electron Microscopy (STEM) can be used to gain the desired information. Thereby, a focus will be on state of the art and quantitative techniques like 4-dimensional STEM, where real as well as momentum space are mapped to derive information on composition, but also on electric fields. These properties will be correlated to fundamental excitations of the charge carrier system at interfaces, e.g., excitons, probed by monochromated Electron Energy Loss Spectroscopy (EELS).

O 4: Solid-Liquid Interfaces: Structure

Time: Monday 10:30–13:00 Location: H4

O 4.1 Mon 10:30 H4

The Impact of the Gold Interface on the Structure and Properties of Aqueous Sodium Citrate Solution — •Elspeth Smith and Marialore Sulpizi — Ruhr-Universität Bochum, Bochum, Germany

Gold nanoparticles (AuNPs) are used widely, with many commercial applications due to their being well suited for catalysis. Owing to the method of production/stabilisation, AuNPs are often suspended in a solution of aqueous sodium citrate, a system with complicated interplays which we seek to elucidate in this work.

Through the use of a previously developed polarisable gold model we have performed all atom classical molecular dynamics simulations of a variety of systems and concentrations of sodium citrate solution, employing the SPC/E water model and a CHARMM based citrate model, with and without a gold interface. In order to better understand the dual effect of both the gold interface and sodium citrate on the water's structure, we employ a number of widely used order parameters for water. As the structure of water in close proximity to AuNPs is difficult to observe experimentally and has possibly large applications for their use in catalysis, we hope to obtain a better understanding of this elusive phenomenon.

O 4.2 Mon 10:45 H4

Rationalizing the "Anomalous" Electrochemical Stark Shift of CO at Pt(111) Through Vibrational Spectroscopy and Density-Functional Theory Calculations — •Elias Diesen[1], Mehmet Ugur Coskun[2], Sergio Díaz-Coello[2], Vanessa J. Bukas[1], Julia Kunze-Liebhäuser[2], and Karsten Reuter[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Department of Physical Chemistry, University of Innsbruck, Austria

We employ infrared reflection absorption spectroscopy (IRRAS) and first-principles density-functional theory (DFT) to revisit the reported "anomalous" negative Stark shift of the CO stretch frequency at Pt(111) in aqueous electrolyte [1]. Our measurements confirm the existence of a potential region with negative Stark shift around 0.5 V vs. RHE at sufficiently high CO concentration in the electrolyte. As these are exactly the same conditions for the occurrence of a phase transition from a (2×2)–3CO to a $(\sqrt{19} \times \sqrt{19})$R23.4°–13CO adsorbate structure [2], we explicitly compute the Stark shift for these two phases using DFT. Neither phase exhibits a negative Stark shift, but the absolute stretch frequencies of atop CO in the two structures are slightly shifted with respect to each other. Remeasuring IRRAS with high resolution indeed reveals a doublet character of the absorption band in the potential region corresponding to the negative Stark shift. Separate fits of the two components then yield positive Stark shifts in quantitative agreement with the calculated values.

[1] Stamenkovic et al., J. Phys. Chem. B 109, 678 (2005); [2] Wei et al., J. Phys. Chem. C 125, 3066 (2021)

O 4.3 Mon 11:00 H4

Adatom Dynamics at Water/Pt(111) Interface from Ab Initio Free Energy Analysis — •Sung Sakong[1], Jonas Lindner[2], Ulrich Ross[3], Michael Seibt[3], Christian Jooss[2], and Axel Gross[1] — [1]Institute of Theoretical Chemistry, Ulm University, 89081 Ulm, Germany — [2]Institute of Materials Physics, University of Göttingen, 37077 Göttingen, Germany — [3]4th Institute of Physics Solids and Nanostructures, University of Göttingen, 37077, Göttingen, Germany

Recent electron diffraction experiments investigated the local structures of the water/Pt(111) interface, a selected model system for investigating the structural properties of the electric double layer (EDL). The reconstructed phase signals of the diffraction data yield the time average of the interface structures with Angstrom resolution and observe the static Pt lattice and dynamic particles above the lattice. Since the time-averaged signals from experiments are often

challenging to relate to the corresponding atomic structures of dynamic particles, we probe the interface structure by including Pt adatoms using the ab initio molecular dynamics (AIMD) method. The free energy of Pt adatoms is analyzed by including the vibrational entropy calculated from the AIMD trajectories using the two-phase thermodynamics method. While the dynamics of water molecules are captured within the AIMD trajectories, the relatively slow Pt adatom dynamics are estimated by a free energy analysis, Blue Moon ensemble sampling. By comparing the Water/Pt(111) and Vacuum/Pt(111) models, we will discuss the role of surrounding water molecules and try to relate the model EDL configurations to the experimental findings.

O 4.4 Mon 11:15 H4

Effect of the damping function in dispersion corrected density functional theory on properties of liquid water — •Knut Nikolas Lausch[1,2], Redouan El Haouari[1,2], Daniel Trzewik[1,2], and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany

Accounting for non-local dispersion interactions is essential to achieve chemical accuracy when applying approximate density functional theory (DFT) to large molecular or condensed systems. A popular approach is to add a damped correction potential, based on the London formula, after convergence. Damping is required to avoid the diverging short-range behavior of the London formula and double counting of interactions treated locally by the exchange-correlation (xc) functional. Often two forms of damping, known as zero- and Becke-Johnson-damping, are employed and it is generally assumed that the choice has only a minor impact on performance even though the resulting correction potentials differ quite dramatically. Here, we demonstrate that the choice of damping function can have a major impact on properties obtained from molecular dynamics simulations of liquid water suggesting that the significance of damping in dispersion corrected DFT needs to be reevaluated.

O 4.5 Mon 11:30 H4

Elucidating the double layer structure of protic ionic liquid electrolytes for next-generation fuel cells — •Christian Rodenbücher, Yingzhen Chen, Federico Parisi, Piotr M. Kowalski, and Carsten Korte — Forschungszentrum Jülich GmbH, Institute of Energy Technologies (IET-3 & IET-4), 52425 Jülich, Germany

Polymer electrolyte membrane fuel cells (PEMFCs) are the backbone of a future hydrogen-based renewable energy system. Increasing their operation temperature to 100–160 °C would allow for a simpler water management and the use of waste heat. In this temperature range, conventional proton conducting polymers such as Nafion are not applicable, since they rely on the presence of water. Hence, we study immidazolium-based protic ionic liquids, which provide a high thermal and chemical stability and a high proton conductivity. We present experimental investigations using impedance spectroscopy, infrared spectroscopy, and atomic force microscopy combined with atomistic simulations by molecular dynamics and density functional theory. Our results reveal that depending on the electrode charge, a dense layered structure of alternating anion and cation layers is formed. Upon the addition of water, which is naturally produced during fuel cell operation, the structuring becomes distorted resulting in the accumulation of water at the interface and the increase of the onset potential of the oxygen reduction reaction. Our findings illustrate that the kinetics of the fuel cell reactions is influenced not only by bulk properties of the electrolyte but also by the adsorption at the electrode, which may be tuned by designing ionic liquids with bespoke properties.

O 4.6 Mon 11:45 H4

Polarizable model of graphite and its applications to nanotechnology — Krishan Kanhaiya[1], Hendrik Heinz[2], and •Marialore Sulpizi[3] — [1]Ruhr-Universität Bochum — [2]University of Colorado Boulder — [3]Ruhr-Universität Bochum

Graphitic materials are of significant importance in the research and industrial community due to their tunable electrical conductivity, band gap, thermal property and high strength to mass ratio. They are used in battery or fuel cells as electrodes, refractory material, lubricant, aerospace, water purification, and biosensing etc.. We present a realistic, all-atom polarizable model of graphite with flexible dummy electrons to model the polarizable nature of electron cloud, similar to the approach which was used to describe image charge effects for ions approaching metal surfaces. The models predict density, lattice parameters, surface energy, hydration energy, water contact angle and elastic constants within 1%, 1%, 5%, 5%, 5% and ~15 % respectively as per the Interface Force Field protocol. Additionally, the model also reproduces experimental and DFT data on binding energies and profiles for cations , anions and neutral molecules (water, amino acids, and organic molecules). We further discuss friction coefficient across the graphene surface and nanotubes in order to model flow characteristics of water over such surfaces . An accurate description of such systems is key to design improved functional materials and devices for water desalination and blue energy (electric energy from salinity gradient in two different electrolyte solutions).

O 4.7 Mon 12:00 H4

Elucidating the interaction of small organic pollutants at ice surfaces with sum-frequency generation spectroscopy — •Gurivi reddy Yettapu[1,2], Luca B. Manning[2], and Jenee D. Cyran[2] — [1]University of Duisburg-Essen, Duisburg, Germany — [2]Boise State University, Boise, USA

Small organic pollutants interacting with ice and water surfaces in the troposphere are relevant for atmospheric compositional changes.[1] Their interactions with hexagonal basal-plane oriented single crystalline ice have been scarcely revealed.[2] Methanol and acetone are two smallest organic molecules that interact differently with single crystalline ice surfaces. Herein, we probed their direct interaction on ice and water interfaces with surface-specific, mode selective sum-frequency generation spectroscopy. Our results show significant difference in the frequency of H-bonding O-H oscillators of water molecules present at the ice interface.[3] The distinct behavior of the adsorption of these molecules could explain their relevant atmospheric compositions. [1] F. Dominé and P. B. Shepson, Science, 297, 1506-1510 (2002). [2] J. D. Cyran et al., Angew. Chem. Int. Ed., 58, 3620-3624 (2019). [3] G. R. Yettapu et al., Faraday Discussions, just accepted (2024).

O 4.8 Mon 12:15 H4

Exploring Charged Aqueous Interfaces with Depth-Resolved SFG/DFG Vibrational Spectroscopy — •Sarabjeet Kaur, Álvaro Díaz Duque, Alexander Fellows, Martin Wolf, and Martin Thämer — Department of Physical Chemistry, Fritz Haber Institute of the Max Planck Society

Charged aqueous interfaces are crucial in biological, atmospheric, and chemical processes, where surface electric fields influence ion distributions and interfacial dynamics. Water mediates these interactions, with effects spanning nanometers. The Gouy-Chapman (GC) model and variants describe ion distributions but oversimplify water as a continuous medium, neglecting molecular-level behaviors like impact of structure, orientation, and hydrogen-bonding dynamics. This omission leaves important aspects of interfacial phenomena unexamined. We address these gaps using depth-resolved vibrational spectroscopy combining phase-resolved sum- and difference-frequency generation (SFG and DFG). This technique reveals depth-dependent water responses and connects electric potential anisotropy with molecular reorientation. Our findings identify two distinct interfacial layers, challenging the single-layer GC model. Spectral analysis shows structural differences between the compact and diffuse layers. Additionally, concentration-dependent studies highlight discrepancies between the observed decay length of orientational anisotropy and the predicted Debye length. These results underscore the limitations of the GC variant model and continuum solvent approaches in capturing water's molecular-level behavior at charged interfaces.

O 4.9 Mon 12:30 H4

Resolving the water structure at iron-oxide/water interface — •Harsharan Kaur[1], Moritz Zelenka[1,2], and Ellen Backus[1,2] — [1]University of Vienna, Faculty of Chemistry, Institute of Physical Chemistry, Währinger Str. 42, 1090 Vienna, Austria — [2]University of Vienna, Vienna Doctoral School in Chemistry (DoSChem), Währinger Str. 42, 1090 Vienna, Austria

Among different iron-oxide polymorphs, Fe3O4 is utilized as a catalyst for industrial-gas shift and photocatalytic water splitting reactions, where it often encounters water. [1] Fe3O4 surface is known to protonate and deprotonate on contact with pH-variant aqueous media. [1] However, less is known about the interfacial species and their molecular orientation under ambient condition. Herein, we explore these attributes at the magnetite-water interface as function of solution pH with macroscopic amount of water. Magnetite films of ~50 nm thick were prepared using magnetron sputtering and were found to sustain Fe3O4 phase combined with FeO or γ-Fe2O3 state. The interface was examined with SFG vibrational spectroscopy. Due to its selection rule, a vibrational spectrum of only the interfacial species is obtained in case of centrosymmetric bulk materials like Fe3O4 and water. We observed a pH-dependent variation in the H-bonding strength of the interfacial water molecules and the presence of Fe-OH groups at alkaline pH. Besides, the water orientation varies with pH. By comparing the results for Fe3O4 to Fe2O3, a detailed molecular picture of interfacial water at these relevant iron oxides will be presented. [1]. Z. Bielan, S. Dudziak, A. Kubiak, E. Kowalska, Appl. Sci. 11 (2021) 10160.

O 4.10 Mon 12:45 H4

Structural and dynamical properties of the Solvated Electron From Ab Initio Molecular Dynamics Simulations — •Anna Karolyna Macieira Silva Gomes and Marialore Sulpizi — Ruhr-University Bochum, Bochum, Germany

The solvated electron is a critical species in plasma/liquid and plasma/solid/liquid interfaces, serving as the primary reducing agent generated at plasma electrodes in contact with liquids. Recently, experimental studies have revealed differences in the properties of solvated electrons formed via plasma compared to other methods, such as water radiolysis. It has been proposed that the unique conditions at plasma interfaces, including electric fields, may alter the electron's solvation properties.

Despite extensive investigations into solvated electrons, their behavior in the presence of electric fields remains unexplored. This project employs atomistic molecular dynamics simulations to explore the influence of electric fields on the structure and dynamics of solvated electrons in aqueous solutions. Ab Initio Molecular Dynamics (AIMD), utilizing hybrid functionals, have been shown to offer a accurate approach to modeling the electronic properties of this system, while remaining computationally feasible for capturing relevant time and length scales.

O 5: Scanning Probe Microscopy: Light-Matter Interactions at the Atomic Scale I

Time: Monday 10:30–13:00 Location: H6

O 5.1 Mon 10:30 H6

Simulated tip-enhanced Raman scattering fingerprints of doped triangulenes — •Orlando Silveira[1,2], Markus Junttila[1], Shawulienu Kezilebieke[2,3], and Adam Foster[1,4] — [1]Department of Applied Physics, Aalto University, Espoo, Finland — [2]Department of Physics, Nanoscience Center, University of Jyvaskyla, Jyvaskyla, Finland — [3]Department of Chemistry, University of Jyvaskyla, Jyvaskyla, Finland — [4]WPI Nano Life Science Institute (WPI-NanoLSI), Kanazawa University, Kakuma-machi, Kanazawa, Japan

Triangulenes are organic molecules promising for future applications in spintronics technologies, and fine tunning their electronic and magnetic properties will only extend the potential applications. A reliable possibility for such control is doping the triangulenes with different atoms such as nitrogen and boron. Usually, the reaction yield of triangulenes is quite small, and it is prohibitive to use techniques with high cross section such as Raman to chemically characterize the triangulenes. In the other hand, scanning probe microscopy (SPM) techniques have been successfully used for their structural characterization. In this work, we propose that the tip-enhanced Raman scattering (TERS) can be used for simultaneous chemical and structural characterization of the triangulenes. Our work offers a new perspective to study the triangulenes, as their vibrational properties have not yet been fully investigated, and the same simulation protocol used here can be applied to any other type of molecule.

O 5.2 Mon 10:45 H6

Plasmon-induced reaction in hydrogen-bonded molecular networks studied by laser-coupled STM — •Youngwook Park, Adnan Hammud, Martin Wolf, and Akitoshi Shiotari — Fritz Haber Institute of the Max Planck Society, Berlin, Germany

Hydrogen-bonded molecular networks are widely found in natural systems and play an important role in the development of functional molecular assemblies. Understanding chemical reactions within these networks requires molecular-level spatial resolution, which is challenging for photochemical studies. In this talk, we present a plasmon-induced reaction in 2D hydrogen-bonded assemblies, studied with a laser-coupled scanning tunneling microscope (STM). We investigated triphenylene-2,6,10-tricarboxylic acid forming a honeycomb network on Au(111) through hydrogen bonds. Our findings showed that photo-induced deformation of the network was localized to a few molecules beneath the Ag tip under visible laser illumination. In contrast, a PtIr tip, which lacks plasmonic activity in the visible range, failed to trigger the reaction. By varying the laser wavelength, we identified that non-thermal (hot) electrons generated by plasmons mediate the reaction. This was confirmed by initiating the reaction with non-thermal electrons from the STM tip without laser irradiation. Our results highlight the potential of plasmonic STM tips for precise control over molecular network structure and reactivity.

O 5.3 Mon 11:00 H6

Motion of molecular motors on ultra-thin NaCl islands on Cu(111) — •Monika Schied[1,2], Grant J. Simpson[1], Ken Kolar[1], Dongdong Liu[3], James M. Tour[3], and Leonhard Grill[1] — [1]University of Graz, Austria — [2]CNR-IOM, Italy — [3]Rice University, USA

Molecular motors are designed to overcome nature's random motion by converting external energy into controlled, uni-directional rotation. Studying them on a solid surface can be advantageous, as it offers confinement in two dimensions, making it easier to observe the directionality of their motion. In previous studies on metallic surfaces, indeed uni-directional rotation has been observed [1]. However, the activation of the motor functionality is likely suppressed due to the hybridisation of the molecular orbitals with the electron bath of the metal. In order to preserve the inherent electronic structure of the free molecule, we studied Feringa-type motors adsorbed on ultra-thin NaCl layers on Cu(111), which electronically decouples them from the metal substrate, while still permitting measurements with the low-temperature scanning tunnelling microscope (LT-STM). We excited the molecules with UV light, which – in contrast to voltage pulses – acts remotely without altering the local potential energy landscape with the STM tip. In this way, we could induce the motion of individual molecules.

[1] M. Schied et.al., ACS Nano 2023, 17, 4, 3958-3965

O 5.4 Mon 11:15 H6

Triggering chemical reactions in single molecules with ultrashort THz pulses — •Niklas Friedrich, Carmen Roelcke, Tzu-Chao Hung, Yaroslav Gerasimenko, Rupert Huber, and Jascha Repp — Institute of Experimental and Applied Physics, University of Regensburg, Regensburg, Germany

In lightwave-driven scanning tunnelling microscopy (LW-STM), the electric-field transient of ultrashort laser pulses focused into the junction of a tunnelling microscope acts as a bias-voltage transient and thereby controls tunnelling on ultrashort timescales. This allows unravelling the dynamics of quantum systems in pump-probe experiments with atomic spatial and femtosecond temporal resolution [1].

Here, we show that LW-STM can be used to trigger chemical reactions on ultrashort timescales. We study free-base naphthalocyanine molecules (H2Nc) on 2ML NaCl on Cu(111). In DC-biased experiments, this system switches between different tautomers upon injection of high-energy tunnelling electrons [2]. We find that the same reaction is facilitated by ultrashort voltage transients in LW-STM for transients far exceeding the voltage of the lowest unoccupied molecular orbital. Furthermore, even a stepwise deprotonation of the molecule is activated by the ultrashort laser pulses when increasing the voltage transient beyond a threshold value.

[1] Roelcke et al. Nat. Photon. 18, 595-602 (2024) [2] Liljeroth et al. Science 317, 1203-1206 (2007)

O 5.5 Mon 11:30 H6

Spatial coherent phonon spectroscopy on 2H-$MoTe_2$ using THz-STM — •Vibhuti Rai, Junyoung Sim, Florian Faaber, Sergey Trishin, Nils Bogdanoff, Tom Seifert, Tobias Kampfrath, Christian Lotze, and Katharina J. Franke — Freie Universität Berlin, Department of Physics, Arnimallee 14,14195 Berlin, Germany

Scanning tunneling microscopy (STM) offers subnanometer spatial resolution. However, it lacks the temporal resolution required to investigate the dynamics of various elementary excitations such as phonons. By integrating STM with a pump-probe scheme that utilizes two terahertz (THz) pulses acting as transient bias voltages, subpicosecond time resolution can be achieved [1,2]. Here, we demonstrate that our custom-built THz setup, combined with an STM operating at 5K in an ultra-high vacuum, can be used to excite and detect lattice vibrations on the surface of 2H-$MoTe_2$. The time-resolved spectrum shows a long-lasting oscillatory signal that is sensitive to surface defects [3,4]. Fourier analysis reveals the presence of two prominent excitation modes. We correlate the excited modes with coherent phonons. The spatial variation of such coherent phonon spectroscopy further reveals that one of the two excited modes are enhanced by the surface defects.

O 5.6 Mon 11:45 H6

Charge Transfer in Lightwave-Driven Scanning Tunneling Microscopy — •Nils Krane, Jonas Allerbeck, Laric Bobzien, S. Eve Ammerman, and Bruno Schuler — Empa - nanotech@surfaces Laboratory, 8600 Dübendorf, Switzerland

Lightwave-driven STM is a promising technique for exploring ultrafast charge-state dynamics at nanoscale. The tip electrode of the STM provides spatial resolution at the single-atom level, while single-cycle lightwave pulses supply an ultrafast voltage source at GHz to multi-THz frequencies that injects charge carriers to the system. In contrast to optical far-field measurements, the STM tip interacts with the investigated system also between the pulses where the applied voltage is low. This allows for ultrafast back tunneling of electrons from an excited charge state via discharging to the tip electrode, resulting in zero net current. Equal magnitude of forward and backward tunneling hence quenches the time-integrated charge rectification and imposes a major challenge on investigating ultrafast nanoscale charge dynamics. In this talk, I discuss the consequences of back tunneling for lightwave-driven STM and time-domain pump-probe techniques, at the example of picosecond charge-state lifetimes related to selenium vacancies in WSe_2 studied with THz-STM. I outline pathways to overcome this challenge by utilizing effects such as the Franck-Condon blockade or spin multiplicity for the promotion of unidirectional charge transport. A theoretical model

based on the master equation, accurately reproduces the time-dependent tunneling processes observed in the experiments.

O 5.7 Mon 12:00 H6

Ultrafast Coulomb blockade in an atomic-scale quantum dot — Jonas Allerbeck[1], •Laric Bobzien[1], Nils Krane[1], S. Eve Ammerman[1], Daniel E. Cintron Figueroa[2], Joshua Robinson[2,3], and Bruno Schuler[1] — [1]Empa - nanotech@surfaces Laboratory, 8600 Dübendorf, Switzerland — [2]Department of Chemistry, The Pennsylvania State University, University Park, 16802, PA, USA — [3]Department of Physics and Department of Materials Science and Engineering, The Pennsylvania State University, University Park, 16802, PA, USA.

Controlling electron dynamics at optical clock rates is a fundamental challenge in lightwave-driven nanoelectronics. At the example of individual selenium vacancies (Vac_{Se}) in few-layer tungsten diselenide (WSe_2), which are prototypical atomic-scale quantum dots with localized defect states, I present ultrafast charge transfer in the time domain using lightwave-driven scanning tunneling microscopy (LW-STM). Layer-dependent decoupling of Vac_{Se} in WSe_2 varies the average charge-state lifetime of defect states from 1.2 ps (1L) to 3 ns (4L), showing an unexpected sub-exponential. Picosecond terahertz (THz) source pulses, focused onto the picocavity of the STM, control and read the charge state of individual Vac_{Se} quantum dots. THz pump-THz probe time-domain sampling of the defect charge population captures atomic-scale snapshots of the transient Coulomb blockade, a signature of charge transport via quantized defect states. These results open new avenues for exploring charge dynamics and lightwave-driven electronics at the space-time limit.

O 5.8 Mon 12:15 H6

THz Pulse induced Luminescence in a Scanning Tunneling Microscope — •Kurt Lichtenberg, Johannes Schust, Felix Huber, Ines Hartkopf, Susanne Baumann, and Sebastian Loth — University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany

Light-matter interaction at the atomic scale lies at the heart of many processes in nature and technology, ranging from light harvesting to quantum communication applications. But experimental tools to access the respective dynamics at this scale with sufficient time resolution are rare.

Here we show a proof-of-concept combination of the ultrafast time resolution of THz scanning tunneling microscopy (THz STM) with tunneling-induced light emission at the atomic scale (Scanning Tunneling Luminescence).

We use intense sub-cycle THz pulses to excite plasmons in the tunnel junction consisting of a gold tip and a bare silver sample. We find that THz-induced voltage transients ignite luminescence in ultrashort time intervals within a fraction of a single period of the THz pulse that was used for the excitation. These ultrafast luminescence bursts can be used to sample the waveform of a second THz pulse with femtosecond time resolution.

This work contributes to a new line of methodology, that can probe the rich dynamics of light emission from single atoms and molecules.

O 5.9 Mon 12:30 H6

Ultrafast manipulation of charge-density wave order with THz-STM — Shaoxiang Sheng[1,2], Kurt Lichtenberg[1], Susanne Baumann[1], and •Sebastian Loth[1,3] — [1]University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany — [2]Max Planck Institute for Solid State Research, Stuttgart, Germany — [3]Center for Integrated Quantum Science and Technology (IQST), University of Stuttgart, Stuttgart, Germany

Charge-density wave (CDW) materials present unique opportunities for exploring the interplay between structural distortions and the collective dynamics of complex electronic phases at the atomic scale. We use terahertz spectroscopy in the scanning tunneling microscope (THz-STM) to investigate charge-order dynamics in the prototypical CDW materials 2H-$NbSe_2$ and 1T-TaS_2. By employing tip-enhanced terahertz electric fields, we directly excite phase dynamics of the charge order and probe their local electronic response by terahertz-induced electron tunneling. Our measurements show that the incommensurate CDW of $NbSe_2$ features slow phase dynamics in the proximity of defects [1], whereas the commensurate CDW of TaS_2 exhibits fast reconfigurations within individual domains. The presented spatially resolved dynamics of CDWs demonstrate how atomically localized THz excitation can be leveraged to manipulate electronic states with femtosecond temporal precision, offering insights into the fundamental mechanisms of electronic or structural phase transitions in different materials.

O 5.10 Mon 12:45 H6

Tracking phonon-induced electronic dynamics on atomic scale with ultrafast tunnelling spectroscopy — Carmen Roelcke, Lukas Kastner, Maximilian Graml, Jan Wilhelm, Jascha Repp, Rupert Huber, and •Yaroslav Gerasimenko — Department of Physics and Regensburg Centre for Ultrafast Nanoscopy, University of Regensburg, 93040 Regensburg, Germany

Atomic-defect-based quantum systems in monolayers and moiré heterostructures of 2D materials have attracted huge interest for their qubit and single-photon emission functionalities, but directly observing the interplay of their electronic structure with elementary excitations remained a long-held dream.

We directly resolve in space, time and energy how spin-orbit-split bound states of an individual Se vacancy – an atomic single-photon emitter – evolve under coherent lattice vibrations in moiré-distorted WSe_2 using lightwave-driven scanning tunnelling spectroscopy [1]. We selectively launch a drum phonon mode with a THz pulse coupled to the tip and take ultrafast snapshots of electronic spectrum on atomic scales faster than a vibration period. Such ultrafast tunnelling spectra reaching ~300 fs temporal resolution reveal transient energy shifts of the lower vacancy state by up to 40 meV, depending on the amplitude and phase of the coherent lattice vibration. We discuss how THz fields can couple via the Coulomb interactions to the drum mode, and how the interplay of Se-W bonds distortion and image charge renormalization affect the energy levels of the vacancy.

O 6: Oxides and Insulator Surfaces: Structure, Epitaxy and Growth

Time: Monday 10:30–12:45 Location: H8

O 6.1 Mon 10:30 H8

Characterizing Approximants of Oxide Quasicrystals with a Novel Geometric Approach — •Martin Haller, Sebastian Schenk, Stefan Förster, and and Wolf Widdra — Martin-Luther-Universität Halle-Wittenberg, 06120 Halle, Germany

Oxide quasicrystals (OQCs) are aperiodic 2D oxide films exhibiting dodecagonal symmetry, which are grown on hexagonal metal substrates. This dodecagonal symmetry arises from a square-triangle-rhombus tiling, derived from Ba, Sr, or Eu hosted within a Ti-O network [1]. Approximants are periodic structures composed of the same tiling elements, thus exhibiting a close structural relationship to the OQC. Variations in stoichiometry lead to the emergence of different approximant structures, ranging from simple tilings with a triangle:square:rhombus frequency ratio of 4:2:0 to more complex configurations such as the 60:22:8 approximant [2]. In this presentation, we will introduce newly discovered approximant phases identified in the Sr-Ti-O/Pd(111) and Eu-Ti-O/Pd(111) systems through STM and LEED. Specifically, we will discuss two hexagonal approximants with tiling frequency ratios of 20:3:6 and 8:0:3, as well as an oblique 10:3:2 approximant. Additionally, we will apply a novel geometric approach for characterizing the tilings derived from STM data [3]. This innovative method provides a measure in a 4D hyperspace for classifying the relationship of approximants to the parent OQC.

O 6.2 Mon 10:45 H8

Chromium Oxide Thin Films on Pt(111): An STM and DFT Excursion through the Phase Diagram — •Ghada Missaoui[1], Piotr Igor Wemhoff[1], Claudine Noguera[2], Jacek Goniakowski[2], and Niklas Nilius[1] — [1]Carl von Ossietzky University, Institute of Physics, D-26111 Oldenburg, Germany — [2]CNRS-Sorbonne University, UMR 7588, INSP, F-75005 Paris, France

Formation of chromium oxide thin films on Pt(111) was investigated by electron diffraction and low-temperature scanning tunneling microscopy. Depending on the nominal Cr coverage and the oxygen-chemical potential used for preparation, two oxide phases were identified. A $(\sqrt{3} \times \sqrt{3})R30^\circ$ phase emerges at sub-monolayer Cr exposure and O-rich oxidation conditions, while a (2x2) phase develops at higher coverage and after a vacuum-annealing step. For both phases, the atomic nature of cationic and anionic sub-lattices and the chemical composition were determined in detail. Guided by this experimental input, a global structure optimization was performed by genetic algorithms and key configurations were refined by density functional theory calculations afterwards. For the $(\sqrt{3} \times \sqrt{3})R30^\circ$ phase, good agreement was revealed for a Cr_3O_6 trilayer, comprising a mixture of Cr^{3+} and Cr^{4+} ions in the central cationic plane. The (2x2) phase matches well a Cr_6O_{11} film, in which an O-Cr-O trilayer is capped by a Cr_2O_3 honeycomb plane. The identified configurations not only reproduce structure and symmetry deduced from experiment but also have the most favorable energetics at the employed oxygen chemical potential.

O 6.3 Mon 11:00 H8

Ferroelectric perovskite oxides: from bulk to surface polarization — •Dominik Wrana[1], Llorenç Albons[2], Marta Macyk[1], Andrzej Jasicki[1], Aji Alexander[2], Jesus Redondo[2], Igor Sokolovic[3], Pavel Kocan[2], Konrad Szajna[1], Martin Setvin[2], and Franciszek Krok[1] — [1]Institute of Physics, Jagiellonian University, Krakow, Poland — [2]Department of Surface and Plasma Science, Charles University, Prague, Czechia — [3]Institute of Applied Physics, TU Wien, Vienna, Austria

In leveraging the spontaneous polarization of ferroelectrics for photo-, pyro-, and piezocatalysis, it is essential to develop a comprehensive model of ferroelectricity's impact on perovskite surfaces.

Here we investigate oxide perovskites, which are known to exhibit record-high efficiencies toward water spitting. Careful analysis of ferroelectricity exhibited on surfaces of single crystals of as-cleaved ferroelectric $BaTiO_3(001)$ and $KNbO_3(001)$ compared to quantum paraelectric $KTaO_3(001)$ reveals phenomena at both single-atom and macroscales. Polarization optical and scanning electron (SEM) microscopy data provides the spatial information of 90° ferroelectric domains, which typically have a width of 5-20 μm and length of up to hundreds of um. Actual domain structure and their directionality are provided by piezoresponse force microscopy (PFM) imaging, which also provides the correlation of surface reactivity with polarization.

qPlus ncAFM is used to demonstrate a reversible ferroelectric polarization of (1x1) surfaces at the nanoscale, by application of different tip-sample bias voltages.

O 6.4 Mon 11:15 H8

The influence of strain-induced ferroelectricity on the fracture of oxide perovskites — •Christian Ritterhoff and Bernd Meyer — Interdisciplinary Center for Molecular Materials and Computer Chemistry Center, FAU Erlangen-Nürnberg

The cleaving of bulk crystals using mechanical force is a common procedure to obtain well-defined surfaces under UHV conditions. While this method avoids chemical changes in the surface composition due to etching and annealing procedures, the strain necessary for cleavage can induce ferroelectric phase transitions during the fracture process whose influence is still visible on the as-cleaved surface, as shown, for example, by Sokolović *et al.* [1] for mechanically cleaved $SrTiO_3$.

Here, we present density-functional theory calculations to discuss the influence of increasing strain on the magnitude of possible ferroelectric distortions and the development of a spontaneous polarization for three prototype perovskite oxides: cubic $SrTiO_3$, ferroelectric $BaTiO_3$, and polar $KTaO_3$. First, we estimate the critical strain for mechanical cleavage in fracture Mode 1 and Mode 2. Subsequently, we calculate the polarization of the material at the point of fracture and discuss the implication on surface charges and the formation of surface defects.

O 6.5 Mon 11:30 H8

Segregation Effects in 2D Mixed Oxide Nano-Islands: Edge Structure and Composition in Mixed V-Fe Oxide Monolayers — Ying Wang[1], Piotr Igor Wemhoff[1], Ghada Missaoui[1], •Niklas Nilius[1], Jacek Goniakowski[2], and Claudine Noguera[2] — [1]Carl von Ossietzky University, Institute of Physics, D-26111 Oldenburg, Germany — [2]CNRS-Sorbonne University, UMR 7588, INSP, F-75005 Paris, France

Low-coordinated atoms residing at the edges of oxide nanostructures play an important role in heterogenous catalysis. Their local configuration is however hardly available, especially for ternary materials with variable stoichiometry. In this study, low-temperature STM is employed to analyze the edge configurations of V-Fe-O honeycomb islands grown on Pt(111) as a function of film composition. The islands are delimited by zigzag and armchair edges, the latter with a tendency to reconstruct into sequences of four, five, six and seven-membered rings. STM spectroscopy is used to identify the chemical nature of the edge atoms. The thermodynamic forces for V or Fe segregation to the edges, both oxygen and cation terminated, are analyzed by DFT calculations. In an oxidizing environment, formation of vanadyl-terminated (VO-) edges is energetically favorable, while Fe atoms segregate towards the edges at O-poor conditions. The observed behavior is explained by the higher oxygen affinity of V versus Fe edge cations, and reflected in the higher stability of terminal vanadyl compared to ferryl groups. Our findings indicate a new pathway to tailor the chemical composition and catalytic reactivity of oxide edges via cationic mixing.

O 6.6 Mon 11:45 H8

Mapping the Energy-Angle-Landscape in lab-based X-ray photoelectron spectroscopy for Depth Profiling of Oxide Layers — •Martin Wortmann[1,4], Beatrice Bednarz[2], Olga Kuschel[2,3], Klaus Viertel[4], Negin Beryani Nezafat[5], Jan Schmalhorst[1], Gabi Schierning[5], Joachim Wollschläger[3], Andreas Hütten[1], and Timo Kuschel[1,2] — [1]Bielefeld University, Bielefeld, Germany — [2]Johannes Gutenberg University Mainz, Mainz, Germany — [3]University of Osnabrück, Osnabrück, Germany — [4]Bielefeld University of Applied Sciences, Bielefeld, Germany — [5]University of Duisburg-Essen, Duisburg, Germany

Many metals are reactive to atmospheric oxygen, forming stable nanometer-thin oxide layers by spontaneous self-passivation. Such native oxide layers are commonly analyzed by X-ray photoelectron spectroscopy (XPS). We previously introduced a method to calculate depth profiles from single fixed-angle spectra by fitting all emission peaks instead of just one, thus resembling energy-resolved XPS without the need for a synchrotron [1]. Here, we combine this approach with angular-dependent measurements, fitting the measured intensity ratios of oxide and metal as a function of energy (i.e. inelastic mean free path) and angle. This method not only improves the accuracy of earlier models and peak fittings but also paves the way for a more holistic understanding of the XPS spectrum.

O 6.7 Mon 12:00 H8

The polar spinel $MgAl_2O_4$ (001) surface is stabilized by an aluminum-rich reconstruction — •David Kugler[1], Andrea Conti[1], Johanna I. Hütner[1], Soumyajit Rajak[2], Matthias Meier[1], Nan Jiang[2], Florian Mittendorfer[1], Michael Schmid[1], Ulrike Diebold[1], Gareth S. Parkinson[1], and Jan Balajka[1] — [1]Institute of Applied Physics, TU Wien, Vienna, Austria — [2]Department of Chemistry, University of Illinois Chicago, USA

The atomic-scale surface structure of spinel oxides is key to understanding their catalytic properties. Magnesium aluminate ($MgAl_2O_4$, spinel), which gave this class of materials its name, is a wide-gap insulator and poses considerable challenges for experimental surface structure determination. Noncontact atomic force microscopy (nc-AFM) with a qPlus sensor and a well-defined tip apex allowed us to directly resolve the surface structure with atomic resolution and chemical sensitivity. The $MgAl_2O_4(001)$ surface adopts a $c(2\times4)$ reconstruction accompanied by an increase of the Al/Mg ratio, as detected by x-ray photoelectron spectroscopy (XPS). The reconstructed surface is enriched in aluminum and contains ordered pairs of octahedrally coordinated magnesium atoms replacing their tetrahedral bulk sites. This charge redistribution within the reconstructed surface layer stabilizes the otherwise polar $MgAl_2O_4(001)$ termination. The proposed surface reconstruction is similar to those observed on other spinel oxides, such as $Fe_3O_4(001)$ and $Mn_3O_4(001)$, suggesting a universal mechanism for compensating the polarity of spinel (001) surfaces.

O 6.8 Mon 12:15 H8

Elucidating the Growth Mechanism of 2D GaS on Sapphire in a Multitechnique Approach — •Stefan R. Kachel[1,2], Robin Günkel[2], Leonard Neuhaus[1], Oliver Massmeyer[2], Lukas Erlemeier[1], Kassandra Zoltner[1], Florian Münster[1], Carsten von Hänisch[1], Kerstin Volz[2], and J. Michael Gottfried[1] — [1]Department of Chemistry, Philipps-Universität Marburg, Germany — [2]Material Sciences Center and Department of Physics, Philipps-Universität Marburg, Germany

The utilization of 2D layers of GaS with its ultraviolet bandgap holds promise for applications in solar-blind photodiodes and LEDs. However, the growth of these 2D layers remains a significant challenge, driving considerable interest in understanding the growth mechanism underlying the metal-organic chemical vapor deposition (MOCVD) process. This study investigates the growth of 2D GaS using conventional precursors as well as a newly synthesized single-source precursor (SSP) on sapphire in a multitechnique approach. Scanning transmission electron microscopy (STEM) reveals that the formation of a closed Ga layer on the sapphire surface is a prerequisite for GaS growth. This finding is supported by temperature-programmed desorption (TPD) experiments showing intact desorption of the S-precursor, while the Ga-precursor decomposes partially even at low temperatures, leaving Ga residues on the surface, as confirmed by X-ray photoelectron spectroscopy (XPS). The new SSP enables the deposition of thin mixed layers of Ga and S on sapphire. Refining such single-source precursors could provide a pathway toward efficient growth of 2D GaS.

O 6.9 Mon 12:30 H8

Surface Reconstructions Govern Ice Nucleation on Silver Iodide – A Noncontact-AFM Investigation — •Johanna I. Hütner[1], Andrea Conti[1], David Kugler[1], Franziska Sabath[3], Florian Mittendorfer[1], Michael Schmid[1], Angelika Kühnle[2], Ulrike Diebold[1], and Jan Balajka[1] — [1]Institute of Applied Physics, TU Wien, Vienna, 1040, Austria — [2]Department of Chemistry, Bielefeld University, Bielefeld, 33615, Germany — [3]Max Planck Institute for Polymer Research, Mainz, 55128, Germany

Silver iodide (AgI) is used as a cloud seeding material due to its ability to nucleate ice efficiently, which is explained by the good lattice match between AgI and hexagonal ice. However, AgI consists of stacked planes of positively charged Ag^+ alternating with negatively charged I^-. Cleaving a AgI crystal along the (0001) plane thus exposes Ag^+ and I^- terminated surfaces. Both terminations are polar and inherently unstable.

We present atomically resolved noncontact atomic force microscopy (NC-AFM) images that show how AgI(0001) surfaces compensate for this non-zero electric dipole perpendicular to the surface. Both Ag and I terminated surfaces

form reconstructions, whose structure affects their ice nucleating abilities. NC-AFM images of UHV-cleaved surfaces exposed to water vapor reveal that ice forms an epitaxial layer only on the Ag terminated surface, whereas on the I termination ice forms three-dimensional clusters.

These atomic-level observations could enhance our understanding of ice formation processes in the atmosphere.

O 7: Focus Session Ultrafast Electron Microscopy at the Space-Time Limit I

Shaping functionalities on the nanoscale is one of the most essential challenges in modern condensed matter research. It requires a comprehensive understanding of the complex interplay of the electronic, spin, and lattice degrees of freedom in materials and requires tailoring energy transfer and dissipation pathways on the smallest length and fastest timescales. Recent instrumentation breakthroughs in different varieties of pump-probe ultrafast electron microscopy have opened the way for accessing electronic and structural dynamics at surfaces, interfaces, and nanostructures with down-to-attosecond resolution in time. While ultrafast photoemission electron microscopy techniques provide supreme sensitivity to spin and electron dynamics in real momentum space, bright ultrashort electron pulses in the ultrafast implementation of more traditional electron microscopes can probe optical states, local magnetization, and lattice dynamics with a nanometer spatial resolution.

This focus session highlights recent advances in ultrafast high-resolution electron probing. These include new instrumentation and techniques, excitations from the THz to X-ray regime, and studying novel phenomena and materials systems. At the same time, it will bring together researchers from the different areas of ultrafast condensed matter physics to foster discussions and new collaborations to explore emergent scientific questions in this field.

Organized by Armin Feist (MPI Göttingen) and Benjamin Stadtmüller (University Augsburg).

Time: Monday 10:30–12:45 Location: H11

O 7.1 Mon 10:30 H11

Ultrafast Low-Energy Electron Microscopy — •Johannes Otto[1,2,3], Leon Brauns[1,2], Benjamin Schröder[1,2], and Claus Ropers[1,2,3] — [1]Department of Ultrafast Dynamics, Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]4th Physical Institute, University of Göttingen, Göttingen, Germany — [3]Max Planck School of Photonics

Low-Energy Electron Microscopy (LEEM) allows for imaging the first atomic layers of a surface with nanometer resolution by reflecting a low-energy electron beam [1]. This contribution reports on the first implementation and initial results of Ultrafast LEEM. We replaced the electron source of a conventional instrument with a laser-triggered tip-shaped photoemitter enabling imaging with nanometer spatial and picosecond temporal resolution [2]. We show first real-space dynamics including a thermally-induced intensity suppression (transient Debye-Waller effect) and strain-wave propagation. Additionally, we report on stimulated inelastic electron-light scattering (IELS) at beam energies below 100 eV, as recently proposed theoretically [3]. The demonstrated capabilities of the instrument open up new possibilities to investigate a wide range of dynamical phenomena at surfaces.

O 7.2 Mon 10:45 H11

Ultrafast Electron Dynamics in Surface Plasmon Polariton Nanofoci — •Pascal Dreher, Alexander Neuhaus, Michael Horn-von Hoegen, and Frank Meyer zu Heringdorf — Faculty of Physics and Center for Nanointegration, Duisburg-Essen (CENIDE), University of Duisburg-Essen, Germany

Surface plasmon polaritons (SPPs) are collective wave-like excitations of the electron system of a metal surface that hold great potential for enhancing light-based energy conversion processes. Such enhancement is based on the efficient generation of highly-excited hot electrons via the decay of SPPs on a femtosecond timescale. To understand the corresponding microscopic dynamics, it is essential to gain a direct view into the plasmonically-generated hot electron distributions and to distinguish them from optically-generated hot electrons.

We achieve these goals by combining topologically-robust SPP nanofoci with time- and angle-resolved photoelectron spectroscopy in a photoemission microscope. This approach allows us to investigate the ultrafast non-equilibrium electron dynamics driven by SPPs on the native length-, momentum-, time-, and energy scales. We observe plasmonically-driven above-threshold electron emission, and ponderomotive shifts of the electron emission spectra provide us with a direct measure of the local SPP field strength. For different exemplary metal surfaces with distinct surface band structures we gain a direct view into the hot electron distributions generated via the coherent and incoherent decay of SPPs.

O 7.3 Mon 11:00 H11

Mechanisms and Dynamics of Electron Emission from Graphitic Surfaces: Insights from Correlated and Time-Resolved Spectroscopies — •Alessandra Bellissimo[1], Florian Simperl[1], Felix Blödorn[1], Wolfgang S.M. Werner[1], Gyula Halasi[2], László Óvári[2], Csaba Vass[2], Nikolett Oláh[2], Zoltán Filus[2], Tímea Grósz[2], Chinmoy Biswas[2], Balázs Major[2], Imre Seres[2], Aref Imani[1], Paolo A. Carpeggiani[1], Maosheng Hao[1], and Florian Libisch[1] — [1]TU WIEN, Vienna, Austria — [2]ELI-ALPS, Szeged, Hungary

The electron emission behaviour of graphitic surfaces was investigated using advanced spectroscopic methods alongside static & time-resolved Photo-Electron Emission Microscopy (PEEM). At TU WIEN, electron-pair coincidence spectroscopy on pyrolytic graphite detected *correlated* electron pairs from single scattering events, directly linking energy-loss processes to the secondary electron (SE) spectrum. The $(\pi + \sigma)$-plasmon was resolved in terms of the involved interband transitions revealing strong final-state resonances in the SE spectrum. Static photoemission from graphite(0001) was studied using PEEM at the NanoESCA end station at ELI-ALPS, employing extreme ultraviolet linearly polarised photons generated via High-Harmonic Generation in Argon. The k-space-resolved photoelectron (PE) signal associated to the above-mentioned final-state resonances in the SE-spectrum reflects the symmetry of the conduction bands involved in the PE-emission process. Attosecond time- and k-space-resolved RABBITT measurements provided insights into PE-emission dynamics across the Brillouin zone.

Invited Talk O 7.4 Mon 11:15 H11

Nanoimaging the electronic, plasmonic, and phononic structure and dynamics of 2D materials — •Sarah King — University of Chicago, Chicago, IL, United States

Heterogeneity plays a critical role in chemistry and physics, from the role of defect states in the carrier dynamics of semiconductors to interfaces and surfaces in catalysis. However, our ability to visualize nano-scale domains and properties in materials and their effect on material dynamics has been hampered by the simple challenge of our inability to meet the necessary nanometer and femtosecond timescales. I will discuss recent efforts by my group to determine the interplay of heterogeneity and morphology on the intrinsic optoelectronic and thermoelectric properties of materials. Using polarization-dependent photoemission electron microscopy (PD-PEEM) we have imaged the spatially dependent optical selection rules of black phosphorus, distinguishing edge-specific modes, and antiferroelectric domains of β'-In2Se3, with spatial resolution as good as 25 nm. Through ultrafast transmission electron microscopy, we've been able to determine how the bond anisotropy and structural morphology of few-layer black phosphorus impacts phonon dynamics. Ultimately my group seeks to identify ways to modify the impact of structural heterogeneity in materials and rationally design energy efficient interfaces on the nanoscale.

O 7.5 Mon 11:45 H11

Time-resolved momentum microscopy with fs-XUV photons at high repetition rates with flexible energy and time resolution — •Karl Schiller[1], Lasse Sternemann[1], Matija Stupar[1], Alan Omar[2], Martin Hoffmann[2], Jonah Nitschke[1], Valentin Mischke[1], David Janas[1], Stefano Ponzoni[1,3], Giovanni Zamborlini[1,4], Clara Saraceno[2], and Mirko Cinchetti[1] — [1]TU Dortmund University, Dortmund, Germany — [2]Ruhr University Bochum, Germany — [3]Ecole Polytechnique, Paris, France — [4]Karl-Franzens-University Graz, Austria

We present a versatile setup for time-resolved ARPES that combines an energy-filtered momentum microscope with a custom-designed high-harmonic generation (HHG) photon source [1]. The HHG source is powered by a commercial

multi-100 kHz Yb-based ultrafast laser system delivering femtosecond pulses in the extreme ultraviolet range. A nonlinear pulse compression stage, utilizing spectral broadening in a Herriott-type bulk multi-pass cell, enables flexible control of the driving pulse duration. This adaptability allows two distinct operational modes, optimized for either energy or time resolution, making the setup highly suitable for ultrafast photoelectron microscopy at the space-time limit. We demonstrate the system's capabilities by tracking conduction band dynamics in the valleys of a bulk WS_2 crystal. Using uncompressed laser pulses, we achieve an energy resolution better than (107 ± 2) meV. Compressed pulses, in contrast, yield a time resolution of (48.8 ± 17) fs.

[1] Optica Open Preprint 115282 (2024)

O 7.6 Mon 12:00 H11

Dark field photoelectron momentum microscopy of electric field gated 2D semiconductors — •Jan Philipp Bange[1], Bent van Wingerden[1], Jonas Pöhls[1], Wiebke Bennecke[1], Paul Werner[1], David Schmitt[1], AbdulAziz AlMutairi[3], Daniel Steil[1], R. Thomas Weitz[1], G. S. Matthijs Jansen[1], Stephan Hofmann[3], Giuseppe Meneghini[2], Samuel Brem[2], Ermin Malic[2], Marcel Reutzel[1], and Stefan Mathias[1] — [1]Georg-August-Universität Göttingen, Germany — [2]Philipps-Universität Marburg, Germany — [3]University of Cambridge, U.K.

A possibility to tune many-body interactions in two-dimensional semiconductors is in-situ electric field gating, which allows precise and reversible control of the filling of states in a moiré potential. In combination with ARPES for static band structure measurements, this approach has been shown to be a powerful experimental probe [1]. However, the study of excited states in gated 2D material structures, such as interlayer excitons [2] and trions, has so far remained elusive.

Here we combine time-resolved momentum microscopy with dark field imaging techniques to gain access to many-body interactions on femtosecond time and nanometer lengthscales [3]. We use this method to study electric field gated homobilayer WSe_2 and report the ultrafast formation of quasiparticles as a function of applied gate voltage.

O 7.7 Mon 12:15 H11

Plasmonic spin meron pair: Spatio-temporal topology revealed by time resolved polarimetric photo-emission microscopy — Pascal Dreher[1], •Alexander Neuhaus[1], David Janoschka[1], Alexandra Roedl[1], Tim Meiler[2], Bettina Frank[2], Timothy J. Davis[1,2,3], Harald Giessen[2], and Frank Meyer zu Heringdorf[1] — [1]Faculty of Physics and Center for Nanointegration, Duisburg-Essen (CENIDE), University of Duisburg-Essen, 47048 Duisburg, Germany — [2]4th Physics Institute and Research Center SCoPE, University of Stuttgart, 70569 Stuttgart, Germany — [3]School of Physics, University of Melbourne, Parkville Victoria 3010, Australia

We have developed a novel method, polarimetric photo-emission electron microscopy (polarimetric PEEM), which combines an optical pump-probe polarimetry with photo-emission electron microscopy. This method enables the accurate generation and measurement of surface plasmon polariton fields at deep sub-wavelength spatial resolution and sub-cycle temporal resolution. Using polarimetric PEEM, we extend the study of electromagnetic fields on surfaces to a spin quasi-particle with the topology of a meron pair and analyze its topology by calculating the Chern number. We find the Chern number to be C=1 and constant over time, demonstrating the stability of the plasmonic meron pair on a femtosecond time scale. Additionally, we show that the in-plane vectors of the three-dimensional field are constrained by the embedding topology of the space as dictated by the Poincare-Hopf theorem.

O 7.8 Mon 12:30 H11

Momentum microscopy with attosecond time resolution at ELI ALPS to map the full Brillouin zone — Gyula Halasi[1], Csaba Vass[1], Nikolett Oláh[1], Zoltán Filus[1], Tímea Grósz[1], Chinmoy Biswas[1], Tamás Csizmadia[1], Lénárd Gulyás Oldal[1], Balázs Major[1], Péter Jójárt[1], Felix Blödorn[2], Florian Simperl[2], Aref Imani[2], Paolo Carpeggiani[2], Péter Dombi[1], Wolfgang S.M. Werner[2], Alessandra Bellissimo[2], and •László Óvári[1] — [1]ELI ALPS, Szeged, Hungary — [2]Vienna University of Technology, Austria

Time-resolved photoemission is a highly efficient tool for unraveling surface electron dynamics. The coupling of a photoemission electron microscope (PEEM) with an imaging hemispherical analyzer in our NanoESCA end station allows for the combination of spectroscopy and microscopy in real or momentum space. The NanoESCA end station is attached to a high harmonic generation (HHG) beamline, hence time-resolved momentum microscopy studies can be performed in a pump-probe scheme. To illustrate the performance of our user-ready system, the first results obtained by the RABBITT (Reconstruction of Attosecond Beating By Interference of Two-photon Transitions) scheme are presented. In this experiment, a graphite(0001) single crystal was studied, and RABBITT oscillations have been identified throughout the whole Brillouin zone, with attosecond precision, in the form of a time-resolved momentum space movie.

O 8: Focus Session Molecular Nanostructures on Surfaces: On-Surface Synthesis and Single-Molecule Manipulation I

This focus session aims to discuss recent advances in the on-surface synthesis, manipulation, characterization, and understanding of complex molecular architectures on surfaces. The interest in surface-confined molecular nanostructures emerges from their prospective applications in nanoscale (opto-) electronics, spintronics, solar cells, energy storage devices, and other fields. The bottom-up fabrication of surface-supported nanostructures can be based on molecular self-assembly utilizing non-covalent intermolecular interactions, covalent on-surface synthesis, or the direct manipulation of molecules. Molecular self-assembly usually leads to highly ordered nanostructures, controlled by non-covalent interactions, adsorbate-substrate interactions, as well as thermodynamic and kinetic factors. On-surface synthesis by covalent coupling of reactive precursors adsorbed on metallic, semiconducting, or even insulating surfaces has emerged as a powerful method that has opened new possibilities in exploring new routes towards the synthesis of complex low-dimensional nanostructures with unprecedented material properties, often via novel chemical reactions not available in conventional organic chemistry. Finally, the direct manipulation of molecules with the tip of a scanning probe microscope allows for unprecedented chemical transformations or structural modifications, as envisioned by the pioneers of nanotechnology. This focus session is intended to provide a platform for addressing current trends in these closely linked fields from various perspectives in experiment and theory.

Time: Monday 10:30–13:00 Location: H24

Invited Talk O 8.1 Mon 10:30 H24

Chiral reactions at surfaces elucidated by machine learning and enhanced sampling — Raymond Amador[1], Enrico Trizio[2], Peilin Kang[2], Umberto Raucci[2], Hannah Bertschi[1], Marcella Iannuzzi[3], Jacob Wright[1], Roland Widmer[1], Oliver Gröning[1], Michele Parrinello[2], and •Daniele Passerone[1] — [1]Empa, Swiss Federal Laboratories for Materials Science and Technology, Dübendorf, Switzerland — [2]Italian Institute of Technology, Genova, Italy — [3]Department of Chemistry, University of Zurich, Switzerland

Experiments performed at the surface of the chiral intermetallic compound PdGa unleash a fascinating surface chemistry phenomenology including regioselectivity and enantioselectivity, in which the energetics is dominated by mid-range dispersive molecular interactions with the substrate. The corresponding modelling of chiral and prochiral adsorption and reactions requires both a high level of electronic structure theory and an appropriate statistical sampling of the reactants, transition state and products ensemble. We show that machine learning potentials based on DFT molecular dynamics trajectories and recently introduced enhanced sampling techniques allow to describe both the thermodynamics and the kinetics of reactions investigated in the laboratories next-door,

such as an Orito-like reaction catalysed by PdGa. Moreover, we study a chirality switching of a bianthracene molecule by applying a method introduced by some of us, based on the committor function and the variational principle that it obeys: its minimum uses a self-consistent procedure that starts from information limited to the initial and final states and reveals the transition state ensemble.

O 8.2 Mon 11:00 H24

On-surface molecular recognition driven by chalcogen bonding — •Luca Camilli — University of Rome Tor Vergata

The manipulation of organic architectures on surfaces through supramolecular interactions has been achieved by using, for example, H- and halogen-bonding. Chalcogen bonding interactions (ChBIs), which belongs to the same category, have not. The interest in ChBIs relies on its orbital mixing nature that provides semiconducting properties to the assemblies.[1] Here, we combine scanning tunnelling microscopy measurements and quantum chemistry calculations to present the first example of ChBI-driven molecular self-assembly on metal surfaces.[2] We show that pyrene-based modules bearing chalcogenazole pyridine moieties undergo self-assembly into dimers through double Ch***N interactions on Au(111) and Ag(110). Synchrotron-based spectroscopy techniques are used to gain more insights into the chemistry of the ChBI and to reveal its fingerprint [unpublished data]. Finally, experimental scanning tunnelling spectroscopy and its simulations based on the framework of density functional theory are used to investigate the electronic properties of the self-assembled systems [unpublished data]. This study sheds light on a promising avenue for future research in the bottom-up engineering of two-dimensional monolayered supramolecular chalcogenide-type materials, as we delve into the novel role of ChBIs in surface-based molecular recognition.

O 8.3 Mon 11:15 H24

Self-assembly, electronic structure, and switching of norbornadiene derivative photoswitches — •Shreya Garg[1], Vishakya Jayalatharachchi[1], Pedro Ferreira[2], Roberto Robles[3], Sajjan Mohammad[1], Shivani Singh[1], Nicolás Lorente[3,4], Kasper Moth-Poulsen[2], Meike Stöhr[1,5], and Sabine Maier[1] — [1]Department of Physics, Friedrich Alexander University Erlangen-Nürnberg, Germany — [2]Polytechnic University of Catalonia, Catalonia, Spain — [3]Centro de Física de Materiales CFM/MPC (CSIC-UPV/EHU), Donostia-San Sebastian, Spain — [4]Donostia International Physics Center (DIPC), San Sebastian — [5]University of Applied Sciences of the Grisons, Switzerland

Molecular photoswitches such as norbornadiene (NBD) derivatives are promising energy storage compounds due to their ability to switch to the metastable quadricyclane (QC) isomer with long half-lives and high-energy storage density. However, the NBD/QC derivative photoswitches remain largely unexplored on the surface. Here, we discuss the self-assembly, electronic structure, and switching of carboxylic acid- functionalized NBD derivative on the Au(111) surface using scanning tunneling microscopy complemented by density functional theory calculations. To explore the impact of the molecule-surface interactions, we also studied them on graphene, which acts as a decoupling layer. We observed distinct hydrogen-bonding motifs between the NBD derivatives on the two surfaces. Our study highlights differences in the electronic properties between the Au(111) and graphene surface, providing insights into optimizing their switching performance on surfaces.

O 8.4 Mon 11:30 H24

Kinetics of the on-surface reactions of 3,3"-dibromo-p-terphenyl on Cu(111): Cis-trans isomerization as rate limiting step towards the final configurations — •Mohit Jain[1], Tamam Bohamud[1], Daniel Kohrs[2], Nathaniel Ukah[2], Hermann A. Wegner[2], and Michael Dürr[1] — [1]Institut für Angewandte Physik and Zentrum für Materialforschung, Justus-Liebig-Universität Giessen, Germany — [2]Institut für Organische Chemie and Zentrum für Materialforschung, Justus-Liebig-Universität Giessen, Germany

The kinetics of the on-surface synthesis reactions of 3,3"-dibromo-p-terphenyl were investigated at fixed surface temperature of 300 K. The initially adsorbed molecules linked through C-Cu-C bonds were found in configurations consisting of long, chain-like and few shorter ring-like structures. With the progression of the reaction through time at 300 K, the configurations showed a shift from long chains and closed structures to 3-molecule ring structures. These structures then slowly aligned to form surface-wide phases of 3-molecule closed-ring structures.

The lateral surface mobility of the molecules was observed to be high at 300 K along with the frequent cleavage and re-formation of the C-Cu-C bond; nevertheless the actual transformation of chain structures towards complete ring structures was detected at a much longer timescale. By quantitative analysis, the trans-to-cis isomerization of the molecules which is necessary for closed-ring formation, was found to be the rate limiting step. To further consolidate the results, experiments with different substitution patterns of the p-terphenyl molecules were performed.

O 8.5 Mon 11:45 H24

Stability and Reactivity of Fe-DCA 2D Metal-Organic Framework on Graphene — •Zdeněk Jakub[1], Dominik Hrůza[1], Taduáš Lesovský[1], Ayesha Jabeen[1], Jakub Planer[1], Pavel Procházka[1], and Jan Čechal[1,2] — [1]CEITEC - Central European Institute of Technology, Brno University of Technology, Purkyňova 123, Brno 61200, Czechia — [2]Institute of Physical Engineering, Faculty of Mechanical Engineering, Brno University of Technology, Technická 2896/2, Brno 61200, Czechia

2D Metal-Organic Frameworks (2D MOFs) are promising materials for applications in catalysis, sensing or spintronics. 2D MOFs based on 9,10-dicyanoanthracene (DCA) linker molecules are particularly intriguing due to their recently demonstrated magnetic and topological properties. Here, we study the reactivity of Fe-DCA supported on a weakly-interacting substrate, graphene/Ir(111). Using Scanning Tunneling Microscopy (STM), X-Ray Photoemission Spectroscopy (XPS) and Low-Energy Electron Microscopy/Diffraction (LEEM/LEED) we test how the Fe-DCA responds to exposure to CO, O_2, and thermal annealing. Our data indicate that CO readily adsorbs at room temperature, and the 2D MOF remains stable. In contrast, adsorption of O_2 causes structural collapse of the 2D MOF, leaching the Fe cations from the Fe-DCA islands and leaving patches of self-assembled DCA on the surface. Thermally, the Fe-DCA structure decomposes upon annealing above 100 °C. Overall, our work addresses the limits of thermal and chemical stability of metal-DCA systems; such knowledge is relevant for any potential application of these materials.

O 8.6 Mon 12:00 H24

Tuning the properties of 2D Metal-Organic Frameworks by doping of the support — •Ayesha Jabeen[1], Zdeněk Jakub[1], Dominik Hrůza[1], Lenka Černá[1], Pavel Procházka[1], Jakub Planer[1], and Jan Čechal[1,2] — [1]CEITEC-Central European Institute of Technology, Brno University of Technology, Purkyňova 123, Brno 61200, Czech Republic — [2]Institute of Physical Engineering, Faculty of Mechanical Engineering, Brno University of Technology, Technická 2896/2, Brno 61200,Czech Republic

2D metal-organic frameworks (MOFs) are extensively studied due to their tailorable properties, which make them promising for applications in catalysis, energy storage and sensing. Here, we show how the properties of 2D MOFs can be further tuned by varying the energy-level alignment with the supporting surface. We demonstrate this on the case of Ni-TCNQ 2D MOF, that we synthesized atop graphene/Ir(111) with different doping levels. The graphene doping is achieved by intercalation of heteroatoms at the graphene/Ir(111) interface; namely oxygen (for p-doping) and dysprosium (for n-doping). The changes in the support*s Fermi level position are clearly identified by photoemission techniques (XPS/UPS/ARPES). The Ni-TCNQ 2D MOFs supported on differently doped graphene show distinct properties, as evidenced by STM, XPS and LEEM/LEED. Most notably, XPS suggests that the charge state of the embedded Ni atoms can be controlled, as we observe two distinct components of Ni core levels, whose ratio depends on the support′s doping level. These findings highlight the potential of support doping for tailoring the properties of designer 2D MOFs.

O 8.7 Mon 12:15 H24

Theoretical Investigation of Dibromopyrene and Iodotriphenylene on Sodium Chloride Coated Copper Substrate — •Florian Pfeiffer[1], Julian Ernst[1], André Schirmeisen[2], Daniel Ebeling[2], and Simone Sanna[1] — [1]Institute for Theoretical Physics, Justus Liebig University Giessen, Germany — [2]Institute for Applied Physics, Justus Liebig University Giessen, Germany

Organic 2D materials are of great interest for various applications in molecular electronics. Increasingly sophisticated methods of on-surface manipulation via probe tips extend the scope of possible structure modifications to tune the (electronic) properties of such nanostructures.

Halogenated organic precursors such as DBP and IT are the building blocks for the assembly of more complex structures. A sodium chloride bilayer helps to electronically decouple the metallic Cu(111) substrate from adsorbates, increasing mobility and thus simplifying manipulation.

The Vienna Ab initio Simulation Package [1] implementation of density functional theory was used to calculate potential energy surfaces and nudged elastic bands for modelling adsorption behaviour and diffusion pathways, respectively. Comparability with experimental results [2] was achieved by simulation of scanning tunneling and atomic force microscopy using the Probe-Particle Model [3].

O 8.8 Mon 12:30 H24

On-Surface Design of Highly-Ordered Two-Dimensional Networks Stabilized by Nonmetal Atoms — •Alisson Ceccatto[1,3], Gustavo Campi[2], Vanessa Carreño[1], Eidsa Ferreira[1], Natalie J. Waleska-Wellnhofer[3], Eva Marie Freiberger[3], Simon Jaekel[3], Duncan John Mowbray[2], Christian Papp[3,4], Hans-Peter Steinrück[3], and Abner de Siervo[1] — [1]Geb Wataghin Physics Institute - University of Campinas - Campinas/Brazil —

[2]School of Physical Sciences and Nanotechnology, Yachay Tech University, 100119 Urcuquí, Ecuador — [3]Lehrstuhl für Physikalische Chemie II, Friedrich-Alexander-Universität Erlangen-Nürnberg, Egerlandstr. 3, 91058 Erlangen, Germany — [4]Angewandte Physikalische Chemie, FU Berlin, Arnimallee 22, 14195 Berlin, Germany

Supramolecular nanoarchitectures have been widely explored to precisely design low-dimensional materials at atomic and molecular levels. Herein, by combining STM measurements and DFT calculations, we report the 2D self-assembled of 1,3,5-tris[4-(pyridin-4-yl)-[1,1-biphenyl])benzene (TPyPPB) molecules on Ag(111) in the presence of Cl adatoms. The adsorption of the TPyPPB molecules on the clean Ag(111) surface forms a porous SAM stabilized by hydrogen bonds. Such packing can be explored as a host-guest material for atom/molecular confinement. However, in the presence of Cl adatoms, the molecular arrangement changes dramatically. The molecular assembly changes its geometry, forming a non-porous SAM stabilized by unconventional H–Cl–H bonds.

O 8.9 Mon 12:45 H24

On-surface synthesis of drone-shaped oligomers via carbenes — •Yunjun Cao[1], Joel Mieres-Perez[2], Julien Frederic Rowen[3], Akshay Hemant Raut[3], Paul Schweer[1], Wolfram Sander[3], Elsa Sanchez-Garcia[2], and Karina Morgenstern[1] — [1]Physical Chemistry I, Ruhr-Universität Bochum, D-44801 Bochum, Germany — [2]Lehrstuhl Physikalische Chemie I, NC 5/72, Ruhr-Universität Bochum, 44801, Bochum — [3]Organic Chemistry II, Ruhr-Universität Bochum, D-44801 Bochum, Germany

The development of on-surface synthesis strategies opens opportunities to fabricate sophisticated nanostructures with tailored geometries, symmetries, and other properties. Here, we demonstrate that carbenes can be used as building blocks for fabricating highly branched oligomers with different symmetries on a Ag(111) surface. We synthesize highly symmetric drone-shaped oligomers, which are formed via C=C coupling of two carbenes to create a core, followed by C-H activation of the core with additional carbenes to create branches. Less symmetric drone-shaped oligomers are formed through the cyclodehydrogenation of the highly symmetric oligomers. The products are investigated by scanning tunneling microscopy and supported by ab initio theoretical modeling.

O 9: Surface Reactions

Time: Monday 10:30–12:30 Location: H25

O 9.1 Mon 10:30 H25

Co_2 reduction by solvated electrons at the NH_3/Cu(111) interface. — •Maya Heine, Lukas Gierster, and Julia Stähler — Humboldt-Universität zu Berlin, Institut für Chemie

Understanding CO_2 reactivity is crucial; the amount of CO_2 in the atmosphere continues to rise with no imminent peak in fossil emissions in sight [1]. Previously, solvated electrons (e_s) have been suggested to activate CO_2 , e.g. by forming surface bound CO_2^- radicals [2]. With time-resolved two-photon photoemission and the amorphous NH_3/Cu(111) interface, we can study the energetics and dynamics of e_s on femtosecond timescales [3]. Here, the electrons are localised at the surface and their lifetime depends exponentially on NH_3 coverage. On an ultrafast timescale, we can now use e_s to decipher the fundamental rate and steps of CO_2 activation. We observe a systematic decrease in the e_s lifetime as CO_2 is added and conclude that CO_2 opens a new decay channel for e_s. Further, increases in the work function serve as indicators of possible reactions: electron attachment to CO_2 or activated CO_2^- which has a dipole moment. For thick NH_3 films we see a much larger work function increase and bleaching of e_s. This suggests that the film thickness controls the lifetime of charged reaction intermediates and thus the reaction pathway. Moreover, we show that e_s attachment to CO_2 occurs on a 10s of ps timescale.

O 9.2 Mon 10:45 H25

Exploring on hydrogen evolution reaction performance of borophene monolayer — •Jing Liu and Axel Gross — Institute of Theoretical Chemistry, Ulm University, Oberberghof 7, 89081 Ulm, Germany

Borophene, a unique graphene-like 2D material composed of boron atoms, has gained significant attention due to its exceptional properties [1]. This study investigates its performance in catalyzing the hydrogen evolution reaction (HER). We focus on four distinct borophene configurations: α, $\beta12$, $\gamma3$, and trigonal structures [2]. Using density functional theory (DFT), we assess the HER performance of pristine monolayers as well as their interaction with an Ag(111) substrate.

The results show that α, $\beta12$, and $\gamma3$ monolayers possess exceptional HER activity, evidenced by their optimal Gibbs free energy for H-adsorption. However, their performance is markedly suppressed upon interaction with a Ag(111) support, where borophene-support interaction alters the hydrogen binding properties. By contrast, trigonal structure exhibits limited HER activity in both conditions, reflecting structural characteristics unfavorable for HER.

This work highlights the intrinsic catalytic potential of borophene monolayers while emphasizing the critical influence of substrate interactions.

O 9.3 Mon 11:00 H25

Realistic Representations of IrO2 Catalyst Surfaces through Extensive Sampling — •Hao Wan, Hendrik H. Heenen, Christoph Scheurer, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin

Iridium oxides catalyze the oxygen evolution reaction with unparalleled activity and stability, even under harsh acidic conditions. However, this performance is sensitively correlated to strong structural, compositional and morphological changes of the working catalyst. At the atomic level little is presently known about the true active state, aside from the unlikelihood of it being ideal rutile IrO2.

This situation spans a vast configurational space, the extensive sampling of which (e.g. via parallel tempering) would be intractable with predictive-quality first-principles calculations. Training a machine-learning interatomic potential (MLIP) as an efficient surrogate is challenged by an unprecedented diversity of training structures, as even the bulk structure and composition is unknown. To this end, we create a comprehensive training set by first assembling prototype bulk structures for various IrOx stoichiometries from existing databases. In an active learning loop, this set is then augmented through extensive sampling of diverse surface structures created from the prototypes. The resulting trained MLIP identifies hexagonal ring structures on the rutile (110), (100), (111) facets as most stable configurations under operating potential, aligning with experimental indications. Activity evaluations on these structures using established descriptors effectively capture trends consistent with experimental observations.

O 9.4 Mon 11:15 H25

Hydrogen Atom Scattering from Graphene on Nickel — •Sophia Tödter, Yvonne Dorenkamp, and Oliver Bünermann — Institute of Physical Chemistry, Georg-August University, Göttingen, Germany

Previously, H atom scattering from graphene grown on a Pt(111) substrate was investigated in detail by our group [1]. Depending on the experimental conditions, two energy loss channels were observed, one quasi-elastic and one strongly inelastic. For a C-H bond to form, the delocalized electronic structure of graphene has to be locally destroyed. This gives rise to an adsorption barrier. If the hydrogen atom cannot cross the barrier, it is elastically reflected. However, if the atom can cross the barrier, it loses a large amount of energy, which can lead to it sticking to the surface [1]. Pt(111) was chosen because it is a weakly interacting substrate. This allows comparison of the experimental data with simulations of H atom scattering from free-standing graphene. Although good qualitative agreement is achieved between experiment and theory, quantitative agreement cannot be achieved because of the non-negligible substrate effect.

To experimentally study the substrate effect we chose Ni(111) as an additional substrate and performed the same experiments. Ni(111) is a strongly interacting substrate and a much larger substrate effect is expected.

O 9.5 Mon 11:30 H25

On-Surface Photoreactivity via Reactive Intermediates on a Metal Versus an Insulator — •Iheb Baklouti[1], Julien F. Rowen[2], Dave Austin[3], Lilian N. Alsayed[1], Talat S. Rahman[3], Wolfram Sander[2], and Karina Morgenstern[1] — [1]Ruhr-Universität Bochum, Chair of Physical Chemistry I, Bochum, Germany — [2]Ruhr-Universität Bochum, Chair of Organic Chemistry II, Bochum, Germany — [3]University of Central Florida, Department of Physics, Orlando, FL, USA

Organic azides play a pivotal role in click chemistry, serving as versatile precursors in synthesizing complex molecules across synthetic chemistry, pharmacology, materials science, and catalysis. Despite their importance, investigations into the surface reactivity of azides remain sparse. This study elucidates the behavior of 2-azidofluorene (2AF) on two distinct surfaces: metallic Ag(100) and ionic NaBr(100), under cryogenic conditions (7 K). Utilizing Infrared Reflection

Absorption Spectroscopy (IRRAS) and Scanning Tunneling Microscopy (STM), reactions initiated by ultraviolet illumination are analyzed. Nitrene formation from 2AF is hindered by charge transfer interactions with Ag(100), emphasizing the need for low-interaction surfaces like NaBr(100). Illumination at 254 nm induces 2AF dissociation, forming 2-fluorenylnitrene. Subsequent exposure to 450 nm light leads to didehydroazepines, a process reversible under 405 nm. This study sheds light on azide surface-mediated dynamics and introduces a framework for investigating reactive intermediates in surface chemistry.

O 9.6 Mon 11:45 H25

Sustainable argon irradiated MWNT-based filters for efficient remediation of methylene blue dye from wastewater: characterization and mechanism — •Emad Elsehly — Physics Department, Faculty of Science, Damanhour University, 22516, Damanhour, Egypt

This study handles the irradiation of the multi-walled carbon nanotubes by argon ion beam and their potential application for dye removal from wastewater. The obtained data revealed that Argon ion irradiation can induce various structural changes and defects in MWNTs as confirmed by Raman spectroscopy. Moreover, the structural integrity of R-MWNTs is preserved during irradiation as shown by SEM. R-MWNTs yielded smaller crystallites, reaching a size of 4.4 nm. The adsorption efficiency of R-MWNTs was examined by remediation of methylene blue (MB) from wastewater. The results demonstrated that the remediation percentage of R-MWNTs enhanced and could reach 98%. The adsorption mechanism of methylene blue onto R-MWNTs is spontaneous, and almost chemical adsorption process. R-MWNTs have greater surface area and more active sites for adsorption. The irradiation tool offers an alternative approach to enhance the structure of MWNTs-based filters and present a highly effective solution for the removal of dyes from wastewater.

O 9.7 Mon 12:00 H25

On-surface Synthesis of Non-Benzenoid Nanographenes Embedding Azulene and Stone-Wales Topologies — •Qifan Chen[1], Kalyan Biswas[2], Sebastian Obermann[3], Ji Ma[3], Diego Soler-Polo[1], Jason Melidonie[3], Ana Barragán[2], Ana Sánchez-Grande[1], Koen Lauwaet[2], Rodolfo Miranda[2], David Écija[2], Pavel Jelínek[1], Xinliang Feng[3], and José Urgel[2] — [1]Institute of Physics of the Czech Academy of Science, CZ-16253 Praha, Czech Republic — [2]IMDEA Nanoscience, C/Faraday 9, Campus de Cantoblanco, 28049 Madrid, Spain — [3]Center for Advancing Electronics Dresden & Faculty of Chemistry and Food Chemistry, Technische Universität Dresden, D-01069 Dresden, Germany

The incorporation of non-benzenoid motifs in graphene nanostructures significantly impacts their properties. Understanding of the specific reaction mechanism of forming non-benzenoid nanographene structures with tailored electronic/magnetic properties remains limited. In this work, we report a theoretical study addressing an on-surface synthetic strategy toward fabricating non-benzenoid nanographenes containing different combinations of pentagonal and heptagonal rings. We employ the Quantum Mechanics/Molecular Mechanics (QM/MM) approach to analyze the optimal reaction pathways on Au(111) surface and explore the roles of an adatom on the activation energy barrier of the reaction. Our work provides atomistic insight into the reaction mechanism of single gold atom-assisted synthesis of novel NGs containing nonbenzenoid motifs.

O 9.8 Mon 12:15 H25

Enhanced Sampling of Chiral Molecules on Chiral PdGa Surfaces Using Machine Learning — •Raymond Christopher Amador[1,2], Umberto Raucci[3], Peilin Kang[3], Enrico Trizio[3], Hannah Bertschi[4], Jacob Wright[2], and Daniele Passerone[1,2] — [1]nanotech@surfaces laboratory, Empa, Zürich, Switzerland — [2]ETH Zürich, Zürich, Switzerland — [3]Italian Institute of Technology, Genova, Italy — [4]Max Planck Institute, Hamburg, Germany

The interaction of chiral molecules with chiral surfaces plays a fundamental role in enantioselective catalysis and molecular recognition processes. In this work, we present a novel machine learning-assisted framework for enhanced sampling of chiral molecule dynamics on chiral PdGa surfaces. Using high-dimensional descriptors of molecular-surface interactions and leveraging state-of-the-art neural network potentials, our approach significantly accelerates the exploration of configurational space while maintaining chemical accuracy. Detailed analysis reveals how chiral PdGa surfaces influence molecular adsorption, orientation, and reaction pathways, providing new insights into the enantioselective mechanisms. These findings demonstrate the potential of integrating machine learning techniques with surface science to address challenges in heterogeneous catalysis.

O 10: Focus Session Ultrafast Electron Microscopy at the Space-Time Limit II

Shaping functionalities on the nanoscale is one of the most essential challenges in modern condensed matter research. It requires a comprehensive understanding of the complex interplay of the electronic, spin, and lattice degrees of freedom in materials and requires tailoring energy transfer and dissipation pathways on the smallest length and fastest timescales. Recent instrumentation breakthroughs in different varieties of pump-probe ultrafast electron microscopy have opened the way for accessing electronic and structural dynamics at surfaces, interfaces, and nanostructures with down-to-attosecond resolution in time. While ultrafast photoemission electron microscopy techniques provide supreme sensitivity to spin and electron dynamics in real momentum space, bright ultrashort electron pulses in the ultrafast implementation of more traditional electron microscopes can probe optical states, local magnetization, and lattice dynamics with a nanometer spatial resolution.

This focus session highlights recent advances in ultrafast high-resolution electron probing. These include new instrumentation and techniques, excitations from the THz to X-ray regime, and studying novel phenomena and materials systems. At the same time, it will bring together researchers from the different areas of ultrafast condensed matter physics to foster discussions and new collaborations to explore emergent scientific questions in this field.

Organized by Armin Feist (MPI Göttingen) and Benjamin Stadtmüller (University Augsburg).

Time: Monday 15:00–17:45 Location: H2

Invited Talk O 10.1 Mon 15:00 H2

Probing coherent optical emission processes with ultrafast scanning electron microscopy — •Albert Polman — NWO Institute AMOLF, Amsterdam, the Netherlands

High-energy electron beams are unique probes of optical materials properties as their time-varying electric field can create strong materials polarizations. The subsequent light emission (cathodoluminescence, CL) provides a fingerprint of the local optical density of states at the nanoscale.

CL from plasmonic and dielectric nanostructures has a coherent phase relation with the excitation process, which enables self-referenced measurements to perform holography and metrology. Electron excitation of semiconductors creates a sequence of fs-ps-ns materials excitations, that lead to bunched CL photon emission.

New developments in ultrafast electron microscopy enable the creation of picosecond electron pulses and pump-probe spectroscopy where light and electrons serve as pump and probe or vice versa. The interaction of pulsed electrons with optical metasurfaces enables novel ways to shape the quantum mechanical electron wavepackets in space and time and may eventually create entirely new forms of ultrafast materials spectroscopy.

O 10.2 Mon 15:30 H2

Spectrally resolved free electron-light coupling strength in a transition metal dichalcogenide — •Soufiane El kabil[1], David Lerchenberger[1], Niklas Müller[1], Jonathan Weber[1], Alexander Schröder[1], and Sascha Schäfer[1,2] — [1]University of Regensburg, Regensburg, Germany — [2]Regensburg Center for Ultrafast Nanoscopy, Regensburg, Germany

In ultrafast transmission electron microscopy (UTEM), combining precisely controlled free-electron beams with localized light fields enables the creation of intricate electronic states and the visualization of transient optical near-fields via PINEM [B. Barwick, et al. Nature 462.7275 (2009): 902-906]. However, optical nearfields in photonic structures typically exhibit a strong wavelength dependence, which has so far only been partially captured by PINEM approaches.

To address this, we use strongly chirped broadband light pulses to explore the spectrally resolved interaction between free electrons and light at the edge of a

MoS2 thin film [N. Müller, et al. arXiv preprint arXiv:2405.12017(2024).]. As a fast electron traverses the optical field near the MoS2 flake, it absorbs or emits multiple photons, producing photon sidebands in its energy spectrum. By varying the electron-light delay at the sample, different spectral components of the near-field can be investigated. Numerical simulations reveal that the observed spectral and spatial modulations stem from interactions between incident and reflected light fields, as well as guided thin-film optical modes. Our results highlight the ability of PINEM to resolve the optical properties of semiconductors spatially and spectrally.

O 10.3 Mon 15:45 H2

Simulating Quantum Spin Dynamics in Transmission Electron Microscopy — •Santiago Beltrán Romero[1,2], Dennis Rätzel[3], Stefan Löffler[2], and Philipp Haslinger[1,2] — [1]VCQ, Atominstitut, TU Wien, Stadionallee 2, 1020 Vienna, Austria — [2]University Service Centre for Transmission Electron Microscopy,TU Wien, Wiedner Hauptstraße 8-10/E057-02, 1040 Wien, Austria — [3]ZARM, Unversität Bremen, Am Fallturm 2, 28359 Bremen, Germany

Transmission Electron Microscopy (TEM) has revolutionized nanoscale research by enabling unprecedented simultaneous spatial and temporal resolutions, thanks to advancements such as aberration correction, cryogenic techniques, and ultra-fast probing. However, the capabilities of TEM to probe spin dynamics – critical for understanding quantum materials – are, to date, quite limited and could be significantly improved by novel microwave spectroscopic tools [1, 2]. Building on recent innovations in that direction, we present a framework that integrates scattering theory and multislice simulations to describe the probing of spin samples on the nanoscale with time-resolved TEM. Our simulations offer insights into both elastic and inelastic processes - including the electrons backaction on the spin. They reveal how the choice of set-up parameters influence the precision of spin detection, identifying optimized conditions for enhancing the signal-to-noise ratio (SNR) and contrast. This work sets the stage for combining spin resonance tools with cutting-edge TEM capabilities, paving the way for breakthroughs in spin imaging and manipulation at the atomic level.

O 10.4 Mon 16:00 H2

Ultra-Nonlinear Subcycle Photoemission of Few-Electron States from Sharp Gold Nanotapers — •Germann Hergert, Rasmus Lampe, Andreas Wöste, and Christoph Lienau — Institut für Physik, Carl-von-Ossietzky Universität, 26129 Oldenburg, Germany

Generating attosecond electron pulse trains by coherent modulation of swift electrons enabled attosecond resolution in ultrafast transmission electron microscopy [1,2]. The possibility to transfer photon statistics to the electron number statistics in multiphoton photoemission (MPP) from nanotapers [3], opens up a window to increase photoemission nonlinearities of few-electron states and generating subcycle electron pulses. This provides an alternative road to reach subcycle resolution in electron microscopy.

Here, we present MPP of few-electron wavepackets triggered by near-infrared pulses from gold nanotapers, demonstrating 20th-order nonlinearities for electron triplets. Event-based interferometric autocorrelations of the photoemission yield are quenched to single-peak traces with 0.8 fs duration. We observe a modulation of the electron yield by the carrier-envelope phase, indicating the emission of subcycle isolated electron beams, with prospects to improve the temporal resolution in ultrafast point-projection electron microscopy.

Invited Talk O 10.5 Mon 16:15 H2

Ultrafast exciton dynamics in momentum space — Alexander Neef[1], Tommaso Pincelli[1,2], Lawson Lloyd[1], Shuo Dong[1], Samuel Beaulieu[1], Tania Mukherjee[1,2], Sebastian Hammer[3], Malte Selig[2], Dominik Christiansen[2], Andreas Knorr[2], Martin Wolf[1], Jens Pflaum[3], Laurenz Rettig[1], and •Ralph Ernstorfer[1,2] — [1]Fritz-Haber-Institut der Max-Planck-Gesellschaft, 14195 Berlin, Germany — [2]Technische Universität Berlin, 10623 Berlin, Germany — [3]Julius-Maximilian-Universität Würzburg, 97070 Würzburg, Germany

Time- and angle-resolved photoemission spectroscopy (trARPES) provides a quantum-state-resolved picture of the ultrafast dynamics of many-body states like excitons in non-equilibrium states of matter. Following the formation and scattering of excitons in momentum space in real time reveals all key properties of the excitons like binding energy, exciton-phonon coupling, and the real-space distribution of the many-body wave functions. Additionally, information about the orbital properties and Berry curvature is encoded in the multidimensional trARPES signals. Applied to heterostructures, the ultrafast exciton and charge dynamics across interfaces reveal the mechanism of charge and energy transfer processes. We will exemplify this approach for transition metal dichalcogenides heterostructures, molecular crystals, and layered semiconducting antiferromagnets.

O 10.6 Mon 16:45 H2

Subcycle band-structure videography of quantum materials — •Vincent Eggers[1], Manuel Meierhofer[1], Jakob Helml[1], Lasse Münster[1], Robert Wallauer[2], Giacomo Inzani[1], Sarah Zajusch[2], Suguru Ito[2], Leon Machtl[1], Yin Hao[3], François C. Posseik[3], Changhua Bao[1], Jens Güdde[2], F. Stefan Tautz[3], Rupert Huber[1], and Ulrich Höfer[1,2] — [1]Department of Physics and Regensburg Center for Ultrafast Nanoscopy, University of Regensburg, 93040 Regensburg, Germany — [2]Department of Physics, Philipps-Universität Marburg, 35037 Marburg, Germany — [3]Peter Grünberg Institut (PGI-6), Forschungszentrum Jülich GmbH, 52428 Jülich, Germany

We introduce the next generation of subcycle band-structure videography. By combining atomically strong few-cycle mid-infrared lightfields with sub-10-femtosecond XUV pulses in a momentum microscope, lightwave-driven dynamics can now be investigated throughout the entire Brillouin zone. Here, we observe electrons driven by carrier fields of light reaching amplitudes as high as MV/cm in graphene. Subcylce analysis of the timing of these lightwave-driven currents reveals femtosecond scattering times. Our novel setup provides a new platform to explore strong-field phenomena ranging from inter- and intraband dynamics to Bloch oscillations and the emergence of Floquet-Bloch states directly in subcycle videos covering the full band structure.

O 10.7 Mon 17:00 H2

Approaching Atomic Resolution in Ultrafast Transmission Electron Microscopy — •Sophie Schaible[1,2], Till Domröse[1,2], and Claus Ropers[1,2] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]4th Physical Institute, University of Göttingen, Germany

Ultrafast transmission electron microscopy (UTEM) [1] extends the study of structural heterogeneity in conventional TEM by introducing femtosecond temporal resolution, providing the means to map structural phase transitions at the nanoscale. However, access to atomic-scale ultrafast dynamics remains a major challenge due to the limited brightness of pulsed photoelectron beams. In this contribution, we explore approaches to atomic-resolution imaging of a structural transformation in a UTEM employing a high-coherence photoelectron source. Highly dose-efficient imaging is crucial to make optimum use of the available electron signal. We further gauge the impact of experimental parameters on the achievable spatiotemporal resolution such as sample drift, acquisition time, repetition rate and electron pulse length with and without optical excitation of the specimen.

O 10.8 Mon 17:15 H2

Towards Detection of Spin Resonance Excitations with TEM — •Antonín Jaroš, Johann Toyfl, Benjamin Czasch, Michael Stanislaus Seifner, Isobel Claire Bicket, Santiago Belrán-Romero, and Philipp Haslinger — VCQ, Atominstitut, TU Wien, USTEM, Stadionallee 2, 1020 Vienna, Austria

Microwave (MW) excitations of spin systems induce precessional spin motion at GHz frequencies. Traditional spin resonance spectroscopy techniques, such as Electron Spin Resonance (ESR) and Ferromagnetic Resonance (FMR), are employed to determine key parameters like gyromagnetic ratios and damping constants in magnetic materials. However, these methods often lack the spin sensitivity and spatial resolution required for spin studies at the atomic level. We present a novel approach that synergistically combines spin resonance techniques with Transmission Electron Microscopy (TEM). Spin state polarization is induced by the magnetic field of the TEM pole piece, while spin system excitation is achieved through an impedance-matched micro-resonator integrated into a custom-designed sample holder. The detection of spin resonance excitations in TEM might represent an important step towards MW driven spin studies with highly controlled electron probe at the nanoscale.

O 10.9 Mon 17:30 H2

Laser-driven cold-field emission source for ultrafast transmission electron microscopy — Alexander Schröder[1], •Andreas Wendeln[1,2], Jonathan Weber[1,2], Masaki Mukai[3], Yuji Kohno[3], and Sascha Schäfer[1,4] — [1]Department of Physics, University of Regensburg, Regensburg, Germany — [2]Insitute of Physics, Carl-von-Ossietzky Universität Oldenburg, Oldenburg, Germany — [3]JEOL Ltd., Tokio, Japan — [4]Regensburg Center for Ultrafast Nanoscopy (RUN), Regensburg, Germany

In recent years ultrafast transmission electron microscopy (UTEM), which combines the nanometer spatial resolution of a TEM with the femtosecond temporal resolution of a pump-probe approach, has become an increasingly important tool for investigating nanoscale dynamics. Further improving the spatiotemporal resolution in time-resolved electron imaging experiments requires femtosecond photoelectron sources with a higher degree-of-coherence. Here, we present the development of a laser-driven cold field electron source integrated in a UTEM instrument [1]. This approach yields 220-fs electron pulses with elec-

tron energy widths down to 360 meV, photoelectron spot sizes of 2 Å, and a peak normalized beam brightness exceeding $6.5 \cdot 10^{13}$ A/m^{2}sr, providing a new level of spatial and spectral precision in observing ultrafast nanoscale dynamics for UTEM applications. Lastly, we discuss the implementation of laser-driven cold-field emitters in a probe-aberration-corrected electron microscope potentially leading to smaller spot sizes with less coherent beams and significantly increased electron currents. [1] Schröder et al., arXiv:2410.23961, (2024).

O 11: Electronic Structure of Surfaces: Spectroscopy, Surface States I

Time: Monday 15:00–18:00 Location: H4

O 11.1 Mon 15:00 H4

Optimizing the photon detection in inverse photoemission — •Jan Willermann, Fabian Schöttke, and Markus Donath — Physikalisches Institut, Universität Münster, Münster, Germany

The detection of vacuum-ultraviolet photons ($\hbar\omega$ = 9.9 eV) in inverse-photoemission experiments is usually carried out with gas-filled counting tubes. Commonly, iodine/argon gas fillings were used for Geiger-Müller type photon detection. Recently, the gas filling was replaced by acetone to increase stability and the operation was changed to proportional mode [1]. While doing this, the counting tube geometry must not necessarily be changed. We carried out systematic measurements to understand the photon detection process in acetone-filled counting tubes and optimize the geometry accordingly. In the range of optimal gas pressures, we found that the photon mean free path in acetone is in scale of a few millimeters instead of a few centimeters as in iodine/argon. Furthermore, we observed that the electron mean free path in proportional-type counting tubes is also reduced to few millimeters. In comparison, the mean free path of electrons in Geiger-Müller-type counting tubes is in the range of the radius of the counting tube. As a consequence, the position of the cathode wire close to the entrance window becomes a critical parameter for the detection efficiency.

O 11.2 Mon 15:15 H4

Excitation-Mediated Transport through Nano-scale Josephson Junctions in the Coulomb Blockade Regime — •Zhengyuan Liu, Sebastian Scherb, Werner M.J. van Weerdenburg, Daniel Wegner, Nadine Hauptmann, and Alexander A. Khajetoorians — IMM, Radboud University Nijmegen, the Netherlands

Josephson junctions (JJs) are essential for superconducting quantum computing and sensing technologies. It has been shown that superconductivity in elemental BCS superconductors, including those typically used for JJs [1], can persist down to the 2D limit. However, the effects of such quantum confinement on both the electronic structure of a JJ and its subsequent transport remains unclear, and fabricating conventional source-drain JJ devices at the nanometer scale is challenging. Here, we use low-temperature scanning tunneling microscopy and spectroscopy to study the electronic structure and transport of model nano-JJ stacks grown on Si(111) surface. We first characterize the quantum well states and superconducting gap of the underlying layer. Then, we explore how both the dielectric and overlying metallic layer affect the electronic and superconducting states. We study the tunneling transport in the Coulomb blockade limit for a number of JJ stacks, revealing that the conductance is dominated by an excitation mediated process. We also discuss the superconducting properties of these stacks, and the potential to detect superconductivity through their charge transport. [1] Werner M. J. van Weerdenburg et al. Sci. Adv. 9, eadf5500 (2023).

O 11.3 Mon 15:30 H4

Double Photoemission Spectroscopy of C_{60} on $SrTiO_3$ (001) with high efficiency high-order harmonic light source — •Kathrin Plass[1], Robin Kamrla[1], Frank O. Schumann[2], and Wolf Widdra[1] — [1]Institute of Physics, Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Germany — [2]Max Planck Institute of Microstructure Physics, Halle (Saale), Germany

The photoemission spectroscopy is one of the main tools for studying the electronic structure of solids. However, the effects of electron correlation can only be inferred indirectly. In contrast, double photoemission spectroscopy (DPE) enables the direct observation of such phenomena by detecting pairs of correlated photoelectrons ejected following the absorption of a single photon [1].

C_{60} is considered a strongly correlated material, exhibiting a highly structured valence band spectrum. Recently, we discovered orbital-resolved correlation-induced two-electron binding energy shifts in C_{60}. In this study, we analyzed DPE data from C_{60} thin films on $SrTiO_3$(001) obtained using a laboratory-based high-order harmonic generation (HHG) light source operating at MHz repetition rates [2]. By boosting the HHG light source to higher photon energies and repetition rates, we are now able to investigate plasmon-assisted double photoemission in C_{60}, predicted recently [3].

O 11.4 Mon 15:45 H4

Surface Orbitroscopy: Emergent Phenomena of Orbital Angular Momentum — •Maximilian Ünzelmann[1], Tim Figgemeier[1], Begmuhammet Geldiyev[1], Hendrik Bentmann[2], and Friedrich Reinert[1] — [1]Exp. Physik VII and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, Germany — [2]QuSpin, NTNU Trondheim, Norway

Quantum degrees of freedom in electronic states are a key facet of modern quantum materials. Recently, the orbital angular momentum (OAM) — an orbital analogue of electron spin — has attracted broad attention in condensed matter and surface physics. For instance, orbitronics has been predicted as a promising route towards new functionalities, such as low-dissipation orbital currents or magnetization switching by orbital torques. In this talk, I will present orbital-sensitive angle-resolved photoemission spectroscopy experiments that demonstrate three key features of the OAM: (i) it acts as a central mediator between lattice and spin in spin-orbit-coupled systems, such as Rashba-type surface states [1,2], (ii) it might be associated with orbital currents, and (iii) its momentum texture carries topological information, giving rise to intriguing paradigms like OAM monopoles [3] or momentum-space quantum vortices [4].

O 11.5 Mon 16:00 H4

Computationally Efficient First-Principles Treatment of Scattering States in Photoemission: A Pseudo-potential Approach — •Gian Parusa[1,2,3] and Michael Schüler[1,2,3] — [1]PSI Center for Scientific Computing, Theory and Data, 5232 Villigen PSI, Switzerland — [2]National Centre for Computational Design and Discovery of Novel Materials (MARVEL), Paul Scherrer Institute, 5232 Villigen PSI, Switzerland — [3]Department of Physics, University of Fribourg, 1700 Fribourg, Switzerland

The calculation of photoemission matrix elements requires the consideration of several key factors, including Bloch states, light-matter coupling, and scattering states. The evaluation of scattering states in solids from first-principles, particularly within a plane-wave basis, is computationally demanding due to the large number of plane waves required at high energies. A well-established strategy for reducing the computational cost in the treatment of valence states involves the use of pseudo-potentials. In this work, we extend the concept of optimized norm-conserving pseudo-potentials to scattering states, utilizing a non-local Vanderbilt projector to restore the wave function properties at a specified target energy. This approach is applied to scattering states, specifically for energies above 1 Rydberg. The method is validated by simulating the photoemission spectrum of graphene and hexagonal boron nitride (h-BN) with the results compared to all-electron calculations, demonstrating both the accuracy and computational efficiency of the proposed technique.

O 11.6 Mon 16:15 H4

Electronic structure of ferromagnetic CrTe — •Chien-Wen Chuang[1], Muthu P.T. Masilamani[1], Hibiki Orio[1], Maximilian Ünzelmann[1], Chia-Nung Kuo[2,3], Chin-Shan Lue[2,3], Ashish Chainani[4], and Friedrich Reinert[1] — [1]Exp. Physik VII and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, Würzburg, Germany — [2]Department of Physics, National Cheng Kung University, Tainan, Taiwan — [3]Taiwan Consortium of Emergent Crystalline Materials, National Science and Technology Council, Taipei, Taiwan — [4]National Synchrotron Radiation Research Center, Hsinchu, Taiwan

Recent studies showed that CrTe and doped CrTe exhibit various emergent properties, such as a large magnetocaloric effect, spontaneous skyrmions and ferromagnetism with high Curie temperature T_C~340 K. We carried out Cr L-edge ($2p$-$3d$) X-ray absorption spectroscopy (XAS) and resonant photoemission spectroscopy (Res-PES) with right and left circularly polarized light on single crystal CrTe to investigate the role of Coulomb correlations in Cr $3d$ density of states(DOS). The Res-PES spectra showed a resonantly enhanced sharp peak at a binding energy of 1.5 eV, which corresponds to the Cr main $3d$ DOS, while states at the Fermi level do not show a clear resonance enhancement. A small circular dichroism of Cr $3d$ DOS was observed. In addition, we observed the Cr $3d$ two-hole L_3VV Auger feature which corresponds to a correlation satellite. Using the Cini-Sawatzky method, we estimate the on-site Coulomb interaction energy in Cr $3d$ states to be U_{dd}~3 eV.

O 11.7 Mon 16:30 H4

Unveiling the Role of Inelastic Mean Free Path in Photoelectron Diffraction: A Computational Study by Multiple Scattering — •Trung-Phuc Vo[1,2], Olena Tkach[3], Sylvain Tricot[4], Didier Sébilleau[4], Aimo Winkelmann[5], Olena Fedchenko[3], Yaryna Lytvynenko[3,6], Dmitry Vasilyev[3], Hans-Joachim Elmers[3], Gerd Schönhense[3], and Ján Minár[1] — [1]Univ. West Bohemia, Czech Republic — [2]Institute of Physics, Czech Academy of Sciences, Czech Republic — [3]Univ. Mainz, Germany — [4]Univ. Rennes, IPR, France — [5]AGH Univ. Krakow, Poland — [6]Institute of Magnetism of the NAS of Ukraine and MES of Ukraine, Ukraine

The inelastic mean free path (IMFP) of electrons near solid surfaces describes the average distance an electron travels through a solid before losing its kinetic energy via inelastic collisions. In surface analysis techniques such as photoelectron diffraction (PED), a short IMFP makes photoelectrons highly surface sensitive, allowing precise structural determination of surfaces. Conversely, a longer IMFP allows access to deeper layers, facilitating the study of bulk properties. The influence of the IMFP on PED is particularly evident with the advent of advanced time-of-flight (ToF) measurements. Controlling this key parameter is crucial. In this work, we summarize the PED implementation within the SPRKKR package and systematically explore its application over a wide kinetic energy range (106-1036 eV) for Ge 3d core levels. Our computational efforts provide insight into both Kikuchi diffraction patterns and their relation to valence band mapping, thus bridging PED analysis with electronic structure studies.

O 11.8 Mon 16:45 H4

Towards accessing the initial state by dichroic photoemission — •Jakub Schusser[1,2], Hibiki Orio[1], Maximilian Ünzelmann[1], Johannes Hessdörfer[1], Muthu Prasath Thirugnanasambandam Masilamani Masilamani[1], Florian Diekmann[3,4], Kai Rossnagel[3,4], and Friedrich Reinert[1] — [1]Experimentelle Physik VII and Würzburg- Dresden Cluster of Excellence ct.qmat, Universität Würzburg, Würzburg, Germany — [2]University of West Bohemia, Pilsen, Czech Republic — [3]Ruprecht Haensel Laboratory, DESY, Hamburg, Germany — [4]Institute of Experimental and Applied Physics, Kiel University, Germany

Despite its many advantages, photoemission has so far not allowed direct experimental access to detailed information about the initial state of solids. Dichroism in angle-resolved photoemission spectroscopy arises inherently from the matrix-element effects that depend on the initial and final states as well as the light field perturbation. By comparing both experimental and theoretical soft X-ray data in bulk WSe_2 we show the robustness of the newly introduced dichroic technique against variation of photon energy, light polarization and angle of incidence. Such robustness of the matrix-element effect represents a leap towards accessing the initial state by this differential technique with high relevance in the field of topological materials, layered systems and other material classes.

O 11.9 Mon 17:00 H4

Surface electronic structure of Te chains on Au(100) via ARPES — •Begmuhammet Geldiyev[1], Maximilian Ünzelmann[1], Tim Figgemeier[1], Hendrik Bentmann[2], and Friedrich Reinert[1] — [1]Experimentelle Physik 7 and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg — [2]Center for Quantum Spintronics, Department of Physics, NTNU, Norway

In this talk, we will provide a comprehensive description of the surface electronic band structure in epitaxial Te chains grown in the submonolayer regime on a Au(100) substrate. First, the deposition of 0.25 ML Te results in an adlayer square lattice superstructure with $p(2\times2)$ periodicity. Particularly, the band structure of this system features an interface state – derived from hybrid Te-Au orbitals – that exhibits an anisotropic spin and orbital Rashba effect [1]. Second, by slightly increasing the Te coverage to 0.30 ML, the earlier square arrangement evolves into a chain structure with c(10 × 2) periodicity [2]. Here, we will address whether the latter system inherits an analogous Rashba effect scenario. Furthermore, we will unravel a flat electronic band with a bandwidth of ≈ 20 meV, indicating an almost perfect one-dimensional character.

O 11.10 Mon 17:15 H4

Unoccupied electronic structure of the AgTe/Ag(111) surface alloy: A spin-resolved inverse photoemission study — •Marcel Holtmann, Carolin Benfer, and Markus Donath — Physikalisches Institut, Münster University, Germany

The AgTe/Ag(111) surface-alloy system has recently been investigated to understand the microscopic origin of the Rashba effect [1]. ARPES measurements suggest that tellurium p orbitals hybridize with states of the Ag(111) substrate resulting in two p_{xy} valence bands. For the unoccupied band structure, a third hybridization state with out-of-plane symmetry is detected using two-photon photoemission. Apart from this, the unoccupied electronic structure of AgTe/Ag(111) remains unexplored.

We employed spin- and angle-resolved inverse photoemission (IPE) to measure the unoccupied electronic structure with a broader scope. Using our rotatable spin-polarized electron source, we were able to measure the three-dimensional spin texture of the unoccupied states. As expected in [1], we found that the hybridization state shows a large Rashba-type spin splitting, which is untypical for non-heavy-metal systems. Using several photon detectors at different take-off angles to measure the angular distribution of the emitted photons, we gained access to the orbital symmetries of the involved electronic states. In addition, like the pristine Ag(111) surface, the AgTe/Ag(111) surface hosts an image-potential state.

O 11.11 Mon 17:30 H4

Surface Sensitivity of the VLEED Scattering Process at Pt(111) — •Hannah Unterberg, Christoph Angrick, and Markus Donath — Universität Münster, Germany

The diffraction pattern of low-energy electrons (LEED) from Pt(111) shows a three-fold symmetry, although the surface layer exhibits a six-fold symmetry. This result proves the non-neglible influence of the second and deeper atomic layers resulting from the finite probing depth of the electrons. Here, we report on a spin-polarized very-low-energy electron diffraction (VLEED) [1,2] experiment on Pt(111). The reflected specular beam is measured at a fixed polar angle of incidence $\Theta = 45°$, while the azimuthal angle of incidence is varied over a wide range. This allows us to probe the surface sensitivity of the VLEED scattering process.

Our measurements at the non-reconstructed Pt(111) surface reveal distinct differences in the electron reflectivity and the spin-orbit-induced reflection asymmetry along the high symmetry directions $\overline{\Gamma}\,\overline{M}$ and $\overline{\Gamma}\,\overline{M}'$. These directions are equivalent (non-equivalent) in the case of six (three)-fold rotational symmetry. Our result indicates a substantial contribution from both the first and subsequent atomic layers to the VLEED scattering process. In contrast, results for the Au(111) surface, which hosts the prominent herringbone reconstruction, exhibit only minor differences between $\overline{\Gamma}\,\overline{M}$ and $\overline{\Gamma}\,\overline{M}'$. The different results for Pt(111) and Au(111) are discussed in view of the reconstruction.

O 11.12 Mon 17:45 H4

Broadband THz Non-Linear Response In Topological Noble Metal Dichalcogenides — George de Coster[1,2], Lucas Lafeta[3], Stefan Heiserer[1], Zdeněk Sofer[4], Achim Hartschuh[3], Georg Duesberg[1], and •Paul Seifert[1] — [1]Institute of Physics, University of the Bundeswehr Munich, EIT, Werner-Heisenberg-Weg. 39, 85577 Neubiberg, Germany — [2]DEVCOM Army Research Laboratory, 2800 Powder Mill Road, Adelphi, Maryland, United States — [3]Department of Chemistry and Center for NanoScience (CeNS), Ludwig-Maximilians-Universität München, Butenandtstraße 5-13 (E), 81377 Munich, Germany — [4]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Technická 5, 166 28 Prague 6, Czech Republic

Noble metal dichalcogenides belong to the material class of layered 2D materials and were shown to host type-II Dirac semi-metallic behavior, as well as topological surface states and superconductivity. Intriguingly, noble metal dichalcogenides display strong second harmonic generation and second order photocurrent response despite their centrosymmetric crystal structure. We investigate the spectrally-resolved optical response and reveal second and third order nonlinear response at both, optical frequencies as well as in the THz range. The latter is analyzed in polarization resolved spectroscopy, that points towards spin-polarized bands at the symmetry broken surface as origin of the non-linearities. Our results elucidate the spectral opto- electronic response at low energies and discuss its anisotropy in light of underlying symmetry constraints.

Imaging standing phonons within topological defect in strong coupling superconductor by scanning tunneling microscopy — •Qili Li, Thomas Gozlinski, Rolf Heid, Jörg Schmalian, and Wulf Wulfhekel — Karlsruhe Institute of Technology, Karlsruhe, Germany

Electron-phonon coupling plays an important role in conventional superconductors. Understanding the behavior of phonons will promote the applications of conventional superconductors. However, it is difficult to observe the spatial behavior of phonons. Here, we utilize inelastic scanning tunneling microscopy (ISTS) at 45 mK to investigate phonons within topological defect, i.e. stacking fault tetrahedron (SFT), in the strong coupling superconductor Pb(111) [1]. We find that the local Eliashberg function [2,3] is significantly enhanced by SFTs. Moreover, lateral standing waves of phonon are also observed on SFTs. Compared with phonon bandstructure, we find that the SFTs have strong confinement on transverse acoustic phonons, while the longitudinal acoustic phonons are less confined. Our findings pave the way to phonon engineering in strong coupling superconductors. [1] PRL 14, 108 (1965). [2] Sov. Phys. JETP 11, 696 (1960). [3] PRL 114, 047002 (2015).

O 12.2 Mon 15:15 H6

Directing far- and nearfield scattering with dielectric Mie Voids — •Benjamin Reichel[1], Mario Hentschel[1], Adrià Canós Valero[2], Thomas Weiss[2], and Harald Giessen[1] — [1]4th Physics Institute and Research Center SCoPE, University of Stuttgart, 70569 Stuttgart, Germany — [2]Institute of Physics, University of Graz, and NAWI Graz, Graz 8010, Austria

Controlling the behavior of light at the nanoscale is a significant challenge in various applications such as metadevices, diffraction gratings, and resonant surfaces. Recently, Mie voids created in high-index dielectric host materials have emerged as a promising platform for confining electromagnetic waves in small values, possibly extending down to ultraviolet wavelengths in air. Therefore understanding and theoretical modeling the electromagnetic scattering behavior of Mie voids are crucial for their effective use.

In this study, we perform a spectral multipolar decomposition for the far- and near-field scattering behavior of dielectric Mie voids upon plane wave or local point dipole illumination. Dielectric Mie voids exhibit strong forward far-field scattering behavior, whereas in the near-field strong backscattering behavior is observed. These insights will be important in the development of resonance and meta structure designs, especially when deriving a generalized Kerker condition. Finally, leveraging the full resolution of electromagnetic Mie voids will open avenues for embedding quantum emitters in high index substrates.

O 12.3 Mon 15:30 H6

Influence of Plasma on the Electrode and the Electrolyte during Plasma Electrolysis — •Lukas Forschner[1], Jan-Luca Gembus[2], Peter Awakowicz[2], Andrew R. Gibson[3], Timo Jacob[1], and Albert K. Engstfeld[1] — [1]Ulm University, Institute of Electrochemistry, Ulm, Germany — [2]Ruhr University Bochum, Chair of Applied Electrodynamics and Plasma Technology, Bochum, Germany — [3]University of York, York Plasma Institute, Heslington, United Kingdom

During plasma electrolysis, a plasma is ignited in a thin vapor layer between the powered electrode and the liquid electrolyte. The plasma interacts with both the electrode[1] and the electrolyte, which can modify their properties.[2] In this work, we focus on a metal electrode used as a cathode, where nanoparticle formation can be observed during plasma electrolysis. To gain fundamental insight into nanoparticle formation, we studied the gas sheath surrounding the electrode (including the plasma) and the respective interfaces in detail. Specifically, we use optical emission spectroscopy and high-speed camera imaging to analyze the processes on a milli- to microsecond time scale. We elucidate the structural changes on the electrode induced by the plasma under these conditions with scanning electron microscopy imaging. Based on these results, we discuss mechanisms leading to the formation of nanoparticles in the solution from the electrode.

O 12.4 Mon 15:45 H6

Structural, morphological and chemical characterization of plasma-treated NiCoO electrolyzer anodes — •Timo Wagner[1], Nicolas Wöhrl[1], Vineetha Vinayakumar[2], Christian Marcks[3], Anna Mechler[3], Doris Segets[2], and Axel Lorke[1] — [1]Faculty of Physics and CENIDE, University Duisburg-Essen, Germany — [2]IVG-PST and CENIDE, University of Duisburg-Essen — [3]AVT.ERT, RWTH Aachen University

Plasma surface pre and post treatment are important steps to tailor characteristics for later manufacturing steps, or as a finishing step to engineer surface characteristics for later applications. We developed a nitrogen microwave plasma process to be used as pre and post treatment for NiCoO coatings for electrolyzers. The plasma treatment resulted in significant modification of the NiCoO films. For example a porous structure, as measured by AFM, SEM and TEM, leads to enhanced accessibility of the active material. Organic species from the spray coating were removed and the plasma-treated NiCoO layers also exhibited a highly hydrophilic surface, which facilitated better interaction with the electrolyte. X-ray absorption spectroscopy (XAS) studies indicated a higher Fe uptake from the electrolyte, which is beneficial for the oxygen evolution reaction (OER). Raman studies showed a more reversible oxidation behavior in the plasma-treated layers. Overall, these modifications contributed to an enhanced OER performance of the NiCoO anodes due to the plasma post-treatment as characterized electrochemically by cyclic voltammetry (CV) and measuring the electrochemically active surface area (ECSA).

O 12.5 Mon 16:00 H6

Artificial Atoms: Energy-Level Engineering and Shape-Dependent Reactivity — •Marco Weiss, Fabian Stilp, Michael Roessner, Max Reinhart, and Franz J. Giessibl — Institute of Experimental and Applied Physics, University of Regensburg

Artificially arranged nanostructures can confine the quasi-free two-dimensional electron gas present on noble metal surfaces, giving rise to a series of resonant eigenstates [e.g. 1-3]. These structures, often referred to as artificial atoms, exhibit remarkable parallels to natural atoms, including the ability to form chemical bonds with natural atoms or repulsive interactions with chemically inert molecules. [4] In our previous investigations using atomic force microscopy (AFM), we successfully identified the occupation of resonant eigenstates that intersect the Fermi level. Notably, we observed a probe-tip-induced energy shift of these states during the measurements. [4] Building on these findings, we developed a method to estimate the energy of artificial atomic states based on their electron occupation. This approach enables precise tuning of the energy levels of these states with meV-scale accuracy. Additionally, we discovered that the distance-dependent repulsive interaction between a chemically inert molecule and the resonant eigenstates of the artificial atom is influenced by the geometric shape of the nanostructure. This holds the potential to tailor nanoscale interactions through precise structural design. [1] Crommie et al., Science 262 (1993), [2] Manoharan et al., Nature 403 (2000), [3] Freeney et al., SciPost Phys. 9 (2020), [4] Stilp et al., Science 372 (2021)

Increasing the lifetime of confined electronic states in an artificial quantum structure — Marco Weiss, •Michael Schelchshorn, Fabian Stilp, Alfred J. Weymouth, and Franz J. Giessibl — Institute of Experimental and Applied Physics, University of Regensburg, 93053 Regensburg, Germany

Understanding and tuning the factors influencing the lifetime of confined electronic states is a basic concept of quantum mechanics, whereas achieving large lifetimes in artificial nanostructures holds great potential for advancing quantum technologies. An example of such artificial structures are CO-based quantum corrals. In this study, tunneling spectroscopy measurements reveal a strong correlation between the size of the quantum corral and spectral width, characterized by a predominant Gaussian line shape. We attribute this dominant Gaussian-shaped lifetime broadening to the interaction of surface state electrons with the corral boundary. To further investigate this phenomenon, we constructed corrals of varying wall densities. Our findings indicate that elastic processes, such as tunneling, are more sensitive to the wall density than coupling to the bulk.

O 12.7 Mon 16:30 H6

Template-Assisted Synthesis of Fe_3O_4 Nanodots for High-Density Resistive Switching Memory — •Yifan Xu[1,2], Connie Bednarski-Meinke[2], Erkai Wang[3], Asmaa Qdemat[2], Emmanuel Kennzinger[2], Felix Gunkel[3], Regina Dittmann[3], Yen-Po Liu[3], Oleg Petracic[2,1], and Mai Hussein Hamed[2,4] — [1]Heinrich Heine University Düsseldorf, Faculty of Mathematics and Natural Sciences, 40225 Düsseldorf, Germany — [2]Jülich Centre for Neutron Science (JCNS-2), JARA-FIT, Forschungszentrum Jülich GmbH, 52425 Jülich, Germany — [3]Peter Grünberg Institute and JARA-FIT, Forschungszentrum Jülich GmbH, Jülich, Germany — [4]Faculty of Science, Helwan University, 11795 Cairo, Egypt

The growing demand for high-density memory solutions has driven the exploration of innovative fabrication techniques. We introduce a bottom-up approach for synthesizing ordered Fe_3O_4 nanodots for nanoscale resistive switching memory applications. Using anodic aluminum oxide (AAO) templates as masks, Fe_3O_4 nanodots on Nb:$SrTiO_3$ substrate were fabricated via pulsed laser deposition. Scanning electron microscopy (SEM) confirms the nanodots' uniformity. Grazing incidence X-ray scattering (GISAXS) reveals a high degree of long-range ordering. Magnetometry measurements show that the Verwey transition temperature (T_V) and coercivity are preserved compared to continuous thin films. Conductive atomic force microscopy (cAFM) confirms well-defined nanodots using current maps. By sweeping the voltage on a single nanodot, set and reset processes are observed within ±2V.

O 12.8 Mon 16:45 H6

Intercalation of graphene nanoribbons — •Lüthi Dominik[1], Lin Yang[2], Ji Ma[2], Akimitsu Narita[3,4], Xinliang Feng[2], Klaus Müllen[3], Pascal Ruffieux[1], Roman Fasel[1], and Gabriela Borin Barin[1] — [1]Empa, Ueberlandstrasse 129, 8600 Dübendorf, Switzerland — [2]Center for Advancing Electronics Dresden, TU Dresden, 01062 Dresden, Germany — [3]Max Plank Institute for Polymer Research, 55128 Mainz, Germany — [4]Okinawa Institute of Science and Technology, Okinawa 904-0495, Japan

Atomically precise graphene nanoribbons (GNRs) exhibit unique properties due to electron confinement and tunable band gaps, making them ideal for applications ranging from transistors to spintronics. Precise fabrication is critical, and on-surface synthesis enables the creation of various GNR types with tailored edge topologies, giving rise to intriguing properties such as spin-polarized edges and topological quantum states.

For device integration, GNRs must be transferred from metallic to insulating substrates. However, the high chemical reactivity of zigzag edges has hindered studies of their transport properties. To address this, we explore intercalation to decouple GNRs from metallic substrates, enabling dry-transfer in ultra-high vacuum. This preserves intrinsic properties and facilitates integration into device architectures.

We investigate intercalation with transition metal halides, providing a platform to study interactions with magnetic layers, combining decoupling benefits with potential applications in quantum technologies.

O 12.9 Mon 17:00 H6

Facilitating On-Surface Synthesis on Inert Surfaces by Using a Noble Gas Atmosphere — •Lukas Grossmann[1], Sascha Korn[2], Rochus Breuer[3], Michael Schmittel[3], Heiko Weber[2], Wolfgang Heckl[1], and Markus Lackinger[1] — [1]Deutsches Museum, Munich, Germany — [2]Friedrich-Alexander University, Erlangen, Germany — [3]University of Siegen, Siegen, Germany

A decisive milestone of On-Surface Synthesis (OSS) is the transition from reactive to inert surfaces for the covalent coupling of molecules. This is desirable, because conventionally used metal surfaces strongly interact with organic adsorbates. Thus, adsorption on metals alters the intrinsic properties of the synthesized nanostructures, compromising their applicability. In contrast, inert surfaces leave the adsorbed nanostructures unperturbed. But synthesis is aggravated since activation energies for coupling reactions on inert surfaces are generally higher than on metals. Consequently, reactants desorb before the activation temperature required for their covalent coupling is reached. Here, we explore the OSS of covalent thioether-linked Sierpinski triangles from 1,3,5-tris(4-mercaptophenyl)benzene on inert graphite surfaces. As shown by Scanning Tunneling Microscopy, covalent coupling is feasible by annealing in an argon atmosphere of 1 bar instead of in a vacuum. This protocol kinetically inhibits the premature desorption of reactants, and could be successfully transferred to even more weakly interacting graphene surfaces. The adsorbed Sierpinski triangles exhibit superior thermal stability compared to identical structures on gold and are air stable, underscoring the advantages of inert surfaces.

O 12.10 Mon 17:15 H6

Functionalization of Surfaces with Ordered Arrays of Fullerenes — •Lukas Spree, Caroline Hommel, Pierre Josse, and Andreas Heinrich — IBS Center for Quantum Nanoscience, 52 Ewhayeodae-gil, Daehyeon-dong, 03760 Seoul, South Korea

Endohedral fullerenes are a fascinating class of compounds that facilitate the stabilization of exotic configurations of few-atom structures within the confines of a carbon cage. Depending on the combination of carbon cage and encapsulated species, they provide very stable compounds with highly desirable physical properties. Among the compounds isolated and characterized so far are single molecule magnets with high blocking temperatures and promising candidates for spin qubits with long coherence times.

The exceptional chemical stability of endohedral fullerenes makes them very promising candidates for real-world applications. To achieve their full potential as nanometer sized magnets or quantum sensors, it is necessary to characterize and control the spatial orientation and surrounding of each individual molecule. Scanning probe microscopy techniques lend themselves well for the characterization of ordered assemblies on atomically flat substrates, as they offer an unparalleled combination of spatial and energy resolution.

In this presentation we will show our ongoing efforts of preparing ordered low-dimensional assemblies of endohedral fullerenes on surfaces through chemical functionalization and on-surface synthesis approaches, and discuss possibilities to preserve their desirable properties, like slow magnetic relaxation and potentially long coherence times.

O 12.11 Mon 17:30 H6

Well-defined nanostructures for energy storage and conversion applications — •Ningxiang Wu, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Template-based technique provides a perfect approach to realize well-defined arrayed nanostructures within large-scale.[1]We have developed nanostructuring techniques mainly using anodic aluminum oxide templates with scalable, parallel and fast processes for fabricating different three-dimensional and surface nanostructures.[2]The obtained well-defined nanostructures possess large-scale arrayed configuration, high structural density, perfect regularity and cost-effectiveness, and are highly desirable for constructing different nano-devices especially for energy storage and conversion applications, including rechargeable sodium-ion and potassium-ion batteries, supercapacitors, and photo electrochemical devices.[3-4]The device performances demonstrated that the obtained nanostructures benefit these applications through the precise control over the structural features enabled by the geometrical characteristics of the templates. These achievements indicate the high potential and importance of template-based nanostructuring techniques for both basic research and device applications.[1] Nat.Commun.,2022,13,2435, [2] Nat.Nanotechnol.,2017,12,244, [3] Nat.Commun.,2018,9,1720, [4] Nat.Commun.,2016,7,10348

O 13: Organic Molecules on Inorganic Substrates: Adsorption and Growth

Time: Monday 15:00–17:30 Location: H8

O 13.1 Mon 15:00 H8

Identical Fe-N4 Sites with Different Reactivity: Elucidating the Effect of Support Curvature — •Dominik Hrůza[1], Zdeněk Jakub[1], Jakub Planer[1], Azin Shahsavar[1], Jiří Pavelec[2], and Jan Čechal[1,3] — [1]CEITEC - Central European Institute of Technology, Brno University of Technology, Czech Republic — [2]Institute of Applied Physics, TU Wien, Vienna, Austria — [3]Faculty of Mechanical Engineering, Brno University of Technology, Czech Republic

Understanding the atomic-scale mechanisms of single-atom catalysts (SACs) is pivotal for advancing their design and application. Using a 2D metal-organic framework (MOF) featuring Fe-N4 sites on a graphene/Ir(111) support, we uncover how the curvature of an inert substrate can significantly influence adsorption properties. We show that a 0.4 Å corrugation induced by the inert graphene/Ir(111) moiré leads to pronounced variations in adsorption energy of TCNQ (tetracyanoquinodimethane) molecules adsorbed on the 2D MOF. Molecules adsorbed above the "valleys" of the graphene/Ir moiré exhibit binding energies significantly stronger than those above the "hills," resulting in a temperature stability difference of over 60 °C. Our findings based on STM and DFT highlight those small structural distortions in SAC structure can profoundly impact the adsorption properties.

O 13.2 Mon 15:15 H8

Small atoms – large influence: Structural evolution upon dehydrogenation — •Jonas Brandhoff[1], Alina Preibsch[1], Richard Berger[2], Felix Otto[1], Roman Forker[1], Oliver T. Hofmann[2], and Torsten Fritz[1] — [1]Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany — [2]Institute of Solid State Physics, Technical University Graz, Petersgasse 16, 8010 Graz, Austria

Molecular self-assembly is governed by the delicate balance between molecule-substrate and intermolecular interactions. Surface reactions can modulate this balance, enabling the engineering of tailored molecular architectures. Dehydrogenation is one of such surface reactions. Despite hydrogen being often overlooked as the smallest atom, its removal can significantly alter molecular interactions. In this study, 2,3,6,7,10,11-hexahydroxytriphenylene (HHTP) serves as a prototypical molecule to investigate dehydrogenation processes on surfaces. HHTP contains six equivalent hydroxy groups, allowing for varying degrees of dehydrogenation. These can be controlled via variation of the substrate temperature during deposition or using annealing steps post-deposition. Utilizing distortion-corrected Low-Energy Electron Diffraction (LEED), Scanning Tunneling Microscopy (STM), and Density Functional Theory (DFT), we examine the structural properties of (dehydrogenated) HHTP monolayers on Cu(111). Our analysis reveals distinct HHTP motifs and elucidates their interactions, providing deeper insights into the design of molecular architectures through controlled surface chemistry.

O 13.3 Mon 15:30 H8

Optical and Electronic Properties of Epitaxial Lead Phthalocyanine Monolayers and Bilayers on Graphite and Graphene — •Roman Forker, Marco Gruenewald, Matthias Spoddeck, and Torsten Fritz — Friedrich-Schiller-Universität Jena, Institut für Festkörperphysik, Helmholtzweg 5, 07743 Jena, Germany

The optical and electronic properties of the near-infrared absorber lead phthalocyanine (PbPc) on graphitic surfaces are measured by means of differential reflectance spectroscopy (DRS) and scanning tunneling spectroscopy (STS), respectively. This is corroborated by a thorough structural characterization using scanning tunneling microscopy (STM) and low-energy electron diffraction (LEED), demonstrating the similarity of the adlayer structures on graphite and graphene substrates. The dielectric function of PbPc monolayers (ML) extracted from our DRS measurements exhibits monomer character, and thus provides evidence that there is no significant electronic coupling between the molecular film and graphite or graphene. From 1 to 2 ML the dielectric function changes drastically, indicating the formation of physical dimers. Concomitantly, for PbPc bilayers the electronic properties are found to be caused by the formation of face-to-face stacked molecules, resulting in a splitting of the dI/dV-features associated with the PbPc HOMO and LUMO upon bilayer formation. Our results are compared to previous photoelectron spectroscopy data of this system, where a similar splitting of the HOMO-related features was reported.

O 13.4 Mon 15:45 H8

Growth of N-heterocyclic carbenes on modified silicon surfaces — •Marie-Louise Fraser[1], Milan Kubicki[1], Ankita Das[2], Mowpriya Das[2], Preeti Chahar[2], Martin Franz[1], Frank Glorius[2], and Mario Dähne[1] — [1]Technische Universität Berlin, Institut für Festkörperphysik, Berlin, Germany — [2]Universität Münster, Organisch-Chemisches Institut, Münster, Germany

Today's semiconductor industry is mainly based on silicon, thus the growth of organic films on silicon surfaces is a highly promising research field. However, the high number of dangling bonds typically present on silicon surfaces renders them often less suitable for molecular growth. With surface modifications more suitable silicon substrates can be produced. One such modification is a rare earth silicide layer on the Si(111) surface enabling growth of highly ordered monolayers [1]. Another suitable substrate is Si(111) modified by boron, as demonstrated e.g. for N-heterocyclic carbenes (NHCs) [2]. NHCs have been demonstrated to be particularly promising ligands for surface modification and functionalization. Here, scanning tunneling microscopy is used to examine the growth of the NHC molecule BIMe on both boron and rare-earth modified Si(111) surfaces. On both substrates, films with coverages ranging from submonolayers to complete monolayers could be successfully grown, allowing the determination of the adsorption geometry and of the ordering behavior in the monolayer. [1] M. Kubicki et al., *J. Phys. Chem. C* **128**, 13347 (2024). [2] M. Franz et al., *Nat. Chem.* **13**, 828 (2021).

O 13.5 Mon 16:00 H8

Imaging Dihydrogen Bond-Driven Assembly of Borazine on Au(111) — •Matthias Zeilerbauer, Marco Thaler, Barbara Obwaller, Milan Ončák, and Laerte L. Patera — Universität Innsbruck, Austria

Dihydrogen bonding (DHB) is a peculiar type of attractive interaction occurring between a partially positively charged hydrogen atom and a partially negatively charged hydrogen atom. Borazine represents a prototypical molecule exhibiting dihydrogen bonding in both gas phase, as well as in its crystalline form. For borazine assemblies on solid surfaces, a direct observation and characterization of dihydrogen bonding has remained elusive, possibly due to an intricate interplay of substrate-molecule and intermolecular interactions. Here we present evidence of dihydrogen bonding occurring in borazine assemblies on a Au(111) surface. By means of low-temperature scanning tunneling microscopy, we unveiled distinct configurations, exhibiting single and double dihydrogen bonding. Density functional theory calculations elucidate the interplay between substrate adsorption and intermolecular interactions to stabilize the formation of borazine dimers on Au(111), being the building blocks for the formation of larger assemblies.

O 13.6 Mon 16:15 H8

From Physical Trends to Structural Control: Insights into Phase Transition Times at Metal-Organic Interfaces — •Anna Werkovits, Simon B. Hollweger, and Oliver T. Hofmann — Institute of Solid State Physics, Graz University of Technology, Austria

At many metal-organic interfaces, molecules in the wetting layer undergo lying-standing transitions, significantly altering interface properties. Understanding the kinetics governing these transitions is essential for controlling structural evolution over time. This knowledge is particularly critical for tailoring interfaces based on either kinetically trapped or thermodynamically favoured structures.

To facilitate the design of interfaces, we develop a physically motivated surrogate model that estimates the phase transition times across a wide range of metal-organic interfaces. Using a systematic set of kinetic Monte Carlo simulations, incorporating variations in energetic landscapes and relative molecule sizes (representing hypothetical interface systems), we extract the physical relationships governing the timescales of phase transitions. These dependencies are analysed as functions of adsorption energies (lying and standing), kinetic barriers for reorientation and diffusion, molecule sizes, and environmental parameters such as temperature and pressure. This approach yields a formula that serves as a foundation for understanding trends, controlling structural evolution, and estimating timeframes for experiments and applications to ensure phase stability. Additionally, it enables the design of systems that remain stable over long periods, even in metastable states, advancing experimental and practical applications.

O 13.7 Mon 16:30 H8

Controlled Ion Beam Deposition supplied by Electrospray (ES-CIBD) - enabling UHV deposition of large, reactive or fragile building blocks for functional nano-architectures — •Andreas Walz[1,2], Annette Huettig[1,2], Michael Walz[1,2], Hartmut Schlichting[1,2], and Johannes V. Barth[2] — [1]pureions GmbH, Gilching, Germany — [2]Technical University of Munich, Germany

Cutting-edge research in the field surface- and nano- science using organic molecules requires control and unbiased understanding of structure and composition. Standard deposition techniques for the underlying building blocks restrict possible candidates: Thermal evaporation in vacuum (MBE, OMBE) is limited to volatile substances. Solution-based techniques such as drop casting, spin coating or inkjet printing are versatile but often lack purity and quality. Electrospray ionization (ESI) combined with mass selection and soft-landing of molecules unravels the vast potential of large, reactive or bio-relevant building blocks. The pool of possible molecules spans a wide spectrum from small organic molecules, over graphene nanoribbons (GNRs) up to several kilo- and megadalton proteins, DNA, but also inorganic clusters and larger nanoparticles may be possible. In-line with this, we present an UHV ion beam deposition device and its functionalities. Deposited layers are analyzed via STM. The main body of the device contains RF-driven ion guides with high transmission (>80% efficiency). A digital square-wave quadrupole mass filter (dQMF) provides virtually unlimited m/z-range. The footprint is benchtop in size, 0,5 x 1 m.

O 13.8 Mon 16:45 H8

Reactions of benzoporphyrins with Cu(111) — •Maximilian Muth, Majid Shaker, Julien Steffen, Alexander Wolfram, Simon Steinbach, Andreas Görling, Hans-Peter Steinrück, and Ole Lytken — Friedrich-Alexande-Universität Erlangen-Nürnberg, Germany

Porphyrins are molecules with many interesting properties that change upon adsorption on solid substrates. This can lead to something as simple as a change in conformation of the molecule or something more drastic as a reaction with - or catalyzed by - the substrate. We have focused on three molecules: free-base tetraphenyl transdibenzoporpyhrin, copper tetraphenyl transdibenzoporpyhrin and free-base tetraphenyl tetrabenzoporpyhrin adsorbed on Cu(111). Using temperature-programmed desorption, X-ray photoelectron spectroscopy, scanning tunneling microscopy and density-functional theory calculations, we have identified three reactions in the temperature range from 280 to 1000 K. In the first reaction step at 350 - 480 K the free-base benzoporphyrins react with copper atoms from the substrate, forming metalloporphyrins. At 480 - 650 K, the phenyl rings and pyrrole/benzo rings undergo a ring fusion reaction. Finally, at 650 - 950 K, the molecules polymerize and all remaining hydrogen atoms desorb from the surface as H2.

O 13.9 Mon 17:00 H8

Supercharging Polymorphism of Organic/Inorganic Interfaces — •Christoph Wachter and Oliver T. Hofmann — Institute of Solid State Physics, Graz University of Technology, Graz, 8010, Austria

The polymorphism of organic/inorganic interfaces heavily influences a multitude of their properties. Therefore, altering the polymorphism by changing the substrate or modifying the intermolecular interactions has been studied extensively. However, the extent to which charge transfer affects polymorphism has yet to be investigated systematically. Based on the hypothesis that there is a link between the band width of polymorphs and their relative energy, we expect that polymorphs with larger band width are preferred if charge is transferred uniformly across the organic monolayer.

Conversely, it is also possible for charge to localize in individual adsorbates instead of spreading out across the monolayer. Such localized charge transfer occurs when the electronic coupling of the organic molecules to each other and to the substrate is small. In that case the relation stated above is not well-defined anymore.

To investigate the impact of both localized and delocalized charge transfer on polymorphism, we employ density functional theory in conjunction with a machine-learning based structure search algorithm. To properly capture charge localization, we go beyond the standard semi-local functionals by utilizing hybrid functionals and report whether the expected relation still holds in the case of localized charge transfer.

O 13.10 Mon 17:15 H8

Towards 2D metal-organic frameworks on weakly interacting substrates: FeDCA on coinage metals and Bi_2Se_3(111) surfaces — •Anna Kurowská[1], Matthias Blatnik[1], Veronika Stará[1], Pavel Procházka[1], Čestmír Drašar[2], and Jan Čechal[1,3] — [1]Central European Institute of Technology, Brno University of Technology — [2]Faculty of Chemical technology, University of Pardubice — [3]Institute of Physical Engineering, Brno University of Technology, Czech Republic

The formation of 2D metal-organic frameworks (MOFs) on a surface of topological insulator (TI) is a promising path to design quantum materials with exotic properties. MOFs featuring ferromagnetically coupled metal atoms are theoretically predicted to induce an exchange gap in the TI's surface band structure, potentially leading to a quantum anomalous Hall effect. However, the knowledge of self-assembly on TI substrates is still scarce. Here, we demonstrate the first experimental realization of 2D MOF, Fe-dicyanoanthracene (FeDCA), on the surface of a strong TI Bi2Se3. The structure and morphology were studied via scanning tunneling microscopy (STM) and low-energy electron microscopy (LEEM) and diffraction (LEED). We compare the growth of FeDCA on the Bi_2Se_3(111) surface with coinage metals and gr/Ir(111) surfaces, and discuss the conditions at which we obtain typical mixed Kagomé-honeycomb lattice and at which a new hexagonal lattice appears. The demonstration of 2D MOF/TI hybrid material presents a milestone on the way toward their application in fault-tolerant spin interconnects in future quantum devices.

O 14: 2D Materials Beyond Graphene: Growth, Structure and Substrate Interaction (joint session O/HL)

Time: Monday 15:00–18:00 Location: H11

O 14.1 Mon 15:00 H11

Hexagonal structures of europium oxides on Pd(111) studied with LEED and STM — •Muriel Wegner, Stefan Förster, and Wolf Widdra — Martin-Luther-Universität Halle-Wittenberg, Germany

With an increasing interest in technological applications of oxide materials, also two-dimensional (2D) oxides came into focus. The large flexibility in the variation of the cationic species, including even a combination of different cations, promises a rich variety of properties [1,2]. So far, the center of attention has been on transition metal sesquioxides M_2O_3 of corundum structure.

Here, we expand this field towards lanthanides. We present a combined scanning tunneling microscopy (STM) and low-energy electron diffraction (LEED) study of the growth of submonolayer coverages of europium oxide on a Pd(111) surface. Upon annealing the as deposited Eu in oxygen containing environments at temperatures above 800 K, long-range ordered multilayer islands of Eu_2O_3 are obtained. From LEED a $\begin{pmatrix} 8/3 & 4/3 \\ -4/3 & 4/3 \end{pmatrix}$ superstructure on Pd(111) is derived, which corresponds to a hexagonal lattice with a lattice parameter of 6.35 Å. This structure exhibits a large stability range. Only upon annealing to 1175 K in UHV an additional (2×2) superstructure evolves, which is seen as a hexagonal array of pores at a distance of 12.70 Å in STM.

By addition of small amounts of Ti atoms, the transformation into planar two-dimensional films is achieved. These mixed-metal oxides form a honeycomb lattice with a lattice parameter of 7.2 Å. In contrast to pristine Eu_2O_3, the Ti containing honeycomb can easily be resolved in STM.

O 14.2 Mon 15:15 H11

Growth of an Fe buckled honeycomb lattice on Be(0001) — Hermann Osterhage[1], Abid H. Khan[2], Karoline Oetker[1], Radek Dao[1], Samaneh Setayandeh[2], Patrick Burr[2], Roland Wiesendanger[1], and •Stefan Krause[1] — [1]University of Hamburg, Germany — [2]University of New South Wales, Sydney, Australia

The Be(0001) surface is considered to be an ideal model system to host a 2D electron gas with pronounced electron-electron and electron-phonon interactions that are decoupled from the bulk [1,2]. In a combined scanning tunneling microscopy (STM) and density functional theory (DFT) study the growth of Fe on a clean Be(0001) surface is investigated on the atomic scale [3]. At low Fe coverage, the nucleation of terraced nanoislands with a disordered surface is observed experimentally with STM. Increasing the Fe coverage results in the growth of extended films exhibiting a well-ordered p(2×2) superstructure. DFT is applied to investigate the growth of Fe on a Be(0001) surface from individual atoms to extended films.

The Fe buckled honeycomb lattice formation on Be(0001), as derived from our study, provides evidence for the realization of a very peculiar non-trivial electronic and magnetic model system. The results will be presented and discussed in terms of their implications for the emergence of novel electronic and magnetic phases resulting from the interactions between the 2D electron gas and the magnetic atoms.

O 14.3 Mon 15:30 H11

Electronic structure and edge states in the 2D Kagome lattice Ta_2S_3 / Au(111) — •Thais Chagas[1], Alessia Bardazzi[1], Samuel M. Vasconcelos[2], Alan C. R. Souza[3], Catherine Grover[1], Alice Bremerich[1], Kai Mehlich[1], Daniel Weber[1], Mario S. C. Mazzoni[3], Michael Rohlfing[2], and Carsten Busse[1] — [1]Department Physik, Universität Siegen, Germany — [2]Institute of Solid State Theory, Universität Münster, Germany — [3]Departamento de Física, Universidade Federal de Minas Gerais, Brazil

Kagome structures are a key model system in quantum physics, representing one of the most geometrically frustrated 2D magnetic lattices. In these systems, magnetic moments condense into a spin liquid phase at low temperatures, leading to intriguing physical phenomena. The characteristic Kagome bands in this lattice consist of a Dirac cone that gives rise to massless Dirac fermions with high mobility and a flat band that, in contrast, leads to fermions with infinite effective mass.

In this work, we investigate the 2D Ta_2S_3 Kagome phase on Au(111) using scanning tunneling microscopy (STM). STM images reveal bright island edges as a consequence of an enhanced density of states, indicating the presence of edge states. Additionally, we observe a significant dependence of atomic contrast on tunneling conditions, suggesting a complex electronic band structure near the Fermi level. Furthermore, we analyze the impact of growth parameters on defect formation. Finally, density functional theory (DFT) was employed to study the electronic structure of this material on Au(111), providing deeper insight into its electronic properties and interactions.

O 14.4 Mon 15:45 H11

Spectroscopic and microscopic study of (car)borane based 2D materials — •Martha Frey[1], Julian Picker[1], Jakub Visnak[2], Christof Neumann[1], Tomas Base[2], and Andrey Turchanin[1] — [1]Friedrich Schiller University Jena, Institute of Physical Chemistry, Lessingstraße 10, 07743 Jena, Germany — [2]The Czech Academy of Sciences, Institute of Inorganic Chemistry, 250 68 Husinec-Rez, c.p. 1001, Czech Republic

Boranes are electron-delocalized molecular clusters containing boron and hydrogen. Their electron-deficient bonding and structural diversity as well as their high thermal stability make them attractive for applications ranging from optoelectronics to energy storage. Here we present the fabrication of a novel boron-based, carbon free two-dimensional (2D) material via electron-induced crosslinking of borane-based self-assembled monolayers (SAMs) on silver substrates. The SAMs, crosslinking process and resulting nanomembranes were analyzed using complementary surface-sensitive techniques including X-ray and ultraviolet photoelectron spectroscopy (XPS, UPS), low-energy electron diffraction (LEED) and scanning tunneling and electron microscopies (STM, SEM). Furthermore, the results were compared with carborane-based 2D nanomaterials studied previously in our labs. The results demonstrate that properties of the 2D (car)borane nanosheets can be adjusted and tailored by the respective SAM constituents and that these structurally diverse cluster molecules open up new avenues for engineering novel functional 2D materials.

O 14.5 Mon 16:00 H11

Growth and Structure of Titanium Ditelluride Films on Au(111) — •Andreas Raabgrund, Alexander Wegerich, Lutz Hammer, and M. Alexander Schneider — Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

Aiming at the MBE growth of transition metal ditelluride (MTe_2) films particularly in the single-layer limit, the formation of and interaction with the interface is of fundamental interest. The growth of a MTe_2 film can be achieved either by the tellurization of the desired metal substrate [1] or by the reactive deposition of Te and the corresponding transition metal M on a suitable substrate [2].

In this contribution we follow the latter approach and investigate both single-

and multilayer $TiTe_2$ films on Au(111) by LEED-IV, DFT, and STM. At first glance, LEED suggests a (4×4) superstructure with three $TiTe_2$ on four Au(111) unit cells. STM topography, however, reveals a mismatch of about 1% of the growing film w.r.t. the Au(111) substrate which indicates a relaxed $TiTe_2$ layer. LEED-IV results favor a film in close contact with Au substrate (Te-Au layer distance: ≈ 2.7 Å). By DFT total energy calculations we find that neither Te nor Ti substitution is favored in the topmost Au layer. Continuing the reactive deposition of Ti and Te a multilayer $TiTe_2$ film grows epitaxially as found by LEED-IV with a Pendry R factor of 0.12. Further, we discuss the transferability of this growth recipe to other MTe_2 films on Au(111).

O 14.6 Mon 16:15 H11

Growth and Edge Reconstruction of 2D MnI_2 on Ag(111) — •Daniel Rothhardt[1,2,3], Christopher Penschke[4], Hans Josef Hug[1,2], Regina Hoffmann-Vogel[3], and Amina Kimouche[3] — [1]Empa, 8600 Dübendorf, Switzerland — [2]Department of Physics, University of Basel, 4056 Basel, Switzerland — [3]Institute of Physics and Astronomy, University of Potsdam, 14476 Potsdam, Germany — [4]Institute of Chemistry, University of Potsdam, 14476 Potsdam, Germany

The reduced dimensionality of thin transition metal dihalide films on single-crystal surfaces enables a wide array of magnetic and electronic phenomena. However, producing stoichiometric monolayer islands demands thorough control over growth parameters. In this work, we utilize scanning probe microscopy (SPM) to explore the growth of MnI_2 on Ag(111) through single-crucible evaporation. The Ag(111) surface's catalytic activity promotes dehalogenation of MnI_2, resulting in a reconstructed iodine adlayer that serves as a template for the formation of truncated hexagonal MnI_2 islands. These islands display alter-nating edge lengths and distinctive Kelvin potentials, as revealed by Kelvin Probe Force Microscopy (KPFM). Density Functional Theory (DFT) calculations corroborate the experimental observations, including island heights, lattice parameters, and edge formation energies for both pristine and reconstructed edges. The asymmetry in edge lengths arises from differences in formation energies, determined by the orientation (up or down) of iodine atoms at the edges, as confirmed by DFT.

O 14.7 Mon 16:30 H11

Low defect density in MoS_2 monolayers grown on Au(111) by metal-organic chemical vapor deposition — •Julian Picker, Ziyang Gan, Christof Neumann, Antony George, and Andrey Turchanin — Friedrich Schiller University Jena, Institute of Physical Chemistry, Jena, Germany

Monolayers of transition metal dichalcogenides (TMDs) possess high potential for applications in novel electronic and optoelectronic devices and therefore the development of methods for their scalable growth is of high importance. Among different suggested approaches, metal-organic chemical vapor deposition (MOCVD) is the most promising one for technological applications because of its lower growth temperature compared to most other methods, e.g., conventional chemical vapor or atomic layer deposition (CVD, ALD). Here we demonstrate the epitaxial growth of MoS_2 monolayers on Au(111) by MOCVD at 450 °C. We confirm the high quality of the grown TMD monolayers down to the atomic scale using several complementary methods. These include Raman spectroscopy, non-contact atomic force microscopy (nc-AFM), X-ray photoelectron spectroscopy and scanning tunneling microscopy (STM). The topographic corrugation of the MoS_2 monolayer on Au(111), revealed in a moiré structure, was measured as 20 pm by nc-AFM. The estimated defect density calculated from STM images of the as-grown MoS_2 monolayers is in the order of 10^{12} vacancies/cm^2. The defects are mainly caused by single sulfur vacancies.

J. Picker *et al.*, Micron **186**, 103708 (2024).

O 14.8 Mon 16:45 H11

Characterization of a large-scale single-domain MoS_2 monolayer — •Fabian Schöttke[1], Luka Pirker[2], Martin Vondráček[3], Michaela Hanušová[2], Václav Valeš[3], Jan Honolka[3], Otakar Frank[2], Matěj Velický[2], and Markus Donath[1] — [1]Physikalisches Institut, Universität Münster, Münster, Germany — [2]J. Heyrovský Institute of Physical Chemistry, Czech Academy of Sciences, Prague, Czech Republic — [3]Institute of Physics, Czech Academy of Sciences, Prague, Czech Republic

To fully utilize the outstanding optical and electronic properties of single-layer transition metal dichalcogenide (TMDC) in devices, a perfect single-domain film is needed. From the wealth of available preparation methods, exfoliation seems to provide the highest film quality. This method, however, commonly results in small flakes within the micrometer regime only. Exfoliation onto, or assisted by, a Au(111) surface is able to result in large-scale single-domain samples of several millimeters in diameter. We experimentally confirm the high quality of a MoS_2 monolayer on Au(111) by characterizing several sample properties: optical appearance, long-range structural order, work function changes, and the occupied & unoccupied electronic structure. Optical inspection and diffraction patterns easily identify millimeter-sized single domains. The electronic structure of MoS_2 is clearly distinguished from Au(111) states, especially measured by inverse photoemission in the L gap of Au(111). In summary, our experimental data of a MoS_2 monolayer exfoliated onto Au(111) demonstrate the capability of this procedure to produce large-scale single-domain TMDC samples.

O 14.9 Mon 17:00 H11

Kinetics of borophene growth on Ir(111) via boron segregation from the bulk — •Marin Petrović[1], Sherif Kamal[1], Borna Radatović[1], Marko Kralj[1], Matteo Jugovac[2], Iulia Cojocariu[2], Andrea Locatelli[2], and Tevfik Onur Menteş[2] — [1]Centre for Advanced Laser Techniques, Institute of Physics, 10000 Zagreb, Croatia — [2]Elettra - Sincrotrone Trieste S.C.p.A, 34149 Trieste, Italy

Segregation of boron atoms to the Ir(111) surface and their self-assembly into a borophene monolayer were tracked by low-energy electron microscopy (LEEM). Real-time monitoring of sample temperature, boron adatom concentration and borophene coverage reveals the kinetics of boron segregation from the iridium bulk and different modalities of borophene epitaxial growth. It is found that the temperature-triggered boron segregation to the surface is accompanied by instantaneous nucleation of borophene islands and condensation of boron adatoms, followed by rapid propagation of island perimeter along the iridium terraces. Subsequent growth of borophene proceeds by displacement of iridium surface steps, which is energetically expensive and thus relatively slow process that heavily depends on the step morphology. By identifying and analyzing quasi-equilibrium conditions on the sample surface during borophene growth, formation enthalpy of a boron monomer from borophene was estimated, which agrees well with the available theoretical calculations of the boron-iridium system.

O 14.10 Mon 17:15 H11

Growth and etching of hBN on Cu(111): Impact on substrate step dynamics and morphology — •Patrick Seleš[1,2], Marin Petrović[1], Smruti Ranjan Mohanty[3], and Frank Meyer zu Heringdorf[3] — [1]Center for Advanced Laser Techniques, Institute of Physics, Bijenička 46, Zagreb, Croatia — [2]Faculty of physics, University of Rijeka, Radmile Matejčić 2, Rijeka, Croatia — [3]Faculty for Physics, University of Duisburg-Essen, Lotharstrasse 1-21, Duisburg, Germany

The interaction of precursors and oxygen molecules with metal surfaces plays an important role in the growth dynamics of two-dimensional material such as graphene and hexagonal boron nitride (hBN). By using low-energy electron microscopy (LEEM), in this study we investigate the influence of hBN growth on Cu(111) step dynamics at various stages ranging from borazine precursor dosing to oxygen etching. Real-time monitoring of Cu step displacement underneath and next to hBN islands revealed step pinning and a significant decrease in step velocities compared to the pristine Cu surface, highlighting the stabilizing effect of hBN. After the removal of hBN islands by oxygen etching, Cu steps accelerated back to the pre-growth velocities and rearranged into a new surface morphology. Our findings elucidate the interplay between surface dynamics and step motion during hBN growth on Cu(111). By analyzing step displacement and morphological evolution, we contribute to a deeper understanding of metal-catalyzed chemical vapor deposition growth of hBN.

O 14.11 Mon 17:30 H11

In-situ growth and characterization of 2D $TaSe_2$ on Au(111) — •Cathy Sulaiman[1], Lars Buss[1], Raquel Sánchez-Barquilla[1], Jens Falta[2], and Jan Ingo Flege[1] — [1]Applied Physics and Semiconductor Spectroscopy, BTU Cottbus-Senftenberg, Cottbus, Germany — [2]Institute for Solid State Physics, University of Bremen, Bremen, Germany

Group V dichalcogenides such as TaX_2 (X = S, Se, T) have extensively been investigated in recent decades due to their diverse electron correlation effects, including the occurrence of charge density waves and Mott-Hubbard transitions. In 2D, two polytypes, 1T and 1H, exist, which exhibit distinct properties, making selective growth of each polytype crucial. Using low-energy electron microscopy (LEEM), we have successfully observed the growth of two $TaSe_2$ phases on Au(111) *in situ* after the co-deposition of Ta and Se. At elevated temperature, micron-sized, triangle-shaped islands with bright contrast nucleate first and grow at a higher rate. However, this phase turns out to be meta-stable as it suddenly transitions into a more stable phase (with dark contrast) and continues to grow at a reduced rate. Low-energy electron diffraction shows the presence of $TaSe_2$; bandstructure-sensitive I(V)-LEEM analysis reveals substantial differences in electron reflectivity between both phases. A comparison with TaS_2 suggests that the metastable and stable phases are 1T- and 1H-$TaSe_2$, respectively.

O 14.12 Mon 17:45 H11

CVD growth of monolayer transition metal dichalcogenides heterostructures using liquid precursors — •Md Tarik Hossain[1], Axel Printschler[1], Julian Picker[1], Christof Neumann[1], Moritz Quincke[2], Johannes Biskupek[2], Ute Kaiser[2], and Andrey Turchanin[1] — [1]Institute of Physical Chemistry, Friedrich Schiller University Jena, Jena 07743, Germany — [2]Central Facility of Electron Microscopy, Electron Microscopy Group of Material Science, University of Ulm, Ulm 89081, Germany

Heterostructures (HSs) formed of transition metal dichalcogenide (TMD) monolayers have attracted substantial research interest due to their unique physical properties. However, engineering the HS configurations (lateral and vertical) including the domain size for each TMD remains challenging. Here we present a facile route for the synthesis of different types of HSs of TMD monolayers using liquid precursors for transition metals. We characterized the TMD HSs by several complementary spectroscopy and microscopy techniques. Our results suggest that the HS configurations, lateral length and area of each TMD can be tuned by varying concentration ratios of the precursors. In addition, the overall heterostructure sizes can also be tuned from few to hundreds of micrometers. The developed method paves the way to obtaining high-quality lateral and vertical HS of $MoSe_2$-WSe_2 with controllable domain sizes.

O 15: Focus Session Many-Body Phenomena in Nanomagnets: Kondo, Spinons, Spinarons and Beyond (joint session O/TT)

The electron spin, a fundamental quantum mechanical property, plays a crucial role in determining the electronic and magnetic properties as well as the dynamics of matter. Its role becomes even more important at surfaces, 2D materials and nanomagnets as the low-dimensionality increases electron correlation. A fundamental understanding of spin excitations is significant for both fundamental science and modern applications. For decades, the interpretation of experimental signatures of spin excitations were focused on the Kondo effect paradigm, with Co atoms on the (111) surface of noble metals as the prototypical example. However, recent first-principles predictions and spin-polarized scanning tunnelling spectroscopy in high magnetic fields have demonstrated the existence of many-body states, called spinarons. These states arise from the binding of electronic states to spin excitations in the presence of spin-orbit coupling. Such findings, along with other studies, challenge the Kondo interpretation. Furthermore, related non-trivial many-body states may emerge in thin-film geometries, as shown by photoemission spectroscopy and first-principles manybody investigations or in quantum spin liquids. These examples testify that many-body phenomena are not only critically important for the fundamental understanding of spin excitations, they also impact a wide range of material characteristics, including electronic, magnetic, thermodynamic, and transport properties. This focus session will provide a forum to discuss intriguing many-body states driven by spin excitations, and serve as a forum to discuss the current knowledge on their origins, unique properties, and implications.

Organized by Matthias Bode (Würzburg University), Yujeong Bae (Swiss EMPA), and Stefan Blügel (FZ-Jülich).

Time: Monday 15:00–18:15 Location: H24

Invited Talk O 15.1 Mon 15:00 H24

Kondo and Yu-Shiba-Rusinov resonances: transport and coupling — •Laëtitia Farinacci[1,2,3], Gelavizh Ahmadi[3], Gaël Reecht[3], Benjamin W. Heinrich[3], Contanstin Czekelius[3], Felix von Oppen[3], and Katharina J. Franke[3] — [1]University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany — [2]Carl-Zeiss-Stiftung Center for Quantum Photonics Jena-Stuttgart-Ulm, Germany — [3]Fachbereich Physik, Freie Universität Berlin, Germany

The exchange coupling between a magnetic impurity and a superconducting substrate leads to the formation of magnetic bound states, known as Yu-Shiba-Rusinov (YSR) states, inside the superconducting gap, as well as a Kondo resonance outside the gap. Studying these two many-body phenomena in parallel provides valuable insights into their characteristic properties.

We observed striking correlations between the asymmetries of the YSR state and the Kondo effect induced by FeTPyP molecules on Pb(111) in a scanning tunneling microscope (STM) [1]. We show that both asymmetries originate from interfering tunneling paths via a spin-carrying orbital and the highest occupied molecular orbital.

Additionally, we studied the formation of YSR bands in a self-assembled kagome lattice of magnetic molecules on Pb(111) and track YSR hybridization from kagome precursors to larger islands [2]. This work will motivate further studies to resolve possible spin-liquid or Kondo-lattice-type behavior.

Invited Talk O 15.2 Mon 15:30 H24

Electron delocalization in a 2D Mott insulator — •Amadeo L. Vazquez de Parga[1,2,4,5], Cosme G. Ayani[1,2], Michele Pisarra[3], Iván M. Ibarburu[1], Clara Rebanal[1], Manuela Garnica[2,4], Fabián Calleja[2], and Fernando Martín[1,2] — [1]Universidad Autónoma de Madrid, Madrid, Spain — [2]IMDEA Nanociencia, Madrid, Spain — [3]Universitá della Calabria, Rende, Italy — [4]Instituto Nicolás Cabrera, Madrid, Spain — [5]Condensed Matter Physics Center (IFIMAC), Madrid, Spain

We follow by means of low temperature Scanning Tunneling Microscopy and Spectroscopy, the buildup of a 2D Kondo lattice in a system composed by a 2D Mott insulator, a single 1T-TaS2 layer, stacked on the surface of a metallic crystal, 2H-TaS2. When the sample temperature is lower than 27K, the magnetic moments present in the Mott insulator experience the Kondo screening by the conduction electrons of the metal, leading to the appearance of a Kondo resonance at the Fermi level. Below 11 K, a gap opens within the Kondo resonance, which is the signature of the formation of a coherent quantum state that extends all over the sample, i.e., a Kondo lattice [1]. Quasi particles interference maps reveal the emergence of a Fermi contour in the 2D Mott insulator when the temperature drops below 11K, indicating the delocalization of the highly correlated Mott electrons [2]. The observed modifications in the LDOS are well explained by state-of-the-art Density Functional Theory calculations.

Invited Talk O 15.3 Mon 16:00 H24

Kondo or no Kondo, that is the question — •Alexander Weismann, Neda Noei, Niklas Ide, and Richard Berndt — Institut für experimentelle und angewandte Physik, Christian-Albrechts-Universität zu Kiel, Kiel, Germany

The spin properties of individual atoms and molecules can produce distinctive spectral features in tunneling spectra near zero bias. Among these features, Kondo resonances and inelastic spin-flip excitations are often challenging to distinguish, despite their markedly different spectral line shapes. A Kondo resonance indicates a non-magnetic ground state, where the atomic spin is screened by conduction band electrons. In contrast, spin-flip excitations observed in zero-field tunneling spectra require magnetic anisotropy, which arises from spin-orbit coupling (SOC), to play a significant role. In this study, we demonstrate that the well-known Co/Cu(111) system, long believed to exhibit a Kondo resonance, instead adopts a magnetic ground state that is protected from Kondo screening by substantial magnetic anisotropy. The zero-bias anomaly in scanning tunneling spectra undergoes significant modification when Co atoms are attached to monoatomic Cu chains. Measurements conducted at 340 mK in a magnetic vector field reveal clear signatures of inelastic spin-flip excitations, with the anisotropy axis tilted away from the surface normal. The magnitude and orientation of this anisotropy are consistent with density functional theory (DFT) calculations. Moreover, quantum Monte Carlo many-body simulations confirm that the Kondo effect is suppressed when SOC is properly accounted for.

Invited Talk O 15.4 Mon 16:30 H24

Evidence for spinarons in Co atoms on noble metal (111) surfaces — •Artem Odobesko — Physikalisches Institut, Universität Würzburg, Am Hubland, 97074 Würzburg

The zero-bias anomaly in the tunnelling differential conductance of Co atoms on Au(111) [1], long attributed to the Kondo effect, has recently been reinterpreted [2] as evidence of the spinaron – a novel many-body excitation arising from the interplay between spin excitations and conduction electrons. In our study, we used spin-polarized scanning tunneling spectroscopy (STS) on Co atoms on Cu(111) and Au(111) under high magnetic fields, revealing field-induced energy shifts and spin-resolved spectral features that challenge the conventional Kondo interpretation. Instead, our findings provide the first experimental confirmation of the spinaron [3].

We also investigated the role of hybridization with the substrate in spinaron formation, focusing on the reconstructed Au(111) surface. The unique local electronic environments created by the herringbone reconstruction strongly influ-

ence the hybridization strength and spectral features of Co adatoms, revealing a clear link between adsorption site, hybridization, and spinaronic excitations. Our results shed light on the fundamental mechanisms driving spinaron formation.

Invited Talk O 15.5 Mon 17:00 H24

Spinarons: A new view on emerging spin-driven many-body phenomena in nanostructures — •Samir Lounis — Peter Grünberg Institut, Forschungszentrum Jülich & JARA, D-52425 Jülich, Germany — Faculty of Physics, University of Duisburg-Essen and CENIDE, 47053 Duisburg, Germany — Institute of Physics, Martin Luther University Halle-Wittenberg, 06120 Halle (Saale), Germany

Many-body phenomena are crucial in physics, particularly in condensed matter, influencing electronic, magnetic, thermodynamic, and transport properties. They leave distinct spectroscopic signatures, such as Kondo, excitonic, and polaronic features, arising from specific degrees of freedom. Since more than two decades Cobalt atoms on the (111) surfaces of noble metals have been a paradigm for the Kondo effect in scanning tunnelling spectroscopy experiments [1]. However, our recent first-principles predictions [2] followed by STS experiments in high magnetic fields [3,4] challenge this notion. Our findings reveal that the observed transport anomalies stem from spin excitations of Co atoms, forming a new many-body state – the spinaron – distinct from the Kondo resonance. I will delve into the spinaron origins, their unique properties, and implications explored through the recent atomic manipulation experiments. This work opens pathways to investigate and engineer these hybrid states in nanostructures, offering new insights into fundamental many-body states.

[1] V. Madhavan et al., Science 280, 567 (1998); [2] J. Bouaziz et al., Nat. Commun. 11, 6112 (2020); [3] F. Friedrich et al., Nat. Phys. 20, 28 (2024); [4] N. Noei et al., Nanoletters 23, 8988 (2023)

O 15.6 Mon 17:30 H24

Emergence of spinaronic states in Fe adatoms — Ilias Klepetsanis[1,2], Juba Bouaziz[4], •Philipp Rüssman[1,3], and Samir Lounis[1,2] — [1]Forschungszentrum Jülich & JARA, Germany — [2]University of Duisburg-Essen and CENIDE, Germany — [3]University of Würzburg, Germany — [4]Research Center for Advanced Science and Technology, University of Tokyo, Japan

In recent years, spinarons, predicted from first-principles calculations [1], have been observed in Co adatoms on the Cu(111) surface, using spin-polarized scanning tunnelling spectroscopy (STS) in high magnetic fields [2]. Spinarons leave a non-trivial spectroscopic signature, for long interpreted to originate from the Kondo effect [3]. Here, we employ relativistic time-dependent density functional and many-body perturbation theory, to investigate the case of Fe adatoms on the Cu(111) surface, which carry a large magnetic moment of $3.25\mu_B$ preferring an out-of-plane orientation as dictated by a magnetic anisotropy energy of 2meV. In contrast to the Co adatom, the spinarons in Fe do not overlap with trivial spin-excitations. We discuss the spinaronic response to an out-of-plane magnetic field, the orbital character and the impact of spin-orbit coupling. [1] J. Bouaziz et al., Nat. Commun. 11, 6112 (2020); [2] F. Friedrich et al., Nat. Phys. 20, 28 (2024); [3] V. Madhavan et al., Science 280, 567 (1998)

O 15.7 Mon 17:45 H24

Revising the Superconductivity in Iron Based Superconductors from the Perspective of Electron Phonon Coupling — •Lanlin Du[1,2] and Sheng Meng[1,2,3] — [1]Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences, Beijing, China — [2]School of Physical Sciences, University of Chinese Academy of Sciences, Beijing, China — [3]Songshan Lake Materials Laboratory, Dongguan, Guangdong, China

There are currently two mainstream superconducting pairing mechanisms, namely electron phonon coupling and spin fluctuation, which are believed to play a dominant role in conventional superconductors like simple metal superconductors and unconventional superconductors like Copper oxides, respectively. Iron based superconductors are believed to connect these two aspects, that is, both mechanisms are important in it. In fact, some studies have shown that electron phonon coupling is also important in cuprates, and even provide evidence for s-wave pairing symmetry in them. Therefore, it is important to consider the role of electron phonon coupling in unconventional superconductors. Here, we revise the superconductivity in Iron based superconductors using Migdal-Eliashberg formalism and electron phonon coupling strength corrected by many body method from the two perspectives of doping and pressurization. Our results are in good agreement with the experiments. Based on this, we predict a new two-dimensional high-Tc Iron based superconductor.

O 15.8 Mon 18:00 H24

Theoretical model for multiorbital Kondo screening in strongly correlated molecules with several unpaired electrons — •Manish Kumar[1], Aitor Calvo-Fernandez[2], Diego Solar-Polo[1], Asier Eiguren[2], Maria Blanco-Rey[3], and Pavel Jelinek[1] — [1]Institute of Physics, Academy of Sciences of the Czech Republic , Cukrovarnicka 10, Prague 6, CZ 16200, Czech Republic — [2]Department of Physics, University of the Basque Country UPV-EHU, 48080 Leioa, Spain — [3]Department of Polymers and Advanced Materials: Physics, Chemistry and Technology, University of the Basque Country UPV-EHU, 20018 Donostia-San Sebastián, Spain

The mechanism of Kondo screening in strongly correlated molecules with several unpaired electrons on a metal surface is still under debate. Here, we provide a theoretical framework that rationalizes the emergence of Kondo screening involving several extended molecular orbitals with unpaired electrons. We introduce a perturbative model, which provides simple rules to identify the presence of antiferromagnetic spin-flip channels involving charged molecular multiplets responsible for Kondo screening. The Kondo regime is confirmed by numerical renormalization group calculations. In addition, we introduce the concept of Kondo orbitals as molecular orbitals associated with the Kondo screening process, which provide a direct interpretation of experimental dI/dV maps of Kondo resonances. We demonstrate that this theoretical framework can be applied to different strongly correlated open-shell molecules on metal surfaces, obtaining good agreement with previously published experimental data.

O 16: Scanning Probe Techniques: Method Development

Time: Monday 15:00–18:00 Location: H25

O 16.1 Mon 15:00 H25

Fast and quantitative nanomechanical mapping using photothermal off-resonance tapping atomic force microscopy (AFM) — •Gunstheimer Hans[1,2], Fläschner Gotthold[1], Adams Jonathan[1], Hölscher Hendrik[2], and Hoogenboom Bart[1] — [1]Nanosurf AG, Gräubernstrasse 12-14, 4410 Liestal, Switzerland — [2]Institute of Microstructure Technology (IMT), Karlsruhe Institute of Technology, Karlsruhe, Germany

Multifunctional imaging, makes AFM a powerful tool for nanoscale surface analysis. However, most scanner-based methods for measuring mechanical properties are slow, limiting their use in fast mapping of mechanical characteristics. The main source of limitation is the piezo scanner, used to modulate tip-sample distance. This can be overcome by direct cantilever actuation, such as photothermal excitation. By moving the cantilever's comparably smaller mass, higher actuation bandwidths are accessible, enabling new approaches for AFM-based nanomechanical characterization. Here, we share insights on applying photothermal off-resonance tapping to fast nanomechanical property mapping. Based on simulations of cantilever bending due to laser-induced heating, we predict the cantilever response and propose a procedure to convert thermomechanical cantilever behavior into a calibrated nanomechanical measurement. We present the experimental method validation by measurements of polymer samples and reference structures. This novel photothermal off-resonance tapping mode enables quantitative nanomechanical mapping at frequencies of several tens of kHz, unlocking new insights into dynamic sample behavior.

O 16.2 Mon 15:15 H25

Multifrequency Excitation and High Dynamic Range Tunneling Spectroscopy — Philipp E.J. Maier, Ajla Karić, Carolina A. Marques, Berk Zengin, and •Fabian D. Natterer — Department of Physics, University of Zurich, Winterthurerstrasse 190, CH-8057, Switzerland

The massive number of spectra required for high-resolution quasiparticle interference of low-dimensional quantum materials motivates the development of faster point spectroscopies. While the advent of parallel spectroscopy and compressive sensing enhancements has provided welcome speed boosts, these come at a cost. The application of a sinusoidal voltage on the nonlinearities in the current-voltage characteristics of a tunneling junction generates a frequency comb of higher order current-harmonics. While their parallel measurement enables faster tunneling spectroscopy, it unfortunately averages longest where the currents are largest, leading to poor signal-to-noise ratios for smaller signals associated with features close to the Fermi level. Here, we introduce a multifrequency excitation mode that increases the averaging time for small currents, enabling fast and high-resolution spectroscopy. Additionally, the AC excitation of our method can be used to dramatically increase the dynamical current range by exactly and deliberately suppressing the large amplitude, low order harmonics that would otherwise saturate the preamplifier stage.

O 16.3 Mon 15:30 H25

Dynamics on the atomic-scale: Use and limitations of stochastic resonance spectroscopy — •Nicolaj Betz[1,2], Vivek K. Rajathilakam[1], Laëtitia Farinacci[1,3], Susan N. Coppersmith[4], Susanne Baumann[1], and Sebastian Loth[1,2] — [1]University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany — [2]Center for Integrated Quantum Science and Technology (IQST), University of Stuttgart, Stuttgart, Germany — [3]Carl-Zeiss-Stiftung Center for Quantum Photonics Jena-Stuttgart-Ulm, Germany — [4]School of Physics, University of New South Wales, Sydney, Australia.

Stochastic dynamics offer valuable insight into the internal structure of a system and its interactions with the environment. However, in atomic-scale systems investigated using scanning tunneling microscopy, comprehensive and accurate characterization is often a significant challenge. In this talk, we discuss a new type of measurement technique, stochastic resonance spectroscopy (SRS), that provides comparatively large signals over a wide range of timescales down to the picosecond range. It uses the effect of stochastic resonance, where the system's state synchronizes with an external harmonic drive. This encodes information about the dynamics in a time-independent signal. Such drive-induced imprinting of time-independent signals can alter the system's dynamics, but this limitation can be mitigated in SRS by its ability to identify and even tune these drive-induced dynamics. This enables targeted investigation of driven quantum systems on the atomic scale.

O 16.4 Mon 15:45 H25

From experiments to insights: processing tool for SPM images with periodic pattern — •Farzin Irandoost[1], Fillippo Federici Canova[2], Tobias Dickbreder[3], Franziska Sabath[3], Angelika Kühnle[3], and Adam S. Foster[1,4] — [1]Department of Applied Physics, Aalto University, Helsinki, Finland — [2]Nanolayers Research Computing Ltd., London, England — [3]Physical Chemistry I, Bielefeld University, Germany — [4]Nano Life Science Institute (WPI-NanoLSI), Kanazawa University, Kanazawa, Japan

Big datasets of Scanning Probe Microscopy (SPM) images are potentially valuable, but robust algorithms are required for preprocessing them due to the high levels of defects and noise introduced during experiments. These issues often render many images unusable, especially for in-liquid SPM studies.

As part of a study on hydration patterns using a dataset of in-liquid calcite, we developed a versatile workflow to clean the data and extract features for further analysis. This workflow automatically corrects non-linear defects, ensuring the outputs closely resemble ideal periodic patterns. Consequently, many previously discarded raw images can be recovered to prepare a large, clean dataset ready for analysis. Afterward, the features of interest could be extracted using pattern decomposition facilitated by Fourier transforms.

This approach provides access to invaluable information about the lattice and hydration patterns for our study. Additionally, it offers a versatile tool for broader analyses of images with periodic structures.

O 16.5 Mon 16:00 H25

True Alternating Current Scanning Tunneling Microscope (ACSTM): tunneling on insulators — •Marcel Rost[1] and Milan Allan[1,2] — [1]Leiden Institute of Physics (LION), Leiden, NL — [2]University of Munich (LMU), Munich, Germany

Scanning Tunneling Microscopy has revolutionized our atomic scale understanding of surfaces and accelerated progress in nanotechnology. This technique, however, is restricted to metal or semiconducting samples, as it requires a tiny current to stabilize the tip-sample distance with atomic scale precision.

We developed a new imaging and feedback method that relies on true alternating current (AC) without any direct current (DC) component. This technique does not only enable the imaging on non-conducting surfaces with atomic resolution, like (thin) glass and oxides, it provides also access to high-frequency electronic sample information. We demonstrate that it is possible to measure on 22nm thick silicon oxide with 10 MHz tunneling current.

O 16.6 Mon 16:15 H25

STM-induced luminescence with a parabolic mirror - millions of counts — •Yannis Hilgers, Andreas Reutter, Mike Stummvoll, Markus Etzkorn, and Uta Schlickum — Institute of Applied Physics - LENA, TU Braunschweig, Germany

In recent years, scanning tunneling microscopy-induced luminescence (STML) has become a powerful technique allowing to record topography with atomic resolution and simultaneous spatially resolved photon count maps. We have built a Photon STM with a large parabolic mirror which was specifically designed for high photon collection efficiency. With this system we detected so far unreached photon counts of about 6 million photons per second at 1 nA tunnelling current that result from the decay of plasmon-polariton excitations between a Ag(111) surface and a Ag tip. Considering losses due to geometry, shadowing, optical components and detectors, we estimate a yield of approximately $5 \cdot 10^{-3}$ photons per tunnelling electron. This is scratching on the theoretical predictions by Johansson et al. [1], Persson and Baratoff [2] and others who all reported conversion factors in the range of 10^{-4} to 10^{-3} at most. In this talk we discuss these results, the instrumental calibrations and assumptions necessary for this estimation and speculate about possible explanations of the high observed excitation efficiency.

O 16.7 Mon 16:30 H25

Momentum-polarized microscopy with van der Waals scanning probe tip. — •Abhisek Kole[1,2,4], Frank Stefan Tautz[1,2,4], Markus Ternes[1,2,3], Jose Martinez Castro[1,2,3], and Felix Lüpke[1,2,5] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, Germany — [2]Jülich Aachen Research Alliance, Fundamentals of Future Information Technology, Germany — [3]Institut fur Experimentalphysik II B, RWTH Aachen, Aachen, Germany — [4]Institut fur Experimentalphysik IV A, RWTH Aachen, Aachen, Germany — [5]II. Physikalisches Institut, Universität zu Köln, Cologne, Germany

Van der Waals materials are celebrated for their remarkable 2D physics, which includes correlated phenomena and topological effects. In this work, we present momentum-polarized microscopy using a van der Waals scanning probe tip. We developed and implemented a novel fabrication method to fabricate van der Waals scanning tunneling tips from exfoliated graphite flakes. The fabricated tips were characterized by atomically resolved scanning tunneling microscopy (STM) on an Ag(111) surface, where differential conductance measurements provided direct evidence of tunneling through the zigzag edge states of graphene. In addition, Friedel oscillations on the Ag(111) surface revealed clear signs of momentum-dependent tunneling, manifesting as anisotropic tunneling conductance. To further validate and investigate the momentum selective properties of the zigzag graphene tips, we have resolved the momentum dependent superconducting gap on FeSe lattices.

O 16.8 Mon 16:45 H25

Image-to-molecule translation for high-resolution SPM images — •Lauri Kurki[1], Jie Huang[1], Niko Oinonen[1,2], and Adam S. Foster[1,3] — [1]Aalto University, Finland — [2]Nanolayers Research Computing Ltd., UK — [3]WPI-NanoLSI, Kanazawa University, Japan

Scanning tunnelling microscopy (STM) and atomic force microscopy (AFM) functionalized with a CO molecule on the probe apex capture sub-molecular level detail of the imaged sample [1]. However, the produced images are often difficult to interpret due to complex tip-sample interactions. To accelerate image analysis, we propose machine learning tools to extract sample properties directly from SPM images.

In recent years, there has been rapid development in image analysis methods in SPM in general and in particular for extracting atomic positions from AFM and STM images [2,3,4]. We build upon these models and achieve improved chemical and physical sensitivity compared to previous results [2]. Additionally, we explore equivariant neural networks [5] and compare their data efficiency and accuracy to traditional deep learning models.

O 16.9 Mon 17:00 H25

Scanning Quantum Microscopy for 2D Superconductors — •Ruoming Peng[1], Malik Lenger[1], Sreehari Jayaram[1], and Joerg Wrachtrup[1,2] — [1]3. Physikalisches Institut, University of Stuttgart, 70569 Stuttgart, Germany — [2]Max Planck Institute for Solid State Research, 70569 Stuttgart, Germany

Visualization of nanoscale dynamics in 2D superconductors provides critical insights into pairing mechanisms and topological electronic responses. Using state-of-the-art scanning quantum microscopy based on nitrogen-vacancy (NV) centers in diamonds, we investigate the local magnetic behavior of the 2D superconductor 2H-NbSe2 with high sensitivity and spatial resolution. This approach enables the first spatial-temporal measurements of vortex dynamics in thin exfoliated 2H-NbSe2, revealing a strong correlation between vortex arrangements and geometric confinement. We observe the melting transition of vortex solids near the critical temperature, alongside cooling-rate-dependent vortex rearrangements across thermal cycles. Additionally, through local magnetic noise probing via spin coherence time (T2) measurements, we uncover unexpected supercurrent fluctuations in reduced dimensionality. These findings highlight the potential of scanning quantum microscopy in advancing our understanding of vortex physics and emergent phenomena in 2D superconducting systems.

O 16.10 Mon 17:15 H25

A high-throughput ESR-STM setup at mK temperatures — •Máté Stark, Jonas Arnold, Luise Renz, Johannes Schwenk, Christoph Sürgers, Wolfgang Wernsdorfer, and Philip Willke — Physikalisches Institut (PHI), Karlsruhe Institute of Technology, Karlsruhe, Germany

Characterizing and controlling single spins using Electron Spin Resonance Scanning Tunneling Microscopy (ESR-STM) [1] benefits from ultra-low tempera-

tures, minimal noise, and efficient RF transmission to the junction. This work details upgrades to an ESR-STM system operating at mK temperatures within a compact dilution refrigerator under UHV conditions. We achieved an electronic temperature below 200 mK while maintaining effective RF transmission up to 40 GHz. In addition, we developed a compact UHV chamber with an automated sputter-annealing stage, allowing for efficient sample preparation and quick exchange of samples with various atoms and molecules atop. In combination with the fast cooldown of the dilution refrigerator, these upgrades greatly streamline the experimental workflows allowing for rapid and high quality ESR-STM measurements. [1] Baumann, S. et al., 350(6259), 2015.

O 16.11 Mon 17:30 H25

Molecular Identification via Molecular Fingerprint extraction from Atomic Force Microscopy images — •Manuel González Lastre[1], Pablo Pou[1,2], Miguel Wiche[3,4], Daniel Ebeling[3,4], Andre Schirmeisen[3,4], and Rubén Pérez[1,2] — [1]Departamento de Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, E-28049 Spain — [2]Condensed Matter Physics Center (IFIMAC), Universidad Autónoma de Madrid, E-28049 Madrid, Spain — [3]Institute of Applied Physics, Justus Liebig University Giessen, Giessen, Germany — [4]Center for Materials Research, Justus Liebig University Giessen, Giessen, Germany

Previous works have already shown that deep learning (DL) models can retrieve the chemical and structural information encoded in a 3D stack of constant-height HR–AFM images, leading to molecular identification.

In this work, we overcome their limitations by using a well-established description of the molecular structure in terms of topological fingerprints, the Extended Connectivity Fingerprints, which provide local structural information of the molecule. In this work, we train a DL model to extract this optimized structural descriptor from the 3D HR–AFM stacks and use it, through virtual screening, to identify molecules from their predicted ECFP4 with a retrieval accuracy on theoretical images of 95.4%. This approach, unlike previous DL models, assigns a confidence score, the Tanimoto similarity, to each of the candidate molecules, thus providing information on the reliability of the identification.

O 16.12 Mon 17:45 H25

The Josephson effect in the dynamical Coulomb blockade regime with high energy resolution — •Xianzhe Zeng[1], Janis Siebrecht[1], Haonan Huang[1], Sujoy Karan[1], Klaus Kern[1,2], and Christian R. Ast[1] — [1]Max-Planck-Institut für Festkörperforschung, Heisenbergstraße 1, 70569 Stuttgart, Germany — [2]Institut de Physique, Ecole Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland

The Josephson effect can be used as a good quantitative indicator of the energy resolution of scanning tunneling microscopy (STM). Recently we have upgraded our mK-STM with low-temperature filtering on our scan head. We measured the Josephson current and found an improvement of the energy resolution by almost an order of magnitude. The high resolution allows us to measure several spectroscopic features in detail, including the superconducting coherence peaks with extreme sharpness and the environmental resonances in the Josephson current at low frequency due to the dynamical Coulomb blockade.

O 17: Poster Focus Session Molecular Nanostructures on Surfaces: On-Surface Synthesis and Single-Molecule Manipulation

Time: Monday 18:00–20:00 Location: P2

O 17.1 Mon 18:00 P2

Synthesis and characterization of a non-planar cyclophenylene on Au(111) — Sergio Salaverria[1], Martin Irizar[2,3,4], Jesus Janeiro[5], Paula Angulo-Portugal[6], Tao Wang[2], Jan Patrick Calupitan[6], •Jonathan Rodriguez-Fernandez[1,7], Aran Garcia-Lekue[2,8], Martina Corso[6], Emilio Artacho[2,3,8,9], Diego Peña[5], Dolores Perez[5], and Dimas G. de Oteyza[1,2] — [1]CINN, CSIC-UNIOVI-PA, El Entrego, Spain — [2]DIPC,San Sebastián, Spain — [3]CIC nanoGUNE, San Sebastián, Spain — [4]PMAS, UPV/EHU, San Sebastián, Spain — [5]CiQUS, Universidade de Santiago de Compostela, Spain — [6]CFM-MPC, CSIC-UPV/EHU, San Sebastián, Spain — [7]Physics Department, University of Oviedo, Spain — [8]Ikerbasque, Basque Foundation for Science, Bilbao, Spain — [9]TCM, University of Cambridge, Cambridge (UK)

Cyclophenylenes, i.e., macrocycles composed of linked benzene rings, have attracted intensive interest because of their appealing structures and potential applications.

In this work, we report the on-surface synthesis of a non-planar Au-coordinated cyclophenylene, containing four meta- and two para- connections, on a Au(111) surface, by undergoing hierarchical, metal-assisted double Ullmann coupling of a 1,10-dibrominated angular phenylene, and subsequent selective C-C bond cleavage of the four-membered rings in the resulting phenylene dimer. The chemical structure was characterized by bond-resolving (BR) STM and further supported by STS and DFT. This study offers the first approach for the synthesis of non-planar cyclophenylenes on surfaces.

O 17.2 Mon 18:00 P2

Experimental benchmark for configuration monitoring during scanning-probe-microscope manipulation — •Mong-Wen Gu[1], Jonas Lederer[2], Joshua Scheidt[1,2], Hadi H. Arefi[1], Kristof T. Schütt[2], Michael Gastegger[2], F. Stefan Tautz[1], Klaus-Robert Müller[2], and Christian Wagner[1] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, Jülich, Germany — [2]Machine Learning Group, Technische Universität Berlin, Berlin, Germany

The scanning probe microscope (SPM) allows nano-objects to be manipulated with single-molecule precision. A critical challenge of this SPM-based technique is to simultaneously manipulate molecules and monitor their configuration. Here, an experimental protocol is developed and evaluated that predicts the molecular configuration based on the physical observables continuously acquired by the SPM. A PTCDA (3,4,9,10-perylene tetracarboxylic dianhydride) molecule on the Ag(111) surface is manipulated to move along a predefined tip trajectory. The measured observables (force gradient) are compared with the results of a DFT trained machine learning model. This work paves the way for the fabrication of a wide variety of nanostructures.

O 17.3 Mon 18:00 P2

Exploring supramolecular rings by scanning tunneling microscopy — •Cagri Turan[1], Elie Benchimol[2], Guido Clever[2], and Karina Morgenstern[1] — [1]Physical Chemistry I, Ruhr-Universität Bochum, Germany — [2]Inorganic Chemistry, Technische Universität Dortmund, Germany

Enzymes inspire the design of supramolecular systems, mimicking their catalytic functions for advanced material applications. Among these systems, supramolecular rings and cages are one of the most suitable candidates for mimicking enzyme-like behavior. The use of two different ligands in the heteroleptic supramolecular rings enhances their complexity, enabling the creation of structures that resemble the sophisticated architectures of enzymes. This study reports deposition, self-assembly and inelastic electron tunneling manipulation of PdL2 rings on the Ag(111) surface. The ring molecules were characterized using low-temperature scanning tunneling microscopy in ultra-high vacuum at 7 K. By utilizing an atomic layer injection system, the acetonitrile solvent, used as a solvent during the self-assembly of ligands, will evaporate before the molecules reach the surface, ensuring that only the ring molecules are deposited onto the substrate. Through inelastic electron tunneling manipulation, site-specific manipulations and ligand dissociation processes were explored, offering insights into reaction mechanisms and molecular dynamics on rings on the metallic substrate. The findings contribute to understanding the interaction of supramolecular systems with metal surfaces, enabling advancements in nanoscale functional materials.

O 17.4 Mon 18:00 P2

Autonomous chemical reactions in scanning tunneling microscopy — •Nian Wu[1], Peter Liljeroth[1], and Adam S. Foster[1,2] — [1]Department of Applied Physics, Aalto University, Espoo, Finland — [2]WPI Nano Life Science Institute, Kanazawa University, Kanazawa, Japan

Scanning tunneling microscopy (STM) has shown great promise in manipulating atoms or molecules in on-surface molecular synthesis. However, the selection of proper parameters for various manipulations requires extensive explorations and strongly depends on domain knowledge. In particular, the coupling of fragments, as a critical step for polymerizations, necessitates more precise control in rotations and distances. To address this problem, we designed a deep reinforcement learning approach to automate the C-C coupling from Zn(II)-5,15-bis(4-bromo-2,6-dimethylpheny)porphyrin (ZnMe4DPP2.) through learning manipulation parameters in STM, thus enabling the assembly of large polymers based on the building blocks.

O 17.5 Mon 18:00 P2

Steering intermolecular interaction and ordering of N-heterocyclic carbenes on metal surfaces — •Duong Tran[1,2], Philipp Wiesener[1,2], Lacheng Liu[1,2], Ankita Das[3], Alex-Cristian Tomut[4], Nikos Doltsinis[4], Frank Glorius[3], Harald Fuchs[1,2], and Harry Mönig[1,2] — [1]Physikalisches Institut, Universität Münster, Wilhelm-Klemm-Straße 10, 48149 Münster, Germany — [2]Center for

Nanotechnology, Heisenbergstraße 11, 48149 Münster, Germany — [3]Organisch-Chemisches Institut, Universität Münster, Corrensstrasse 40, 48149 Münster, Germany — [4]Institut für Festkörpertheorie, Universität Münster, Wilhelm-Klemm-Straße 10, 48149 Münster, Germany

N-Heterocyclic carbenes (NHCs) are established ligands for the chemical and electronic functionalization of surfaces and nanoparticles. Controlling their nucleation and aggregation mechanisms provides valuable opportunities to tune their catalytic- and electro-optical properties. In the present work, we investigate the effect of hydroxyl-side groups on the self-assemblies of IMes on Au(111) and Ag(111) substrates by scanning tunneling microscopy with sub-molecular resolution. Our results are complemented by X-ray photoelectron spectroscopy (XPS) and first-principles calculations. We find that the OH groups can drastically enhance the molecular order, especially on the Ag(111) substrate where extended 2D networks are found. Our findings are essential for robust NHC-based supramolecular networks with tailored properties.

O 17.6 Mon 18:00 P2

Controlling on-surface chemical reactions through photochemistry — •Hao Jiang, Yu He, Jiayi Lu, Zhiwen Zhu, and Qiang Sun — Materials Genome Institute, Shanghai University, 200444 Shanghai , China

On-surface synthesis targets extended nanostructures by covalent coupling of organic molecules on surfaces. The most common way to induce reactions of precursor molecules on the surface is by heating, which will however increase the possibility of forming side reactions and lacks selectivity in many cases, thus limiting wider applications of on-surface synthesis. In contrast to the thermally triggered chemistry, photochemistry provides an alternative way to activate molecules. Light has been demonstrated to break certain covalent bonds in a less constructive fashion. Moreover, light has more adjustable parameters such as intensity, wavelength, polarization, etc., to control reactions more finely. Recently, we demonstrated the use of light polarizations to reveal the mechanism of dehalogenation reaction and realized photo induced dechlorination reactionon metal surfaces.

In this poster, we will showcase the wavelength dependence in on-surface synthesis and demonstrate how to harness photochemistry to achieve reaction selectivity in on-surface reactions. Three organic molecules, each with the same functional group, exhibit different chemical reactivities under photon excitation. Our work provides fundamental insights into photoinduced on-surface reactions and illustrates the potential of photochemistry for achieving highly selective and controllable reactions.

O 17.7 Mon 18:00 P2

Reaction intermediates, organometallic polymers and graphene nanoribbons in on-surface Ullmann-type coupling on coinage metals — R.S. Koen Houtsma[1], Jeanne van Zuilen[1], Floris van Nyendaal[1], Mihaela Enache[1], and •Meike Stöhr[1,2,3] — [1]University of Groningen, Netherlands — [2]Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — [3]University of Applied Sciences of the Grisons, Switzerland

Ullmann-type coupling has been so far the most often employed on-surface reaction for the controlled fabrication of molecular nanoarchitectures in a bottom-up manner. For the case of the prochiral precursor molecule 6,12 dibromochrysene, we compared the influence of substrate material/orientation, annealing temperature and reaction conditions on the reaction outcome. While on Au(111) achiral chevron-type graphene-nanoribbons are formed [1], on Cu(111), Ag(111) [2] and Ag(110) [3] only 1D organometallic polymers were obtained. These 1D polymers are homochiral when Cu(111) was used as substrate whereas they were heterochiral on Ag(111). In the case of Ag(110), their chirality could be even steered via the reaction conditions. With the help of reaction intermediates observed on Ag(111), we obtained key insights into the formation process of the organometallic polymers which is based on the breaking and re-establishing of C-Ag bonds. References: [1] R.S.K. Houtsma et al., Nanoscale Adv. 2022, 4, 3531. [2] R.S.K. Houtsma et al., Adv. Mater. Interfaces 2024, 11, 2300728. [3] R.S.K. Houtsma et al., Commun. Chem. 2024, 7, 51.

O 17.8 Mon 18:00 P2

LT-STM investigations of subphthalocyanine based vertical molecular rotors on Au (111) — •Franz Plate[1], Natasha Khera[1], Suchetana Sarkar[1], Soyoung Park[2,3], Ningwei Sun[2,3], Ebru Cihan[1], Dmitry Ryndyk[1,4], Franziska Lissel[2,3], and Francesca Moresco[1] — [1]Center for Advancing Electronics Dresden, TU Dresden, 01062 Dresden, Germany — [2]Leibniz Institute of Polymer Research Dresden, TU Dresden, 01069 Dresden Germany — [3]Institute of Applied Polymer Physics (IAPP) TU Hamburg, Kasernenstraße 12, 21073 Hamburg Germany — [4]Professur für Theoretische Chemie, TU Dresden, 01062 Dresden, Germany

We present a vertical rotor based on borsubphthalocyaninchloride (SubPC) platforms adsorbed on Au(111), investigated by low temperature scanning tunneling microscopy. SubPC is a well-investigated molecule which is known to form well-ordered structures, to adsorb flat on the surface and to be highly mobile as a single molecule. The boron atom carries an axial ligand. In this study, SubPC was functionalized with different axial ligands, aiming to create a vertical molecular rotor. The adsorption behavior of SubPC functionalized with azobenzene and 2-methylnaphthalene after thermal evaporation and flash deposition on a cold (5K) surface is presented in high resolution STM images supported by density functional theory (DFT) simulations. In addition, the stabilization through co-deposited pure SubPC and SubPC functionalized with 2-methylnaphthalene is presented.

O 17.9 Mon 18:00 P2

Adsorption behavior of organoboroxine and organoborthiine based molecules on Au(111) — •Natasha Khera[1], Franz Plate[1], Karen Marlenne Garcia Alvarez[2], Suchetana Sarkar[1], Andreas Schneemann[2], and Francesca Moresco[1] — [1]Center for Advancing Electronics Dresden, TU Dresden, 01062 Dresden, Germany — [2]Inorganic Chemistry I, TU Dresden, 01069 Dresden, Germany

In this study, we investigate the adsorption behavior of organoboroxine and organoborthiine based molecules on Au (111) surface, employing low temperature scanning tunneling microscopy (LT-STM) and spectroscopy in ultra-high vacuum (UHV) conditions. Organoboroxines provide a model system for constructing Covalent Organic Frameworks (COFs) and are well studied for their applications in catalysis, material science, optoelectronics and energy storage. In contrast, organoborthiines, due to their sulfur mediated interactions, hold promise, making them a compelling area for future research. In this work, a comparative analysis of the adsorption geometries, self-assembled structures and spectroscopic properties of both these molecules is presented.

O 17.10 Mon 18:00 P2

Chemical activation of a single melamine molecule via isomerization and metalation with a copper atom — •Karl Rothe[1], Manex Alkorta[2], Nicolas Néel[1], Thomas Frederiksen[3], and Jörg Kröger[1] — [1]Institut für Physik, Technische Universität Ilmenau, D-98693 Ilmenau — [2]Centro de Física de Materiales and Fisika Aplikatua Saila, University of the Basque Country, E-20018 Donostia - San Sebastián — [3]Donostia International Physics Center, E-20018 Donostia San Sebastián and IKERBASQUE, Basque Foundation for Science, E-48011 Bilbao

The entire sequence of chemically activating an educt, identifying its reactive site, running a chemical reaction and quantifying the involved forces and energies was performed by means of scanning probe methods. The organic molecule melamine adsorbed on Cu(100) serves as a single-molecule model system for activation via tautomerization and consecutive metalation with a single Cu atom. An atomic force microscope with a CO-decorated tip probes the reactive sites of the isomers at which the subsequent single metal atom transfer is initiated using a Cu-terminated probe. Following the interaction between the mutually approached reaction partners up to the verge of chemical-bond formation enables the access to the force and energy involved in the single-molecule metalation process. Total-energy calculations from density functional theory support the experimental findings and illustrate the structure of the reactants.

Funding by the DFG through KR 2912/18-1 and the BMBF through Forlab is acknowledged.

O 17.11 Mon 18:00 P2

Metallocorroles: On-Surface Synthesis, Adsorption Geometry, and Electronic Structure — •Cong Guo, Jan Herritsch, Anastasiya Beliakouskaya, and J. Michael Gottfried — Philipps-Universität Marburg, Fachbereich Chemie, 35043 Marburg, Germany

Tetrapyrrolic macrocycles are widely recognized as fundamental building blocks for interfacial covalent architectures with remarkable stability and atomic precision. Corrole complexes are particularly notable due to their nature as trianionic ligands providing a contracted coordination environment. Herein, we report the on-surface formation and reaction of an octaalkyl-substituted magnesium corrole and an iron triphenylcorrole (FeTPC) on Ag(111). The free-base octaalkylcorrole forms a well-ordered overlayer . Upon vapor deposition of Mg, the metal atoms incorporate into the corrole cavity, forming Mg-corrole complexes. However, XPS and STM studies show that excessive Mg deposition induces structural deformation and alters the electronic properties of the complex. FeTPC forms different long-range ordered adsorbate structures on Ag(111). During annealing, the degradation of FeTPC occurs, with cyclodehydrogenation leading to the planarization of the ligands, as indicated by XPS and STM. In addition, the ligation of nitric oxide at the Fe center, resulting in significant changes in the electronic properties of the complex, was investigated. These findings highlight the tunability of corrole complexes for tailored applications in catalysis and materials science.

O 17.12 Mon 18:00 P2

Theoretical investigation of 3,3"-dibromo-p-terphenyl on copper substrate — •Kevin Eberheim[1], Simone Sanna[1], Michael Dürr[2], and Mohit Jain[2] — [1]Institut für Theoretische Physik, Justus-Liebig-Universität Gießen, 35392 Gießen, Germany — [2]Institut for Applied Physics, Justus-Liebig-University Gießen, Germany

Chemoselectivity is a key parameter for building customized organic nanostructures via bottom-up approaches. Therefore, strategies are needed that allow con-

necting molecular entities at a specific stage of the assembly process in a chemoselective manner. Studying the mechanisms of such reactions is the key to apply these transformations for the buildup of organic nanostructures on surfaces. Especially, the knowledge about the precise adsorption geometry of intermediates at different stages during the reaction process and their interactions with surface atoms or adatoms is of fundamental importance, since often catalytic processes are involved. With first-principles simulations we can determine the adsorption geometry of the 3,3"-dibromo-p-terphenyl as well as adsorbed mono/diradicals and the halogens. For further comparability with experimental results simulations of Nudged Elastic Band (NEB) have been calculated for transitions between the observed linear chain and ring structures.

O 18: Poster Focus Session Ultrafast Electron Microscopy at the Space-Time Limit

Time: Monday 18:00–20:00 Location: P2

O 18.1 Mon 18:00 P2

Extending machine-learning-based band structure reconstruction into the time domain. — •Mirko Myksa[1], Rui Patrick Xian[1], Vincent Stimper[2], Martin Wolf[1], Ralph Ernstorfer[1], and Laurenz Rettig[1] — [1]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [2]Max Planck Institute for Intelligent Systems, Tübingen, Germany

Reliably extracting the electronic band dispersion from angle-resolved experimental photoemission (ARPES) data poses a challenging task, which often relies on specific line shape models and underlying assumptions, and thereby limiting a systematic and large-scale band structure extraction from volumetric ARPES data. For such purposes, we recently developed a band-structure reconstruction pipeline, including probabilistic machine learning and the associated data processing [1]. This pipeline shows an excellent performance on benchmarks for the reconstruction of three-dimensional photoemission (kx, ky, E) data from various materials. Here, the prospect for extending such analysis towards further dimensions such as pump-probe delay time-resolved ARPES will be discussed.

O 18.2 Mon 18:00 P2

Accessing energy- and momentum-dependent electron-phonon coupling from multidimensional photoemission data — •Hossein Yousofniadarzi, Julian Maklar, Martin Wolf, Ralph Ernstorfer, and Laurenz Rettig — Fritz Haber Institute of the Max Planck Society

Time- and angle-resolved photoemission spectroscopy (trARPES) provides a powerful method for probing ultrafast electron dynamics and their interactions with lattice vibrations. The electron-phonon (e-ph) interaction and its momentum dependence play an important role in many quantum materials, e.g., at the origin of charge-density-wave (CDW) formation. Here, we present an approach based on Fourier analysis, combined with a fitting procedure [1], that allows access to the energy and momentum dependence of the e-ph coupling strength for various coherent phonon modes in several CDW compounds. We discuss how these interactions vary across the Brillouin zone and contribute to the electronic structure modifications characteristic of the CDW phase. This work demonstrates the effectiveness of trARPES as a valuable technique for studying interactions in complex quantum materials.

O 18.3 Mon 18:00 P2

Machine learning-based denoising and artefact removal for multidimensional photoemission data — •Joshka Laird, Tommaso Pincelli, and Laurenz Rettig — Fritz haber institute of the Max Planck Society, Berlin, Germany

Angle-Resolved Photoemission Spectroscopy (ARPES) is a powerful tool for investigating the electronic structure of materials. While modern approaches such as momentum microscopy provide rich, multidimensional photoemission data, they pose challenges for achieving high statistics data and good signal-to-noise ratios. Additionally, image distortions such as mesh artefacts often complicate the analysis. Traditional denoising techniques, while effective in specific scenarios, can fail to preserve the fine structural details essential for accurate interpretation.

Here, we present a machine learning-based denoising and artefact removal approach for multidimensional photoemission data. Based on recent results using convolutional neural networks [1], we discuss how to extend such networks to higher dimensions to cope with data e.g. from time-resolved momentum microscopy.

O 18.4 Mon 18:00 P2

Towards the Investigation of Spin Systems With Electron Microscopy Tools — Antonín Jaroš[1,2], Johann Toyfl[1,2], Benjamin Czasch[1,2], •Michael Stanislaus Seifner[1,2], Isobel Claire Bicket[1,2], and Philipp Haslinger[1,2] — [1]Vienna Center for Quantum Science and Technology, Atominstitut, TU Wien, Stadionallee 2, 1020 Vienna, Austria — [2]University Service Centre for Transmission Electron Microscopy, TU Wien, Stadionallee 2, 1020 Wien, Austria

Electron spin resonance (ESR) spectroscopy is a method for studying unpaired electrons in various samples with applications in medicine, biology, chemistry, and physics. Typically, the spatial resolution of classical ESR is limited to a few micrometers preventing studying spin systems and their dynamics at the atomic level. To obtain a better understanding of such dynamics, this project aims to develop an ESR setup inside a transmission electron microscope by using the magnetic field created by the objective lens of the microscope to generate energetically separated spin states. A specially designed microcoil integrated into a standard specimen holder allows for exciting spin systems, and various approaches for measuring the resulting resonances are presented. Our results point out potential ways of investigating spin dynamics with sub-nanometer spatial resolution and high temporal resolution. The developed setup will enrich the field of electron microscopy by providing a non-invasive tool to investigate spin systems as well as certain electron beam-induced sample damage.

O 18.5 Mon 18:00 P2

Characterization and Improvement of the Electron Beam Stability and the Measurement Noise in Ultrafast Low-Energy Electron Microscopy — •Ole Böttger[1,2], Johannes Otto[1,2,3], Leon Brauns[1,2], and Claus Ropers[1,2,3] — [1]Department of Ultrafast Dynamics, Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]4th Physical Institute, University of Göttingen, Göttingen, Germany — [3]Max Planck School of Photonics

Ultrafast Low Energy Electron Microscopy (ULEEM) promises to uncover real-space dynamics on surfaces with few-picosecond temporal and nanometer spatial resolutions. Our group is currently developing such an instrument and has obtained first promising results [1]. The extended measurement durations required in this scheme require a high degree of long-term stability of the system. Here, we present results of energy, beam position and intensity stability measurements under various operating conditions, applied to both the laser pump and electron probe beam used. Moreover, we show results of state-of-the-art drift correction algorithms [2] applied to first ULEEM data [1].

O 18.6 Mon 18:00 P2

Monochromatization of Electron Beams with Spatially and Temporally Modulated Optical Fields — •Neli Laštovičková Streshkova[1], Petr Koutenský[1], Tomáš Novotný[2], and Martin Kozák[1] — [1]Department of Chemical Physics and Optics, Faculty of Mathematics and Physics, Charles University, Ke Karlovu 3, CZ-121 16 Prague, Czech Republic — [2]Department of Condensed Matter Physics, Faculty of Mathematics and Physics, Charles University, Ke Karlovu 5, Prague CZ-12116, Czech Republic

Inelastic interaction between coherent light and free electrons is a powerful tool for modulating electron wave packets, typically resulting in periodic sidebands in the electron energy spectra. We present a novel approach leveraging a time-dependent frequency modulation of light fields to achieve spectral squeezing and monochromatization of free electron pulses. This method compensates for the energy chirp inherent to dispersive propagation in electron sources like TEMs and SEMs, where finite coherence lengths lead to broadened energy spectra. By correcting the chirped wave packet in the energy-time domain through inelastic interaction with tailored optical fields, we enable significant spectral narrowing. Up to 26% of the electron distribution is concentrated within a narrowed energy band, achieving spectral compression by a factor of five. This advancement has implications for high-resolution quantum sensing and electron-based spectroscopy, addressing a critical need for low-loss electron monochromatization.

Spatio-Temporal Electron Propagation Dynamics in Au/Fe/MgO(001) in Nonequilibrium — Markus Heckschen[1], Yasin Beyazit[1], Elaheh Shomali[1], Florian Denizer[1], J. Jayabalan[1], Ping Zhou[1], Detlef Diesing[2], Markus Gruner[1], Rossitza Pentcheva[1], Axel Lorke[1], Björn Sothmann[1], and •Uwe Bovensiepen[1] — [1]University of Duisburg-Essen, Faculty of Physics and CENIDE, 47048 Duisburg — [2]University of Duisburg-Essen, Faculty of Chemistry, 45141 Essen

Since the mean free path of hot electrons is only a few nanometer, insights into the spatio-temporal electron dynamics are desired for the analysis of ultrafast microscopy. We determine the energy-dependent electron propagation time through epitaxial Au/Fe(001) as a function of Au layer thickness [1] by femtosecond time-resolved two-photon photoemission spectroscopy at energies 0.5-2.0

eV above E_F. By combining real-time time-dependent density functional theory and microscopic electron transport simulations we identify ballistic transport of minority electrons of the optically excited electron population. At lower energy, superdiffusive transport with 1-4 scattering events dominates. The effective electron velocity accelerates from 0.3 to 1 nm/fs with an increase in the Au layer thickness from 10 to 100 nm which is explained by electron transport that becomes preferentially aligned with the interface normal for thicker Au layers. On this basis the electron momentum or energy can be selected by the choice of the propagation layer thickness. We acknowledge funding by the DFG through SFB 1242. Studying Higher-Order Interaction Driven Non-Coplanar Spin Structures Using SP-STM — •Arved Heilmann, Roland Wiesendanger, and Kirsten von Bergmann — Universität Hamburg, Germany

Complex magnetic order arises from competing interactions between magnetic moments. Higher-order interactions (HOI), involving more than two spins, can lead to three-dimensional magnetic configurations known as multi-Q states. Spin-polarized scanning tunneling microscopy (SP-STM) is a powerful tool for studying these systems, enabling real-space imaging of atomic-scale magnetic structures. HOI-driven hexagonal 3Q states have been observed at the atomic and nanoscale in Rh/Mn/Re(0001) and Fe/Rh/Ir(111), respectively [1,2].

To identify further HOI-driven magnetic states, we investigate other systems with Mn/Rh and Fe/Rh interfaces grown on Re(0001). Our findings reveal distinct spin structures that depend on the layer sequence of the pseudomorphic layers. Mn monolayers grown on single or double Rh layers form the Néel state, while Mn grown directly onto the substrate exhibits a non-coplanar 3Q state [3]. For Fe, deposition on two Rh layers results in a distorted quasi-hexagonal magnetic lattice, contrasting with the substrate's ideal hexagonal symmetry. This two-dimensional modulation of the spin texture suggests it also arises from HOI.

O 19.2 Mon 18:00 P2

Design of a STM/ nc-AFM head to quantify the magnetic exchange interaction between individual atoms — •Karoline Oetker, Zhengyuan Liu, Henning von Allwörden, Alexander A. Khajetoorians, and Nadine Hauptmann — IMM, Radboud University, Nijmegen, The Netherlands

STM methods are highly powerful tools to quantify the magnetic coupling between single adatoms and with the atom at the tip [1,2]. These current-based methods prohibit to probe the atomic-scale magnetic properties of adatoms on thick insulating layers. However, it was shown that thicker insulating layers with a 4-fold symmetry, as MgO, can prohibit single-electron induced ground state transitions and only allow higher-order excitation processes, which stabilizes the magnetic moment of the adatom [3]. Therefore, a force-based method, such as magnetic exchange force microscopy (MExFM), is a promising tool to quantify the different magnetic coupling mechanisms between individual adatoms on thick insulating layers. We present the design of a 1K STM/nc-AFM setup dedicated for MExFM measurements in magnetic fields up to 9T, based on the tuning fork design. Our goal is to quantify the different distance-dependent magnetic interactions between different magnetic atoms, e.g. 3d and 4f elements. We will utilize functionalized tips with different magnetic atoms, to probe the distance-dependent magnetic exchange force between the tip and adatoms on thick insulating layers. 1.Meier, F. et al., Science 320, 82-86 (2008), 2. Baumann, S. et al., Science 350, 417-420 (2015). 3.Donati, F. et al., Science 352, 318-321 (2016).

Time: Monday 18:00–20:00 Location: P2

O 20.1 Mon 18:00 P2

Generation of single cycle terahertz pulses for a THz-STM and improvement of the current measurement noise — •Paul Wiechers, Christian Lotze, Florian Faaber, Vibhuti Rai, and Katharina J. Franke — Freie Universität Berlin, Fachbereich Physik,Arnimallee 14, 14195 Berlin, Germany

Terahertz Scanning Tunneling Microscopy (THz-STM) aims to combine the atomic spatial resolution of STM with the sub-picosecond time resolution commonly achieved through optical pump-probe techniques.

We generate single-cycle terahertz pulses by optical rectification and short optical pulses of various wavelengths. Particular care is taken to minimize pointing deviations of the beams, ensuring proper focusing in the STM junction, even under varying beam delay positions.

In a THz-STM experiment, the measured quantity is the low-bandwidth tunneling current. The THz-induced part of that current, due to the low duty cycle ($\sim 10^{-5}$) of the THz pulses, is very small. Thus, a thorough understanding of the limiting noise sources in the measurement is important. Here, we characterize a cryogenic low-noise ammeter and increase its prohibitively low bandwidth by more than two orders of magnitude.

O 20.2 Mon 18:00 P2

Local excitation of coherent phonons in 2H-$MoTe_2$ by THz driven scanning tunnelling microscope — Vibhuti Rai, Junyoung Sim, •Florian Faaber, Sergey Trishin, Nils Bogdanoff, Tom Seifert, Tobias Kampfrath, Christian Lotze, and Katharina J. Franke — Freie Universität Berlin, Department of Physics, Arnimallee 14,14195 Berlin, Germany

The coupling of THz pulses into a scanning tunnelling microscope has emerged as a unique technique to achieve picosecond time resolution while maintaining sub nanometer spatial resolution [1,2]. By delaying one THz pulse with respect to the other while recording the current rectified by the two pulses, a pump-probe scheme can be realized [3]. In this work, we use this scheme to investigate the quasi 2D semiconducting transition metal dichalcogenide (TMD) 2H-$MoTe_2$ at 7K in ultra-high vacuum and find a large oscillatory rectified current that is slowly decaying over 50 ps. We attribute these oscillations to the excitation of coherent phonons and discuss the effect of defects and DC bias voltage on the excited modes.

O 20.3 Mon 18:00 P2

Charging of atomic defects in 2H-$MoTe_2$ under infrared illumination — •Friedemann Lohss, Florian Faaber, Vibhuti Rai, Junyoung Sim, Christian Lotze, and Katharina J. Franke — Freie Universität Berlin, Department of Physics, Arnimallee 14,14195 Berlin, Germany

The electronic properties of semiconductors are heavily shaped by the concentration and type of defects present in the material. The sub-nanometer resolution of scanning tunneling microscopy (STM) allows to locally probe such defects. Here we characterize the response of the semiconductor 2H-$MoTe_2$ to infrared illumination in an STM at cryogenic temperature. We observe the formation of disc-shaped regions of increased conductivity around some local defects, likely stemming from charging and tip-induced band bending. We characterize the different defect states occuring in this material.

O 20.4 Mon 18:00 P2

Two-Color Pump-Probe STM of Coherent Phonon Dynamics in Ultrathin ZnO/Ag(111) — •Henrik Wiedenhaupt[1], Shuyi Liu[2], Akitoshi Shiotari[1], Adnan Hammud[1], Daniel Wegkamp[1], Martin Wolf[1], Takashi Kumagai[3], and Melanie Müller[1] — [1]Fritz Haber Institute of MPG, Berlin, Germany. — [2]Huazhong University of Science & Technology, Wuhan, China. — [3]Institute for Molecular Science, Okazaki, Japan.

We use photon-assisted ultrafast scanning tunneling microscopy (ph-USTM) to study coherent phonon (CP) dynamics in optically excited ZnO/Ag(111). In recent work, we have shown that resonant single-color ph-USTM enables CP spectroscopy on 3ML-ZnO/Ag(111) with nanometer spatial resolution [1], where the optical resonance between an interface state (IS) and the ZnO conduction band edge (CBE) appears to play an important role, as also observed in tip-enhanced Raman spectroscopy (TERS) [2]. However, the detailed mechanisms by which the CPs modulate the photocurrent and of their local excitation remain unclear. To gain further insight, we implement two-color ph-USTM for the selective on- and off-resonant ultrafast excitation of the IS-CBE transition on 2ML-ZnO and 3ML-ZnO. Besides demonstrating local CP spectroscopy also on 2ML-ZnO, our results show that CPs can also be excited off-resonantly, while optically resonant photon-assisted tunneling seems to be more crucial for local CP detection via ph-USTM. We explain our observations by phonon-induced transient changes in the local dielectric response.

Plasmonic STM-luminescence driven by a high-power spintronic THz emitter — •Alkisti Vaitsi, Luis Enrique Parra López, Vivien Sleziona, Martin Wolf, and Melanie Müller — Fritz Haber Institute of the Max Planck Society, Berlin, Germany

We demonstrate THz-induced STM-luminescence (THz-STML) from a plasmonic tunnel junction driven by broadband single-cycle THz pulses generated from a high-power rotating spintronic THz emitter (STE). By measuring the dependence of the plasmonic luminescence on the static STM bias and the THz-STM bias, we aim for a purely data-driven approach to calibrate the THz peak bias via reconstruction of the THz-STML spectra from the static reference STML spectra. Our results proof the capability of the rotating STE to generate several Volts peak THz bias in a metallic STM junction and pave the way for future time-resolved gating of STM-luminescence from excitonic quantum emitters.

O 20.6 Mon 18:00 P2

Scanning Quantum Microscopy for Emergent Phases of Matter — •Ruoming Peng[1], Sreehari Jayaram[1], Malik Lenger[1], King Cho Wong[1], Xuankai Zhou[1], Yan Tug Kong[1], and Joerg Wrachtrup[1,2] — [1]3. Physikalisches Institut, University of Stuttgart, 70569 Stuttgart, Germany — [2]Max Planck Institute for Solid State Research, 70569 Stuttgart, Germany

Scanning quantum microscopy using NV centers in diamond enables direct visualization of condensed matter phenomena. Applying this technique, we uncover the emergence of a super-Moiré magnetic texture in twisted double bilayer CrI3, distinct from the geometric Moiré periodicity at small twist angles. Additionally, we investigate vortex dynamics in thin-layer 2H-NbSe2, revealing vortex melting behaviors during different thermal cycling and unconventional magnetic noise arising from the vortex dynamics. Our findings highlight the strong capability of scanning quantum microscopy to unravel nanoscale magnetic interactions and dynamic phases in 2D materials.

O 20.7 Mon 18:00 P2

A theoretical perspective on electroluminescence, photoluminescence and photocurrent generation in a scanning tunneling microscope — •Tomáš Neuman[1], Sofia Canola[1], Rodrigo Ferreira[1], Anna Rosławska[2], Katharina Kaiser[3], Alex Boeglin[4], Andrei Borisov[5], Guillaume Schull[4], and Martin Švec[1] — [1]Institute of Physics of the Czech Academy of Sciences, Prague, Czechia — [2]Max Planck Institute for Solid State Research, Stuttgart, Germany — [3]Georg-August-Universität Göttingen, Göttingen, Germany — [4]Université de Strasbourg, IPCMS, CNRS, UMR 7504, Strasbourg, France — [5]Université Paris-Saclay, Institut des Sciences Moléculaires d'Orsay, CNRS, UMR 8214, Orsay, France

The phenomena occurring in a scanning tunneling microscope (STM) that lead to the generation of light or are triggered by light (STM+light, STM+L), including the STM-induced luminescence and photocurrent generation in single molecules, allowed for studying excited states of molecules in a STM. As the underlying principles of these phenomena involve electron tunneling, plasmon-enhanced optical absorption and spontaneous emission, and vibronic effects, interpreting these STM+L experiments hinges on the development of theoretical models. I will show such modelling strategies and showcase its application to recent experiments. In particular, I will focus on the theory of mapping of orbitals of a multireference excited state of a small molecule (perylene tetracarboxylic dianhydride - PTCDA) via photocurrent generation, whose explanation requires all the mentioned ingredients.

O 20.8 Mon 18:00 P2

Neutral Exciton-Libron Coupling via Resonant Energy Transfer in Single Molecules — •Thiago G. L. Brito[1], Klaus Kuhnke[1], Klaus Kern[1,2], and Anna Rosławska[1] — [1]Max Planck Institute for Solid State Research, Heisenbergstr. 1, 70569 Stuttgart, Germany — [2]École Polytechnique Fédérale de Lausanne, CH-1015 Lausanne, Switzerland

The optical properties of single molecules can vary depending on their environment. In some surroundings, vibrations due to frustrated rotations (librations) may occur if the molecules feature some rotational freedom. In this study, we provide evidence of coupling between neutral excitons and libration modes (librons). We observed this coupling through light emission resulting from resonant energy transfer (RET). We measured neutral and charged exciton emissions in isolated zinc phthalocyanine (ZnPc) and ZnPc-platinum phthalocyanine (PtPc) assemblies deposited on NaCl/Ag(111) using scanning tunneling microscopy induced luminescence (STML). For isolated ZnPc, we observed a broad peak from the neutral exciton and exciton-libron coupling for the charged exciton. In contrast, in ZnPc-PtPc structures, we found libronic signatures in the neutral emission of ZnPc when excited via RET from PtPc. This study is providing deeper insights into exciton-libron dynamics in single molecules.

O 20.9 Mon 18:00 P2

Mapping adsorbed states of iron(II) phthalocyanine on Ag surfaces by plasmon-enhanced Raman spectroscopy — Borja Cirera[1], •Rodrigo Cezar de Campos Ferreira[2,3], Amandeep Sagwal[2], Jiří Doležal[3], Martin Švec[2,3], and Pablo Merino[1] — [1]Instituto de Ciencia de Materiales de Madrid, Spain — [2]Institute of Physics, Czech Academy of Sciences, Czech Republic — [3]Institute of Organic Chemistry and Biochemistry, Czech Academy of Sciences, Czech Republic

The high spatial confinement of a plasmonic field in LT-SPM has become a valuable tool for near-field spectroscopies. Among the techniques, Raman scattering enables chemical identification, investigation of relations between adsorption geometry and vibrational fingerprints in real space at single-molecule level.[1,2] Here we studied different adsorption configurations of iron(II) phthalocyanines (FePc) on Ag(110) and Ag(111) crystal surfaces. Real-space mapping reveals the appearance of shifted Raman states when adsorbed in specific geometries. Results and simulations suggest that the breaking in symmetry with respect to the main crystallographic directions of the substrates are the leading reason for this phenomenon. [1] Y. Zhang et. al. Nature 498, 82-86 (2013). [2] R. Zhang et. al. National Science Review, Volume 6, 2019, 1169-1175.

O 20.10 Mon 18:00 P2

Investigations of the plasmon excitation of C60 multilayers on Au(111) using STM induced luminescence — •Andreas Reutter, Yannis Hilgers, Markus Etzkorn, and Uta Schlickum — Institute of Applied Physics - LENA, TU Braunschweig

In recent years, Scanning Tunneling Microscopy induced luminescence (STML) has gathered great interest, as it allows to investigate optical properties in addition to normal STM measurements, both with atomic spatial resolution. Since its development, the main challenge of this method is to obtain reasonable photon intensities.

We succeeded in building a setup with a greatly increased detection efficiency by using a parabolic mirror inside the STM, that covers 75% of the upper hemisphere.

Here, we present STML measurements of surface plasmons on C60 on Au(111) as a model system for the effects of an organic semiconductor on a metal surface [1]. We will present conductance and optical spectroscopy measurements as well as photon yields for different number fo C60 layers and different applied voltages.

O 20.11 Mon 18:00 P2

Resonant energy transfer as a function of distance between metal-phthalocyanine molecules — •Roel Burgwal, Nikhil Seeja Sivakumar, Joëlle J. A. Schrijer, Alexander A. Khajetoorians, and Daniel Wegner — Institute for Molecules and Materials, Radboud University, 6500 GL Nijmegen, The Netherlands

Resonant transfer of energy (RET) between molecules is a process ubiquitous in nature that also has interesting technological applications. The rate of RET decreases as the molecules involved are spaced further apart, with the distance dependence determined by the exact mechanism responsible for energy transfer. Two possible mechanisms are electrodynamical Förster energy transfer (FRET) and the electron tunneling-based Dexter energy transfer (DET). Recent advances in scanning tunneling microscope-induced luminescence (STML) have made it possible to observe energy transfer between single molecules and to control the spacing between these with sub-nanometer precision. So far, STML measurements of RET distance dependence resemble more the exponential behavior of DET, in contrast with the commonly assumed FRET mechanism. However, it has been proposed this apparent behavior may be a plasmonic effect arising from the varying distance between STML-tip and acceptor molecule. Here, we study RET between different metal-phthalocyanine molecules while elucidating the role of the plasmon through complementary measurements.

O 21: Poster Heterogeneous Catalysis

Time: Monday 18:00–20:00 Location: P2

O 21.1 Mon 18:00 P2

Disentangling Transport and Kinetics in Complex Reaction Chambers by Novel Reduced-Order Modeling Approaches — •Tobias Hülser[1], Maryke Kouyate[1], Uzair Qureshi[2], Daniel Runge[3], Georg Brösigke[2], Christian Merdon[3], Jürgen Fuhrmann[3], Karsten Reuter[1], Christoph Scheurer[1], and Sebastian Matera[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Technische Unviversität Berlin — [3]Weierstraß-Institut für Angewandte Analysis und Stochastik, Berlin

Operando catalytic characterization chambers are governed by mass transport interplaying with highly-nonlinear chemical kinetics, which needs to be accounted for by corresponding coupled simulations. Often, these chambers can not be modelled with established reactor models, instead requiring high-cost Computational Fluid Dynamics simulations. We have developed reduced-order methods which disentangle the computational treatment for transport and kinetics into an offline (OffPh) and online phase (OnPh). In the OffPh, we determine a suitable solution space of the transport operator, which is independent of the employed kinetic model and therefore reusable. In the OnPh, the solution from this space is determined from the balance of transport and kinetics at the catalytic surfaces. This drastically reduces the costs as the OffPh is a linear problem and, particularly, the nonlinear online phase typically involves only very few degrees of freedom. We demonstrate this idea on mesoscale core-shell particles, an asymptotic expansion for small catalyst samples and a quasi-exact reduced basis strategy for general problem settings.

O 21.2 Mon 18:00 P2

Bayesian Inference of Kinetic Models of Heterogeneous Catalysis by Normalizing Flows — •Andreas Panagiotopoulos[1], Javed Mudassar[2], Jens-Uwe Repke[2], Georg Brösigke[2], and Sebastian Matera[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Technical University Berlin

Estimating kinetic parameters is typically done by classical fitting a model to experimental reactor data, which, however, suffers from a number of fundamental problems like ill-posedness, multiple possible solutions and the lack of reliable uncertainty estimates. By reformulating the problem in a probabilistic language, Bayesian inference cures these problems, but also requires to sample from a high-dimension probability distribution. Because of their high non-linearity and sensitivity, this becomes challenging for kinetic models and established sampling approaches become inefficient. We investigate Normalizing Flows in conjunction with Quasi Monte Carlo sampling to address this problem. In this approach, a bijective nonlinear parameter transformation is sequentially learned such that a uniform sampling from the transformed parameters leads to a good importance sampler of the Bayesian posterior. We investigate the performance of the proposed approach on an empirical model for methanol synthesis on Cu based catalysts using synthetic and experimental data.

O 21.3 Mon 18:00 P2

Model Catalytic Studies on the Thermal Dehydrogenation of the Benzaldehyde/Cyclohexylmethanol LOHC System on Pt(111) — •Marius Steinmetz[1], Valentin Schwaab[1,2], Felix Hemauer[1,2], Eva Marie Freiberger[2], Natalie J. Waleska-Wellnhofer[2], Hans-Peter Steinrück[2], and Christian Papp[1] — [1]Angewandte Physikalische Chemie, Freie Universität Berlin (FU Berlin), Arnimallee 22, 14195 Berlin, Germany — [2]Lehrstuhl für Physikalische Chemie II, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Egerlandstr. 3, 91058 Erlangen, Germany

We investigated the dehydrogenation reaction and the thermal decomposition of the liquid organic hydrogen carrier (LOHC) pair benzaldehyde/cyclohexylmethanol on a Pt(111) model catalyst via temperature-programmed desorption experiments and synchrotron radiation photoelectron spectroscopy. The LOHC pair has a hydrogen storage capacity of 7.0 mass%, stored in a cyclohexyl ring and a primary alcohol group. We observed a stepwise dehydrogenation mechanism, starting with the dehydrogenation of the alcohol group, followed by the dehydrogenation of the cyclohexyl ring. We also observed different dehydrogenation behaviors for low and high coverages, probably caused by steric hindrance for high coverages. Even though the LOHC pair achieves high hydrogen storage capacity, early decomposition at low temperatures between 250 and 350K limits the use of the molecule pair as a reversible hydrogen carrier.

O 21.4 Mon 18:00 P2

Size-selected metal nanoparticles on tungsten: influence of the deposition angle — •Sumanasa Begur Prakash and Mathias Getzlaff — Institute of Applied Physics, University of Düsseldorf

Metal nanoclusters and nanoparticles, especially those composed of iron (Fe), nickel (Ni), and their alloys, are fascinating due to their unique electronic and magnetic properties which vary significantly with particle size. This feature makes them not only interesting for fundamental research but also highly promising for advanced technologies including catalysis, magnetic storage, and sensing. However, interaction with the substrate during and after deposition significantly influences the particle's properties.

Our contribution is focused on size-selected Fe, Ni, and Fe-Ni alloy nanoparticles which are deposited on a W (110) substrate. Using a magnetron sputter source (Haberland-type) we vary the deposition angle to understand how this parameter influences the particle size, structure, and overall distribution of nanoparticles on the substrate surface. This approach allows us to probe the relationship between deposition conditions and particle characteristics. The size and structural properties are investigated by scanning tunneling microscopy (STM) and low energy electron diffraction (LEED) under ultra-high vacuum (UHV) conditions.

Optimized BiVO4/g-C3N4 Heterojunctions for Efficient Photocatalytic Green Ammonia Production — •Susana D. Rojas[1], Nicolás A. Soto[1], Pablo E. Salinas[1], Daniel Saavedra[2], Marcelo A. Cisternas[1], and Ulrich G. Volkmann[2] — [1]Escuela de Ingeniería Industrial, Universidad de Valparaíso, Santiago, Chile — [2]Instituto de Física, Pontificia Universidad Católica de Chile, Santiago, Chile

BiVO4 nanostructures were synthesized via a hydrothermal method, and g-C3N4 nanosheets by urea pyrolysis. The materials were characterized using Fourier transform IR spectroscopy (FTIR), UV-Vis and X-ray photoelectron spectroscopy, X-ray diffraction, and scanning electron microscopy to confirm their chemical and morphological structures. Photocatalytic ammonia production was evaluated in a cylindrical reactor with a Xenon discharge lamp, using an aqueous catalyst dispersion under magnetic stirring and a nitrogen flow at atmospheric pressure. Ammonia production was analyzed via the Nessler method with ammonium chloride (NH4Cl) calibration curves for the aqueous phase and in situ FTIR spectroscopy with a 16 m optical path gas cell for the gas phase [1, 2]. This work advances the understanding of photocatalytic processes for sustainable ammonia production and the development of efficient, eco-friendly methods for synthesizing this essential compound. Acknowledgements: ANID project SIA77210032 (SR, MC), UVA22991 (SR, MC), ANID Fellowship (DS), and Puente UC 2024-25 (UV). Ref.: [1] P. Huang, et al., Nature Comm. 13, 7908 (2022). [2] S.Z. O 21.6 Mon 18:00 P2

Tuning the ceria island orientation: from (111) to (100)-oriented islands — •Maja Atlas, Raquel Sanchez-Barquilla, and Jan Ingo Flege — Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology Cottbus-Senftenberg, Germany

Inverse catalysis systems, where the reducible oxide is anchored on the metallic support, have shown a better performance compared with its traditional counterparts due to the strong metal support interaction. Among catalytic materials, ceria (CeO_2) is used in a wide range of applications, due to its oxygen storage and redox properties. In particular, the catalytic activity of Cu(111) can be substantially enhanced when depositing CeO_x on top, achieving direct methanol production from CO_2. In situ near ambient pressure X-ray photoemission spectroscopy (NAP-XPS) measurements have shown that the activated CO_2 molecule is stabilized by Ce^{3+} sites during the reaction. Moreover, epitaxially grown CeO_2 islands can have two different orientations on Cu(111): the (111)-oriented islands appear first and with lower oxygen pressure, while the (100)-oriented phase can be enhanced by increasing the oxygen exposure. Here, we present a structural and chemical study of the ceria islands growth as a function of temperature, oxygen pressure and deposition rate. By varying these parameters, we can study the relation between the phase and the Ce^{3+}/Ce^{4+} ratio, using XPS, low energy electron diffraction (LEED) and scanning tunneling microscopy (STM).

O 21.7 Mon 18:00 P2

Structure and chemical properties of Pt clusters and particles deposited on CeO_2(111) — •Shuang Chen, Zairan Yu, Alexei Nefedov, Christof Wöll, and Yuemin Wang — Institute of Functional Interfaces (IFG), Karlsruhe Institute of Technology (KIT), 76344 Eggenstein-Leopoldshafen, Germany

CeO_2-supported Pt nanoparticles are of significant technological interest due to their unique catalytic properties and wide range of applications in numerous chemical reactions. However, the catalytic performance of various Pt species remains a highly debated topic. This arises primarily from the complexity of Pt/CeO_2 powder catalysts and the scarcity of accurate reference data obtained from well-defined model systems. Here, we report systematic IR reflection absorption spectroscopic (IRRAS) investigations of Pt deposited on oxidized CeO_2(111) single-crystal surfaces. By employing polarization-resolved IRRAS with CO as a probe molecule and grazing-emission XPS, we were able to track the structural and electronic evolution of Pt on CeO_2(111) as a function of the deposition amount. Various Pt species, ranging from single atoms to small clus-

ters and large particles, were identified. Our results provide solid evidence of strong electronic interactions between Pt and the ceria substrate, offering profound insights into the dynamic behavior of Pt clusters under different conditions. This work was funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) -Project-ID 426888090- SFB 1441.

O 21.8 Mon 18:00 P2

Photoelectrochemical nitrate reduction by copper oxide-based semiconductors — •Jasmin A. Zitzmann[1,2], Maximilian Christis[1,2], Saswati Santra[1,2], and Ian D. Sharp[1,2] — [1]Walter Schottky Institute, Technical University of Munich, Germany — [2]Physics Department, TUM School of Natural Sciences, Technical University of Munich, Germany

The photoelectrochemical nitrate reduction reaction (PEC-NO_3RR) offers a route to ambient ammonia (NH_3) synthesis and recycling of NO_3^- pollutants. Copper oxide-based semiconductors, such as Cu_2O, CuO and $CuBi_2O_4$ exhibit suitable band energetics to drive this reaction. While Cu_2O is reported for PEC-NO_3RR, further studies are required to optimize reaction conditions and minimize photocorrosion. With this aim, the PEC-NO_3RR performance characteristics of Cu_2O, CuO and $CuBi_2O_4$ are investigated in alkaline and neutral aqueous electrolytes. The dominant reaction product observed is nitrite (NO_2^-) with Cu_2O producing the highest yields. In addition, NH_3 is generated by Cu_2O, with an increase in selectivity at lower potentials. Photocorrosion is most pronounced for CuO, whereas $CuBi_2O_4$ shows the most consistent PEC stability. Our findings indicate the potential-dependent PEC-NO_3RR product selectivity, with further research necessary to optimize the electrochemical conditions to improve PEC-NO_3RR stability and NH_3 yield using these promising copper oxide-based semiconductors.

O 22: Poster Surface Reactions

Time: Monday 18:00–20:00 Location: P2

O 22.1 Mon 18:00 P2

TRACE/TRIADE: A setup to investigate tritium accumulation of solids — •Marie-Christine Schäfer, Dominic Batzler, James Braun, Robin Grössle, Philipp Haag, Elizabeth Paine, Marco Röllig, Marius Schaufelberger, and Kerstin Trost — Tritium Laboratory Karlsruhe, Eggenstein-Leopoldshafen, Germany

In the context of the KArlsruhe TRItium Neutrino experiment (KATRIN), sufficient knowledge of the accumulation of tritium on surfaces is crucial for minimising systematic effects, thus optimising the experiment. On a bigger scale, the understanding of these specific tritium gas-surface interactions is relevant when it comes to fusion reactors and their fuel cycles. In search of materials with small tritium memory effects, the Tritium Activity Chamber Experiment (TRACE) at Tritium Laboratory Karlsruhe (TLK) provides the possibility of exposing solid samples to high purity tritium gas while monitoring the near-surface activity via beta-induced X-ray-spectrometry (BIXS). Similarly, the TRItium Adsorption Desorption Experiment (TRIADE) also measures the tritium accumulation via the BIXS method but is being upgraded to additionally provide the option of studying adsorption and desorption processes at temperatures down to 100 K. For this, a newly designed sample holder is currently being tested. Besides investigating the tritium accumulating properties of different materials, the compatibility with UV/ozone in the context of decontaminating the surfaces is also of relevance. For this, experiments with an additional setup are set to be conducted in the near future. This contribution will present the TRACE/TRIADE setups as well as their planned modifications.

Exploring TiO_2-water-interfaces with AIMD and Machine Learning Force Fields — •Johannes Laurenz Wolf, Christian Dressler, and Malte Grunert — Technische Universität Ilmenau, Department of Physics, 98693 Ilmenau, Germany

Titanium dioxide (TiO_2) is a pivotal material in photocatalysis, particularly for water splitting applications in artificial leaves. In this study, we employ ab initio molecular dynamics (AIMD) and machine learning force fields (MLFF) within the MACE framework to investigate systems comprising, TiO_2 layers in different crystalline phases on indium phosphide (InP) and water. A central focus is placed on the structural and dynamic properties of the TiO_2-water interface.

To enhance our understanding of interfacial interactions, we introduce nanoscale pinholes into the TiO_2 layer, exploring their impact on water adsorption and hydrogen bonding dynamics. AIMD simulations provide atomic-scale insights, while MLFF extends these analyses to longer time scales, enabling a comprehensive investigation of adsorption mechanisms, titanium coordination, and local surface distortions.

O 22.3 Mon 18:00 P2

Investigation of the water-GaN(10$\bar{1}$0) and water-GaN(0001) interface by ab initio molecular dynamics simulations — •Marius Otto, Christian Dressler, Fabian Ullmann, and Stefan Krischok — Technische Universität Ilmenau

We have performed ab initio molecular dynamics simulations to investigate the dissociative adsorption of water at the water-GaN(10$\bar{1}$0) and water-GaN(0001) interfaces. Our results confirm that water undergoes dissociative adsorption on both surfaces, with notable differences in the protonation states of the adsorbed oxygen species. On the non-polar GaN(10$\bar{1}$0) surface, Ga atoms are exclusively coordinated by hydroxyl (OH) groups, whereas the polar GaN(0001) surface shows a mixed coverage of hydroxyl (OH) and water (H_2O) species. The dissociation of water is significantly more pronounced on the GaN(10$\bar{1}$0) surface due to the availability of distinct adsorption sites for both hydrogen and hydroxyl groups. In contrast, on the GaN(0001) surface, steric shielding of the adsorption sites inhibits water dissociation, resulting in reduced reactivity. In addition, we have also compared our simulations to XPS and UPS measurements.

O 22.4 Mon 18:00 P2

kinetics and thermodynamics of dehalogenation on metal surfaces — •Yu He[1], Hao Jiang[1], Zhiwen Zhu[1], Juan Xiang[1], Jinyang Xu[2,3,4], Zhaofeng Liang[2], Lei Xie[2], Fei Song[2], and Qiang Sun[1] — [1]Materials Genome Institute of Shanghai University,Shanghai,China — [2]Shanghai Synchrotron Radiation Facility, Shanghai Advanced Research Institute, Chinese Academy of Sciences, Shanghai,China — [3]Shanghai Institute of Applied Physics, Chinese Academy of Sciences, Shanghai,China — [4]University of Chinese Academy of Sciences, Beijing,China

In the field of on-surface synthesis, dehalogenative aryl-aryl coupling has become the key strategy for the fabrication of covalently bonded carbon-based nanomaterials. However, studies on the kinetics and thermodynamics of these reactions are still scarce. Also, most of the works focus on debromination while overlooking the dechlorination reaction which is a fundamental reaction with significant implications for environmental protection and sustainable chemistry. Here, we combined synchrotron-based x-ray photoelectron spectroscopy (XPS) and scanning tunneling microscopy (STM) to study the dehalogenative polymerization reactions of chlorinated and brominated aromatic hydrocarbons on the Au(111) surface. We resort to high-resolution surface-sensitive techniques to identify the reactants and products as well as the important reaction intermediates. Using the fast XPS, we are able to extract the kinetic curves of the reactions and obtain detailed insight into the reaction process. Our research deepens the understanding of the reaction mechanism.

O 22.5 Mon 18:00 P2

Self-assembly and reactions of benzonitriles on metal surfaces — •Anran Bao[1] and Wenshao Yang[2] — [1]Physikalische Chemie I, Ruhr-Universität Bochum, Bochum, Germany — [2]Hangzhou Institution of Advanced Studies, Hangzhou, China

Surface synthesis enables innovative material design, with the self-assembly of organic molecules on metal surfaces. Among on-surface reactions, the Ullmann coupling is significant. Notably, despite the considerable differences in the chemical structures of cyanides and halogen atoms, they exhibit similarities in organic reactions. This provides a new perspective on surface synthesis and possibilities for synthesizing novel nanomaterials. This study focuses on the unique self-assembly and chain formation of benzonitrile derivatives, particularly isophthalonitrile (IPN), tere-phthalonitrile (TPN) and ortho-phthalonitrile (OPN), on the Co(0001) surface. We observed that IPN and TPN molecules adsorb randomly at room temperature using Scanning Tunneling Microscopy. However, these molecules undergo significant transformations upon annealing, forming chain-like structures. OPN forms disordered chains at room temperature, which become more linear and ordered upon heating. Compared to Au(111) and Ag(111), where simpler self-assemblies or dimers form, Co(0001) uniquely enables complex, ordered chain formation. This work provides critical insight into the catalytic properties of cobalt, enhancing understanding of molecular assembly on metal surfaces and offering new directions for designing nanostructured materials with precise molecular ordering.

O 22.6 Mon 18:00 P2

Characterization of an unexpected mu3 adsorption of molecular oxygen on Ag(100) with LT-STM — •Merve Ercelik[1], Andrés Pinar Solé[1], Liang Zhang[2], Hua Guo[2], Andreas J. Heinrich[1], Yujeong Bae[1], and Dmitriy Borodin[1] — [1]Center for Quantum Nanoscience, Institute for Basic Science, Seoul 03760, South Korea — [2]Department of Chemistry and Chemical Biology, Center for Computational Chemistry, University of New Mexico, Albuquerque, New Mexico 87131, USA

The interaction between molecular oxygen and metal surfaces is a key topic in quantum chemistry and surface science, with significant implications for electrochemistry and heterogenous catalysis. Using low-temperature scanning tunneling microscopy (STM), we investigate a previously unknown adsorption state of molecular oxygen on Ag(100), where the molecule binds to three silver atoms simultaneously (mu3-O2). We characterize vibrational excitations through inelastic electron tunneling spectroscopy (IETS): out-of-plane hindered rotation, in-plane hindered rotation, and in-plane hindered translation. Tunneling electron induced rotations reveal a rotational isomerization barrier of 69.3 meV. Interestingly, GGA-level DFT calculations fail to identify mu3-O2 as a stable adsorption state, likely due to self-interaction errors affecting the description of localized charges. We speculate that the mu3-O2 configuration corresponds to a formal molecular oxygen anion, with the 11 meV excitation observed in IETS attributed to a transition between spin-orbit states of the surface-bound molecular anion.

O 23.1 Mon 18:00 P2

Charge Density Waves and Doublon Lifetime in Doped 1*T*-TaS_2 — •J. Jayabalan[1], Gaël Reecht[1], Florian Diekmann[2], Ping Zhou[1], Walter Schnelle[3], Kai Rossnagel[2], Manuel Gruber[1], and Uwe Bovensiepen[1] — [1]Universität Duisburg-Essen, Germany. — [2]Christian-Albrechts-Universität zu Kiel, Germany. — [3]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany.

Below a certain critical temperature, the periodic rearrangement of atoms into a long-range ordered star-like pattern transforms the metallic 1*T*-TaS_2 into an insulating state by opening a band gap [B. Sipos, *et al.*, Nature Materials **7**, 960 (2008)]. This metal-to-insulator transition progresses through distinct charge density wave (CDW) states, driven by the interplay between electron-electron and electron-lattice interactions. In the commensurate CDW state of 1*T*-TaS_2, the carriers excited into its upper Hubbard band (UHB), also known as a doublon state, decay in less than 20 fs due to the presence of unintentionally doped holes in the sample [M. Ligges, *et al.*, Phys. Rev. Lett., **120**, 166401 (2018)]. Through ultraviolet time-resolved photoemission spectroscopy at the Γ point, we identify a long-lived feature near the upper Hubbard band (UHB) energy in 1*T*-$Ta_{(1-x)}W_xS_2$. Through variations in temperature, doping concentration, and pump-induced effects, we identify this observed feature as long-lived doublons. With STM measurements, we show a long living hole dynamics through localized excitations at specific locations of the sample. Funding by the DFG through FOR 5249 QUAST is gratefully acknowledged.

O 23.2 Mon 18:00 P2

Ultrafast low-energy photoelectron diffraction for the study of surface-adsorbate interactions with 100 femtosecond temporal resolution — Hermann Erk[1], Carl Erik Jensen[1], •Stephan Jauernik[1], and Michael Bauer[1,2] — [1]Institute of Experimental and Applied Physics, Kiel University, 24098 Kiel, Germany — [2]Kiel Nano, Surface and Interface Science KiNSIS, Kiel University, 24118 Kiel, Germany

In this contribution a novel method of ultrafast electron diffraction for the study of structural dynamics at surfaces is presented. In our photoemission-based experiment we analyze the energy-momentum distribution of low-energy photoelectrons excited by a near ultraviolet (NUV) ultrafast laser pulse in graphite that are diffracted as they pass through an ordered tin-phthalocyanine adsorbate layer. The probing electron pulse is generated in the immediate vicinity of the surface. This limits the propagation distance of the electron pulse before diffraction to a few nanometers and thus minimizes pulse broadening effects due to space charge and dispersion. We experimentally demonstrate a time resolution of this ultrafast low-energy photoelectron diffraction (ULEPD) of about 100 fs [1], which is only limited by the pulse width of the NUV laser pulse and exceeds reported values of conventional ultrafast low-energy electron diffraction [2] by a factor of 10.

[1] H. Erk *et al.*, Phys. Rev. Lett. **133**, 226201 (2024)
[2] S. Vogelgesang *et al.*, Nat. Phys. **14**, 184 (2017)

O 23.3 Mon 18:00 P2

Studying electron-phonon interaction in $MoTe_2$ using time-resolved and frequency-domain ARPES — •Carl Eric Jensen[1], Stephan Jauernik[1], Petra Hein[1], and Michael Bauer[1,2] — [1]Institute of Experimental and Applied Physics, Kiel University, 24098 Kiel, Germany — [2]Kiel Nano, Surface and Interface Science KiNSIS, Kiel University, 24118 Kiel, Germany

The layered transition metal dichalcogenides $MoTe_2$ and WTe_2 attracted significant attention in the recent years due to the topological properties of their non-centrosymmetric T_d-phase and their manipulation by coherent phonon excitation [1,2]. In this contribution we present time-resolved and frequency-domain ARPES (FD-ARPES) data of 1T'-$MoTe_2$. Optical excitation of the electronic system by a near-infrared (1.5 eV) pump pulse results in the excitation of coherent phonons in this material. The frequencies of the observed coherent phonon modes agree with all-optical measurements of $MoTe_2$ [2,3]. A Fouriertransform of the time-resolved ARPES data into the frequency-domain proviedes further insights into the interaction between electrons and phonons: The FD-ARPES data reveal the electronic band-selectivity of the indivitual coherent phonon modes. The results are compared with published work on WTe_2 [4].

O 23.4 Mon 18:00 P2

Ultrafast Charge Transfer and Band Renormalization in Bilayer Graphene/single layer Ag/SiC — •Eduard Moos[1], Zhi- Yuan Deng[1], Hauke Beyer[1], Arpit Jain[4], Chengye Dong[4], Joshua A. Robinson[4], Kai Rossnagel[1,2,3], and Michael Bauer[1,2] — [1]Kiel University, Germany — [2]Kiel Nano, Surface and Interface Science KiNSIS, Germany — [3]Electron Synchrotron DESY, Germany — [4]Pennsylvania State University, United States

Intercalated monoelement metals between mono- to multi-layer graphene/SiC interfaces are a new type of van der Waals heterostructures with extraordinary properties. In the monolayer limit, silver (MLAg) exhibits a metal-semiconductor transition and enables ultrafast charge transfer between layers. Due to the twisted arrangement of the Brillouin zones, low binding energy of the valence band maximum of MLAg and the resulting band gap of bilayer graphene (BLGr), this is an interesting model system to investigate charge transfer and interlayer coupling mechanisms.

In this contribution, time- and angle-resolved photoemission spectroscopy (TRARPES) with a time resolution of 35 fs is used. The data show clear evidence for a net charge transfer between Ag and graphene on a time scale of 50 fs. On longer time scales, the electronic structure of BLGr undergoes significant changes, including an enhancement of the intrinsic splitting of the pi band as well as a reduction of the band gap. We associate these with changes in the electronic and/or structural symmetry of BLGr.

O 23.5 Mon 18:00 P2

Ultrafast dynamics of thin films of small PAHs — •Lorenzo Maddii Fabiani, Tobias Reiker, and Helmut Zacharias — Center for Soft Nanoscience, Busso-Peus-Str.10 48149 Münster Germany

Polycyclic aromatic hydrocarbons (PAHs), which are estimated to constitute approximately 10% of the total carbon content in space, are omnipresent in interstellar environments. Molecular reactions of molecules in space, such as ionization, fragmentation and dissociation are fundamental to the chemical evolution of the interstellar medium. To investigate the initial electronic dynamics in alternant and non-alternant PAHs in the condensed phase following optical excitation, we performed time-resolved two-photon photoemission (tr-2PPE) experiments. Thin films of PAHs were prepared on gold-coated quartz substrate. In the range from femtosecond to 200 ps up to three lifetimes after excitation of S1, S2 or S3 were observed. We provide experimental ultrafast lifetimes of nine different alternant and non-alternant small PAH molecules in thin films. For the alternant molecules an increase of the lifetimes with molecular size is found, and the lifetimes decrease generally with increasing of the probe photon energy. In contrast, non-alternant PAHs exhibited less predictable behavior. Overall, the dynamics of excited electronic states provide a fundamental basis for unraveling the reaction processes occurring within the interstellar medium.

O 23.6 Mon 18:00 P2

Transient IR pump-probe spectroscopy on AuNP-TiO_2 structures — •Lisa Mehner[1], Wouter Koopman[1], Felix Stete[1], Steven Berth[1], Alexander von Reppert[1], and Matias Bargheer[1,2] — [1]Insitute for Physics and Astronomy, University of Potsdam — [2]Helmholtz-Zentrum Berlin

Photocatalysts can enhance redox reactions by supplying energetic electrons and holes. Combining gold nanoparticles (AuNP) and TiO_2 nanoparticles (NP) presents a promising route for realizing broad band photocatalysts as AuNP allow broad band absorption and TiO_2NP provide a long excited carrier lifetime. Electrons excited in the AuNP can transfer into the semiconductor if the energy is sufficient to overcome the interfacial Schottky barrier. Transferred electrons are expected to have a prolonged lifetime in the TiO_2 conduction band, since no vacancies are available for recombination in the valence band. Here, we present our initial findings on charge transfer of a TiO_2NP+AuNP sample

measured by transient pump-probe spectroscopy with optical pump-pulses and IR probe-pulses. Our measurements confirm the transfer of charges to the conduction band . Comparing TiO_2NP+AuNP to pure TiO_2NP suggests that both electron transfer from Au to TiO_2 as well as direct excitation of TiO_2 trap states occurs. The decrease in carrier lifetime with increasing fluence moreover indicates back transfer of charges from TiO_2 to Au.

O 23.7 Mon 18:00 P2

Photo-induced electron pressure drives THz phonon in Platinum-Copper superlattice — •Jan-Etienne Pudell[1], Marc Herzog[2], Max Mattern[2], Alexander von Reppert[2], Daniel Schick[3], Ulrike Boesenberg[1], Angel Rodriguez-Fernandez[1], Wonhyuk Jo[1], Roman Shayduk[1], Wei Lu[1], Felix Brause[1], Michel Hehn[5], Matias Bargheer[2,4], and Anders Madsen[1] — [1]European XFEL, Germany — [2]Institut für Physik, Uni Potsdam, Germany — [3]MBI, Berlin — [4]HZB Berlin, Germany — [5]IJL, Université Lorraine, France

Using ultrafast X-ray diffraction (UXRD) at the MID end-station at the European XFEL, we investigate the ultrafast lattice dynamics of metal-metal superlattice (SL) with few atomic layers of Pt and Cu upon femtosecond photoexcitation. Our results reveal that the absorbed optical energy is rapidly localizes within the Pt layers, driving the excitation of a coherent artificial THz phonon mode defined by the superlattice period. The signal's amplitude and phase modulation of the SL Bragg peaks induced by the lattice excitation i.e. the artificial THz phonon, are predominantly driven by electron pressure within the first picoseconds. This response is faster than the Debye-Waller effect, which is limited by the electron-phonon coupling time.

O 23.8 Mon 18:00 P2

Ultrafast current response of solids - limits of quasi-classic current formula — •Jelena Schmitz, Adrian Seith, Jan Wilhelm, and Ferdinand Evers — Institute of Theoretical Physics and Regensburg Center for Ultrafast Nanoscopy (RUN), University of Regensburg, D-93053 Regensburg, Germany

In a quasi-classical picture, the velocity of an electron with crystal momentum $\mathbf{k}$ is given by [1] $\mathbf{v}_n(\mathbf{k}) = \partial\epsilon_n(\mathbf{k})/\partial\mathbf{k} + q\,\mathbf{E}(\mathbf{t}) \times \mathbf{\Omega}_n(\mathbf{k})$(1), where $\epsilon_n(\mathbf{k})$ denotes the band structure and $\mathbf{\Omega}_n(\mathbf{k})$ the Berry-curvature associated with the n-th band. Expression (1) is expected to describe the material's current response to a time-dependent external field, $E(t)$, in the limit of slow and weak driving. Motivated by recent progress in generating ultrashort laser pulses, we study the limits of applicability of Eq.(1) in the limit of fast and strong driving. To this end, we adopt the framework of the Semiconductor-Bloch Equations (SBE) [2,3]; we derive Eq.(1) using a perturbative expansion of the SBE leading to analytical expressions for the limits of applicability and compare Eq.(1) with numerical solutions of the full SBE [4].

For massive Dirac Fermions, we find the bandgap energy and the Fermi level as the parameters determining the frequency domain as well as the maximum E-field strength for which the SBEs lead to matching results with Eq.(1).We also calculate corrections to Eq.(1) that enable us to identify Berry-curvature terms at higher frequencies.[1] Xiao, Di et. al., Rev. Mod. Phys. 82, 1959 (2010) [2] Schmitt-Rink, Stefan et. al., Phys. Rev. B 37, 941 (1988) [3] Wilhelm, Jan et. al., Phys. Rev. B 103, 125419 (2021) [4] https://github.com/ccmt-regensburg/CUED/

O 23.9 Mon 18:00 P2

XUV pulses with variable photon energy, pulse duration and bandwidth for time-resolved ARPES — •Isabella Alexandra Hofmeister, Niklas Hofman, Michael Schildbach, and Isabella Gierz — University of Regensburg, Regensburg, Germany

Time- and angle-resolved photoemission spectroscopy (trARPES) provides an unprecedented view on non-equilibrium quasiparticle dynamics and band structures in momentum space. Extreme ultraviolet (XUV) pulses generated by high harmonics generation (HHG) in noble gases are usually required to gain access to the complete first Brillouin zone. HHG yields a broad spectrum containing all the odd harmonics of the driving frequency up to a cut-off energy determined by the intensity and frequency of the drive. Therefore, a single harmonic is typically selected for trARPES using grating monochromators, multilayer mirrors, or a combination of filters. We compare different approaches implemented in a single trARPES setup with respect to their bandwidth and pulse duration and present strategies to enable complementary trARPES measurements with either good energy or good temporal resolution.

O 23.10 Mon 18:00 P2

Terahertz Excitation Source for Next Generation Time-of-Flight Momentum Microscopy at FLASH — Michael Herb[1], •Stefan Miedaner[1], Thomas Seitz[1], Jure Demsar[2], Stephan Winnerl[3], and Isabella Gierz[1] — [1]University of Regensburg, Germany — [2]Johannes Gutenberg University of Mainz, Germany — [3]Helmholtz Center Dresden-Rossendorf, Germany

We will combine the broad spectral tunability of the free-electron laser FLASH with Terahertz excitation for next-generation time-of-flight momentum microscopy (ToF-MM). This unique combination will enable unprecedented access to the non-equilibrium electronic and structural properties of novel quantum materials using a variety of time-resolved spectroscopic, diffraction, and microscopic techniques. This requires the design and installation of a compact Terahertz pump source operating at Megahertz repetition rate. Here, we present the current status of the photoconductive-emitter-based source [1] and its characterization by electro-optic sampling.

[1] Optics Express 29, 427247 (2021)

O 23.11 Mon 18:00 P2

table-top source for x-ray absorption spectroscopy with photon energies upto 350 eV — •Rajdwip Bhar, Oscar A. Naranjo-Montoya, Lukas Kalkhoff, Marika Schleberger, Heiko Wende, Alexander Tarasevitch, and Uwe Bovensiepen — University of Duisburg-Essen, Duisburg, Germany

Material science research aims to understand electronic properties and dynamics of complex materials. Performing pump-probe experiments using optical pump and x-ray probe enables capturing element-specific snapshots of the pump induced changes in a material. This contribution describes the development of a tabletop soft x-ray spectroscopy setup based on high harmonic generation using noble gases in a hollow core waveguide (HCW) [1].

To generate high harmonics with higher photon energies, a near-infrared driving laser source based on optical parametric chirped-pulse amplification (OPCPA) was developed [2]. Starting with an 800 nm seed and a 1030 nm pump, the OPCPA generates 1.5 μm and 3 μm pump pulses with pulse energies of 1.8 mJ and 0.8 mJ, respectively. The 1.5 μm pulses, compressed to ~ 40 fs using chirped mirrors, pump the HCW, generating harmonics that reach photon energies up to 350 eV. Near-edge x-ray absorption spectroscopy at the B K-edge in crystalline boron and hexagonal boron nitride (hBN) samples was performed, showing excellent agreement with literature data.

New end-station for time- and angle-resolved photoelectron spectroscopy in Artemis facility — •Yu Zhang, Charlotte E. Sanders, Bruce Weaver, Tiffany Walmsley, James O. F. Thompson, Richard T. Chapman, and Emma Springate — Central Laser Facility, STFC Rutherford Appleton Laboratory, Research Complex at Harwell, Harwell, United Kingdom

Artemis, located at the Central Laser Facility in the UK, is a user facility offering time- and angle-resolved photoelectron spectroscopy (TrARPES) utilizing extreme ultraviolet (20-45 eV) photon sources based on high harmonic generation of ultrafast laser. After more than a decade of operation, Artemis has established itself as a leading facility in the research of ultrafast electron dynamics on surfaces. Recently, Artemis received an significant upgrade of its end-station, which will provide users with state-of-the-art techniques in ultrafast time-resolved measurements. These new capabilities include both momentum and real-space mapping, large-angle E-k mapping with a deflector, and a closed-loop cryostat for low-temperature measurements. Detailed information about these features can be found in the poster. Along with the recently upgraded 100kHz laser source, Artemis is committed to delivering high-performance TrARPES for its user communities.

O 23.13 Mon 18:00 P2

Temporal evolution of surface plasmon polariton skyrmions — •Philipp Gessler, Alexander Neuhaus, Maria Azhar, Pascal Dreher, Frank Meyer zu Heringdorf, and Karin Everschor-Sitte — University of Duisburg-Essen, Germany

In recent years, structures reminiscent of those found in magnets [1] have been predicted and observed in Surface Plasmon Polaritons (SPPs). Of particular interest are topological SPP structures such as skyrmion lattices [2,3] or merons [4]. In particular, these structures have been identified in various quantities related to the electric field, many of which exhibit amplitudes that oscillate over time. Building on insights from micromagnetism, our objective is to explore the dynamic behavior of these novel SPP states beyond mere temporal oscillations.

O 23.14 Mon 18:00 P2

Femtosecond momentum microscopy of field-effect gated bilayer WSe_2 and monolayer graphene — •Bent van Wingerden, Jan Philipp Bange, Jonas Pöhls, Wiebke Bennecke, Paul Werner, Daniel Steil, Matthijs Jansen, R. Thomas Weitz, Marcel Reutzel, and Stefan Mathias — I. Physikalisches Institut, Georg-August Universität Göttingen, Germany

Atomically-thin transition metal dichalcogenides and their respective Moiré heterostructures can host a variety of strongly correlated electronic phases, such as Wigner crystals and Mott insulators. The formation of these phases critically depends on the precise occupation of the corresponding Moiré superlattice states [Regan *et al.* Nature 579, (2020)], and might therefore be controlled by field-

effect doping of charge carriers [Nguyen *et al.* Nature 572 (2019)]. In our work, we realized this in combination with a table-top time-resolved ARPES setup, i.e. our Göttingen femtosecond momentum microscopy experiment [Schmitt *et al.*, Nature 608, (2022)]. Our extension of ARPES experiments on field-effect gated heterostructures into the time domain on a laboratory scale will facilitate the study of non-equilibrium dynamics of strongly correlated phases and charged quasiparticles, e.g. trions. We provide proof-of-principle data on field-effect gated monolayer graphene and present time-resolved photoemission data of a WSe_2 bilayer at different charge carrier densities.

O 23.15 Mon 18:00 P2

Towards ultrafast momentum microscopy of exciton dynamics at ZnO surfaces — •Hashima Marukara, Junde Liu, and Stefan Mathias — Georg-August-Universität Göttingen, I. Physikalisches Institut, Germany

The semiconductor ZnO, known for its wide band gap and high exciton binding energy, stands out as a promising material among transparent conductive oxides for applications in optoelectronics and catalysis[1,2]. Surface excitons, i.e. bound electron-hole pairs localized at the material's surface, play a crucial role in mediating its optical and electronic properties, significantly influencing energy conversion processes at the surfaces [3]. An ideal tool to study these ultrafast processes is time- and angle-resolved photoelectron spectroscopy, which gives access to the exciton landscape and the relevant excitation and relaxation pathways. In our new project within the CRC1633 "Proton-coupled electron transfer", we aim to study the ultrafast surface exciton dynamics at the ZnO(10-10) surface using our Göttingen time-resolved momentum microscopy setup. By using this technique, which gives us access to full energy and momentum space, we aim to gain detailed information on the ZnO's exciton momentum and real-space properties (localized/delocalized/defect/etc.) and the accompanying exciton dynamics [4].

O 23.16 Mon 18:00 P2

Towards momentum microscopy of plasmon excited WSe_2 — •Mattis Langendorf[1], Paul Werner[1], Marco Merboldt[1], Jan Philipp Bange[1], Wiebke Bennecke[1], Jonas Pöhls[1], Tobias Meyer[2], Thomas R. Weitz[1], Marcel Reutzel[1], and Stefan Mathias[1] — [1]Georg-August-Universität Göttingen, I. Physikalisches Institut, Germany — [2]Georg-August-Universität Göttingen, Institut für Materialphysik, Germany

Femtosecond momentum microscopy represents a uni measurement technique that effectively integrates the advantages of angle-resolved photoemission spectroscopy (ARPES) and photoelectron emission microscopy (PEEM) within a single microscope. The capacity to transition between real- and momentum-space imaging in time-resolved photoelectron spectroscopy enables the investigation of quasiparticles in both regimes [Bange et al., Nature Photonics, in press (2024)]. In this contribution, we pursue the characterization of electron-hole pairs, i.e. excitons, which were excited by a collective excitation of charge carriers, i.e. a surface plasmon polariton (SPP). In this approach, the propagating SPPs are imaged with photoemission electron microscopy, and the formation of excitons in the TMD is then visualized with time-resolved dark-field imaging techniques.

O 23.17 Mon 18:00 P2

Control and manipulation of low-energy electrons — •Dennis Epp[1], Frank Long[1,2], Benjamin Schröder[1], and Claus Ropers[1,2] — [1]Max-Planck-Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]4th Physical Institute, University of Göttingen, Germany

In surface science and materials physics, electron pulses are a powerful probe of structural dynamics in time-resolved diffraction and microscopy experiments. A fundamental challenge lies in the Coulomb interaction [1] and initial energy distribution, which negatively affects the electron beam size and pulse duration after propagation towards the sample. Active control of electron pulse properties by compression schemes has proven to enhance temporal resolution [2-4]. This is particularly important for low-energy electrons and their high dispersion due to low propagation velocity [4]. In this paper, we demonstrate longitudinal and transversal phase-space manipulation of low-energy electron pulses using synchronized RF fields in the gigahertz frequency range [4]. Furthermore, novel beam shaping concepts including electron pulse streaking, compression and deflection are discussed.

Band-resolved studies of laser-induced ultrafast dynamics in gold — •Stephanie Roden, Tobias Held, Sebastian T. Weber, and Baerbel Rethfeld — Department of Physics and Research Center OPTIMAS, RPTU in Kaiserslautern

The irradiation of a metal with a short-pulsed optical laser leads to the excitation of electrons, which absorb energy in accordance with their orbital characteristics. To analyze the resulting state of thermodynamic non-equilibrium, the thermalization of the excited electrons and relaxation processes with the phonon system to a joint temperature can be calculated in a kinetic manner by coupled Boltzmann collision integrals.

In this work we extend our existing energy-resolved model based on one effective band for the electrons [1] to a two-band model for a thin metal film that distinguishes between the free sp- and more localized d-electrons [2]. By considering the different electron bands separately, we can investigate the influence of intra- and interband relaxation in the electron system on the dynamics of the entire sample. We are focusing especially on the effect on the band occupation and the coupling strengths between the electron systems and the phonons.

O 23.19 Mon 18:00 P2

Ultrafast intra- and interlayer charge transfer at the FePc/WSe_2 interface — •Gregor Zinke[1], Sebastian Hedwig[1], Benito Arnoldi[1], Martin Anstett[1], Lu Lyu[1,2], Martin Aeschlimann[1], and Benjamin Stadtmüller[1,2] — [1]Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern - Landau, Erwin-Schroedinger-Straße 46, 67663 Kaiserslautern, Germany — [2]Experimental Physics II, Institute for Physics, University of Augsburg, Universitätsstraße 1, 86159 Augsburg

Tailoring the optoelectronic properties of 2D-van-der-Waals materials by material design is a promising approach for functionalizing charge and spin carriers in low-dimensional materials. In this work, we demonstrate how optically excited ultrafast charge carrier dynamics of TMDCs can be altered by the formation of molecule/2D material heterostructures. Here, we focus on an ordered FePc monolayer film deposited on the surface of a bulk WSe_2 crystal. Using time- and angle-resolved photoemission in a VIS-pump, XUV-probe setup, we will elucidate the ultrafast response of the electronic system to an optical excitation on fs-timescales. Of particular interest is the investigation of intra- and interlayer charge carrier dynamics at the FePc / WSe_2 interface, which can be disentangled by the characteristic momentum space signatures of the WSe_2 Bloch-like states and molecular orbitals. We will further illustrate the impact of ultrafast charge separation across the interface on transient changes of the interfacial energy level alignment.

O 23.20 Mon 18:00 P2

Influence of ballistic electrons on temperature equilibration in bulk gold — •Lukas Jonda, Tobias Held, Markus Uehlein, Christopher Seibel, Sebastian T. Weber, and Baerbel Rethfeld — Department of Physics andResearch Center OPTIMAS, RPTU Kaiserslautern-Landau

During femtosecond laser irradiation of gold, electrons are excited to a state of non-equilibrium in space and energy. Highly excited electrons transport energy ballistically into the bulk due to their relatively long mean free path. On a picosecond timescale, electrons transfer energy to the crystal lattice via electron-phonon collisions.

The objective of this study is to analyze the influence of non-equilibrium electrons on energy transport. Therefore, a two-temperature model will be coupled with a kinetic Monte Carlo simulation. With the former we describe diffusive transport as well as the electron-phonon equilibration, while the latter describes the primary electron excitation by the laser pulse, secondary electron generation, and transport of non-equilibrium electrons above the Fermi level.

O 23.21 Mon 18:00 P2

Hot carrier dynamics and band gap formation in lead intercalated graphene on Ni(111) — Martin Mitkov[1], Lu Lyu[2], Eva Walther[1], Martin Anstett[1], •Alexander Schmid[2], Christina Schott[1], Gyula Halasi[3], Nikolett Oláh[3], Csaba Vass[3], Zoltán Filus[3], László Óvári[3], Martin Aeschlimann[1], and Benjamin Stadtmüller[2] — [1]RPTU Kaiserslautern-Landau — [2]University of Augsburg — [3]ELI ALPS, Szeged, Hungary

The intercalation of atoms between 2D materials and surfaces offers an intriguing opportunity to tune spin functionalities at surfaces. The combination of heavy metal atoms and magnetic surfaces allows to tune the band structure of 2D materials through the interplay of spin-orbit coupling and magnetic proximity effects. In this poster, we present our recent findings on the band structure and hot electron dynamics of a Pb-intercalated graphene layer on Ni(111).

The highly reactive Ni substrate causes a charge transfer into the graphene layer, which leads to n-doped Dirac cones. Pb intercalation leads to a decoupling of the graphene, resulting in a quasi-free standing graphene layer on Ni.

Our time-resolved momentum microscopy experiment allows us to determine the influence of Pb intercalation on the ultrafast carrier dynamics of the Gr/Ni(111) interface. We discuss the momentum space distribution of the optically excited carriers at the K-point for the bare and Pb intercalated graphene and present indications for a modification of the magnetization dynamics of the Ni substrate by energy and charge transfer from the Pb-intercalated graphene.

O 24: Poster Scanning Probe Techniques: Method Development

Time: Monday 18:00–20:00 Location: P2

O 24.1 Mon 18:00 P2

Comparative Analysis of Work Function Measurements Using STM/AFM Techniques — •Daryoush Nosraty Alamdary, Matthias Bode, and Artem Odobesko — Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany

The engineering of the work functions at the interface of complex materials is sometimes the key [1] for an energy band tuning that supports proximity-induced effects [2]. While there are handful of established methods that allow a precise measurement and determination of the work function, STM-based methods constitute a class of their own since they are based on a local probe. In this work we present a comparative study of 3 different techniques based on a combined STM/AFM setup. For a few well-characterized sample systems we analyze the benefits and difficulties of each method. Finally, we draw a conclusion as to which method is the more precise and reliable method, whereby the special focus lies on the accuracy and the challenges of the interpretation.

O 24.2 Mon 18:00 P2

Cryogenic, ultrahigh vacuum sample transfer between electrospray ion beam deposition (ESIBD) and scanning probe microscopy (SPM) — •Alejandro Lynch Gonzalez, Stephan Rauschenbach, Lukas Eriksson, Benjamin Mallada, Tim Esser, and Marko Grabarics — University of Oxford

Electrospray ion beam deposition (ES-IBD) is currently the only viable method for cleanly and selectively depositing large and complex molecules which do not have a vapour pressure while preserving their chemical structure. In our lab, ESIBD[1] and SPM instruments are physically separate and sample transfer between them is performed using a vacuum suitcase system which maintains UHV and cryogenic conditions during transfer, essential for suppressing surface diffusion, conformational changes, and contamination during the transfer. Here, we present the design, implementation, and benchmarking of a cryogenic UHV suitcase and showcase applications.

O 24.3 Mon 18:00 P2

Ultra-broadband Terahertz Time-Domain Spectroscopy for Space Exploration — •Dominic Azih[1,2], Yookyung Ha[2], Jonas Woeste[1,2], Nikola Stojanovic[2], and Michael Gensch[1,2] — [1]Technical University, Berlin, Germany — [2]DLR Ínstitute of Optical Sensor Systems, Berlin, Germany

Femtosecond lasers have in recent years been shown to be space qualified and with the development of compact femtosecond laser systems [1,2], Terahertz Time-Domain Spectroscopy (THz TDS) allows meanwhile to cover an essential part of the molecular fingerprint spectral range and has several technological advantages over the commonly used Fourier-Transform Infrared techniques (FTIR). The advantages are compactness, replacement of components (cryogenic) spectrally broadband infrared detectors with electro-optic/acousto-optic photonic techniques and the potential to be chip-integrable. Here we show our progress enroute to a THz time-domain spectroscopic setup for space applications with a bandwidth of over 30THz and a resolution of better than 100GHz [3].

O 24.4 Mon 18:00 P2

High-collection efficiency optical scanning probe microscopy with on-axis parabolic mirror — •Aleksander Bogucki[1], Magdalena Grzeszczyk[1], Yeon-ji Kim[1], Yewon Kim[1], German Orlov[1], Lei Fang[1], Wonjun Jang[1,2], and Andreas Heinrich[1,2] — [1]Center for Quantum Nanoscience, Institute for Basic Science (IBS), Seoul, South Korea — [2]Department of Physics, EWHA Womans University, Seoul, South Korea

Scanning probe microscopy (SPM) techniques are essential for investigating surface physics, from single atoms to complex systems like organic molecules. Combining SPM with optical spectroscopy enhances our ability to explore system dynamics. However, existing setups face photon collection efficiency challenges due to spatial constraints, particularly for systems with long-lived excited states.

We present a homemade optics-integrated scanning probe microscope using a centered on-axis parabolic mirror with a short focal length. The scanning component employs a combined AFM/STM qPlus sensor with a long tip. Free-beam optics maximize photon collection efficiency, reaching an estimated upper limit of 90%. This design eliminates chromatic aberrations, enables polarization measurements, and operates under ultra-high vacuum (UHV) at low temperatures (4K), ensuring high stability and precision.

O 24.5 Mon 18:00 P2

Electron wavefront shaping with light — •martino zanetti[1,2], Tilman Kraeft[1,2], Luis Alfredo Ixquiac Mendez[1,2], Alexandra Pernishova[1,2], and Thomas Juffmann[1,2] — [1]University of Vienna, Faculty of Physics — [2]University of Vienna, Max Perutz Laboratories

Electron Microscopes (EM) are common and fundamental tools in many research fields, as they can image samples with resolutions down to the nanometric scale. The ability to arbitrarily shape the electron beam of an EM with light can help overcome intrinsic limits like electron lens aberrations and pave the way to new EM techniques [1].

For shaping the electron beam, a modified Scanning-EM is coupled to a high-power pulsed laser. The electron-light interaction takes place in the SEM chamber. The electrons are then detected after free propagation to measure their spatial distribution. Here, we present our advancements in applying the electron beam shaping technique to demonstrate single electron wavefront modulation. The intensity profile of a TEM01 laser mode is imprinted on the wavefront of the electron, which thus resembles that of an electron going through a double slit. Adding up the detection of multiple electrons, we expect to see an interference pattern that proves the effective modulation of the electron wavefront. The need for micrometric resolution measurements required us to develop a single-electron detector which outperforms many commercially available ones in the 20-30 keV range, being at the same time more flexible and cheaper.

[1] Mihaila et al., Phys. Rev. X 12, 031043 (2022)

O 24.6 Mon 18:00 P2

Optimizing ESR-STM for mK Temperatures in a Closed-Cycle Dilution Refrigerator — •Luise Renz, Máté Stark, Jonas Arnold, Johannes Schwenk, Christoph Sürgers, Wolfgang Wernsdorfer, and Philip Willke — Physikalisches Institut (PHI), Karlsruhe Institute of Technology, Karlsruhe, Germany

Using Electron Spin Resonance (ESR) combined with Scanning Tunneling Microscopy (STM), electronic and magnetic properties of single atoms and molecules can be studied. However, the possibility of applying RF voltages to the tip often limits the achievable minimum temperature of the STM. We here describe an ESR-STM setup mounted in ultra-high vacuum (UHV) in a closed-cycle Dilution Refrigerator (DR). The focus here is on the wiring of the STM, the material choice and the filtering of the RF and DC cables with the goal of having a good transmission of the RF lines but nevertheless also mK-temperatures in the STM junction. The resulting bandwidth and transmission of these cables, the noise level of the STM as well as the electronic temperature of the STM junction, is presented. The electronic temperature is estimated on a Pb(111) crystal by evaluating the superconducting gap and the Josephson peak (using a superconducting tip).

O 24.7 Mon 18:00 P2

Detection and Localization of Atoms and Molecules on Different Surfaces Using Computer Vision — •Lovis Hardeweg, Johannes Schwenk, Wantong Huang, Kwan-Ho Au-Yeung, Máté Stark, Paul Greule, Christoph Sügers, Wolfgang Wernsdorfer, and Philip Willke — Physikalisches Institut (PHI), Karlsruhe Institute of Technology, Karlsruhe, Germany

Scanning Probe Microscopy (SPM) methods are unparalleled in their ability to image and manipulate structures on the atomic scale. In combination with machine learning techniques, this allowed to automate processes such as removing a molecule from a thin layer [1] or moving an adsorbed molecule to a specific position [2]. However, this often relies on prior human interaction to identify and localize objects of interest, like a thin film or a single adsorbate. Here, we discuss methods that automate several steps in SPM experiments, with the goal of advancing single atomic and molecular spin detection experiments. For that, we employ computer vision techniques to STM topography data and are able to extract information, such as the location of single atoms and molecules or the presence of different sample surfaces, for instance ultra-thin MgO films grown on Ag(001). We believe that these abilities, once sufficiently developed, can lead to a significant reduction in the need for human intervention in the automated use of high-resolution low temperature SPM. [1] P. Leinen et al. Sci. Adv., vol. 6, no. 36, p. eabb6987, Sep. 2020, doi: 10.1126/sciadv.abb6987. [2] B. Ramsauer et al. J. Phys. Chem. A, vol. 127, no. 8, pp. 2041-2050, Mar. 2023, doi: 10.1021/acs.jpca.2c08696.

O 24.8 Mon 18:00 P2

A Closed-Cycle Atomic Force Microscopy Setup for Electron Spin Resonance Measurements at mK Temperatures — •Adrian Seiler, Lovis Hardeweg, Luise Renz, Arian Vosoghi Marand, Kwan Ho Au-Yeung, Wantong Huang, Paul Greule, Máté Stark, Christoph Sürgers, Wolfgang Wernsdorfer, Johannes Schwenk, and Philip Willke — Physikalisches Institut (PHI), Karlsruhe Institute of Technology, Karlsruhe, Germany

Combining scanning probe techniques with electron spin resonance (ESR) provides a unique tool for the investigation as well as the manipulation of individual surface-adsorbed spins. Most experiments up to date are relying on Scanning Tunneling microscopy (STM) and thus conductive samples [1]. As a result, scattering of electrons with the spin system is a major source of decoherence and relaxation. In contrast, atomic force microscopy (AFM) provides the possibility to reduce the scattering intensity with the conducting electrodes. Here, we present the first implementation steps of a commercial AFM head and ultra-high vacuum setup in a compact dilution refrigerator. The final setup is designed to reach milli-Kelvin temperatures (≈ 50 mK) with short cool-down times on the order of several hours. In addition to the dilution unit, the system utilizes a closed-cycle cryocooler allowing longtime stable operation. We further improve the time-consuming sample preparation by automation of the sputter and annealing process to allow for a rapid turnaround of samples in the future.

O 24.9 Mon 18:00 P2

Lightwave driven magnetic field scanning tunneling microscopy — •Leo Ringer, Andreas Rank, Peter Menden, Christian Meineke, Rupert Huber, and Jascha Repp — University of Regensburg, Regensburg, Germany

Lightwave driven scanning tunneling microscopy (LW-STM) is based on the key idea to directly steer electron tunneling in STM by ultrashort light pulses. Combining the development of LW-STM with a tunable magnetic field would allow following spin dynamics - e.g. spin precession - in molecules and other atomistic structures with single-electron sensitivity. To this end, we develop a novel lightwave driven scanning tunneling microscope including an external magnetic field to resolve single-spin dynamics with atomic spatial and ultrafast temporal resolution. Instrumental challenges of this development will be discussed, and we present the resulting instrument design including the head of the scanning tunneling microscope, the laser source as well as the solution to introduce the laser transient from outside the vacuum system to the tip-sample junction.

O 24.10 Mon 18:00 P2

Implementation of radio-frequency magnetic fields for electron spin resonance atomic force microscopy — •Raffael Spachtholz, Lisanne Sellies, Franziska Bruckmann, Sonja Bleher, Philipp Scheuerer, and Jascha Repp — Department of Physics, Universität Regensburg

Implementing electron spin resonance in scanning tunneling microscopy represents a milestone in controlling spin systems at atomic scales [1]. In this emerging research field the required radio-frequency (RF) signal is provided as an electric field, translating to an effective magnetic field.

Here we report the integration of a radio-frequency (RF) magnetic field, in the frequency range of 0.1 to 3 GHz, into a scanning-probe microscope. We utilized a flexible polyimide printed-circuit-board coil to generate the RF magnetic fields. Additionally, an insulating sample, coated with a gold microstructure, was designed to locally enhance the RF magnetic field while mitigating the screening effects caused by a metallic substrate. Up to 3 GHz the transmission only moderately depends on frequency and exhibits no sharp resonances. This development enabled the implementation of electron spin resonance in atomic force microscopy, as demonstrated for individual pentacene molecules [2].

O 24.11 Mon 18:00 P2

Implementation and characterization of all-electronic pump-probe spectroscopy on a low-temperature scanning tunneling microscope — •Guido Hiller, Gaël Reecht, and Manuel Gruber — Universität Duisburg Essen, Duisburg

Pump-probe spectroscopy is a powerful technique for investigating non-equilibrium dynamics, where the time resolution is determined by the duration of the pump and probe pulses rather than the detectors bandwidth. When combined with a scanning tunneling microscope (STM), this method enables dynamic measurements at the level of individual atoms and molecules, achieving both high temporal and spatial resolutions [1].

In this work, we implement an all-electric pump-probe scheme on a low-temperature STM. Cross-correlation measurements on an Au(111) surface reveal a time resolution of 100 ns. This resolution is constrained by the broadening of voltage pulses during transmission to the STM junction [2]. To address this, we conducted a detailed analysis of the frequency-dependent transmission function of the instrument. Funding support from the CRC 1242 is gratefully acknowledged.

O 25: Overview Talk Jörg Kröger

Time: Tuesday 9:30–10:15 Location: H24

Topical Talk O 25.1 Tue 9:30 H24

Exploring quantum physics with scanning probe methods — •Jörg Kröger — Institut für Physik, Technische Universität Ilmenau, Germany

It is hardly possible to ignore the importance of scanning probe techniques for the understanding of mechanisms and principles in the quantum behavior of condensed matter. This Overview Talk presents contributions of atomic force microscope experiments to controlling and quantifying interactions involved in bonding processes at the single-atom level. It then demonstrates that scanning tunneling spectroscopy is successfully used in exciting and detecting quantum vibrations and spins as well as in characterizing the charge transport across the metal-superconductor interface. Funding by the DFG through KR 2912/17-1, 18-1, 21-1 and the BMBF through ForLab is acknowledged.

O 26: Focus Session Ultrafast Electron Microscopy at the Space-Time Limit III

Shaping functionalities on the nanoscale is one of the most essential challenges in modern condensed matter research. It requires a comprehensive understanding of the complex interplay of the electronic, spin, and lattice degrees of freedom in materials and requires tailoring energy transfer and dissipation pathways on the smallest length and fastest timescales. Recent instrumentation breakthroughs in different varieties of pump-probe ultrafast electron microscopy have opened the way for accessing electronic and structural dynamics at surfaces, interfaces, and nanostructures with down-to-attosecond resolution in time. While ultrafast photoemission electron microscopy techniques provide supreme sensitivity to spin and electron dynamics in real momentum space, bright ultrashort electron pulses in the ultrafast implementation of more traditional electron microscopes can probe optical states, local magnetization, and lattice dynamics with a nanometer spatial resolution.

This focus session highlights recent advances in ultrafast high-resolution electron probing. These include new instrumentation and techniques, excitations from the THz to X-ray regime, and studying novel phenomena and materials systems. At the same time, it will bring together researchers from the different areas of ultrafast condensed matter physics to foster discussions and new collaborations to explore emergent scientific questions in this field.

Organized by Armin Feist (MPI Göttingen) and Benjamin Stadtmüller (University Augsburg).

Time: Tuesday 10:30–13:00 Location: H2

Invited Talk O 26.1 Tue 10:30 H2

Attosecond Electron Microscopy — •Peter Baum — Universität Konstanz, Germany

All processes in materials, nanostructures and devices are on a fundamental level defined by electronic and atomic motion from initial to final conformations. Our approach for a direct, real-space visualization is pump-probe electron diffraction

and microscopy with single-electron wavepackets under the control of laser light. The resulting few-femtosecond and attosecond time resolution allows to see almost any light-matter interaction or structural dynamics on fundamental scales in space and time. We report selected results on strongly correlated materials, rotational phonons, electronic circuitry, free-electron quantum phenomena and attosecond dynamics in nanomaterials.

O 26.2 Tue 11:00 H2

Steady-State and Time-Resolved Cathodoluminescence of III-Nitride Semiconductors — •Kagiso Loeto, Aidan Flynn Campbell, Domenik Spallelk, and Jonas Lähnemann — Paul-Drude-Institut für Festkörperelektronik, Berlin, Deutschland

Cathodoluminescence (CL), in steady-state and time-resolved modes, has advanced the study of semiconductor optical properties, crucial for microelectronics and III-nitride optoelectronics. A new state-of-the-art time-resolved CL (TRCL) microscope at the Paul-Drude-Institut features a high-performance SEM with a stable electron source and advanced light collection system, enabling optimized imaging and high spatial resolution at acceleration voltages as low as 0.35 kV. The system features a UV-optimized CCD camera for studying UV-emitting materials like III-nitrides. Time-resolved operation is enabled by an ultrafast beam blanker paired with detectors achieving temporal resolutions of tens of picoseconds, offering new insights into the dynamic optical properties of advanced semiconductors. It will be employed in three focus areas, highlighting its distinct capabilities. First, very-low acceleration voltage operation will enable high-resolution mapping of individual point defects in AlGaN quantum well structures, revealing their impact on AlGaN-based UV LEDs. Second, ultraviolet-optimized photon detectors will study temperature-stable excitonic bands in AlN with high spectral resolution, providing insights into their origins. Lastly, the instrument's time-resolved capabilities combined with spatial mapping will explore the interplay between carrier dynamics and localization in InGaN pseudosubstrates.

O 26.3 Tue 11:15 H2

Spin Resonance Spectroscopy meets Transmission Electron Microscopy — •Philipp Haslinger — Atominstitut, USTEM, Technische Universität Wien, Austria

Coherent spin resonance methods such as nuclear magnetic resonance and electron spin resonance spectroscopy have led to spectrally highly sensitive, non-invasive quantum imaging techniques. Here, we will present a spin resonance spectroscopy approach developed for transmission electron microscopy [1,2] and will explain different techniques to sense with electrons for microwave manipulated spin states of the sample. This could enable state-selective observation of spin dynamics on the nanoscale and indirect measurement of the environment of the spin systems, providing information on, for example, atomic structure, local chemical composition and neighbouring spins.

Boero, I. C. Bicket, and P. Haslinger, Electron Spin Resonance Spectroscopy in a Transmission Electron Microscope, arXiv:2408.16492 (2024).

O 26.4 Tue 11:30 H2

Observation of Kapitza-Dirac effect with fast electrons — •Kamila Moriová[1], Petr Koutenský[1], Marius Constantin Chirita Mihaila[1], Zbyněk Šobáň[2], Andreas Schertel[3], Jaromír Kopeček[2], and Martin Kozák[1] — [1]Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic — [2]Institute of Physics, Czech Academy of Sciences, Prague, Czech Republic — [3]Carl Zeiss AG, Oberkochen, Germany

Advancing ultrafast electron microscopy relies on coherent control of free electron wavefunctions. While most research focuses on electron interactions with optical near-fields, an all-optical approach using ponderomotive forces offers a promising alternative for manipulating pulsed electron beams. The Kapitza-Dirac effect [1], where free electrons diffract coherently from a standing light wave, enables momentum transfer via stimulated Compton scattering. However, its application has been limited to low-energy electrons due to challenges in resolving small deflection angles of electron beams caused by photon absorption and emission.

We report the observation of the Kapitza-Dirac effect in a scanning electron microscope using high-energy (20 keV) electrons. Photon sidebands in the electron transverse momentum spectrum are detected in a convergent beam diffraction geometry using spatial filtering. This effect can serve as a coherent electron beam splitter or phase plate in various types of electron microscopes and paves the way for exploring fundamental electron-light interactions.

[1] Freimund, D. L. et al. Nature 413, 142 (2001)

O 26.5 Tue 11:45 H2

Recent results of the ultrafast scanning electron microscope in Erlangen — •Stefanie Kraus[1], Tomas Chlouba[1], Roy Shiloh[1], Leon Brückner[1], Julian Litzel[1], Zhexin Zhao[1], Viacheslav Korolev[1], Manuel Konrad[1], Tatsunori Shibuya[1,3], and Peter Hommelhoff[1,2] — [1]Department Physik, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), 91058 Erlangen — [2]Department Physik, Ludwig-Maximilians-Universität München (LMU), 80799 München — [3]AIST, Tsukuba, Japan

Ultrafast electron microscopy is revolutionizing the capabilities of electron microscopes, allowing for unprecedented spatial and temporal resolution. Closely related is the coupling of electrons and optical nearfields, which is based on the excellent electron pulse properties an ultrafast scanning electron microscope (USEM) can provide. We have leveraged the interaction of electrons with the near field of a periodic structure to achieve sub-femtosecond electron pulse compression as well as laser acceleration of electrons. This advancement enhances temporal resolution and facilitates large beam energy variations, enabling detailed investigations of ultrafast dynamics. In this talk, we will provide an overview of our recent progress, including electron energy modulation in larger structures illuminated with 10 micrometer light as to enhance the current throughput, electron bunch compression, and the latest experimental results.

O 26.6 Tue 12:00 H2

FEL-based core-cum-conduction momentum microscopy of ultrafast charge-density-wave dynamics — •N. Wind[1,2,3], M. Heber[1,3], D. Kutnyakhov[1], L. Wenthaus[1], J. Dilling[2], L. Bruckmeier[2], S. Chernov[1], O. Tkach[4], A. Mehta[5], J. Koralek[5], G. Dakovski[5], J.A. Sobota[6], P.E. Majchrzak[6], D. Puntel[6], D. Liu[6], G. Schönhense[4], H.J. Elmers[4], Z.X. Shen[6], M. Scholz[1], and K. Rossnagel[1,2] — [1]Deutsches Elektronen Synchrotron DESY, 22607 Hamburg, Germany — [2]Christian-Albrechts-Universität zu Kiel IEAP, 24098 Kiel, Germany — [3]Universität Hamburg, IExP, 22761 Hamburg, Germany — [4]Johannes Gutenberg-Universität, Institut für Physik, 55128 Mainz, Germany — [5]SLAC National Accelerator Laboratory, Menlo Park, CA 94205, USA — [6]Stanford University, Institute for Materials and Energy Science, CA 94305, USA

Transition-metal dichalcogenides (TMDCs) offer a rich platform for studying novel forms of quantum and nanoelectronics in layered structures approaching the 2D limit. Among them, 1-*T* TaS_2 has been extensively studied due to its various charge-density-wave (CDW) phases. Here, we provide novel insights into the CDW melting in 1-*T* TaS_2, using time- and angle-resolved photoemission spectroscopy with a momentum microscope at the free-electron laser FLASH in Hamburg. Our near-infrared pump–FEL probe experiment uncovers momentum-dependent conduction-band dynamics and core-level responses, advancing our understanding of ultrafast coupled electronic and structural dynamics.

O 26.7 Tue 12:15 H2

Developing a versatile fiber-based cathodoluminescence detection system for an ultrafast scanning electron microscope — •Paul H. Bittorf[1], Filip Majstorovic[1], and Nahid Talebi[1,2] — [1]Institute for Experimental and Applied Physics IEAP, Kiel University, 24118 Kiel, Germany — [2]Kiel Nano, Surface and Interface Science KiNSIS, Kiel University, 24118 Kiel, Germany

Cathodoluminescence (CL) is emitted when a high-energy electron beam interacts with materials like minerals, semiconductors and plasmonic nanoparticles. Depending on the underlying interaction mechanisms of electrons with the sample this radiation can be coherent or incoherent, where both spectral and temporal statistics can be unraveled for material characterization. Thanks to the high spatial resolution and large spectral excitation bandwidth of the electron beams, we could resolve the spatial far-field distribution of locally probed photonic modes by CL microscopy. Moreover, we combined a commercial scanning electron microscope (SEM) with an ultrafast laser system to obtain a pulsed electron beam via the photoemission process. In addition to the excitation by the pulsed electron beam, a time-delayed laser pulse is focused onto the sample to induce an optical near-field and achieve a time-resolved pump-probe measurement. The interaction properties of electrons with nanostructured matter are analyzed through the emitted CL. Here, we report on technical aspects and the implementation of a multimode fiber-based CL detection system inside an ultrafast SEM and highlight its functionality by performing CL spectroscopy and time correlated single-photon counting.

O 26.8 Tue 12:30 H2

Ultrafast Electron Diffraction and Microscopy of Structural Phase Transitions at Megahertz Rates — •Till Domröse[1,2] and Claus Ropers[1,2] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]4th Physical Institute, University of Göttingen, Germany

Control over laser-induced structural phase transformations promises tuning of macroscopic materials properties on femtosecond timescales. Ultrafast electron diffraction (UED) elucidates the spatially averaged evolution of lattice symmetries and phonon populations during the transitions. However, resolving nanoscale structural heterogeneity in these measurements remains challenging due to the reduced brightness of pulsed electron beams. Here, we overcome fundamental limitations in the stroboscopic investigation of structural dynamics in thin material films by UED and ultrafast electron microscopy. A high-coherence electron source offers enhanced momentum resolution in collimated electron nanobeams, while thermally-optimized sample supports enable reversible driving of structural transitions at high duty cycles [1]. Utilizing the

associated gain in coherent electron current, we conduct nano-UED investigations of charge-density wave dynamics in layered materials, tomographically reconstructing three-dimensional phase formation kinetics in 1*T*-TaS_2 [2], and revealing a femtosecond structural quench in 1*T*'-$TaTe_2$ cycled at a repetition rate of 2 MHz [3].

From Electron-Photon Ghost Imaging Towards Entanglement Certification — •Alexander Preimesberger[1,2], Sergei Bogdanov[1,2], Phila Rembold[1], Santiago Beltrán-Romero[1,2], Dominik Hornof[1,2], Isobel C Bicket[1,2], Nicolai Friis[1], Elizabeth Agudelo[1], Dennis Rätzel[3], and Philipp Haslinger[1,2] — [1]VCQ, Atominstitut, TU Wien, Vienna, Austria — [2]USTEM, TU Wien, Vienna, Austria — [3]ZARM, University of Bremen, Bremen, Germany

Time-resolved detection of single electrons and their associated cathodoluminescence (CL) photons enables the identification of coincident electron-photon pairs. We recently employed this technique to study the tight momentum correlations generated by coherent CL within a transmission electron microscope [1]. In this contribution, we demonstrate ghost imaging using electron-photon pairs in both near-field and far-field configurations. In photonic quantum optics, the ability to produce such images is used to investigate quantum entanglement in photon pairs [2]. We discuss how to translate this concept to electron-photon states and introduce a robust method to certify and quantify their entanglement using measurements in mutually unbiased bases.

Combining electrochemical scanning tunneling microscopy with force microscopy — •Andrea Auer[1,2] and Franz J. Giessibl[2] — [1]Institute of Physical Chemistry, University of Innsbruck, Austria — [2]Institute of Experimental and Applied Physics, University of Regensburg, Germany

Atomic force microscopy (AFM), which can be performed simultaneously with scanning tunneling microscopy (STM) using metal tips attached to self-sensing quartz cantilevers (qPlus sensors) [1], has advanced the field of surface science by providing unprecedented spatial resolution under ultra-high vacuum conditions. The simultaneous performance of AFM and STM with atomic resolution in an electrochemical cell offers new possibilities for local imaging of electrode structures. Here, we present a combined AFM/STM instrument realized with a qPlus sensor and a custom-built potentiostat for electrochemical applications. Graphite was atomically resolved in both STM and AFM channels in acidic electrolytes [2]. The difference in contrast between AFM and STM images demonstrate the ability to measure conductance at the Fermi level (STM) but also the total charge density (AFM) in an electrochemical environment. This allows us to study important electrode processes that involve a change in charge density, such as adsorption, intercalation, or oxidation processes, and their atomic contrasts in more detail.

O 27.2 Tue 10:45 H4

Small change huge effect – Tuning CO2 reduction to Formaldehyde — •Michael Busch — Luleå University of Technology, Luleå, Sweden

CO_2 reduction is a central technology for energy conversion and as access route to basic feedstock for the chemical industry. Unfortunately, its potential is still hindered by high overpotentials and low selectivity towards post-CO products. So far, post-CO products can only be accessed reliably either through Cu catalysts or selected single atom catalysts like metal phthalocyanines. Recent experiments indicate, that Co phthalocyanine is even able to form formaldehyde in good yields.[1]

Building on these experiments, we will explore the underlying origin of this surprising finding using density functional theory (DFT) computations.[1,2] Our results indicate, that the pure Co phthalocyanine complex does not show any unexpected selectivity. However, upon adjusting potential and pH also the catalyst's protonation state is changed. This minor change in turn shifts the selectivity towards formaldehyde. These surprising insights provide an important puzzle piece for the rational design of improved CO_2 reduction catalysts.

Quantitative Modeling of the Coordination and Solvation Dynamics of Electrically Charged Solvated Systems via Molecular Dynamics Simulations — •Zhenyu Wang, Mira Todorova, Christoph Freysoldt, and Jörg Neugebauer — Max Planck Institute for Sustainable Materials

Chemical and biological processes in water are influenced by the dynamics of the water solvation shell of ions. Despite progress in understanding ion solvation dynamics, the structural changes in the solvation shell with varying charge states remain underexplored. This study uses atomistic molecular dynamics calculations to investigate the solvation shell of a Na ion, as a prototype model, focusing on changes in water molecule arrangement due to charge variations. Gaussian process regression is used to analyze the reorientation of H_2O molecules as the Na-ion charge is changed from negative to positive. Results show significant effects of the ionic charge on the coordination to neighboring water molecules, which form distinct polyhedral structures, such as tetrahedra, triangles, pyramids, and octahedra. These formed patterns can be effectively characterized by using the H_2O-H_2O distance and H_2O-H_2O-H_2O angle. At the highest positive charge, H_2O molecules form an octahedral configuration, transitioning to pyramidal and triangular bipyramidal structures as the charge decreases. At a neutral charge, the solvation shell reveals maximum dispersion, which transitions into a single cluster at negative charges. This study provides valuable insights into ion solvation behavior and significantly enhances the understanding of ion solvation dynamics in aqueous environments.

O 27.4 Tue 11:15 H4

Field-induced water autoionization in two- and three-dimensions — •Yair Litman and Angelos Michaelides — University of Cambridge, Cambridge, U. K.

The behaviour of water under an electric field critically influences the performance of numerous energy conversion and storage devices and remains a subject of active investigation. Recent experiments have shown that at electric field strengths exceeding 10^8V/Å, the water dissociation reaction ($2H_2O \rightleftharpoons H_3O^+ + OH^-$) is significantly accelerated, a phenomenon known as the (secondary) Wien effect [1].

In this work, we employ the modern theory of polarization to perform (periodic) *ab initio* molecular dynamics simulations of water under external electric fields, both in bulk and under nanoconfinement. Our simulations reveal that electric fields facilitate the water dissociation reaction by not only reducing the enthalpy of the reaction but also by increasing the corresponding entropic contribution. Furthermore, we demonstrate that geometric constraints imposed by a 2D confinement can amplify the field-induced reaction rates. These findings highlight the importance of entropy changes in field-induced aqueous reactions and propose nanoconfinement as a promising avenue for enhancing the efficiency of electrocatalytic reactions.

O 27.5 Tue 11:30 H4

Predicting Electrocatalytic Urea Synthesis Using a Two-dimensional Descriptor — •Amy Wuttke and Alexander Bagger — Department of Physics, Technical University of Denmark

Electrochemical synthesis routes offer a sustainable alternative to conventional fossil-based processes for producing chemical commodities. An example is the crucial fertiliser urea ($CO(NH_2)_2$), that can be synthesised by co-reducing CO_2 and nitrite (NO_2^-) on transition metal surfaces [1]. This reaction also serves as a model system for studying electrochemical CN-coupling. However, achieving high selectivity toward urea remains a significant challenge due to the complexity of competing reaction pathways.

In this talk, a predictive framework for urea selectivity is presented based on adsorption energies as descriptors without referring to a full reaction mechanism [2]. Using Density Functional Theory, we calculated 10 adsorption energies as potential descriptors on 19 transition metal surfaces. Through Principal Component Analysis, this high-dimensional dataset is reduced to two key descriptors: *H and *O adsorption energies. Our findings demonstrate that these descriptors effectively explain urea selectivity on transition metals, offering a simplified approach to guide catalyst design.

O 27.6 Tue 11:45 H4

Effect of water on the diffusion barriers of S_{ad} on Cu(100) and Ag(100): DFT-calculations — •Falk Wendorff, Sönke Buttenschön, and Eckhard Pehlke — Institut für Theoretische Physik und Astrophysik, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany

Diffusion of adatoms at the electrochemical interface is affected by the electrolyte in various ways. Here we focus on the effect of pure water at the pzc on the diffusion barriers within Transition State Theory. Due to the dynamics of the H_2O molecules in liquid water the process is complicated to simulate. We have investigated the diffusion of a sulfur adatom on Cu(100) and Ag(100) surfaces in the presence of water using explicit water molecules in DFT simulations. The calculations have been carried out with PWscf and PWneb from Quantum ESPRESSO [1]. We have started from initial water layers generated by the Water Structure Creator by Dávila López *et al.* [2] and performed subsequent MD simulations of the water molecules at fixed sulfur and substrate positions. The results show that water lowers the diffusion barriers of sulfur on the metal surfaces compared to the interface versus vacuum.

Invited Talk O 27.7 Tue 12:00 H4

Ultrafast electrochemistry beyond the RC time constant — •Yujin Tong — Universität Duisburg-Essen, Duisburg

Electrochemistry relies on charge transfer, which can occur on time scales from femtoseconds to seconds or longer. Traditional electrochemical detection methods are limited in their ability to study ultrafast processes such as solvent reorganization and electron tunneling. This presentation focuses on the advancements and challenges in ultrafast electrochemistry, specifically exploring processes occurring on timescales shorter than the RC time constant. Traditional electrochemical processes have typically been studied over longer timescales, often constrained by limitations in mass diffusion and hardware capabilities. However, recent developments in ultrafast laser technology and femtochemistry have enabled the observation of rapid processes with femto /pico second time resolution at electrochemical interfaces, such as ultrafast potential relaxation in electric double layers and the dynamics of solvated electrons [1-3]. [1] G. Zwaschka, F. Lapointe, R. K. Campen, Y. Tong, Curr. Opin. Electrochem. 29, 100813 (2021) [2] F. Lapointe, M. Wolf, R. K. Campen, Y. Tong, J. Am. Chem. Soc. 142, 18619-18627 (2020) [3] Z. Huang, M. Bridger, O. A. Naranjo-Montoya, A. Tarasevitch, U. Bovensiepen, Y. Tong, R. K. Campen, arXiv preprint, doi: 10.48550/arXiv.2304.06684 (2023)

Deciphering the Capacitance of the Pt(111)/Water Interface: A Micro- to Mesoscopic Investigation by AIMD and Implicit Solvation — •Lang Li, Karsten Reuter, and Nicolas Hörmann — Fritz-Haber-Institut der MPG, Berlin

We use *ab initio* molecular dynamics simulations based on density-functional theory to revisit the enigmatic capacitance peak of the electrified Pt(111)/water interface around the potential of zero charge. We demonstrate that counterbalancing the electronic excess charges with partially charged hydrogen atoms constitutes a computationally efficient approach to converged interfacial water structures. The thus enabled detailed analysis of the interfacial water response clarifies that the peak in the capacitance is predominantly due to structural reorientation, although its magnitude is significantly increased by strong internal electronic polarization, also known as charge transfer (CT). We find that CT is more complex than previously thought, resulting from the interplay between chemisorbed water and depolarization effects from surrounding water. Finally, we demonstrate that quantitative agreement with the experimental peak can be achieved through inclusion of the interfacial response into an implicit solvent model for the extended part of the double layer. This suggests that such models can accurately reproduce screened interfacial fields as a function of potential, despite their notoriously small native capacitance. [1] L. Li, K. Reuter, N. G. Hörmann, accepted by ACS Electrochem.

O 27.9 Tue 12:45 H4

Efficient periodic density functional theory calculations of charged molecules and surfaces using Coulomb kernel truncation — •Sudarshan Vijay[1], Martin Schlipf[1], Henrique Miranda[1], Ferenc Karsai[1], Martijn Marsman[1], and Georg Kresse[1,2] — [1]VASP Software GmbH, Berggasse 21, 1090 Vienna, Austria — [2]Faculty of Physics and Center for Computational Materials Science, University of Vienna, Kolingasse 14-16, A-1090 Vienna, Austria

Density functional theory (DFT) calculations of charged molecules and surfaces are critical to applications in electro-catalysis. Periodic DFT implementations such as the Vienna ab-initio Simulation Package (VASP) compute the electrostatic potential under 3D periodic boundary conditions, which necessitates charge neutrality. In this work, I will discuss our recent implementation of 0D and 2D periodic boundary conditions. Unlike 3D boundary conditions, our implementation allows for calculations of charged molecules and surfaces. We implement these boundary conditions using the Coulomb kernel truncation method. We compute the electrostatic potential under 0D and 2D boundary conditions by selectively subtracting unwanted long range interactions from the potential under 3D boundary conditions, removing the need for performing any Fourier transforms in padded supercells. To illustrate the computational efficiency of our method, we perform large supercell calculations of the formation energy of a charged chlorine defect on an NaCl(001) surface and perform long time-scale molecular dynamics simulations on an Au(211) | water electrode-electrolyte interface.

O 28: Graphene: Electronic Structure and Excitations (joint session O/HL)

Time: Tuesday 10:30–12:15 Location: H6

O 28.1 Tue 10:30 H6

Doping of epitaxial graphene by proximitized 2D quantum islands — •Julian Koch[1], Sergii Sologub[1,2], Chitran Ghosal[1], Dorothee Boesler[1], and Christoph Tegenkamp[1] — [1]Institut für Physik, TU Chemnitz, Reichenhainerstr. 70, 09126 Chemnitz — [2]Institute of Physics, NAS of Ukraine, Nauki avenue 46, 03028 Kyiv

The effects of 2D quantum islands on the transport properties of monolayer graphene/SiC(0001) were investigated by magnetotransport. Two types of adsorbates are compared, Bi(110) and Pb(111) islands with average coverages of up to 3.6 bilayers (BL) and 3 monolayers (ML), respectively. The analysis is supported by structural investigations using SPA-LEED and STM. The doping behaviour of both materials is fundamentally different. In the case of Bi, the carrier concentration determined from the SdH oscillations remains at 1×10^{13} cm^{-2} independent of the Bi coverage, although photoemission spectroscopy revealed a strong doping of the graphene by Bi [1]. This strongly indicates a highly anisotropic carrier concentration across the surface and is confirmed by a positive, temperature independent contribution to the magnetoresistivity. The Bi islands rather behave as antidots and reduce the charge carrier mobility slightly from around 2250 cm^2/(Vs) for MLG to 1920 cm^2/(Vs) at 2.4 BL Bi. In contrast, there are no signs of an anisotropic carrier concentration or mobility when Pb is adsorbed. The electron concentration increases uniformly by approximately 5×10^{11} ML^{-1}cm^{-2}. The mobility is reduced from around 1400 cm^2/(Vs) for MLG to 1200 cm^2/(Vs) at 3 ML Pb.

O 28.2 Tue 10:45 H6

Photocurrent control in a graphene-based Floquet topological insulator — •Weizhe Li[1], Daniel Lesko[1], Tobias Weitz[1], Simon Wittigschlager[1], Christian Heide[1,2], Ofer Neufeld[3], and Peter Hommelhoff[1,4] — [1]Department Physik, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), 91058 Erlangen, Germany — [2]Stanford PULSE Institute, SLAC National Accelerator Laboratory, Menlo Park, CA, USA — [3]Schulich Faculty of Chemistry, Technion - Israel Institute of Technology, Haifa, Israel — [4]Department Physik, Ludwig-Maximilians-Universität München (LMU), 80799 München

Topological insulators offer unique opportunities for novel electronics and quantum phenomena. However, intrinsic material limitations often restrict their applications and practical implementation. A circularly-polarized laser pusle can generate topologically non-trivial non-equilibrium states known as Floquet topological insulators (FTIs) which host a variety of topological phenomena. Floquet engineering with strong optical fields opens routes to optically tunable band structures and devices for petahertz electronics.

Here we demonstrate coherent control of photocurrents in light-dressed graphene. Circularly-polarized laser pulses dress the graphene into an FTI, and phase-locked second harmonic pulses drive electrons in the FTI. This approach allows us to measure all-optical anomalous Hall currents and photocurrent circular dichroism, which put FTIs on equal footing with equilibrium topological insulators. The coherent control of photocurrents in graphene-based FTI connects optics tools to condensed matter physics.

O 28.3 Tue 11:00 H6

Electronic structure of intercalated epitaxial graphene: A first principles study — •Andres Unigarro[1], Florian Günther[2], Philip Schädlich[1], Bharti Matta[3], Philipp Rosenzweig[3], Kathrin Küster[3], Ulrich Starke[3], Thomas Seyller[1], and Sibylle Gemming[1] — [1]Institute of physics, TU Chemnitz, Chemnitz, Germany — [2]UNESP, Rio Claro, Brazil — [3]Max-Planck-Institut für Festkörperforschung, Stuttgart

Two-dimensional materials such as graphene are fascinating because they combine unique mechanical and electronic properties. The next level of complexity, however, comprises the assembly of various stacked 2D materials to generate structures with desired properties. Intercalation of epitaxial graphene systems is an effective method to tailor the electronic, optical, and transport properties of graphene while keeping its honeycomb lattice on SiC. Furthermore, intercalation facilitates the synthesis of otherwise unstable 2D layers. A wide range of elements have been used as intercalants below a graphene sheet, forming often well-defined heterobilayers with different functionalities. In particular, intercalation of heavy elements such as Pb and Bi are specially promising since they can introduce additional effects such as spin-orbit coupling to the electron gas of graphene and Rashba spin polarization. Using first-principles methods, we investigate the modifications in the electronic structure of epitaxial graphene due to proximity effects induced by intercalation.

O 28.4 Tue 11:15 H6

Accelerated Exploration of Defective Graphene Superstructures — •Benedict Saunders[1], Lukas Hörmann[1,2], and Reinhard Maurer[1,2] — [1]Department of Chemistry, University of Warwick, Coventry — [2]Department of Physics, University of Warwick, Coventry

Graphene has been meticulously studied due to its remarkable mechanical, electrical, and thermal properties. It is well documented that introducing various dopants and defects to the lattice can be used to tune the material's properties for a specific application, such as in electronics, sensors, or catalysis. In order to design graphene with specific properties, one must achieve precise control over the composition and concentration of defects. This requires a fundamental understanding of the stability of defects and their interaction in a given superstructure. We present a comprehensive method for exploring the configurational space of defective 2D superstructures. We have extended the SAMPLE structure search code to defects in 2D materials. SAMPLE uses Bayesian learning based on sparse Density Functional Theory data for structure exploration. We show the capabilities of our approach for a proof-of-principle application on free-standing graphene with heteroatom defects. Finally, we use the SAMPLE code to gain physical insight into the interactions between these defects, paving the way for effective and rational growth models of topologically designed defective graphene.

O 28.5 Tue 11:30 H6

Polymorphism of a two-dimensional Pb layer underneath charge neutral graphene on SiC — •Markus Gruschwitz, Sergii Sologub, Zamin Mamiyev, Chitran Ghosal, and Christoph Tegenkamp — Institut für Physik, TU Chemnitz, Germany

Since the first studies on graphene, researchers strive to implement its unique properties in industrial relevant processes. The intercalation of epitaxially grown buffer layers on SiC results in high quality, quasi-freestanding graphene, which allows the electronic properties to be modified by varying the intercalants and their arrangement. Pb recently sparked a great interest by reliably providing almost perfectly charge neutral graphene. The Pb layer effectively screens the substrate induced doping. In a novel approach using differential phase contrast in cross-sectional scanning transmission electron microscopy we reveal their vertical charge density distribution. Surprisingly, the charge neutrality is robust against variations in the Pb interface reconstruction. Depending on the preparation, a Pb monolayer often reconstructed in two coexisting phases, the so-called stripe [1] or bubble [2] phase. Intercalated multilayers reveal a similar striped phase arising from two twisted plumbene layers [3]. Here we combine structural investigations by scanning tunneling microscopy and high-resolution low-energy electron diffraction in a model of flexibly arranged grain boundaries releasing lattice mismatch stress.

O 28.6 Tue 11:45 H6

Facet-dependent growth and properties of graphene on Al_2O_3 surfaces from first principles — •Armin Sahinovic and Rossitza Pentcheva — Department of Physics, University of Duisburg-Essen

The direct growth of graphene on functional substrates such as sapphire (Al_2O_3) enables the use in optoelectronic devices without the necessity of sample transfer. We explore the role of the surface orientation of Al_2O_3 on the growth of graphene [1] using density functional theory. The stoichiometric terminations are identified as the most stable surface terminations of the C-, R- and A-plane facets in the framework of *ab initio* thermodynamics. Next, we consider the adsorption of carbon atoms on the different surface facets, varying their position and concentration. The adsorption energy shows the weakest binding at the R-plane and the most favorable at the A-plane. We associate this with the more unsaturated oxygen bonds at the A-plane compared to the R- and C-plane. Furthermore, we explore the graphene - Al_2O_3 interaction and its impact on the electronic properties of graphene. Our results provide a deeper understanding of the role of the surface facets of the substrate in the scalable graphene growth on Al_2O_3.

Funding by GRK2803 2D-MATURE (Project P4) and computational time at the supercomputers MagnitUDE and AmplitUDE are gratefully acknowledged

O 28.7 Tue 12:00 H6

Enhanced light-matter interactions via Sn nanoislands on epitaxial graphene — •Zamin Mamiyev, Narmina Balayeva, Dietrich R.T. Zahn, and Christoph Tegenkamp — Institut für Physik, Technische Universität Chemnitz

Surface-enhanced Raman scattering (SERS) is an advanced technique for coupling light into quasiparticle excitations in low-dimensional materials, offering promising applications in trace detection, enhanced light-matter interactions, photonic energy harvesting, and catalytic processes. Recent studies in this field have focused on integrating noble metal nanostructures with graphene.

In this study, we investigate a novel SERS platform utilizing tin (Sn) nanoislands to enhance graphene Raman signals by up to two orders of magnitude. We examine the SERS performance on Sn-intercalated charge-neutral and intrinsically doped epitaxial monolayer graphene (MLG) on SiC(0001). The increase in the Raman cross-section and enhanced intensity is accompanied by spectral shifts, which may be correlated with the localized surface plasmons (LSPs) of Sn nanoislands as well as dynamic charge transfer between the Sn particles and graphene. This dynamic charge redistribution, primarily determined by the doping concentration and interface interactions, enables control over the SERS response. Additionally, plasmonic and thermalization-induced carrier density propagation across μm ranges indicates efficient coupling between localized and propagating plasmons.

Line-moiré phases of an epitaxial honeycomb monolayer AgTe/Ag(111) — •Romana Ganser, Muthu P. T. Masilamani, Begmuhammet Geldiyev, Maximilian Ünzelmann, and Friedrich Reinert — Experimentelle Physik VII and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, Germany

We present angle-resolved photoemission spectroscopy (ARPES) measurements on tunable one-dimensional moiré phases of an epitaxial honeycomb monolayer AgTe/Ag(111) [1]. In this model system, the moiré structure can be tuned almost continuously in contrast to hardly controllable twist angles in bilayer van-der-Waals heterostructures [2]. We experimentally observe moiré minibands and band gaps of 120 - 170 meV suggesting sizable superlattice potentials. By comparing the experimental data to simple model calculations, we analyze the local character of the potential. This provides important information of interface hybridization effects on the band structure, which may not be limited to the system at hand but rather a broad range of moiré interfaces.

Photoemission Time Scale Determination: the Effect of Crystal Dimensionality and Electronic Correlation — •Fei Guo[1], Dmitrii Usanov[2], Eduardo B. Guedes[2], Mauro Fanciulli[3], Arnaud Magrez[1], Michele Puppin[1], and Hugo Dil[1,2] — [1]Institute of Physics, Ecole Polytechnique Federale de Lausanne, CH-1015 Lausanne, Switzerland — [2]Photon Science Division, Paul Scherrer Institut, CH-5232 Villigen, Switzerland — [3]Laboratoire de Physique des Matériaux et Surfaces, CY Cergy Paris Université, Cergy-Pontoise, 95031, France

Spin polarization of photoelectrons from spin-degenerate dispersive initial states originates from the interference of multiple photoemission channels, measuring the spin polarization with spin- and angle-resolved photoemission spectroscopy

(SARPES) allows the estimation of the phases of the interfering channels, and hence the Eisenbud-Wigner-Smith (EWS) time delay of photoemission, which is the amount of time required by the photoelectron to evolve into a free particle final state. While not directly measurable for solid-state photoemission, this time scale has been measured for gaseous photoionization, which is generally in the attosecond (10^-18s) range.

We present investigations with multiple materials of different properties, and by comparing with previous studies, we propose a relationship between the EWS time delay, electronic correlation mechanism, and dimensionality.

O 29.3 Tue 11:00 H8

Disorder effects in the Band Structure of Transition Metal Dichalcogenide alloys $A_xB_{1-x}Se_2$ (A, B= Cr, Mo, W) — •Sarath Sasi[1], Aki Pulkkinen[1], Laurent Nicolaï[1], Raphaël Salazar[1], Christine Richter[2,3], Karol Hricovini[2,3], and Ján Minár[1] — [1]New Technologies Research Centre, University of West Bohemia, Pilsen, Czech Republic — [2]LPMS, CY Cergy Paris Université, Neuville-sur-Oise, France — [3]Université Paris-Saclay, CEA, CNRS, LIDYL, Gif-sur-Yvette, France

Recent advances in materials synthesis have enabled the creation of 2D TMDC alloys, which offer unique opportunities for tailoring electronic and optoelectronic properties to meet diverse application demands.[1].This study investigates the band structure evolution of $A_xB_{1-x}Se_2$ alloys (A, B = Cr, Mo, W) across varying composition fractions (x). Using the Coherent Potential Approximation (CPA)[2], which accurately models scattering in disordered systems, theoretical calculations were performed with the *SPR-KKR* package[3]. Results reveal that some of the TMDC alloys maintain their band structures without significant disorder effects. Angle-Resolved Photoemission Spectroscopy (ARPES) measurements align closely with one-step model photoemission calculations, confirming theoretical predictions. These insights provide a foundation for tailoring electronic properties, advancing their applicability in next-generation devices.

Unveiling Doping-Induced Electronic Modifications in Antiferromagnetic MPS_3 van der Waals Materials — •Till Willershausen[1], Jonah Elias Nitschke[1], Patrick Merisescu[2], David Janas[1], Lasse Sternemann[1], Michele Capra[1], Mira Arndt[1], Valentin Mischke[1], and Mirko Cinchetti[1] — [1]TU Dortmund University — [2]Bath University

Antiferromagnetic van der Waals (vdW) materials, with scalability to monolayer thickness, semiconducting properties, and intrinsic antiferromagnetic ordering, hold promise for spintronic and quantum technology applications. We investigate alkali metal doping effects on the MPS_3 family (M = Mn, Ni, Co, Fe) of 2D antiferromagnetic vdW materials, revealing doping-induced changes in their electronic structure. X-ray Photoelectron Spectroscopy (XPS) shows shifts in oxidation states in $NiPS_3$, $CoPS_3$, and $FePS_3$, while $MnPS_3$ displays no significant changes, indicating distinct charge transfer. Further investigation with Angle-Resolved Photoelectron Spectroscopy (ARPES) reveals new alkali-metal induced bands appearing above the previous valence band maximum. This analysis highlights doping-induced modifications and contrasts in transition metal behavior in MPS_3, providing insights into doping mechanisms and electronic tunability.

O 29.5 Tue 11:30 H8

Enhanced electron-phonon coupling in few-layer $MoTe_2$ from micro-ARPES — •Thomas P. van Waas[1], Julia Issing[2], Marco Gibertini[3], Christophe Berthod[2], Anna Tamai[2], Felix Baumberger[2,4], and Samuel Poncé[1,5] — [1]European Theoretical Spectroscopy Facility, Institute of Condensed Matter and Nanosciences, Université catholique de Louvain, Belgium — [2]Department of Quantum Matter Physics, University of Geneva, Switzerland — [3]Dipartimento di Scienze Fisiche, Informatiche e Matematiche, University of Modena and Reggio Emilia, Italy — [4]Swiss Light Source, Paul Scherrer Institut, Switzerland — [5]WEL Research Institute, Belgium

Bulk orthorhombic T_d-$MoTe_2$ is a type-II Weyl semimetal with a superconducting critical temperature of T_c = 0.1 K. Transport measurements show a monotonic increase in T_c as the thickness of multilayer $MoTe_2$ is reduced, reaching T_c = 7.6 K in the monolayer. We investigate photoemission kinks in the electron pocket of exfoliated mono- bi-, and trilayer $MoTe_2$ from micro-focused angle-resolved photoemission spectroscopy. We use a custom code to quantify the electron self-energy $\Sigma_n(E)$ for a parabolic non-interacting dispersion, and obtain from $\Sigma_n(E)$ the Eliashberg spectral function $\alpha^2F_n(\omega)$ using the maximum entropy method. We find two dominant phonon modes in $\alpha^2F_n(\omega)$ for the mono- and trilayer, with a large enhancement of the lower-frequency phonon mode in the former. We also provide tentative results for the bilayer, where quantification is more challenging due to a small splitting of the electronic bands.

O 29.6 Tue 11:45 H8

Electronic structure of V-doped WSe_2 — •Jana Kähler[1,2], Florian K. Diekmann[1,2], Matthias Kalläne[1,2,3], Tim Riedel[1,2], Adina Timm[1,2], Anja Yalim[1,2], Jens Buck[1,2], Meng-Jie Huang[2], Jules M. Knebusch[1,2], Luka Hansen[1,3], Jan Benedikt[1,3], and Kai Rossnagel[1,2,3] — [1]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany — [2]Ruprecht Haensel Laboratory, Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg — [3]Kiel Nano, Surface and Interface Science KiNSIS, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany

Spintronics represents a promising and energy-efficient alternative to conventional electronics, with significant potential applications, e.g., in areas such as classical and quantum computing. The vanadium-doped layered transition metal dichalcogenide 2H-WSe_2 is a promising candidate to fulfill the desired properties as a room-temperature magnetic semiconductor with gating tunability. Here, we present a comprehensive electronic structure study of chemical vapor transport-grown pristine and V-doped WSe_2 by soft X-ray, VUV and 11eV-laser ARPES, highlighting the influence of a low V doping concentration on the electronic structure of WSe_2.

O 29.7 Tue 12:00 H8

Unraveling magnetic ordering in a van der Waals correlated material — Tommaso Pincelli[1,2], •Tania Mukherjee[1,2], Lawson Lloyd[2], Shuo Dong[2,3], Yoav William Windsor[1,2], Martin Wolf[2], Laurenz Rettig[2], and Ralph Ernstorfer[1,2] — [1]Technische Universität Berlin, 10623 Berlin, Germany — [2]Fritz-Haber-Institute of the Max Planck Society, 14195 Berlin, Germany — [3]Beijing National Laboratory for Condensed Matter Physics, China

Layered van der Waals (vdW) materials offer a compelling platform to investigate various emergent quantum properties in low dimensions. Fe_3GeTe_2 (FGT), a vdW ferromagnetic metal, is well-known for exhibiting exotic phenomena, ranging from skyrmion formation to heavy fermion behavior. However, an understanding of the magnetic ordering, a key feature for spintronic applications, still remains elusive in this material. In particular, the interplay of both local magnetic moments and an itinerant mechanism in the formation of ferromagnetic ordering in FGT, a non-f-electron correlated system, remains to be clarified. Using time- and angle-resolved photoemission spectroscopy (trARPES) and first-principles calculations, we provide evidence for an ordering mechanism in FGT by observing a pronounced reduction in the Stoner exchange gap. This stands in contrast to earlier temperature-dependent ARPES studies of the electronic structure of FGT, which favored a localized excitation model over the weak-coupling itinerant picture. We also observe the impact of phononic excitations which further confirm our findings.

O 29.8 Tue 12:15 H8

Spin structure of the unoccupied surface state at AgTe/Ag(111) — •Carolin Benfer, Marcel Holtmann, and Markus Donath — Physikalisches Institut, Universität Münster, Germany

The AgTe/Ag(111) surface alloy has recently been investigated as a model system for the role of orbital angular momentum in the formation of spin effects in the electronic structure [1]. Two p-like surface states were detected in ARPES measurements, one shows a Rashba-type spin splitting, while the other one does not. This behavior is attributed to the symmetries of the orbital wave functions of the electrons. For the unoccupied states a third surface state has been predicted. Following the symmetry arguments given in [1], a Rashba-type spin splitting of the state is expected.

We use inverse photoemission (IPE) to directly study the unoccupied state of the surface alloy. Low-energy electron diffraction and scanning tunneling microscopy measurements confirm a homogeneous monolayer film of the surface alloy, which is growing in a honeycomb structure. Angle-resolved IPE measurements detect the predicted surface state with free electron-like dispersion. Spin-resolved IPE measurements reveal a Rashba-type spin structure.

O 29.9 Tue 12:30 H8

Orbital mixing as key mechanism for ferromagnetism in van der Waals CrI3 — •Alessandro De Vita[1,2], Srdjan Stavrič[3], Roberto Sant[4], Nicholas B. Brookes[4], Giancarlo Panaccione[5], Silvia Picozzi[3], Ralph Ernstorfer[1,2], and Tommaso Pincelli[1,2] — [1]Institut für Optik und Atomare Physik, Technische Universität Berlin, Straße des 17 Juni 135, 10623 Berlin, Germany — [2]Fritz Haber Institute of the Max Planck Society, Faradayweg 4-6, 14195 Berlin, Germany — [3]Consiglio Nazionale delle Ricerche CNR-SPIN, c/o Università degli Studi G. D'Annunzio, 66100 Chieti, Italy — [4]ESRF, The European Synchrotron, 71 Avenue des Martyrs, CS40220, 38043 Grenoble Cedex 9, France — [5]Istituto Officina dei Materiali (IOM)-CNR, Laboratorio TASC, in Area Science Park, S.S.14, km 163.5, I-34149 Trieste, Italy

Van der Waals ferromagnets constitute a versatile platform where exotic quantum states can be realized; among them, CrI3 is a prototypical and widely studied 2D ferromagnet, with promising applications in spin- and orbitronics. Despite that, key information on its electronic occupation and stabilization of the magnetic configuration are missing. By means of complementary absorption and

photoemission spectroscopies, and density functional theory calculations, we give a description of the orbital character of bulk CrI3, and demonstrate that the emergence of ferromagnetism in this material is underpinned by the orbital mixing between I p and Cr eg states. Our results have clear impact on the understanding of how microscopic interactions at the orbital level stabilize ordered states in van der Waals ferromagnets.

O 29.10 Tue 12:45 H8

Resonant Photoemission Studies of Transition Metal Sulfides and Selenides — •Yashasvi Mehra[1,2,3], Samuel Beaulieu[4], Mauro Faniculli[1,2], Olivier Heckmann[1,2], Karol Hricovini[1,2], Aki I.O. Pulkkinen[3], Jan Minar[3], and Maria Christine Richter[1,2] — [1]Université Paris-Saclay, CEA, LIDYL, Gif-sur-Yvette, France — [2]CY Cergy Paris Université, CEA, LIDYL, Gif-sur-Yvette, France — [3]University of West Bohemia, NTC, Pilsen, Czech Republic — [4]Universite de Bordeaux CNRS CEA, CELIA, UMR5107, F33405 Talence, France

By performing resonant ARPES measurements and SPR-KKR photoemission calculations on Transition Metal Selenide, Sulfide and the Vanadium intercalated NbS2 systems, we study the interplay between different decay mechanisms in resonant conditions, radiation-less Raman Auger and Classical Auger emissions. Through a method proposed by Cini and Sawatzky we can determine the on-site Coulomb interaction per element in some cases. On the theoretical front the calculations are performed using the SPR-KKR method, which is based on one-step model, that incorporates the effect of all matrix elements which accounts for the photoemission process. Furthermore, we analyze calculated ARPES, XAS, element and orbital resolved band structure underlining agreement with experimental results and helping with its interpretation.

O 30: Surface Magnetism

Time: Tuesday 10:30–12:45 Location: H11

O 30.1 Tue 10:30 H11

Spin-polarized chiral edge modes in the topological nodal-point superconductor Mn/Ta(110) — •Felix Zahner[1], Felix Nickel[2], Roberto Lo Conte[3], Tim Drevelow[2], Roland Wiesendanger[1], Stefan Heinze[2], and Kirsten von Bergmann[1] — [1]University of Hamburg, Germany — [2]University of Kiel, Germany — [3]University of Groningen, The Netherlands

Topological superconducting phases in magnet-superconductor hybrid (MSH) - systems have been investigated recently due to their potential applications in quantum devices. Zero-energy states and chiral edge modes have previously been observed in ferromagnetic 1D [1] and 2D [2] MSH systems. In a 2D antiferromagnet (AFM) MSH and a spin spiral MSH system, gapless topological nodal-point superconducting (TNPSC) phases have been observed [3, 4].

Using scanning tunnelling microscopy/spectroscopy (STM/S), we investigate the mono- and bilayers on a Ta(110) surface. Both exhibit local AFM order and tight-binding calculations indicate that both host a TNPSC phase. Interestingly, we observe edge modes not only at the boundaries between the TNPSC and the topologically trivial superconducting substrate, but also at specific boundaries between these two AFM systems of Mn mono- and bilayer. Our spin-polarized STM measurements reveal a significant spin-polarization of this edge mode, which we discuss based on the tight-binding results.

Interaction of chiral molecules with magnetic substrates: An ongoing DFT puzzle — •Nicolae Atodiresei — Peter Grünberg Institute (PGI-1), Forschungszentrum Jülich, D-52425 Jülich

A challenging puzzle in surface science that has to be solved is the interplay between electron spin and molecular chirality. As an example, the interaction of chiral helical aromatic molecules with magnetic surfaces leads to an enantioselective adsorption, i.e. molecules of opposite handedness would preferentially adsorb to ferromagnetic islands with opposite magnetization [1]. In this talk, I will discuss how state-of-the-art spin-resolved *ab initio* simulations based on density functional theory calculations support and guide the interpretation of scanning tunneling microscopy experiments performed on the adsorption of heptahelicene molecule onto ferromagnetic cobalt islands.

The author acknowledges funding from CRC 1238 of the Deutsche Forschungsgemeinschaft and computing time granted on the supercomputer JURECA at Forschungszentrum Jülich.

O 30.3 Tue 11:00 H11

Spin-lattice relaxation of nitrogen-vacancy centers in nanodiamonds on conducting and non-conducting surfaces — •Izidor Benedičič[1], Yuri Tanuma[1], Bastien Anézo[1,2], Žiga Gosar[1,3], and Denis Arčon[1,3] — [1]Department of Condensed Matter Physics, Jožef Stefan Institute, Ljubljana, Slovenia — [2]Institut des Matériaux de Nantes Jean Rouxel (IMN), Nantes University, Nantes, France — [3]Faculty of Mathematics and Physics, University of Ljubljana, Ljubljana, Slovenia

Nitrogen-vacancy (NV) centers in diamond are versatile probes for the detection of both static magnetic fields and magnetic fluctuations. While single-NV sensors are very capable, they suffer from high cost and experimental complexity. Nanodiamonds with embedded NV ensembles offer a promising low-cost alternative, however, their application in solid-state physics has been largely overlooked. Here, we investigate the use of nanodiamonds for measuring the electrical conductivity of substrates. We measured the temperature dependence of longitudinal relaxation time T_1 of NV centres in nanodiamonds on glass and gold substrates. We find that T_1 is determined both by phononic relaxation processes and the coupling to the magnetic moments at the surface. All samples show a stretched exponential relaxation, hinting at a significant distribution of relaxation processes. The theoretical models show the intrinsic distribution is too wide to reliably detect coupling to electronic states even of very good conductors. Our results hint at the limitations of nanodiamonds for measurements of transport properties in condensed matter systems.

O 30.4 Tue 11:15 H11

Imaging in-plane magnetic domains using magnetic circular dichroism in darkfield laser PEEM — •David Huber[1], Friederike E. Wührl[1], Frank O. Schumann[2], and Wolf Widdra[1] — [1]Martin-Luther-Universität Halle-Wittenberg — [2]Max-Planck-Insitut für Mikrostrukturphyisk, Halle

Magnetic circular dichroism (MCD) in threshold photoelectron emission microscopy (PEEM) enables imaging of magnetic domains at the nanoscale. Utilizing femtosecond (fs) laser excitation in a laboratory setting offers a significant advantage in terms of temporal resolution compared to more commonly used X-ray MCD measurements. However, this poses new challenges with respect to in-plane magnetization, given the previously reported low domain contrast [1, 2].

In this contribution we show that symmetry breaking and photoelectron filtering in momentum and energy help to overcome these challenges. Using this methodology, we obtain MCD contrast for in-plane domains of 11 nm Fe(001)-(1 × 1)-O on MgO(001) using both continuous wave and fs laser excitation at normal incidence and compare these results to a Fe(001)-(1 × 1)-O single crystal in PEEM and μARPES.

Invited Talk O 30.5 Tue 11:30 H11

Resonant molecular transitions in femtosecond second harmonic generation spectroscopy of Fe-porphyrin/Cu(001) — •Andrea Eschenlohr[1], Rui Shi[2], Jinghao Chen[1], Ping Zhou[1], Uwe Bovensiepen[1], Wolfgang Hübner[2], and Georg Lefkidis[2] — [1]Faculty of Physics and CENIDE, University Duisburg-Essen, Lotharstr. 1, 47057 Duisburg, Germany — [2]Department of Physics, RPTU, Box 3049, 67653 Kaiserslautern, Germany

Metal-organic molecular adsorbates on metallic surfaces are potential future materials for (spin-)electronics applications, provided that the molecule-substrate interaction can be analyzed and manipulated in a targeted manner. By combining interface-sensitive optical second harmonic generation (SHG) spectroscopy experiments and electronic structure calculations using coupled cluster methods including optical excitations on iron-octaethylporphyrin (FeOEP) adsorbed on Cu(001), we find that the SHG response of FeOEP/Cu(001) is modified at 2.15-2.35 eV fundamental photon energy compared to the bare Cu(001) surface. We conclude a resonantly enhanced SHG by molecular transitions, which results from a strong charge-transfer character of the molecule-substrate interaction [1]. Pump-probe SHG reveals a markedly slower relaxation time at this resonance, indicating an increased lifetime of the optically induced state compared to the bare Cu(001) surface, which will be discussed in the context of charge transfer dynamics.

O 30.6 Tue 12:00 H11

Single-layer magnetism of epitaxial NiBr2 and FeBr2 on NbSe2 — •Sebastien E. Hadjadj[1], Carmen Gonzalez-Orellana[2], Adriana Candia[3], Pierluigi Gargiani[4], Matthias Muntwiler[5], Jan Dreiser[5], Jorge Lobo[3], Celia Rogero[2], and Maxim Ilyn[2] — [1]Materials Physics Center (MPC), Donostia, Spain — [2]Centro de Fisica de Materiales (CSIC/UPV-EHU), Donostia-San Sebastian, Spain — [3]Instituto de Nanociencia y Materiales de Aragon (INMA),Zaragoza, Spain — [4]ALBA Synchrotron Light Source, Barcelona, Spain — [5]Paul Scherrer Institut, Villigen, Switzerland

Two-dimensional metal dihalides exhibit promising magnetic and electronic properties. Over the past years, the research focus on novel 2D magnetic materials has shifted to transition metal di-halides (TMDH). Recent reports have shown that the first layer of Br-based TMDH grown on Au(111) behaves structurally and magnetically differently from the second layer [1-2]. Here we report the first layer growth of NiBr2 and FeBr2 on NbSe2, which shows no signs of decomposition as observed for NiBr2 on Au(111) and shows unaffected stable magnetic properties ranging from monolayer to multilayer. The structural characterization of the samples revealed a strong temperature dependence in the resulting island growth and appearence of the moiré pattern. XMCD measurements probed magnetic ordering down to the 2D limit, which is in agreement with the literature values. In the case of FeBr2 a strong reduction of the spin magnetic moment has been observed. [1] Djuro Bikaljevic et al., ACS Nano, 15, 14985, (2021) [2] S. E. Hadjadj et al., Chem. Mater., 35, 23, 9847-9856, (2023)

O 30.7 Tue 12:15 H11

Graphene intercalated Eu on magnetic surfaces a DFT study — •Gustav Bihlmayer[1], Polina M. Sheverdyaeva[2], Matteo Jugovac[3], Luisa Ferrari[4], Frederico Mazzola[5], Paolo Perna[6], Nicolae Atodiresei[1], and Stefan Blügel[1] — [1]Peter Grünberg Institute (PGI-1), Forschungszentrum Jülich, D-52425 Jülich — [2]CNR-ISM, 34149 Trieste, Italy — [3]Elettra Sincrotrone Trieste, 34149 Trieste, Italy — [4]CNR-ISM, 00133 Roma, Italy — [5]CNR-IOM, 34149 Trieste, Italy — [6]IMDEA Nanociencia, Campus de Cantoblanco, 28049, Madrid, Spain

Europium can be intercalated between graphene and magnetic surfaces like Co(0001) or Ni(111) forming a $\sqrt{3} \times \sqrt{3}$ layer [1]. The doping of graphene can create a pronounced flat band at the Fermi level and the interaction of the $4f$ states with the π band of graphene leads to spin-selective hybridization and opening of the Dirac cone with interesting consequences for edge channels [2]. This system can be compared to Eu on-top of a graphene covered Co substrate, that changes the magnetic coupling between the lanthanide and the substrate [3] and modifies the graphene's interaction with the $4f$ states. Further stacking combinations are possible and will be discussed [4].

We acknowledge funding from the FLAG-ERA grant SOgrapMEM and from CRC 1238 of the Deutsche Forschungsgemeinschaft.

O 30.8 Tue 12:30 H11

Emergence of Ferromagnetism in 3d-4f Hetero-Bimetallic Surface-Architectures — •Massine Kelai[1], Serim Jeon[1], Dasom Choi[1], Corina Urdaniz[1], Pierre Josse[1], Jaehyun Lee[1], Stefano Reale[1], Yongwoo Kim[1], Weibin Li[2], Pierluigi Gargiani[2], Woo-Suk Noh[3], Dominik Lungerich[4], Christoph Wolf[1], Fabio Donati[1], and Lucinao Colazzo[1] — [1]Center for Quantum Nanoscience, Institute for Basic Science, Seoul, Republic of Korea — [2]ALBA Synchrotron Light Source, 08290 Catalonia, Spain — [3]MPPC/CPM, Max Planck POSTECH, Pohang 37673, Republic of Korea — [4]Center for Nanomedicine, Institute for Basic Science (IBS), 50 Yonsei-ro, Seodaemun-gu, 03722 Seoul, Republic of Korea

Surface-confined metal-organic coordination networks (SMONs) are emerging platforms for designing tunable low-dimensional nanostructures, with 3d-4f hetero-bimetallic systems being promising candidates for high-density memory and qubit applications. However, the mechanisms underlying their formation and magnetic interactions remain largely unexplored. Here, we investigate a novel 3d-4f SMON, Dy-FeTCPP (TCPP = 5,10,15,20-(tetra-4-cyanophenyl)porphyrin), formed on Au(111) via on-surface chemical reaction pathways. Using X-ray absorption spectroscopy, magnetic circular dichroism, scanning tunneling spectroscopy, and density functional theory, we show that lanthanide insertion induces strong substrate-mediated ferromagnetic coupling between 3d units, driven by porphyrin core deformation upon Dy-cyanophenyl bonding. This work advances the understanding of SMONs, paving the way for scalable quantum devices on surfaces.

O 31: Focus Session Molecular Nanostructures on Surfaces: On-Surface Synthesis and Single-Molecule Manipulation II

This focus session aims to discuss recent advances in the on-surface synthesis, manipulation, characterization, and understanding of complex molecular architectures on surfaces. The interest in surface-confined molecular nanostructures emerges from their prospective applications in nanoscale (opto-) electronics, spintronics, solar cells, energy storage devices, and other fields. The bottom-up fabrication of surface-supported nanostructures can be based on molecular self-assembly utilizing non-covalent intermolecular interactions, covalent on-surface synthesis, or the direct manipulation of molecules. Molecular self-assembly usually leads to highly ordered nanostructures, controlled by non-covalent interactions, adsorbate-substrate interactions, as well as thermodynamic and kinetic factors. On-surface synthesis by covalent coupling of reactive precursors adsorbed on metallic, semiconducting, or even insulating surfaces has emerged as a powerful method that has opened new possibilities in exploring new routes towards the synthesis of complex low-dimensional nanostructures with unprecedented material properties, often via novel chemical reactions not available in conventional organic chemistry. Finally, the direct manipulation of molecules with the tip of a scanning probe microscope allows for unprecedented chemical transformations or structural modifications, as envisioned by the pioneers of nanotechnology. This focus session is intended to provide a platform for addressing current trends in these closely linked fields from various perspectives in experiment and theory.

AMAN-SPM: Autonomous Molecular and Atomic Nanofabrication via SPM — •Bernhard Ramsauer[1], Qigang Zhong[2], Bettina Könighofer[3], and Oliver T. Hofmann[1] — [1]Institute of Solid State Physics, NAWI Graz, Graz University of Technology, Graz, 8010, Austria — [2]Institute of Functional Nano & Soft Materials, Soochow University, Suzhou, 215006, China — [3]Institute of Applied Information Processing and Communications, Graz University of Technology, Graz, 8010, Austria

The precise manipulation of individual molecules and atoms using scanning probe microscopy (SPM) offers transformative possibilities for nanofabrication. Yet the inherently stochastic nature at the nanoscale and the labour-intensive process of building nanostructures contains significant challenges. In this contribution, we introduce AMAN-SPM, a tool that integrates reinforcement learning and automation to revolutionize the on-surface synthesis process.

AMAN-SPM employs dedicated reinforcement learning agents to optimize the manipulation parameters, which allows for precise positioning, reorientation, and the controlled breaking and formation of molecular bonds. Coupled with machine vision and path-planning algorithms, this system autonomously constructs nanostructures, eliminating the need for human intervention.

Beyond fabrication, AMAN-SPM enhances real-time data acquisition and analysis, providing detailed physical insights into molecular interactions. This establishes a foundation for scalable nanostructures with tailored properties.

O 31.2 Tue 10:45 H24

Sliding friction over covalent bonds increases with bond order — Shinjae Nam[1], Lukas Hörmann[2,3], Oliver Gretz[1], Oliver T. Hofmann[2], Franz J. Giessibl[1], and •Alfred J. Weymouth[1] — [1]Universität Regensburg, Regensburg, Deutschland — [2]TU Graz, Graz, Österreich — [3]The University of Warwick, Warwick, U.K.

Friction is governed by atomic-scale interactions, yet we lack a complete understanding of its working at this length scale. To address this, we reduce one sliding surface to the limit of a single atom and measure sliding friction with lateral force microscopy over single bonds. We examine islands of PTCDA on Cu(111), which present a rich variety of covalent and hydrogen bonds. There is a large

variety in the maximum energy dissipation over different covalent bonds. The maximum energy dissipation over hydrogen bonds has similar values, although energy dissipation over hydrogen bonds is observed at lower heights than over covalent bonds. With DFT-based simulations and a machine-learning model, we determine that larger bond order is correlated to higher sliding friction.

Invited Talk O 31.3 Tue 11:00 H24

Single molecule machines on surface — •Francesca Moresco — TU Dresden. Germany

Scanning tunneling microscopy is a unique experimental technique to control the motion of a single molecule, testing the boundary between classical and quantum movement and making thermodynamics at the scale of a single molecule accessible to experimental investigation. Under the tip of a scanning tunneling microscope, inelastic tunneling electrons or local electric fields can produce controlled rotations or translations of a single adsorbed molecule, while thermal excitation can modify the energy barrier for motion. In this talk, we will discuss the controlled rotation and translation of asymmetric and chiral model structures adsorbed on the Au(111) surface.

O 31.4 Tue 11:30 H24

How to measure cones of reaction for single-molecule collisions — •Matthew J. Timm[1], Stefan Hecht[2], and Leonhard Grill[1] — [1]Institute of Chemistry, University of Graz, Austria — [2]Department of Chemistry & IRIS Adlershof, Humboldt-Universität zu Berlin, Germany

Collisions between reagents are necessary for bond formation, and hence fundamental to reaction. The collision outcome depends on the collision energy, which must be enough to overcome the reaction barrier, and on the collision geometry, which modifies the height of this barrier. The collision geometry is defined by the relative orientation of reagents at the point of collision and on the miss-distance between their centers of mass (termed the impact parameter). Selection of impact parameter has been demonstrated for on-surface reactions with a 'surface-molecular-beam' of CF2 'projectiles', formed by dissociation of chemisorbed CF3 molecules with a scanning tunneling microscope tip, aimed along Cu-rows of the Cu(110) surface toward chemisorbed 'targets' [1]. However, control over the relative orientation of the target has remained elusive. Here a singly-debrominated molecular species (BTFyl) is chosen as a target, as it adopts many possible adsorption alignments relative to the incoming CF2 projectile. This allows simultaneous control over both the impact parameter and reagent orientation, thus allowing an unprecedented ability to map how collision geometry contributes to collision outcome.

O 31.5 Tue 11:45 H24

Friction Anisotropy in the Sliding Motion of PMMA microsphere on Rippled PVS Surface — •Ebru Cihan[1], Hesam Khaksar[2], Kevin Lubig[3], Stephan Gräf[3], Frank A. Müller[3], and Enrico Gnecco[1,2] — [1]TU Dresden — [2]Jagiellonian University — [3]Friedrich Schiller University Jena

The sliding motion of an elastically driven polymethyl methacrylate (PMMA) microsphere on a rippled polyvinyl siloxane (PVS) surface (laser-induced periodic surface structures LIPSS) was investigated for different values of normal load, scan velocity and temperature. The morphologies of the PMMA spheres and modified PVS surfaces were observed to be geometrically convoluted in AFM topographies recorded simultaneously with friction measurements. The spheres were rubbed both parallel and perpendicular to the LIPSS, and the resulting friction was found to be nearly constant, exhibiting a stick-slip behavior over time. This result differs from the reverse stick-slip observed in friction characterizations with similar PMMA microspheres on harder periodic surfaces, such as wedge-shaped silicon gratings [Trib. Lett. 67, 2019] and rippled stainless steel [Appl. Mater. Interfaces 15, 2023]. In both scanning cases, the friction force was found to increase linearly with increasing load, consistent with the increase in contact area expected from Persson contact theory. Furthermore, friction was observed to increase logarithmically with velocity, and to decrease with increasing temperature in accordance with Eyring's reaction rate theory. The stability of this sample system suggests its possible application as a basic unit for artificial tactile sensors.

O 31.6 Tue 12:00 H24

Electronic and phononic frictional dissipation in single-molecule dynamics at CO-decorated tips — •Lukas Hörmann and Reinhard J. Maurer — University of Warwick, Coventry, UK

Friction causes significant energy loss in any moving mechanical device. As the miniaturisation of devices reaches the quantum limit, so do dynamical dissipation processes. Fundamentally quantum mechanical mechanisms govern friction at the nanoscale. We account for all relevant quantum mechanical effects, such as charge transfer, or van der Waals interactions, by employing density functional theory, machine learning, and non-adiabatic molecular dynamics. Using this approach, we investigate friction energy dissipation at the natural limit of singular atoms. This allows us to explore how the local electronic and geometric structure affects the dissipation of mechanical energy, where electron-phonon and phonon-phonon coupling give rise to electronic and phononic excitations. Focusing on the example of CO on various Cu surface geometries, we find that electron-phonon coupling strongly depends on the local electronic density of states, while the geometric structure significantly influences phonon-phonon coupling. Our findings quantitatively agree with experiment. Finally, we present a mechanistic interpretation of our findings that provides insights into the underlying physics of single-molecule dynamics on surfaces.

O 31.7 Tue 12:15 H24

Manipulation of a CO molecule on a copper surface with lateral force microscopy — •Norio Okabayashi[1], Alfred. J. Weymouth[2], Shinjae Nam[2], Sophia Schweiss[2], Thomas Frederiksen[3,4], and Franz J. Giessibl[2] — [1]School of Mathematics and Physics, Kanazawa University — [2]Institute of Experimental and Applied Physics, University of Regensburg — [3]Donostia International Physics Center — [4]IKERBASQUE, Basque Foundation for Science

The manipulation of a single molecule on a surface by scanning tunneling microscopy (STM) and atomic force microscopy (AFM) has been intensively studied because of its relation to friction research. Recently, we have studied the manipulation process for CO on a Cu(110) surface with AFM, STM and density functional theory [1][2]. We found that at the tip height for the beginning of the manipulation, CO is manipulated from the top to the neighboring top site by transiently using the bridge site, but for lower tip heights, the manipulation occurs from the top to the bridge site and then from the bridge to the neighboring top site. Here, we have extended our experimental technique by incorporating lateral force microscopy, where the tip oscillates laterally [3], to directly observe the energy dissipation during manipulation. Indeed, the observation confirms the validity of our previous claim. This result paves the way for quantitative evaluation of dynamic friction during manipulation. [1] N. Okabayashi, T. Frederiksen, A. Liebig, F. J. Giessibl, Phys. Rev. Lett. 131 (2023) 148001, [2] N. Okabayashi, T. Frederiksen, A. Liebig, F. J. Giessibl, Phys. Rev. B 108 (2023) 165401, [3] A. J. Weymouth, J. Phys.: Condens. Matter 29 (2017).

O 31.8 Tue 12:30 H24

Intermediates, reactions and products of cyclocarbons — •Leo Gross[1], Fabian Paschke[1], Florian Albrecht[1], Yueze Gao[2], Igor Roncevic[3], and Harry L. Anderson[2] — [1]IBM Research Europe - Zurich, Rüschlikon, Switzerland — [2]Oxford University, Chemistry Research Laboratory, Oxford, UK — [3]University of Manchester, Department of Chemistry, Manchester, UK

Cyclocarbons, molecular allotropes of carbon in which all carbon atoms are two-fold coordinated, have been synthesized on surface using tip-induced chemistry [1-4], and the formation of larger cyclocarbons by dimerization of precursors was shown [4]. This presentation will focus on products, reactions and intermediates of cyclocarbons, generated by tip-induced chemistry on ultrathin NaCl layers and characterized by STM and AFM with CO-functionalized tips.

Temperature Induced Ring-Opening Polymerization Reaction for the Synthesis of Carbon Nanoribbons: Strain Influence on the On-surface Synthesis Using [6], [8]-, and [10]Cycloparaphenylenes — •Miguel Wiche[1], Qigang Zhong[2], Daniel Kohrs[1], Qitang Fan[3], J. Michael Gottfried[4], Daniel Ebeling[1], Hermann A. Wegner[1], and André Schirmeisen[1] — [1]Justus Liebig University Giessen, Germany — [2]Soochow University, Suzhou, China — [3]University of Science and Technology of China, Hefei, China — [4]Philipps University Marburg, Germany

As the on-surface synthesis is an emerging reseach field, there is a lack of general understanding of reaction mechanisms, compared to conven- tional organic synthesis. Therefore, comprehensive research studies are required to figure out basic principles in the on-surface reaction mech- anisms of organic molecules. In this work we investigate the strain influence of a set of Cycloparaphenylenes (CPP) in the temperature in- duced on-surface synthesis of biphenylene and graphene nanoribbons, using a strain induced ring opening polymerization (ROP) reaction. The decisive step of the polymerization, the ring opening, is found to strongly depend on the ring size and strain of the CPP molecules. Our work suggests that using smaller, highly strained rings, instead of rings with increasing number of phenyl units facilitates the ROP and nanoribbon formation.

O 32.1 Tue 10:30 H25

Stability and reactivity of metal clusters on rutile TiO_2(110) under near-ambient pressure conditions — •Marina Isabel de la Higuera Domingo, Florian Kraushofer, Matthias Krinninger, Friedrich Esch, and Barbara A. J. Lechner — Technical University of Munich, TUM School of Natural Sciences, Department of Chemistry, 85748 Garching, Germany

Clusters are widely recognized for their unique performance in heterogeneous catalysis as they exhibit discrete electronic states that lead to strongly size-dependent catalytic properties [1]. However, their application in industrial processes is often limited by their instability under reaction conditions. At elevated temperatures, clusters tend to sinter, which reduces their surface area and alters their catalytic behavior.

Reducible oxides, such as titania (TiO_2), are effective supports to stabilize clusters and tune their activity through encapsulation induced by the strong metal-support interaction (SMSI) [2]. While metal nanoparticles on TiO_2 are well-studied, much less is known about the dynamics of clusters, in particular at high temperatures and pressures. In the present work, we employ near-ambient pressure scanning tunneling microscopy (NAP-STM) to study the effect of reducing and oxidizing atmospheres on metal clusters on rutile TiO_2(110). We will also delve into the influence of the sample stoichiometry on its reactivity at different ambient conditions [3].

Structural and chemical analysis of coexisting hexagoal and monoclinic phases of samarium oxide on Cu(111) — •Björn Riedel, lars Buss, Raquel Sanchez-Barquilla, and Jan Ingo Flege — Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology Cottbus-Senftenberg, Germany

The absence of in-depth spectroscopic and structural studies on model systems leads to a knowledge gap in understanding how the structure of samaria influences its chemical behavior. A multi-method approach has been employed to investigate the Cu(111)-supported Sm_2O_3 surface with high structural and chemical sensitivity by using low-energy electron microscopy (LEEM) in combination with X-ray absorption photoemission electron microscopy (XAS-PEEM) and other complementary methods such as micro-spot low-energy electron diffraction (μLEED) and X-ray photoelectron spectroscopy (XPS). Our measurements show the phase coexistence of small hexagonal A-Sm_2O_3(0001) islands and monoclinic B-Sm_2O_3(100) rectangular-shaped islands with different rotated rectangular domains. Furthermore, the redox properties of both Sm_2O_3 phases were studied by exposing the system to reducing (H_2) and oxidizing (CO_2) conditions, indicating a face-dependent reduction and oxidation behavior. Moreover, the monoclinic Sm_2O_3(100) islands appear less stable as they change to the hexagonal phase during annealing. These results indicate a highly dynamic system that can easily be adjusted by adapting the growth conditions, such as growth temperature and oxygen partial pressure.

O 32.3 Tue 11:00 H25

Digital Catalysis: Accelerated Discovery through Human in the Loop — •Charles Pare[1], Aybike Terzi[2], Christian Kunkel[1], Frederik Rüther[2], Frederic Felsen[1], Robert Baumgarten[2], Esteban Gioria[2], Raoul Naumann d'Alnoncourt[2], Christoph Scheurer[1], Frank Rosowski[2,3], and Karsten Reuter[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]BasCat - UniCat BASF JointLab, Berlin — [3]BASF SE, Catalysis Research, Ludwigshafen

Catalyst promoters often form key components of stable and well-performing industrial heterogeneous catalysts. Yet, today's industrial catalysts often only benefit from one or two promoters. This can often be traced back to the laborious empirical research required to identify promising formulations that jointly act to improve catalyst performance. To overcome such hurdles, we implemented an accelerated catalyst discovery approach by globally exploring a large catalyst design space using only a limited number of experiments. Its pillars are an efficient Design-of-Experiment (DoE) planning, a fast parallelized testing protocol and an iterative incorporation of experimental feedback. New and competitive promoter chemistries for the non-oxidative propane dehydrogenation to propylene over supported Pt were discovered in a limited experimental campaign. The results show the potential of iterative DoE strategies for the data-efficient knowledge-generation and optimization in complex, academically and industrially relevant catalytic systems.

O 32.4 Tue 11:15 H25

Synergistic effect of oxygen and water on the environmental reactivity of 2D layered GeAs — •Luca Persichetti[1], Giacomo Giorgi[2], Luca Lozzi[3], Maurizio Passacantando[3], Fabrice Bournel[4], Jean-Jacques Gallet[4], and Luca Camilli[1] — [1]University of Rome Tor Vergata, Italy — [2]University of Perugia, Italy; — [3]University of L'Aquila, Italy — [4]Sorbonne Université, CNRS, Paris, France

GeAs is a fascinating 2D material with compelling properties stemming from its intrinsic anisotropy. However, it reacts strongly with air, forming a Ge-oxide layer that affects its optoelectronic properties, such as contact resistance and refractive index. Investigating GeAs reactivity under realistic device conditions, including humid O2 and water exposure, is therefore crucial.

At the TEMPO beamline of Soleil, near-ambient pressure X-ray photoelectron spectroscopy (NAP-XPS) was employed to study GeAs in the presence of oxygen and water. Results showed minimal reactivity with dry O2 and de-aerated water, while slight humidity (Rw = 0.5%, T = 20°C) in an O2 atmosphere significantly enhanced reactivity. Density functional theory calculations confirmed this synergistic effect, revealing a highly exothermic formation energy for the simultaneous chemisorption of O2 and H2O, compared to the adsorption of each molecule individually.

This research was supported by EU-funded MUR programs PRIN2022 ATYPICAL (2022JW8LHZ) and PRIN 2022-PNRR SPIGA (P2022LXNYN).

A comparative DFT+U study of the oxygen evolution reaction at infinite-layer, brownmillerite and perovskite nickelates — •Achim Füngerlings and Rossitza Pentcheva — Department of Physics, University of Duisburg-Essen, Duisburg, Germany

We present a detailed DFT+U investigation of rare earth nickelates $R\mathrm{NiO}_x$(001), R = La, Nd; x = 2, 2.5, 3 as anode materials for the oxygen evolution reaction (OER). In these materials the Ni reaction sites at the surface exhibit different coordination, i.e. square-planar in the infinite layer (x = 2, IL), fivefold coordination at the (001) perovskite surface (x = 3) and both fourfold and fivefold coordination at the brownmillerite surface (x = 2.5, BM). Voltammetry measurements find a lower onset potential for the catalytically much more active infinite layer compared to the perovskite counterparts.[1] Moreover, x-ray diffraction measurements suggest that the infinite layer gradually transform into brownmillerite during OER.[1] Our calculations confirm a lower overpotential for both the infinite layer and brownmillerite phases over the respective perovskite phase. The results reveal that the oxidation state of surface Ni has a more profound effect on the catalytic activity than the coordination number, with Ni^{2+} (found at the IL and the fivefold coordinated BM site) leading to lower (0.53, 0.56 V for R=La; x=2, 2.5) and Ni^{3+} (at the fourfold coordinated site in BM and the fivefold coordinated site at the perovskite surface) leading to higher overpotentials (0.67, 0.68 V for R=La; x=2.5, 3).

How does lanthanum promote cobalt for ammonia synthesis in Co/La_2O_3 catalysts? — •Clara C. Aletsee, Lau H. Wandall, Ke Zhang, Oliver Christensen, Jens K. Nørskov, and Ib Chorkendorff — Physics, Technical University of Denmark

The interest in developing catalysts for ammonia synthesis, operating under milder reaction conditions than the Haber-Bosch process, has increased in the last decades. Cobalt, typically unreactive, can be activated for ammonia synthesis through the addition of lanthanum in metallic or oxidized form.[1,2] To obtain a comprehensive understanding of the promotion mechanism, we investigate the ammonia formation over Co particles on La_2O_3 by combining experiments with theory. For this, we synthesized defined model catalyst, consisting of mass-selected Co nanoparticles, deposited on La_2O_3 films generated by magnetron sputtering. Their catalytic activity was tested at 1 bar and 350-500°C in a UHV-compatible reaction cell.[3] Catalyst states before and after reaction were analyzed by X-ray photoelectron spectroscopy and low-energy ion scattering. The results, combined with previous findings on the Co/LaN system,[2] suggest that the reaction proceeds on La-promoted Co steps due to spin-mediated effects supported by theoretical calculations.[4] We further demonstrate that the activity of the Co/La_2O_3 can be partially recovered after air exposure.

O 32.7 Tue 12:00 H25

U-Ce charge transfer in epitaxial $Ce_{1-x}U_xO_2$ films grown on Ru(0001): consequences for thermochemical water splitting — •Carlos Morales[1], Rudi Tschammer[1], Thomas Gouder[2], Hicham Idriss[3], and Jan Ingo Flege[1] — [1]Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology, Cottbus, Germany — [2]European Commission, Joint Research Centre (JRC), Karlsruhe, Germany — [3]Institute of Functional Interfaces (IFG), Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany

Reducible metal oxides are crucial in applications like catalysis and solar energy conversion. Among these, cerium oxide (CeO_2) stands out for its stability and activity, yet its reduction requires high energy. Ceria doping or mixing with other elements has been proven successful in increasing the conversion from Ce^{4+} to Ce^{3+}. Uranium cations are the most suitable candidates: substituting a fraction of Ce^{4+} by U^{4+} results in a charge transfer that promotes the formation of Ce^{3+} and U^{5+} states. The fundamental study of the charge transfer process requires model systems, as heat and mass transfer limitations are largely absent compared to polycrystalline powders. By in-situ X-ray photoelectron spectroscopy (XPS) and low-energy electron diffraction (LEED), we explored the redox properties and structural stability of epitaxial (111)-oriented $Ce_{1-x}U_xO_2$ on Ru(0001). The as-grown films, prepared by reactive direct current sputtering from metallic targets, show a high Ce^{4+} to Ce^{3+} conversion, reversible upon reducing-oxidizing cycles. The experimental results are discussed in the light of density function theory (DFT) calculations.

O 32.8 Tue 12:15 H25

Accelerating Surface Adsorption Energy Prediction with Machine Learning Foundation Models — •Karlo Sovic[1,2] and Johannes T. Margraf[2] — [1]University of Zagreb Faculty of Science — [2]University of Bayreuth

Determining the adsorption energies of molecular adsorbates on surfaces is critically important in heterogeneous catalysis, as well as in many other fields of materials science and chemistry. Understanding the nature and strength of adsorbate-surface interaction leads to a more rational design of efficient catalysts and improvements in their performance. While accurate first-principles calculations have brought about a revolutionary advance in our ability to predict properties and design materials *in silico*, high computational costs and poor scaling limit their application in exploring complex real-world materials. Machine-learning interatomic potentials offer a solution to this materials exploration problem. In particular, the recent emergence of pre-trained foundation models offers a data-efficient route to obtain accurate models via fine-tuning. To showcase their efficiency and performance, extensive computational research has been conducted using a fine-tuned MACE-MP-0 model to study the adsorption of glycerol on various metallic surfaces in the gas phase. This talk will present the methodology for investigating the global minima of complex adsorbate molecules on various metal surfaces, determining their respective adsorption energies, and exploring various reaction mechanisms on adsorbent's surface through computational approaches.

O 32.9 Tue 12:30 H25

Role of Co-Catalyst Loading in the Photoreforming of Tertiary Alcohols at Ambient Pressure on Titania P25 — •Paula Neumann, Clara Aletsee, Martin Tschurl, and Ueli Heiz — Chair of Physical Chemistry, School of Natural Sciences & Catalysis Research Center, Technische Universität München, Lichtenbergstr. 4, 85748 Garching, Germany

Efficient semiconductor photocatalysts are usually modified with a so-called co-catalyst, a metal particle which is commonly assumed to promote charge separation, but whose exact role remains elusive. To elucidate the influence of platinum particles loaded onto a titania powder catalyst we investigated the photoconversion of tertiary alcohols in our gas phase-photoreactor at ambient conditions. Different to its usual interpretation but in accordance with UHV studies we show that the co-catalyst facilitates the recombination of surface hydrogen. Thereby, a second reaction pathway is opened up where a C-C coupling product forms on the titania surface. Hence, identifying the mechanistics of alcohol photochemistry is not only providing insights into hydrogen formation but it also sheds light onto complex alkyl coupling reactions.

Reversible transition between (10×10) **and** (11×11) **phases of Pb intercalated EG on 6H/SiC(0001)** — •Sergii Sologub[1,2], Markus Gruschwitz[2], Bharti Matta[3], Andres David Pena Unigarro[2], Philipp Rosenzweig[3], Sibylle Gemming[2], Kathrin Küster[3], Ulrich Starke[3], and Christoph Tegenkamp[2] — [1]Institute of Physics, NAS of Ukraine, Kyiv — [2]Institut für Physik, TU Chemnitz, Chemnitz — [3]Max-Planck-Institut für Festkörperforschung, Stuttgart

Epitaxial graphene (EG) obtained by intercalation of a buffer layer on 6H/SiC(0001) with Pb atoms is the subject of intensive experimental and theoretical studies due to its charge neutrality, the band gap opening and proximity superconductivity. The hallmark of Pb-intercalated EG is the formation of diffraction spots with (10×10) or (11×11) periodicity in the high-resolution LEED patterns. The correlation between these phases and corresponding microstructure, i.e. "striped" and "bubble" Pb intercalated phases, were examined by STM and by dark field imaging in a photoemission electron microscope. We have also established a recipe to reversibly switch between the (10×10) and (11×11) structures. In addition, the ratio of areas occupied by these coexisting phases could be estimated from the intensity ratio of second order LEED spots. Importantly, the degree and ease of intercalation strongly depends on the defect density of the initial buffer layer. The transformation between the different phases can be rationalized by the low diffusion barrier of Pb on SiC observed by density functional calculations.

O 33.2 Tue 13:30 P3

Confinement-mediated intercalation of metals in epitaxial graphene: Unlocking room temperature intercalation — •Kathrin Küster[1], Stefan Wundrack[2,3], Markus Gruschwitz[4], Sawani Datta[1], Bharti Matta[1], Teresa Tschirner[2], Marius Eckert[2,3], Rainer Stosch[2], Christoph Tegenkamp[4], Ulrich Starke[1], Klaus Pierz[2], and Andrey Bakin[2] — [1]Max-Planck-Institut für Festkörperforschung, Stuttgart — [2]Physikalisch-Technische Bundesanstalt, Braunschweig — [3]Institut für Halbleitertechnik - TU-Braunschweig — [4]Institut für Physik, TU Chemnitz

Intercalation of materials underneath epitaxial graphene is an effective way to tune graphene's properties but also to stabilize otherwise unstable 2D materials. Usually, this procedure requires extreme conditions like ultra-high vacuum and elevated temperatures often above 400 °C. Within the DFG research unit FOR 5242 we also investigate alternative routes of intercalation under more accessible conditions. Here, we report on the intercalation of Ga and In under monolayer graphene at ambient conditions. A multi-technique approach combining spectro-microscopy techniques with density functional theory calculations gives detailed insights into the intercalation pathways and the diffusion of the intercalants at the interface between graphene and the SiC substrate. It is evident that the intercalated atoms are strongly bound to the topography of the SiC terraces during their diffusion and exhibit anomalies in their diffusion behavior. The monolayer graphene is transformed into a decoupled bilayer upon intercalation and the intercalated materials develop their own metallic 2D electronic structure.

O 33.3 Tue 13:30 P3

Proximity-effects in epitaxial graphene: recent highlights of our Research Unit FOR5242 — S. Gemming[1], I. Gierz-Pehla[2], K. Küster[3], K. Pierz[4], Th. Seyller[1], U. Starke[3], •C. Tegenkamp[1], T. Wehling[5], and M. Wenderoth[6] — [1]Institut für Physik, TU Chemnitz — [2]Institut für Experimentelle und Angewandte Physik, U Regensburg — [3]Institut für Festkörperforschung, MPI Stuttgart — [4]Physikalisch-Technische Bundesanstalt, Braunschweig — [5]Institut für Theoretische Physik, U Hamburg — [6]IV. Physikalische Institut, U Göttingen

Proximity effects in low dimensional electron gases are essential for the design of new quantum materials with tailored electronic, magnetic and optical properties. A recent example is superconductivity in twisted bilayer graphene. Our Research Unit FOR 5242 studies the influence of proximity-induced spin-orbit interaction (SOI), electronic correlations as well as local electric fields on 2D electron gases, using epitaxial graphene (EG) on SiC substrates as a model system. EG is known for its flexible functionalization schemes including intercalation and adsorption, enabling control of the doping level, hybridization effects, and the strength of the Coulomb interaction. Here, we highlight a few of our recent results including (1) the use of EG for quantum Hall resistance standards, (2) SOI in graphene induced by 2D Pb layers, (3) Mott-Hubbard physics realized by the intercalation of Sn and Si, (4) many-body effects in extremely doped EG and (5) novel 2D interface layers. For further details see www.for5242.de

O 33.4 Tue 13:30 P3

Quasi-freestanding monolayer graphene achieved by Pb intercalation — •S Wolff[1], P Schädlich[1], A D Peña Unigarro[1], B Matta[2], G Ghosal[1], F Schölzel[1], P Richter[1], M Hutter[3], M Stettner[3], K Küster[2], C Kumpf[3], S Gemming[1], U Starke[2], C Tegenkamp[1], and T Seyller[1] — [1]Institute of Physics, TU Chemnitz — [2]MPI für Festkörperforschung, Stuttgart — [3]Peter Grünberg Institut, Forschungszentrum Jülich

Intercalation is a promising approach for tailoring the electronic structure of epitaxial graphene on SiC. Beyond that, it enables the formation of otherwise

unstable 2D phases of elements and opens a route to study the interplay between the two 2D materials and the substrate. We have studied the Pb intercalation process under the buffer layer in detail using low-energy electron microscopy (LEEM), photoelectron spectroscopy (PES), scanning tunneling microscopy (STM), density functional theory calculations (DFT) and X-ray standing wave (XSW). LEEM is used to monitor the intercalation process at different intercalation temperatures, resulting in either a (1 × 1) symmetry or in a (10 × 10) superstructure of the Pb atoms. These findings can be supported by angle-resolved PES and STM. Experiments indicate, in agreement with DFT, different filling of the Pb bands depending on the SiC polytype. Furthermore, XSW was used to determine the interlayer distances, revealing covalent bonding of the intercalant to the substrate and van der Waals bonding to graphene.

O 33.5 Tue 13:30 P3

Liquid metal intercalation of epitaxial graphene Hall bar devices on SiC — •Marc Bothe[1,2], Stefan Wundrack[1,2], Teresa Tschirner[1], Markus Gruschwitz[3], Yefei Yin[1], Klaus Pierz[1], Frank Hohls[1], Rainer Stosch[1], Christoph Tegenkamp[3], Hans Werner Schumacher[1], and Andrey Bakin[2] — [1]Physikalisch-Technische Bundesanstalt, Bundesallee 100, 38116 Braunschweig, Germany — [2]Institut für Halbleitertechnik, TU Braunschweig, Hans-Sommer-Str. 66, 38106 Braunschweig — [3]Institut für Physik, Technische Universität Chemnitz, Reichenhainer Strasse 70, 09126 Chemnitz, Germany

Epitaxial graphene grown on SiC is a promising platform for metal intercalation, enabling the investigation of proximity effects. Metal intercalation relies on the controlled introduction of lattice defect densities in monolayer graphene, achieved through plasma treatment. This is followed by liquid metal intercalation, during which atoms diffuse through lattice defects and propagate beneath the graphene. However, the use of metal intercalated graphene samples for device fabrication presents two challenges. First, solvents used for lithography often lead to metal deintercalation. Second, lattice defects in graphene compromise the structural and electronic integrity of the graphene device. We use an alternative strategy that combines lithography with metal intercalation through predefined channels. Initial measurements of Hall bar structures intercalated with gallium show superconducting behavior, demonstrating the potential of this approach for advanced device applications.

O 33.6 Tue 13:30 P3

Mesoscopic Lateral Intercalation Dynamics of Tin Between the Epitaxial Buffer Layer of Graphene and SiC — •Benno Harling[1], Zamin Mamiyev[2], Christoph Tegenkamp[2], and Martin Wenderoth[1] — [1]IV. Physical Institute, Georg-August-University Göttingen, Germany — [2]Analysis of Solid Surfaces, Nanostructures and Quantum Materials, TU Chemnitz, Germany

Within the challenges of modern electronics, the dynamics of intercalation in layered structures is key for pushing the boundaries of technological limits. Fine-tuned control and a deeper understanding of the intercalation process is needed. Our study focuses on the lateral dynamics of this intercalation process. Whereas penetration of the graphene sheet was already often discussed [1], the lateral atom transport processes according to the mesoscopic landscape of the substrate has been less addressed. Kelvin Probe Force Microscopy (KPFM) was used to investigate an epitaxial graphene buffer layer intercalated with tin. A diffusion edge to the pristine buffer layer can be identified with this method down to the mesoscopic scale below 100 nanometers. On a vicinal surface, we find surface steps as a clear barrier for diffusion. Material transfer over the substrate steps is mediated by a local defect, i.e. local pin-holes. Moreover, we do not observe nucleation on the terrace, but the decoration of the next step by tin. Faster diffusion at the step edges leads to directional growth of the intercalated phase.

Financial support by the DFG within research unit FOR5242 is greatly acknowledged.

O 33.7 Tue 13:30 P3

Magnetic MnPc molecules adsorbed on epitaxial graphene — •James Oyuga[1], Nhung Nguyen[1], Uwe Gerstmann[2], Eva Rauls[3], Julian Koch[1], and Christoph Tegenkamp[1] — [1]Institut für Physik, TU Chemnitz, Germany — [2]Theoretische Physik, Universität Paderborn, Germany — [3]Department of Mathematics and Physics, University of Stavanger, Norway

Phthalocyanines (Pc) are prototype molecules hosting magnetic ions. When adsorbed on surfaces, the spin state of the molecules is influenced by the substrate. In a combined experimental and theoretical study, we investigated this influence for the case of MnPc molecules adsorbed on monolayer graphene/SiC(0001) using STM, magnetotransport and theoretical DFT modeling. The STM measurements showed that the self-assembly of the MnPc molecules results in an almost defect-free monolayer with a (4×2) unit cell accommodating 8 MnPc molecules. The DFT modeling revealed that the structure and thereby the spin states of the molecules are decisively influenced by the substrate. In the gas phase the MnPc molecules are symmetrically bended with a spin state of $S = 3/2$. However, on an epitaxial graphene monolayer this is changed into an even mixture of flat molecules with an $S = 5/2$ spin state and upward bended molecules with an $S = 3/2$ spin state. This mixture allows for a denser arrangement of the molecules in a (4 × 2) unit cell, that is commensurable with both the graphene layer and the underlying SiC substrate. The impact of such molecular structures towards transport in epitaxial monolayer graphene is quantified by magneto transport experiments analyzing the weak (anti) localization.

O 33.8 Tue 13:30 P3

Intercalation of a condensed 2D-Ag phase within the epitaxial graphene/SiC interface — •Sawani Datta[1], Vibha Reddy[1], Bharti Matta[1], Arpit Jain[2], Kathrin Küster[1], Joshua A. Robinson[2] und Ulrich Starke[1] — [1]Max-Planck-Institut für Festkörperforschung, Stuttgart, Germany — [2]Pennsylvania State University, State College, USA

Intercalating 2D materials at the epitaxial graphene (EG)/SiC interface improves their environmental stability, facilitating the use of various ex-situ techniques for their fundamental study and application purposes. In a previous study, we showed that Ag atoms intercalated at the EG/SiC interface form a triangular (1×1) lattice with respect to the SiC and the Ag interlayer is semiconducting [1,2]. Interestingly, intercalating Pb into a previously Ag-intercalated sample results in the complete replacement of Ag by Pb. Subsequently, another round of Ag intercalation can entirely replace Pb, forming a new Ag phase characterized by a 4/3 packing of Ag with respect to the underlying Si layer. Theory suggested the existence of two intercalated 2D material phases also for several other materials [3] and Auger electron spectroscopy mapping indeed shows a higher Ag concentration of the latter Ag phase [4]. In this work, we compare the 2 different Ag phases by low-energy electron diffraction (LEED) and angle-resolved photoemission spectroscopy (ARPES). This ongoing study is supported by DFG through FOR 5242 and by NSF Grant DMR-2011839. [1] Phys. Rev. B 101, 201407(R) (2020). [2] Phys. Rev. B 105, 235428 (2022). [3] arXiv:2011.01914v1 (2020). [4] 2D Materials 8, 41003 (2021).

O 33.9 Tue 13:30 P3

Scanning tunneling potentiometry methods for intercalated graphene systems — •Tim Güldenpfennig[1], Simeon Bode[2], Markus Gruschwitz[1], Martin Wenderoth[2], and Christoph Tegenkamp[1] — [1]Institut für Physik, TU Chemnitz, Germany — [2]IV. Physikalisches Institut, Universität Göttingen, Germany

Graphene and graphene-based (hetero-)systems were subjects in a wide range of studies in the past decades revealing their intriguing electronic properties. Epitaxially grown graphene on SiC plays a vital role as a base for electronic application. By intercalating such grown buffer layer with different elements the electronic properties of the decoupled graphene layer can be precisely manipulated. Recently a great interest in the two dimensional intercalant layers arose as well. The latest advance towards intercalation of heavy elements (Pb, Bi, etc.) comes along with new challenges due to defect-dependent intercalation paths. Macro- and mesoscopic transport experiments on these percolated but multi-scale defective intercalated phases become impractical [1].

For transport investigations at the nanometer scale we utilize scanning tunneling potentiometry (STP). In combination with finite element simulations the conductivity of the intercalated phase and the influence of defects can be separated precisely. Two different setups to investigate the transport properties of intercalated graphene systems on nanoscopic scale are presented. One is implemented in a 4pp-STM/SEM setup with the ability to locally apply transverse voltages. The other setup uses an home-built STM for measurements at 6 K with micro-Volt resolution. [1] Phys. Rev. B 109, 245430 (2024)

O 33.10 Tue 13:30 P3

Electronic and structural properties of a Sn Mott phase proximitized to graphene — C. Ghosal[1], •H.-T. Ngo[1], S. Ryee[2], Z. Mamiyev[1], N. Witt[2,3], T. Wehling[2,3], and C. Tegenkamp[1] — [1]Institut für Physik, TU Chemnitz — [2]Institute of Theoretical Physics, U Hamburg — [3]The Hamburg Centre for Ultrafast Imaging, Hamburg

Graphene, renowned for its exceptional electronic and optical properties as a robust 2D material, traditionally lacks electronic correlation effects. Proximity coupling offers a promising method to endow quantum materials with novel properties. In this study, we achieved such a proximity coupling by intercalating Sn between the buffer layer of graphene on SiC(0001). In the $\sqrt{3}$-areas, the Sn-p_z electrons exhibit robust correlation effects manifest as characteristic Hubbard bands analyzed by STS and EELS. Thereby, the system revealed a spatially modulated hybridization between the Dirac and the correlated electrons depending on the Sn sites with respect to the graphene lattice. The DFT and DMFT calculations show excellent agreement regarding the spectral properties. The analyses revealed further that besides the hybridization and Coulomb interaction also the charge transfer plays an important role for electronic state that emerges in these artificial correlated systems.

Twisted Bilayer Graphene by Hydrogen Intercalation — •Hao Yin[1,2], Andrei Matetskii[1], Frank Stefan Tautz[1,2], François C. Bocquet[1], and Christian Kumpf[1,2] — [1]Peter Grünberg Institut (PGI-3), FZ-Jülich, Germany — [2]RWTH Aachen University, Aachen, Germany

Quasi-free-standing twisted bilayer graphene (TBLG) with a 30° twist angle is achieved on a 6H-SiC(0001) surface via hydrogen intercalation of the zeroth-layer graphene (ZLG). Initially, 0°-rotated monolayer graphene is prepared using the surfactant-mediated epitaxial growth method [PRL **125**, 106102 (2020)]. The processes of hydrogen intercalation and deintercalation were investigated using Low Energy Electron Microscopy (LEEM), with intercalation conducted stepwise, while deintercalation was monitored in real time. Our results provide valuable insights into the mechanisms underlying hydrogen intercalation and deintercalation.

A sharp reaction front was observed, aligned parallel to the step edges, suggesting that hydrogen atoms migrate beneath the ZLG from surface discontinuities, such as step edges or defects.

Deintercalation, taking place 200°C above the intercalation temperature, was significantly faster (within one minute) and occurred uniformly, as indicated by the homogeneous brightness changes in deintercalated regions. This implies a much faster diffusion of H under the TBLG at this temperature, or possibly that H atoms are able to penetrate through the graphene layers.

O 33.12 Tue 13:30 P3

Near-Field Optical spectroscopy of few-layer Graphene's interband resonances to study it's gate-tunable band structures — •Dominique Malik, Lina Jäckering, and Thomas Taubner — I. Institute of Physics (IA), RWTH Aachen University

The band structure of few-layer graphene (FLG) defined by the crystallographic stacking order determines its electronic and optical properties. Optical spectroscopy of interband resonances - the excitation of electron transitions between two electronic bands - allows to directly probe the gate-tunable band structure. Within one flake FLG can exist in different stacking orders. However, conventional far-field spectroscopy is diffraction limited and cannot resolve stacking domains below this limit [1]. Recently, with scanning near-field optical microscopy (s-SNOM) the interband resonances of bilayer graphene (BLG) and 4LG have been retrieved [2]. Due to the stacking specific resonance energy, s-SNOM spectroscopy allowed for the identification of stacking domains on the nanometer scale [2]. The local effect of the application of a gate voltage to FLG has not been studied. Here, we present the theoretical foundation to perform near-field optical spectroscopy of interband resonances of gated trilayer and BLG over the energy range from 0.28 to 0.54 eV to gain insights into gate-tunable modifications of their band structures. We layout the design and fabrication of a suitable sample and show initial results. We expect high-resolution s-SNOM measurements could reveal local variations in band gap opening, which are unachievable with far-field techniques. [1] Lui et al. Nano Lett. 11, 1 (2011) [2] Wirth et al. ACS Photonics 8.2 (2021)

O 33.13 Tue 13:30 P3

non-equilibrium carrier dynamics of a graphene - 2D Mott insulator interface — Maria-Elisabeth Federl[1], •Franziska Bergmeier[1], Zamin Mamiyev[2], Niklas Witt[3], Tim Wehling[3], Christoph Tegenkamp[2], and Isabella Gierz[1] — [1]University of Regensburg — [2]Technical University Chemnitz — [3]University of Hamburg

Hybridization between localized and itinerant electrons is believed to be responsible for the formation of exotic electronic states including heavy-fermion behaviour or unconventional superconductivity. Confinement heteroepitaxy, where novel 2D structures are stabilized at the interface between epitaxial graphene and SiC substrate, provides a pathway to engineer proximity-coupling between the massless carriers in graphene and the carriers in the underlying layer. We intercalated graphene with Sn, where the $(\sqrt{3}\times\sqrt{3})$R30° phase formed on SiC(0001) is believed to be a Mott insulator [1], and used time- and angle-resolved photoemission spectroscopy (trARPES) as well as density functional theory (DFT) to search for indications of interlayer hybridization that might pave the wave towards the realization of exotic electronic phases.

O 33.14 Tue 13:30 P3

Sequential Intercalation of Epitaxial Graphene with Multiple Elements — •Niels Rösch, Mohammad Elkhawaga, Philip Schädlich, Fabian Göhler, and Thomas Seyller — Chemnitz University of Technology, Institute of Physics, 09126 Chemnitz, Germany

The intercalation of epitaxial graphene on SiC(0001) is a field of research that currently attracts attention. On one hand it provides the possibility to fine-tune the properties of the graphene layer. On the other hand it also is a means to fabricate two-dimensional materials in a confined state [1,2].

In this study we test the possibility to synthesize binary compounds by sequential intercalation of two elements. As test cases we have chosen the topological insulator Bi_2Se_3 [3] and the superconductor FeSe [4]. To that end, Bi or Fe is first intercalated using a deposition and annealing approach. This is followed by an exposure to a selenium-rich atmosphere at elevated temperatures. Samples are characterized by photoelectron spectroscopy and electron diffraction.

O 33.15 Tue 13:30 P3

Free-standing graphene films/membranes — •Leon Lasnig, Lukas Kalkhoff, Steffen Franzka, and Marika Schleberger — Faculty of Physics and CENIDE, University of Duisburg-Essen, Duisburg, Germany

Large-area graphene films are usually grown onto a copper sheet via chemical vapor deposition. The transfer of the graphene to another substrate to this date has been done with the help of polymer films, which leads to impurities and residues. These residues can change the properties of graphene. It is therefore necessary to develop new fabrication protocols to prevent or at least minimize contaminations.

Here we present a new technique for fabricating membranes without the requirement of an PMMA layer. The samples were then transferred on hole substrates with a hole diameter of 150 μm. Since a monolayer is not stable enough to cover the hole, samples with multiple layers were prepared. These were characterized using Raman spectroscopy and an optical profilometer. Raman spectroscopy showed that the samples within the holes are very homogeneous in terms of doping and strain. The lack of D mode in the measured Raman spectra indicates a clean sample. The profilometer revealed that the graphene membranes in the holes have an average hight deviation of only 138 nm.

O 33.16 Tue 13:30 P3

Electronic and structural properties of Bi-intercalated epitaxial graphene on SiC(0001) — Niclas Tilgner[1], Susanne Wolff[1], Andres D. Peña Unigarro[1], Philip Schädlich[1], Fabian Göhler[1], Bharti Matta[2], Philipp Rosenzweig[3], Kathrin Küster[2], Mark Hutter[4], Monja Stettner[4], Hao Yin[4], Serguei Soubatch[4], François C. Bocquet[4], Tien-Lin Lee[5], Christian Kumpf[4], Ulrich Starke[2], Sibylle Gemming[1], and •Thomas Seyller[1] — [1]Institut für Physik, TU Chemnitz — [2]Max Planck Institut für Festkörperforschung, Stuttgart — [3]Physikalisches Institut, Universität Stuttgart — [4]Peter Grünberg Institut, Forschungszentrum Jülich — [5]Diamond Light Source, United Kingdom

The intercalation of epitaxial graphene on SiC(0001) is a research area that currently attracts attention. Not only does it provide the possibility to fine-tune the properties of the graphene layer, it also allows fabricating two-dimensional materials in a confined state. Using a variety of experimental (LEED, LEEM, XPS, ARPES, XSW) and theoretical (DFT) approaches we studied the structural and electronic properties of different intercalated Bi phases that are formed depending on the preparation conditions. While a dense phase with a (1×1) periodicity with respect to SiC(0001) shows metallic properties, a diluted $(\sqrt{3}\times\sqrt{3})R30°$ phase appears insulating. Upon annealing in hydrogen, the latter can be transformed into a layer of bismuthene. However, while the bismuthene is arranged with the same periodicity, DFT calculations suggest that the transition is accompanied by a major structural rearrangement.

O 33.17 Tue 13:30 P3

Transport Properties of Epitaxial Graphene on 4H-SiC(0001) and 6H-SiC(0001) on the Local Scale — •Simeon Bode[1], Benno Harling[1], Teresa Tschirner[2], Klaus Pierz[2], and Martin Wenderoth[1] — [1]IV. Physikalisches Institut, Georg-August-Universität Göttingen — [2]Physikalisch-Technische Bundesanstalt (PTB), Braunschweig

Recent experiments on epitaxial graphene on silicon carbide have shown that transport properties strongly depend on the surface termination of the SiC substrate. Here, we study the impact of the polytype of the substrate SiC on various local properties of Polymer Assisted Sublimation Grown (PASG) graphene. Recently, it has been shown that there are two different surface terminations present at 6H-SiC [1], whereas mainly one surface termination was observed on 4H-SiC. The structural properties are investigated by STM and AFM, whereas electronic properties are extracted from STS data. Local transport measurements using Scanning Tunneling Potentiometry (STP) on 6H-SiC reveal variations in the sheet resistance from terrace to terrace when changing the stacking sequence across a step. On the other hand, the local sheet resistances of neighbouring terraces are very similar if the step height is half of a SiC unit cell, i.e., having the same termination on both sides. PASG graphene on 4H-SiC predominantly exhibits steps of half the unit cell. First data on 4H-SiC indicates that also on this system the sheet resistance is only slightly varying across steps. This work was financially supported by the DFG through the FOR5242. [1] Sinterhauf et al., Nat Commun 11, 555, 2020

O 33.18 Tue 13:30 P3

Growth dynamics of the graphene buffer layer on SiC(0001) grown by polymer-assisted sublimation growth (PASG) — •Julia Guse[1], Teresa Tschirner[1], Stefan Wundrack[1], Kathrin Küster[2], Ulrich Starke[2], Philip Schädlich[3], Thomas Seyller[3], Klaus Pierz[1], and Hans Werner Schumacher[1] — [1]Physikalisch-Technische Bundesanstalt, Bundesallee 100, 38116 Braunschweig, Germany — [2]Max-Planck-Institut für Festkörperforschung, Stuttgart — [3]Institut für Physik, TU Chemnitz

Fabrication of two-dimensional (2D) heterostructures using epitaxial graphene on SiC is gaining interest for engineering new electronic material systems. Important for the quality of the epigraphene layer is the 0th graphene layer, the buffer layer, being covalently bonded to the SiC substrate. However, there is still conflicting theoretical and experimental evidence of the structural properties of the buffer layer and its influence on epigraphene. Further, the quality of this buffer layer is not well defined and systematic studies are still lacking. We use an advanced growth technique preventing step bunching and large terrace step heights to achieve high quality buffer layer on millimeter scale. The buffer layer is grown by thermal sublimation in an argon atmosphere and by applying the polymer-assisted sublimation growth (PASG) method. By pretreatment of the SiC substrate which supplies additional carbon during the initial nucleation process the SiC surface is stabilized by rapid buffer layer formation which prevents step bunching. We investigate the growth parameters for homogeneous buffer layer formation and systematically study its growth dynamics.

O 33.19 Tue 13:30 P3

Modeling the intercalation of epitaxial graphene with main group elements from first-principles — Andres D. Peña Unigarro[1], Niklas Witt[2,3], Maria-Elisabeth Federl[4], •Alexander Korn[1], Isabella Gierz[4], Tim Wehling[2], Florian S. Günther[5], and Sibylle Gemming[1,6] — [1]Inst. Physik, TU Chemnitz — [2]Inst. Theoretische Physik, U Hamburg — [3]Theoretische Physik, JMU Würzburg — [4]Inst. Experimentelle und Angewandte Physik, U Regensburg — [5]UNESP, Rio Claro, Brazil — [6]MAIN Center, TU Chemnitz.

Intercalation of epitaxial graphene on silicon carbide (EG) with metallic interlayers opens up a plethora of fascinating physical phenomena, rooted in both spatial confinement and proximity coupling effects. A rich variety of exotic electronic states is obtained by the simultaneous presence of flat and Dirac-like bands with intricate splittings of the spins and pseudospins in EG and the intercalant.

Here, we present first-principles calculations for supercell models, which capture the essential structural and electronic properties of thin intercalation layers in EG. Ordered structures with different interlayer coverages have been studied, which provide distinctly tailored degrees of proximity coupling. Comparing interlayers from the experimentally well-studied main group elements Sn, Pb, and Bi allows distinguishing between isovalent and heterovalent intercalants as well as studying the influence of relativistic effects, in particular spin-orbit coupling (https://www.epigraphene.de/).

O 33.20 Tue 13:30 P3

Influence of doping on non-equilibrium carrier dynamics in graphene — •Leonard Weigl[1], Johannes Gradl[1], Peter Richter[2], Thomas Seyller[2], Camilla Coletti[3], and Isabella Gierz[1] — [1]University of Regensburg, Germany — [2]Technical University of Chemnitz, Germany — [3]Instituto Italiano di Tecnologia, Pisa, Italy

The understanding of non-equilibrium charge carrier dynamics in the quasi-relativistic dispersion of graphene is a key ingredient for the design of future ultrafast electronic devices. Despite its crucial importance for device operation, the role of the doping level remains controversial. Here, we use time- and angle-resolved photoemission spectroscopy (tr-ARPES) to study the energy-resolved photo-carrier relaxation in epitaxial graphene for different doping levels. In contrast to previous studies on the same material [1], we find the energy-resolved relaxation times to be independent of doping. We attribute this to the fact that - with increasing doping level - the peak electronic temperature is found to decrease, making the phase space for carrier relaxation doping-independent. Therefore, we speculate that the previously observed differences in carrier dynamics between graphene resting on C- and H-terminated SiC substrates, respectively, originate from the different interfaces to the substrate rather than the doping level. [1] J. C. Johannsen et al., Nano Lett. 15, 326-331 (2014)

O 33.21 Tue 13:30 P3

Hexagons on Rectangles: Epitaxial Graphene on Ru$(10\bar{1}0)$ — •Lars Buss[1], Giovanni Zamborlini[2], Cathy Sulaiman[1], Moritz Ewert[1], Mirko Cinchetti[2], Jens Falta[3], and Jan Ingo Flege[1] — [1]Applied Physics and Semiconductor Spectroscopy, BTU Cottbus-Senftenberg, Germany — [2]Department of Physics, TU Dortmund University, Germany — [3]Institute of Solid State Physics, University of Bremen, Germany

The miniaturization of integrated electronics drives the demand for barrierless interconnects, with graphene-ruthenium structures emerging as promising candidates. We present an *in situ* study of the growth and electronic properties of graphene on rectangular Ru$(10\bar{1}0)$ grown by high-temperature carbon segregation. Using low-energy electron microscopy (LEEM), it is shown that graphene grows preferentially along the $[1\bar{2}10]$ direction, forming micrometer-sized rectangular islands. Microspot low-energy electron diffraction (μLEED) reveals two predominant graphene orientations, rotated by 0° (R0) and 30° (R30), with indications for the formation of graphene nanoribbons in bilayer graphene/Ru$(10\bar{1}0)$. Microspot angle-resolved photoemission spectroscopy (μARPES) shows that the Dirac cones remain intact in bilayer graphene with reduced n-type doping compared to graphene/Ru(0001), indicating a weaker interaction with the Ru$(10\bar{1}0)$ surface. These results highlight the influence of substrate symmetry and interactions on graphene properties and provide insights for engineering graphene beyond hexagonal substrates.

Free Energy Calculations of Electrolyte Decomposition Reactions on Lithium Battery Electrodes — •Azad Kirsan and Bernd Meyer — Interdisciplinary Center for Molecular Materials and Computer Chemistry Center, FAU Erlangen-Nürnberg

For the development of lithium metal batteries (LMBs) it is essential to understand how a stable solid electrolyte interphase (SEI) is formed. Ethylene carbonate (EC), a commonly used electrolyte, plays a critical role in SEI formation through its electrochemical decomposition at the electrode surface. Thus, insights into the mechanism of the decomposition reaction are of crucial importance for understanding the processes that govern SEI composition, structure and stability.

In this work, *ab initio* molecular dynamics simulations using state-of-the-art enhanced sampling methods (metadynamics, umbrella sampling, well-sliced metadynamics [1]) including explicitly the liquid electrolyte were performed in order to unravel the reaction mechanisms of the first steps of the EC dissociation on a Li_2O surface. The trajectories, encompassing more than 1 ns of sampling time, were used to reconstruct the free energy surfaces and obtain activation barriers for the decomposition reaction.

Optimizing Parameters in Metadynamics Simulations for Free Energy Calculations — •Marlene Sell, Azad Kirsan, and Bernd Meyer — Interdisciplinary Center for Molecular Materials and Computer Chemistry Center, FAU Erlangen-Nürnberg

The calculation of free energy surfaces (FES) is essential for understanding chemical reactions. Especially the free energy differences between educts, products and possible transition states, as well as the structure of the latter, allow insight into the nature of the reactions. Well-sliced metadynamics (WS-MTD) [1] is a novel method to calculate FES. It combines umbrella sampling and metadynamics in order to speed up the simulations. However, it employs several fine-tuning parameters whose exact influence on the efficiency and accuracy of the results is not yet well understood.

In this study, the FES of the reaction of 1,3-butadiene and ethylene to cyclohexene, the simplest Diels-Alder reaction, was calculated by WS-MTD. This reaction is well studied, both experimentally and theoretically, and could thus be used to compare the influence of the studied parameters. Using FES calculated with different values of the relevant parameters, the free energy differences between the educts, transition state and products were determined in the form of the activation barrier and reaction energy. These were compared to literature values from experimental and other theoretical studies.

O 34.3 Tue 13:30 P3

Exploration of the Pt(111)-water interface by high-dimensional neural network potentials — •Daniel Trzewik[1,2], Moritz R. Schäfer[1,2], Alexander L. Knoll[1,2], and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany

Detailed insights into solid-liquid interfaces are crucial for understanding many processes in catalysis and electrochemistry. Accurately modeling these interfaces using first-principles methods is computationally very demanding, which strongly restricts the complexity of the systems that can be studied. Machine learning potentials now can provide an efficient alternative with almost no loss in accuracy. In this study, high-dimensional neural network potentials (HDNNPs)

are employed to investigate the Pt(111)-water interface in detail. After training to DFT reference data, molecular dynamics simulations are utilized to uncover the structural and dynamical properties of the interfacial water molecules.

O 34.4 Tue 13:30 P3

Studying Tricalcium Silicate-Water Interfaces Using High-Dimensional Neural Network Potentials — •Henry Wang[1,2], Bernadeta Prus[1,2], and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany

The advent of machine learning potentials (MLP) trained to energies and forces from electronic structure calculations has revolutionized the simulation of solid-liquid interfaces by molecular dynamics (MD). For instance, High-Dimensional Neural Network Potentials (HDNNP) have shown excellent accuracy for describing the interaction of water with numerous solid minerals. In this study, we investigate interfaces of liquid water with alite (Ca_3SiO_5), an important cement mineral exhibiting various polymorphic states. Using large-scale MD simulations, an analysis of the structural and dynamical properties of interfacial water is presented.

O 34.5 Tue 13:30 P3

Electrocatalytic CO_2 Reduction in Ionic Liquid/Nitrile Electrolytes — •Björn Ratschmeier, Arik Geringswald, Alisa Kamaric, and Björn Braunschweig — University Münster, Institute of Physical Chemistry, Münster, Germany

Room-temperature ionic liquids (RTILs) play an important role in CO_2 reduction reactions (CO_2RR), providing a viable alternative to aqueous electrolytes, but face challenges such as high overpotentials and product selectivity. As we have previously shown for 1-butyl-3-methylimidazolium trifluorosulfonylimide ([BMIM][NTf_2]) electrolytes [1], the accessibility of water as a co-reactant at the interface is a limiting factor for CO formation potentials. To modulate the interfacial structure, different concentrations of acetonitrile and benzonitrile were introduced into [BMIM][NTf_2] electrolytes in the presence of 1.5 M H_2O. The resulting mixtures were investigated in terms of CO_2RR at polycrystalline Au electrodes. The presence of 7.5 M benzonitrile resulted in a 20-fold increase in CO formation, and in even higher CO concentrations with acetonitrile compared to the pure ionic liquid. Consequently, we propose that nitrile additives tune the interfacial structure in such a way that the access of water molecules is improved. In order to validate this hypothesis, we aim for an in-depth investigation of the bulk electrolyte as well as of the interfacial structure using *in situ* IR and SFG spectroscopy. Investigating Zinc Oxide-Water Interfaces with High-Dimensional Neural Network Potentials — •Jan Elsner and Jörg Behler — Theoretische Chemie II, Ruhr-Universität Bochum, Germany, and ResearchCenter Chemical Sciences and Sustainability, Research Alliance Ruhr,Germany

Zinc oxide (ZnO) is a promising material for sustainable hydrogen production via catalytic water splitting. The interface of ZnO with water exhibits complex dynamical behavior, including water dissociation and recombination, as well as long-range proton transport. Traditionally, density functional theory (DFT)-based molecular dynamics has been the primary theoretical tool for probing such mechanisms at the atomistic scale. However, the complexity of the interface, requiring large simulation boxes, and the long time scales associated with dynamical processes pose substantial theoretical challenges for any method relying on explicit electronic structure calculations. High-Dimensional Neural Network Potentials (HDNNPs) offer a solution to these challenges, enabling atomistic simulations with DFT-level accuracy at only a fraction of the computational expense. Here, we present HDNNP-based simulations of ZnO-water interfaces, providing insights into their structure and dynamics.

Comparision of spin and orbital Rashba effect in Bi_xPb_{1-x}/Ag(111) — •Himanshu Lohani — EP7 University of Wurzburg

Superstructure of heavy elements constructed on the surface of noble metals is one of the most celebrated system in the field of spintronics due to giant Rashba spin splitting found in its surface electronic structure. A new perspective of orbitronics has emerged recently for reinvestigating this system after the uprising of orbital based Rashba effect. Angle resolved photoelectron spectroscopy (ARPES) not only visualizes directly the electronic band dispersion but intensity of the photoemission signal itself carries important information of orbital character of the bands. By using the photoemission intensity calculation which is designed on a tight binding model, we successfully capture evolution of the Rashba surface state bands (SSBs) dispersion and intensity as they are observed in our ARPES data on Bi_xPb_{1-x}/Ag(111). This comparative study hints that buckling of Bi/Pb atoms on Ag(111) surface affects spin polarization of the Rashba SSBs more than their orbital polarization

O 35.2 Tue 13:30 P3

High-Dimensional Neural Network Potentials for Molecular Dynamics Simulations of Mineral-Water Interfaces — •Maite Böhm[1,2], Bernadeta Prus[1,2], and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany

In recent years, High-Dimensional Neural Network Potentials (HDNNP), a frequently used type of machine learning potential, have become a popular tool for simulations of complex systems such as mineral-water interfaces. Here, we present a HDNNP trained to density functional theory energies and forces for tricalcium aluminate ($Ca_3Al_2O_6$, C_3A)-water interfaces, which are of high interest for concrete chemistry. After validation, the obtained HDNNP is applied in large-scale molecular dynamics simulations to unravel the interactions of water with this material by computing a series of structural and dynamical properties.

O 35.3 Tue 13:30 P3

Informed Automated Structure Discovery of Atomic Force Microscopy Images — •Azin Alesafar[1], Joakim Jestilä[1], and Adam Foster[1,2] — [1]Department of Applied Physics, Aalto University, Espoo, Finland — [2]Nano Life Science Institute (WPI-NanoLSI), Kanazawa University, Kanazawa, Japan

Atomic Force Microscopy (AFM) enables direct imaging of atomic-level features however, the interpretation of non-planar molecules is challenging due to the fact that only the top layers of these systems interact with the microscope tip. This leads to images deviating from structures familiar to us. Recent Advances in machine learning-based image recognition tools have provided a framework suited to tackle this challenge. However, these methods rely heavily on training data and may produce inaccurate results when faced with unfamiliar structures. An alternative approach is to develop an iterative algorithm that generates realistic 3D structures by comparing simulated and experimental AFM images in a fully automated manner. The final workflow enables the generation of candidate structures using different techniques, such as molecular dynamics, minima hopping, or machine learning models. A deeper understanding of the simulated structural information is achieved through feature detection algorithms and image registration. Furthermore, the simulated structures, and consequently their corresponding AFM images, are automatically evaluated for similarity to reference AFM images using image quality metrics. These approaches are tested on water clusters modeled on gold and copper surfaces using the Neural equivariant interatomic potential (NequIP).

O 35.4 Tue 13:30 P3

In situ electrochemical atomic force microscopy studies of a copper surface during lithium plating and dissolution — •Luca Kaufer[1,2], Daniel Ebeling[1], Thomas Göddenhenrich[1], André Schirmeisen[1], and Jürgen Janek[2] — [1]Institute of Applied Physics, Justus-Liebig-University, Gießen, Germany — [2]Institute of Physical Chemistry, Justus-Liebig-University, Gießen, Germany

This investigation demonstrates the utilisation of atomic force microscopy (AFM) to examine the interactions between liquid electrolytes and copper electrodes. In particular, the focus is on the deposition of lithium on copper surfaces, a crucial process in lithium batteries. Atomic force microscopy (AFM) measurements allow for precise analysis of the surface structure, morphology and dynamic changes during lithium deposition, thereby providing deeper insights into the mechanisms of electrode reactions and the quality of the electrode surface. Such measurements are of great importance to improve the efficiency and lifetime of batteries by helping to understand and control processes such as dendritic growth or non-uniform deposition.[1,2] We will include an examination of the modification of the single-crystal electrode surface, which has been achieved through the utilisation of a bespoke methodology that integrates sputtering, annealing and polishing techniques.

O 36: Poster 2D Materials: Electronic Structure and Exitations (joint session O/HL)

Time: Tuesday 13:30–15:30 Location: P3

O 36.1 Tue 13:30 P3

Spin-orbit coupling in non-van der Waals 2D materials — •Mani Lokamani[1], Gustav Bihlmayer[2], Gregor Michalicek[2], Daniel Wortmann[2], Stefan Blügel[2], and Rico Friedrich[1,3,4] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden — [2]Forschungszentrum Jülich — [3]TU Dresden — [4]Duke University, Durham, USA

In recent years, the emerging class of non-van der Waals 2D materials has attracted considerable interest due to the unique electronic and magnetic properties of the representatives [1]. We study here the role of spin-orbit coupling (SOC) in these non-van der Waals 2D systems and related effects that might eventually lead to topological properties. With several 2D candidates including heavy elements such as Bi and Tl, significant effects due to SOC are present in the electronic structure. For the initial screening, we employ AFLOW [2] with its standardized workflows. In a second step, we retrieve the metadata using AFLOW and adapt the extracted parameters with an AiiDA-plugin [3] for accurate electronic structure calculations using the full-potential all-electron program FLEUR [4] within AiiDA. We discuss the effect of SOC on the band structures and densities of states and also focus on the topologically protected 1D conduction edge channels [5].

O 36.2 Tue 13:30 P3

Influence of surface relaxations on scanning probe microscopy images of the charge density wave material $NbSe_2$ — Nikhil S. Sivakumar[1], Joost Aretz[1], •Sebastian Scherb[1], Marion van Midden Mavric[2], Nora Huijgen[1], Umut Kamber[3], Daniel Wegner[1], Alexander A. Khajetoorians[1], Malte Rösner[1], and Nadine Hauptmann[1] — [1]IMM, Radboud University, Nijmegen, The Netherlands — [2]Jožef Stefan Institute, Ljubljana, Slovenia — [3]Joseph Henry Laboratories and Department of Physics, Princeton University, Princeton, USA

Scanning tunneling microscopy (STM) images of the charge density wave (CDW) in 2H-$NbSe_2$ at voltages around the Fermi level lack a contrast inversion expected for a single-band CDW. Recent works have ascribed this to a multi-band CDW or the displacement of the surface Se atoms. While STM cannot disentangle geometric and electronic structure variations, non-contact atomic force microscopy (nc-AFM) can provide better characterization of the geometric structure due to its sensitivity to the interaction between the charge densities of tip and surface. We employ distance-dependent combined constant-height STM/nc-AFM measurements to characterize the surface relaxations of 2H-$NbSe_2$. Nc-AFM images show different image contrasts depending on distance. Based on ab-initio calculations, we show that the contrast at small distances is dominated by the displacement of the surface Se atoms. For large distances, the contrast is dominated by the interaction of the permanent dipole of the tip with the potential above the surface that is predominantly modulated by the underlying Nb atoms.

O 36.3 Tue 13:30 P3

Investigation of the electronic structure of 1T-$Ta_{1-x}Mo_xS_2$ using 11eV-laser ARPES — •Adina Timm[1,2], Florian K. Diekmann[1,2], Jana Kähler[1,2], Matthias Kalläne[1,2,3], Tim Riedel[1,2], and Kai Rossnagel[1,2,3] — [1]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany — [2]Ruprecht Haensel Laboratory, Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany — [3]Kiel Nano, Surface and Interface Science KiNSIS, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany

The ability to modify the electronic structure of quantum materials by controlling charge density waves (CDWs) offers various possibilities for use in next-generation technologies as electronic and optoelectronic components. A material platform for testing this approach is 1T-TaS_2, which exhibits different temperature-dependent CDWs that we aim to tune by doping. Using 11eV-laser ARPES, we determine the differences in the electronic band structure of both doped and pristine TaS_2 crystals. The dopant molybdenum was introduced into TaS_2 during crystal growth by chemical vapor transport. The photoemission results show that different CDW phases are present at low doping concentrations of less than one percent with modified transition temperatures.

O 36.4 Tue 13:30 P3

Magnetic properties of V-doped WSe2 — •Jules M. Knebusch[1,2], Jana Kähler[1,2], Matthias Kalläne[1,2,3], Tim Riedel[1,2], Florian K. Diekmann[1,2], Adina Timm[1,2], and Kai Rossnagel[1,2,3] — [1]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany — [2]Ruprecht Haensel Laboratory, Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany — [3]Kiel Nano, Surface and Interface Science KiNSIS, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany

Spintronics holds promise for highly efficient classical and quantum computing and is therefore considered a key technology for future innovation. Pristine tungsten diselenide (WSe_2), known as a semiconductor with a two-dimensional hexagonal 2H structure, is expected to transform into a room-temperature dilute ferromagnetic semiconductor upon vanadium doping, making it a highly attractive candidate for spintronic applications. This assumption is supported by density functional theory calculations and scanning transmission electron microscopy studies, and RKKY interactions are predicted as the driving mechanism. The crystals investigated in this study were synthesized in-house employing the chemical vapor transport method. This process produced as-is vanadium-doped WSe_2 crystals with approximately 2% of the tungsten atoms (presumably) substituted by vanadium. The results reported here were obtained using a Physical Property Measurement System (PPMS) in ACMS configuration and provide valuable insights into the magnetic characteristics of this doped material.

O 36.5 Tue 13:30 P3

Polarons in single-layer MoS_2 via downfolding approach to the coupling of electronic and nuclear degrees of freedom — •Laura Pätzold[1], Camiel van Efferen[2], Arne Schobert[1], Tfyeche Y. Tounsi[2], Michael Winter[1], Mark Georger[2], Affan Safeer[2], Christian Krämer[2], Jeison Fischer[2], Jan Berges[3], Thomas Michely[2], Roberto Mozara[1], Wouter Jolie[2], and Tim O. Wehling[1,4] — [1]U Hamburg — [2]U Köln — [3]U Bremen — [4]The Hamburg Centre for Ultrafast Imaging

A polaron is a quasiparticle describing a localized bound state resulting from the interaction of charge carriers with lattice vibrations. Though they are a well-studied phenomenon, experimental observations of polarons in 2D crystals are sparse. Here, we present the theoretical analysis of polaronic distortions in n-doped single-layer MoS_2 via a downfolding approach with linear electron-lattice coupling based on density functional theory calculations [1]. With this, a multi-polaronic distortion, caused by a renormalized M-point phonon, can be stabilized on supercells of up to 18×18. We compare our results to scanning tunneling microscopy measuremens obtained on n-doped single-layer MoS_2, which support the existence of polarons emerging from the coupling of non-polar zone-boundary phonons to Bloch electrons. This tunneling into the vibrationally coupled polaronic states is visible through evenly spaced peaks around the Fermi energy in the differential conductance, whose spacing matches the frequency of the M-point phonon responsible for the multi-polaronic distortion in our simulations.

O 36.6 Tue 13:30 P3

Electronic and phononic characterization of 2H-NbS2 at the atomic scale — •Werner M.J. van Weerdenburg, Margarete Huisinga, and Katharina J. Franke — Fachbereich Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany

Transition metal dichalcogenides (TMDs) are a class of layered materials that can exhibit a variety of electronic properties, including low-temperature quantum phases such as superconductivity and charge density wave (CDW) formation. These phases may coexist, for instance in 2H-NbSe2, and electron-phonon interactions have been suggested as a common driving factor for the two phases [1]. In contrast, the similar compound 2H-NbS2 has a comparable superconducting critical temperature, but lacks a CDW phase [2], highlighting the importance of subtle differences in electron-phonon interactions.

Here, we apply scanning tunneling microscopy and spectroscopy (STM/STS) to investigate the electronic and phononic properties of 2H-NbS2 at the atomic scale. Based on quasiparticle interference mapping, we probe the spatial variation of the electronic density of states and identify the dispersion of the band structure around the Fermi level. Moreover, inelastic excitation spectroscopy reveals the phononic excitations of the material. By mapping the atomic-scale variation of phononic excitations around intrinsic defects of the material and adatoms, we study how electrons and phonons interact at the atomic scale.

O 36.7 Tue 13:30 P3

Characterization of surficial defect states in Mott insulator 1T-TaS_2 — •Junyoung Sim, Vibhuti Rai, Christian Lotze, and Katharina J. Franke — Freie Universtät Berlin, Department of Physics, Arnimallee 14, 14195 Berlin, Germany

The Mott insulating state in 1T-TaS_2, arising from strong correlations among unpaired electrons within its charge density wave superlattice, is distinct from a trivial band insulator and serves as a model system for exploring the dynamics of

exotic many-body states [1]. Here, we investigate bulk 1T-TaS_2 using scanning tunneling microscopy (STM) at 5 K. We find arious nanoscopic defects including vacancies, and domain. Additionally, we adsorb transition metal adatoms on the bare surface. Using tunneling spectroscopy, we map out their electronic signatures and compare them to prior studies [2].

O 36.8 Tue 13:30 P3

FinEstBeAMS: a multipurpose VUV and soft X-ray beamline at the max iv laboratory — •Weimin Wang, Antti Kivimäki, Kirill Chernenko, Calle Preger, and Stephan Appelfeller — MAX IV Laboratory, Lund University, PO Box 118, SE-22100 Lund, Sweden

The Finnish-Estonian Beamline for Atmospheric and Materials Science (FinEstBeAMS), located at the 1.5 GeV storage ring of the MAX IV Laboratory (Lund, Sweden), is a multidisciplinary beamline that was designed to fulfil the various needs of scientific communities in atomic, molecular and optical research, surface science, and photoluminescence research.

The gas-phase end station is equipped for electron and time-of-flight ion spectroscopies in low-density matter, while the photoluminescence end station focuses on luminescence spectroscopy of solid samples. The solid-state end station is dedicated to photoelectron and X-ray absorption spectroscopy of surfaces and interfaces, utilizing a hemispherical electron energy analyzer (PHOIBOS 150 2D-DLD from SPECS). The sample is positioned via a 5-axis motorized manipulator, offering three linear and two rotational motions (polar and azimuthal). A cryostat integrated into the manipulator enables sample cooling with liquid helium (~50 K) and nitrogen (~90 K). Additionally, a preparation chamber allows for sample treatment and analysis using supplementary techniques.

O 37: Poster 2D Materials Beyond Graphene: Growth, Structure and Substrate Interaction (joint session O/HL)

Time: Tuesday 13:30–15:30 Location: P3

O 37.1 Tue 13:30 P3

Two-dimensional hexagonal β-GeSe on Au(111) — •Dina Wilks, Veronika Blecker, Muhammad Ali Martuza, Marina Hammer, Christoph Schuster, Paulus Aleksa, and Carsten Busse — Walter-Flex-Straße 3, 57072 Siegen, Germany

Two-dimensional (2D) group-IV monochalcogenides (general form MX with M=Sn, Ge; X=S, Se, Te) demonstrate a high degree of polymorphism. While the orthorhombic phase, widely studied for its in-plane ferroelectricity, holds significant promise, experimental studies on other polymorphs remain scarce.

Here, we investigate the growth and structure of 2D hexagonal β-GeSe on Au(111). This phase is predicted to exhibit out-of-plane ferroelectricity, which could be more technologically feasible for device integration. Samples are prepared using molecular beam epitaxy (MBE) with GeSe powder as the source material and analyzed with low energy electron diffraction (LEED) and scanning tunneling microscopy (STM). The degree of structural order was found to depend sensitively on the heat treatment. We observe a (5×5) superstructure relative to Au(111), accompanied by a continuously varying density of states (DOS) across the superstructure's unit cell. Additionally, an intriguing self-similar pattern emerges, which can be attributed to antiphase grain boundaries. These boundaries exhibit metallic behaviour near the Fermi level, highlighting their potential significance in the electronic properties of the system.

O 37.2 Tue 13:30 P3

Scanning Tunneling Microscopy and Spectroscopy of epitaxial grown TaS_2 on GaN (0001) — •Jan-Niclas Schmidt, Constantin Hilbrunner, Georg A. Traeger, Jörg Malindretos, Angela Rizzi, and Martin Wenderoth — University of Göttingen, IV. Physikalisches Institut, Fridrich-Hund-Platz 1, 37077 Göttingen

Tantalum Disulfide crystals are interesting due to its complex phase diagram including the effect of Charge Density Waves. We are interested in how the layer thickness influences properties of Tantalum Disulfide. With Molecular Beam Epitaxy a three monolayer thick film of 2H-Tantalum Disulfide was grown on Gallium Nitride. To gain insight into the growth mechanism, the sample was transferred to a low temperature Scanning Tunneling Microscope (STM) operated at 80 K. To avoid any surface contamination, the transfer was done with a portable ultrahigh vacuum chamber. The constant-current STM-topography show small nanometer-sized, trigonal islands on a rough layer with some holes. The spectroscopy data show metallic behavior for the island as well as for the layer below.

This work is financially supported by the DFG through the SFB1073.

O 37.3 Tue 13:30 P3

Growth dynamics of 2D materials on Ir(111) — •Smruti Ranjan Mohanty, Marko Kriegel, Frank Meyer zu Heringdorf, and Michael Horn- von Hoegen — Faculty of Physics and Center for Nanointegration, Duisburg-Essen (CENIDE), University of Duisburg-Essen, 47048 Duisburg, Germany

The structure and morphology of 2D materials are profoundly influenced by the choice of growth substrates, with noble metal substrates offering enhanced catalytic activity and complex surface morphology facilitating precise control over the growth of 2D materials. Employing low-energy electron microscopy (LEEM), we investigated the kinetics of graphene island nucleation during the CVD of ethylene on Ir(111) at growth temperatures ranging from 750°C to 1050°C for various dosing pressures. Graphene islands nucleate heterogeneously at Ir(111) step edges, leading to edge decorations, but a transition to homogeneous nucleation occurs at island densities lower than the step density. The strong variation in island density as a function of growth temperature and dosing pressure is explained by Venables nucleation theory, with the near-linear dependence on dosing pressure attributed to a critical nucleus size (i*) of 5. The work presented here also extends to the growth and characterization of other atomically thin 2D materials, including hexagonal boron nitride (hBN), and borophene on Ir(111). The investigation reveals complex growth mechanisms, the emergence of Moiré superlattices, and substrate-influenced interactions, providing insights for designing heterostructures and functional materials with significant potential for next-generation technological applications.

O 37.4 Tue 13:30 P3

Incommensurability and negative thermal expansion of single-layer hexagonal boron nitride — •Marko Kriegel[1], Karim Omambac[1], Steffen Franzka[2], Frank Meyer zu Heringdorf[1,2], and Michael Horn-von Hoegen[1] — [1]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Lotharstr. 1, 47057 Duisburg, Germany — [2]Interdisciplinary Center for Analytics on the Nanoscale (ICAN), Carl-Benz-Str. 199, 47057 Duisburg, Germany

The emerging field of straintronics, i.e., the control and utilization of the strain state of 2D-materials, is of great importance for their technological development, specifically in view of their future incorporation into van der Waals heterostructures. To gain fundamental insight into structural peculiarities of two-dimensional systems, single-layer hexagonal boron nitride (hBN) grown on Ir(1 1 1) by chemical vapor deposition was used as a prototypical model system: High-resolution reciprocal space mapping reveals the incommensurate nature of the material system by measuring the *h*BN in plane lattice parameter with high precision, facilitated by the moiré magnification effect in electron diffraction. In a growth temperature (T_g) regime of 700 to 1150°C an average lattice parameter of 2.496 ± 0.006 Å was found. Eventually, careful disentanglement of the hBN and substrate behavior for rising T_g allowed the determination of a negative thermal expansion coefficient of $\alpha_{hBN} = 2.4 \pm 1.2 \times 10^{-6}\,K^{-1}$ for free-standing hBN.[1] [1] M. Kriegel et al. Appl. Surf. Sci. 624 (2023) 157156

O 37.5 Tue 13:30 P3

UHV-CVD on Ir(111) for the Growth of 2D Materials — •Niels Ganser[1], Marko Kriegel[1], Karim Omambac[1], Marin Petrovic[2], Christian Brand[1], Steffen Franzka[3], Birk Finke[1], Tobias Hartl[4], Thomas Michely[4], Frank-Joachim Meyer zu Heringdorf[1], and Michael Horn-von Hoegen[1] — [1]Universität Duisburg-Essen — [2]Institute of Physics, Zagreb — [3]ICAN, Duisburg — [4]Universität zu Köln

Hexagonal boron nitride (hBN) can be grown by scalable chemical vapor deposition (CVD) from a borazine $B_3N_3H_6$ precursor. Here we show that the hBN quality depends strongly on the growth temperature T_g and the dosing pressure *p*.

Combined SPA-LEED and LEEM measurements show a strong dependence of *n* on *p*. We find that the quality of the hBN layers that can be achieved by increasing T_g is limited by the process of disintegration of the borazine at $T_g > 950$°C resulting in growth of borophene (2D Boron) instead [1]. Thus, it is possible to selectively grow either hBN or borophene from the same precursor [2].

Corroborating SPA-LEED measurements reveal a negative thermal expansion coefficient of $\alpha = (-2.4 \pm 1.2) \times 10^{-6}\,K^{-1}$ for 2D hBN in the temperature regime between 700 and 1100 °C. This finding can be explained by Lifshitz' membrane effect [3].

Stability and electronic properties of double-layer o-B2N2 in different stacking modes — •Na Li and Claudia Draxl — Department Physics and CSMB, Humboldt-Universit at zu Berlin, D-12489 Berlin, Germany

Two-dimensional orthorhombic boron nitride (o-B2N2) has recently attracted significant attention due to its direct band gap of approximately 1.7eV and excellent visible-light absorption properties. In its layered conformations, the stacking order plays a crucial role in determining the material's stability as well as its electronic and optical properties. In this study, we employ the all-electron full potential code exciting to perform first-principles calculations of four high-symmetry bilayer stacking sequences of o-B2N2, regarding their relative stability and their electronic properties. Our calculations reveal that the AB' stacking sequence has the lowest energy and an optimized interlayer distance of 3.52 Å. The bandgaps of the AA and AA' stacking sequences are reduced relative to the monolayer, where AA' exhibits even semi-metallic behavior. In contrast, the AB and AB' stacking sequences show slightly increased direct bandgaps.

O 38.2 Tue 13:30 P3

In-depth analysis of stratified MoS2 and WS2 2D heterostructures — •Sebastian Klenk, Nikolas Dominik, Cormac Ó Coileáin, Tanja Stimpel-Lindner, and Georg S. Duesberg — University of the Bundeswehr Munich, Institute of Physics, Germany

Starting with graphene roughly two decades ago, two-dimensional (2D) materials have garnered great interest in the scientific community due to their exceptional electrical, mechanical and optical properties. The broad palette of different 2D materials has allowed for the possibility to change and finetune these parameters to one's own liking by combining several 2D materials in one film. Here, we present the metal-organic chemical vapour deposition (MOCVD) synthesis and analysis of MoS2/WS2 heterostructures. We show the ordering of a high-quality 7-layer combination structure of less than 10 nm. The layered nature is confirmed and discussed using XPS, EDX, ToF-SIMS, TEM, AFM and Raman spectroscopy.

O 38.3 Tue 13:30 P3

A Two-dimensional Heterostructure Fabrication System in Ultra-high Vacuum — •Daiyu Geng, Jiabao Yang, Natalie Lehmann, and Niels Schröter — Max Planck Institute of Microstructure Physics, Weinberg 2, Halle (Saale), Germany

We develop an ultra-high vacuum system for the fabrication of two-dimensional heterostructures. The clean transfer and stacking of two dimensional material flakes are realized using a polymer-free method based on SiNx cantilevers coated with Au film (Nature Electronics, 2023, 6(12): 981-990). The system also incorporates multiple surface preparation and characterization techniques like MBE, Plasma sputtering and electron diffraction. All these methods enable us to prepare heterostructures with atomically clean interface, which is important for the spectroscopic investigation of the rich physics effects in two-dimensional heterosystems.

O 38.4 Tue 13:30 P3

Exploring MXenes as Electrodes for Al-ion Batteries: An Ab-initio Study on the Impact of Stacking Configurations and Termination Types — •Amal Raj Veluthedath Nair and Nuala M Caffrey — School of Physics, University College Dublin, Dublin 4, Ireland

MXenes, with their tunable surface chemistry, thin 2D structures, large interlayer spacing, and good conductivity, are promising candidates for battery electrodes. The stacking configuration of MXene layers, determined by their chemistry and surface terminations, influences their electrochemical performance.

This study explores Ti_3C_2 and V_2C MXenes as electrodes for Na, Mg, and Al-ion batteries using density functional theory. We examine four stacking configurations and two coordination sites for intercalated ions. Results reveal that stacking configuration and surface terminations significantly influence change in interlayer distance, with O-terminated octahedral stacking showing the least change in spacing for all intercalants. The smallest interlayer distance change occurs for Al intercalation in V_2C, with a Δd of 0.1 Å, matching experimental findings (Vahidmohammadi et al., 2017). Ion migration studies indicate that prismatic stacking promotes faster ion migration compared to octahedral stacking. O-terminated MXenes significantly enhance the theoretical specific capacity for Al intercalation, reaching a maximum value of 283.48(277.63)mAh/g for $Ti_3C_2O_2(V_2CO_2)$. In contrast, F-terminated MXenes show much lower capacities.

O 38.5 Tue 13:30 P3

Triplet pairing enabled proximity superconductivity in monolayer WTe_2 — •A. Bäder[1,2], T. Wichmann[1,3], J. Martinez-Castro[1,4], P. Rüssmann[5,6], K. Jin[1,4], T. Samuely[7], Z. Lyu[1,3], J. Yan[8], O. Onufriienko[7], P. Szabó[7], F. S. Tautz[1,3], M. Ternes[1,4], S. Lounis[5,9], and F. Lüpke[1,2] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich — [2]II. Physikalisches Institut, Universität zu Köln — [3]Institut für Experimentalphysik IV A, RWTH Aachen — [4]Institut für Experimentalphysik II B, RWTH Aachen — [5]Peter Grünberg Institut (PGI-1), Forschungszentrum Jülich — [6]Julius-Maximilians-Universität Würzburg, Fakultät für Physik und Astronomie — [7]Centre of Low Temperature Physics, Faculty of Science, Pavol Jozef Šafárik University & Institute of Experimental Physics, Slovak Academy of Sciences — [8]Materials Science and Technology Division, Oak Ridge National Laboratory, USA — [9]Fakultät für Physik, Universität zu Duisburg-Essen

We use low-temperature scanning tunneling microscopy to investigate proximity-induced triplet pairing and its role in enabling superconductivity in a monolayer $WTe_2/NbSe_2$ van der Waals heterostructure. Employing the Kohn-Sham Bogoliubov-de Gennes formalism, we find that conventional s-wave pairing fails to induce superconductivity in the WTe_2, in contrast to triplet pairing. Applying an external magnetic field, we examine Abrikosov flux vortices within the heterostructure and exploit them to probe local superconducting properties. Our findings highlight a platform for studying triplet pairing-induced superconductivity with potential topological characteristics.

O 39: Oxides and Insulator Surfaces: Adsorption and Reaction of Small Molecules I

Instrumental Innovations for Model Single-Atom Catalysis — •Jiří Pavelec, David Rath, Chunlei Wang, Nail Barama, Panukorn Sombut, Matthias Meier, Michael Schmid, Ulrike Diebold, and Gareth S. Parkinson — TU Wien, Vienna, Austria

Single-atom catalysts (SACs) reduce reliance on precious materials by using individual atoms as active sites. Infrared spectroscopy of adsorbed CO is widely used to probe these sites, but spectral interpretation and charge-state assignment remain debated. Surface science studies of model SACs could provide valuable benchmarks, but progress has been hindered by a lack of model systems and challenges in detecting low coverages of intermediates.

Here, I introduce a novel approach to infrared reflection absorption spectroscopy (IRAS) that adjusts the incidence angle, which resolves signal-to-noise issues on dielectrics [1]. As a case study, we investigated CO titration of rhodium-based SACs on a $Fe_3O_4(001)$ support. The spectra reveal Rh_1CO monocarbonyls as the dominant species. Meanwhile, the $Rh_1(CO)_2$ gem-dicarbonyl arises solely from the breakup of minority Rh_2 dimers, as confirmed by STM movies and theoretical modeling [2]. Though less prevalent in our UHV study, $Rh_1(CO)_2$ may play a critical role under realistic conditions.

Combining advancements in IRAS with a detailed understanding of model SACs provides valuable benchmarks for theoretical studies and spectral references for researchers working with less-defined, high-surface-area powder catalysts. [1] D. Rath et al., Rev. Sci. Instrum. 95, (2024). [2] C. Wang et al., Angew. Chem. Int. Ed. 63, (2024).

O 39.2 Tue 14:15 H4

Structure and oelic acid adsorption properties of magnetite nanoparticles on $SrTiO_3$ — •mohammad ebrahim haji naghi tehrani[1,2], lucio martinelli[3], daniel silvan dolling[1,2], marcus creutzburg[1], ming chao kao[1,2], alexander meinhardt[1,2], mona kohantorabi[1], heshmat noei[1], and andreas stierle[1,2] — [1]Deutsches Elektronen-Synchrotron (DESY), Hamburg, Germany — [2]Fachbereich Physik Universität Hamburg, Hamburg, Germany — [3]Institut Néel, CNRS, Grenoble INP, Université Grenoble Alpes, Grenoble, France

The underlying explanation for the exceptional mechanical properties of hierarchically arranged magnetite nanoparticle super-crystals is closely linked to understanding the oxide-organic interface between the magnetite nanoparticles (NPs) and the oleic acid (OA) molecules. We studied the shape and surface structure changes of the magnetite NPs induced by crosslinking the OA molecules. In this regard, magnetite NPs were grown by reactive physical vapor deposition on a strontium titanate single crystalline surface (STO(001)). The structural and morphological changes in the NPs were monitored under ultra-high

vacuum (UHV) conditions employing synchrotron-based grazing incidence X-ray diffraction (GIXRD). We evidenced the growth of (001) oriented magnetite NPs with predominant (111) side facets. Additionally, our results indicate an increase in the NP lattice constant after OA adsorption, which may be attributed to the incorporation of oxygen vacancies.

O 39.3 Tue 14:30 H4

Towards Understanding the Photoreactivity of $SrTiO_3$ through Studies in Ultra-High Vacuum — •Anna Lemperle, Philip Petzoldt, Martin Tschurl, and Ueli Heiz — Chair of Physical Chemistry, School of Natural Sciences & Catalysis Research Center, Technische Universität München, Lichtenbergstr. 4, 85748 Garching, Germany

Heterogeneous photocatalysis offers the prospect of utilising solar energy for the zero-carbon production of hydrogen from water. The most prominent photocatalytic materials currently employ $SrTiO_3$ as the light harvesting semiconductor. While these catalysts have been shown to promote a stoichiometric reaction, their photocatalytic performance is still insufficient for economically viable application. As their structural complexity impedes mechanistic studies, model systems are necessary to elucidate individual reaction steps and connect catalytic results to distinct catalyst properties. This approach aims to attain a molecular understanding of the reaction mechanisms involved in water splitting in order to enable a more targeted design of photocatalysts. In this contribution, we discuss first results on the reactivity of water and oxygen on the bare $SrTiO_3(110)$ surface. Results obtained by combining temperature programmed desorption and studies under illumination highlight the importance of bulk and surface oxygen for the reactivity of $SrTiO_3$.

O 39.4 Tue 14:45 H4

Effect of Mn and V Doping on the OER activity of $Co_3O_4(001)$: insights from DFT+U calculations — •Palani Muthu Kumar and Rossitza Pentcheva — Department of Physics, University of Duisburg-Essen

Using density functional theory calculations with a Hubbard U term (DFT+U), we study the effect of Mn and V doping on the oxygen evolution reaction (OER) at the $Co_3O_4(001)$ surface. In bulk, both dopants favor the octahedral over the tetrahedral site, providing a foundation for understanding the incorporation at the surface. Both at the A and the B-terminations of $Co_3O_4(001)$, Mn doping at a surface octahedral site enhances the overpotential, reducing overall the OER efficiency. In contrast, at the B-layer, V doping at a surface octahedral site reduces the overpotential from 0.48V (pristine) to 0.43 V, retaining the Co_{oct} reaction site. At the pristine A-surface, η is higher for a tetrahedral (0.74 V) vs. octahedral surface Co site (0.55 V). This trend is reversed for V-doping in the subsurface octahedral site which leads to the lowest overpotential of 0.18 V at the Co_{tet} reaction site. In all studied cases, the potential determining step is the deprotonation of *OH to *O. The improved catalytic activity due to V doping is attributed to a modified charge redistribution on the surface, leading to favorable binding energies of the intermediates. Funding by DFG within CRC247 and computational time at the Leibniz Rechenzentrum are gratefully acknowledged.

O 39.5 Tue 15:00 H4

Complex structural arrangements at the $CO_2/In_2O_3(111)$ interface — Sarah Tobisch[1], Andreas Ziegler[2], Marco Knapp[1], Michael Schmid[1], Ulrike Diebold[1], Bernd Meyer[2], and •Margareta Wagner[1] — [1]Institut für Angewandte Physik, TU Wien — [2]ICMM & CCC, FAU-Erlangen-Nürnberg

Promising catalysts for the hydrogenation of CO_2 to methanol are highly desired to address the pressing issue of rising carbon emissions. Since reactions take place at the interface, understanding the fundamental properties and behavior of molecular species on well-defined surfaces is crucial for designing model catalysts.

In_2O_3 has gained attention as catalytic material due to its high selectivity for methanol synthesis via CO_2 reduction. In this work, the adsorption and interaction of CO_2 molecules on $In_2O_3(111)$ were investigated in detail at the atomic scale and under UHV conditions. We employ non-contact atomic force microscopy (AFM) and compared our findings with results from temperature programmed desorption (TPD) and x-ray photoelectron spectroscopy (XPS) measurements, as well as density functional theory (DFT) calculations. AFM images of the $In_2O_3(111)$ surface show 10 molecular features per surface unit cell arranged in a systematic and uniform order, albeit breaking the threefold symmetry of the substrate surface. The adsorption sites of all individual molecules were identified; some of them are carbonate species, in agreement to XPS showing a mixture of CO_2 molecules and CO_3^{2-}. Moreover, the desorption and structural evolution with increasing temperature was studied.

O 39.6 Tue 15:15 H4

Adsorption and activation of CO_2 on CeO_2 surfaces — •Zairan Yu, Shuang Chen, Wangtao Li, Alexei Nefedov, Christof Wöll, and Yuemin Wang — Institute of Functional Interfaces (IFG), Karlsruhe Institute of Technology (KIT), 76344 Eggenstein-Leopoldshafen, Germany

CO_2 activation and its subsequent transformation into valuable chemicals pose significant challenges in heterogeneous catalysis. Most studies have focused on powdered catalysts with various facets and unknown defect densities, whereas much less is known about the surface chemistry of CO_2 on well-defined oxide surfaces. Here, we investigate CO_2 adsorption and activation on fully oxidized $CeO_2(111)$ single-crystal surfaces using polarization-resolved IR reflection absorption spectroscopy (IRRAS). The comprehensive IRRAS data reveal that CO_2 is weakly bound to $CeO_2(111)$ at 117 K in a linear, physisorbed state. At elevated temperatures (300 K) and pressures, CO_2 undergoes activation forming an unusual horizontal carbonate. Additionally, in the presence of surface hydroxyl groups, formate and HCO_3 species are identified. These experimental findings are supported by complementary theoretical analysis. Furthermore, the IRRAS results are in excellent agreement with the in situ transmission IR data obtained for CO adsorption on octahedral ceria nanoparticles, which predominantly expose (111) facets. This work was funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) -Project-ID 426888090- SFB 1441.

Manipulation of Optical Phonons in Strained Bi/Si(001) Heterostructures — •Fabian Thiemann and Michael Horn-von Hoegen — University of Duisburg-Essen, Lotharstr. 1, 47057 Duisburg, Germany

Intentionally manipulating phononic properties in materials can cause dramatic changes in their dynamic behavior. A system that responds especially strong to structural changes is Bi due to its strong electron-phonon coupling and its inherent Peierls distortion. This renders the optical A_{1g} mode – oscillating along the [111] direction – sensitive to changes in the electronic system and coherently excitable upon photoexcitation. When grown on Si(001) bismuths lattice matches in the $[1\bar{1}0]$ direction, resulting in a compressive strain in the [110] direction, whereas the films are [111] oriented. The strain is relieved rapidly while increasing the thickness from 10 to 16 BL. This is predicted to influence the Peierls distortion heavily. In this work we extensively studied the impact of strain and confinement on the photoexcited coherent A_{1g} mode's frequency and dephasing in Bi/Si(001) heterostructures by in-situ transient-reflectivity spectroscopy. We observe a dramatic blueshift up to 0.2 THz, that can be preciesely tuned by the film thickness. The frequency however does not follow exactly the strain parameter and behaves differently in two regiemes. We attribute this discrepancy to the confinement in the [111] direction and the influence of the strongly shifting electron surface state.

O 40.2 Tue 14:15 H6

Coherent modulation of the charge density wave gap in 1T-$TiSe_2$ probed by tr-ARPES — •Jan Böhnke, Stephan Schmutzler, Mehul Jotshi, Cornelius Gahl, and Martin Weinelt — Freie Universität Berlin, Fachbereich Physik, Germany

Tuning the charge density wave (CDW) gap in 1T-$TiSe_2$ allows for the de/stabilization of the phase transition. An optical excitation breaks long-range order of the CDW state and results in a semi-metallic state on an ultrafast timescale as free carriers near the Fermi-level enhance Coulomb screening [1,2]. By employing time-resolved ARPES with 1.55 eV pump and 6.2 eV probe pulses, we discover for the first time fluence-dependent coherent modulations of the charge-density wave gap (closing and opening) in 1T-$TiSe_2$ at the Brillouin zone center. While for low excitation fluences, we mainly observe signatures of the CDW connected A_{1g}^* mode (3.45 THz), the optical A_{1g} phonon mode (6.1 THz) modulates the electronic structure near the gap for the high fluence regime. For an intermediate fluence we detect the transition from the A_{1g}^* to the A_{1g} mode. As we additionally find three image-potential states on the surface of 1T-$TiSe_2$, we can confirm the samples' low defect density at the surface after in-vacuum cleavage.

Impact of Coherent Phonons on Time-Resolved Optical Properties of WTe_2 — •Francesco Sammartino[1], Manuel Tuniz[1], Wibke Bronsch[2], Fulvio Parmigiani[1,2], and Federico Cilento[2] — [1]Università degli Studi di Trieste — [2]Elettra - Sinctrotrone Trieste

We study the ultrafast dynamics of tungsten ditelluride (WTe_2) along both its in-plane axes, by time-resolved reflectivity (TR-R) and time-resolved second-harmonic generation (TR-SHG) experiments with a varying pump fluence.

We identify two phonon modes: the shear phonon mode at 0.24 THz, indicative of uniform in-plane atomic shifts and detected in both TR-R and TR-SHG signals, and one at 2.4 THz, detected solely in the TR-R signal. We observe a large, fluence-dependent shift of up to ≈90° in the initial phase of the shear mode coherent oscillation, obtained in a narrow fluence range.

This evidence suggests that the excitation density can be used as a powerful knob to control the initial phase of the atomic displacements in a layered material.

O 40.4 Tue 14:45 H6

Controlled formation of thermodynamically unaccessible surface structures — •Simon B. Hollweger, Anna Werkovits, and Oliver T. Hofmann — Institute of Solid State Physics, Graz University of Technology, Austria

It is well known that organic molecules adsorbed on surfaces can form a variety of different surface structures. Which structure is the most favored one at a given temperature and pressure is determined by thermodynamics. However, in this study, we propose the idea of a mechanism with which we can control the formation of a specific metastable surface polymorph that can not be reached thermodynamically. With targeted temperature and pressure changes, a rearrangement process of the adsorbed molecules out of thermodynamic equilibrium is triggered. For specifically designed systems, this rearrangement of the adsorbed molecules leads to a kinetically trapped metastable surface polymorph. As a proof of principle for this proposed mechanism, kinetic Monte Carlo simulations of planar molecules adsorbing on a square lattice are conducted. We show that a metastable upright-standing structure of the planar molecules can be reached with a specific temperature and pressure profile applied to the system.

O 40.5 Tue 15:00 H6

Out of the Crystalline Comfort Zone: Sampling the Initial Oxide Formation at Cu(111) — •Felix Riccius, Nicolas Bergmann, Hendrik H. Heenen, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin, Germany

The oxidation of transition metal surfaces is widely recognized as a complex process that still bears many open questions, specifically at the microscopic level. Atomistic simulations could potentially uncover crucial insights, but state-of-the-art approaches are predominantly guided by human chemical intuition, leading to highly idealized surface representations. Here we demonstrate a systematic approach to model high-quality surface-phase diagrams, using the early oxidation of the Cu(111) surface as an example. To this end, we train a MACE machine learning interatomic potential (MLIP) to density functional theory calculations and combine its fast and accurate energetics with replica exchange molecular dynamics. We extensively explore the vast, thermodynamically relevant phase space and further develop surface phase diagrams based on increasingly involved theoretical frameworks. Our approach yields a comprehensive structural ensemble that predicts early Cu(111) oxidation to be characterized by O-Cu-O ring patterns, bearing significant disorder. Within the computed surface evolution, we recover trends in O-Cu-O ring distribution as a function of reaction conditions in line with scanning tunneling microscopy data. Our study illustrates how MLIPs and extensive sampling can be leveraged to rationalize metal surface oxidation fully *in silico* without the need to rely on experimental guidance.

O 40.6 Tue 15:15 H6

Photo-induced carrier and structural dynamics in anatase TiO_2 nanosheets — •Zhipeng Huang[1,2], Yan Yan[2], Xinxin Cheng[2,3], R. J. Dwayne Miller[4], and R. Kramer Campen[1] — [1]Faculty of Physics and Center for Nanointegration (CENIDE), University of Duisburg-Essen — [2]Max Planck Institute for the Structure and Dynamics of Matter — [3]SLAC National Accelerator Laboratory — [4]Departments of Chemistry and Physics, University of Toronto

Ultrathin anatase TiO_2 nanosheets with {001} facets have significantly higher activity for light-induced H_2 evolution than other TiO_2-based materials. The mechanism of this enhancement is not understood. Gaining such insight requires understanding the dynamics of charge carriers and their interactions with lattices after optical excitation. Here we characterize structural and charge carrier dynamics in these materials following UV excitation using ultrafast electron diffraction and transient absorption spectroscopy.

We observed an ultrafast lattice expansion and distortion in the nanosheets, occurring earlier than the Debye-Waller effect. Density Functional Theory (DFT) calculations suggest that the lattice expansion and distortion are induced by the trapping of charge carriers and the formation of large electron polarons. Compared to TiO_2 nanoparticles, the nanosheets exhibit significantly higher polaron populations, which explains their enhanced photocatalytic properties.

Oxide growth and oxide/metal interaction in CeO_x/Ni(111) — •Dominic Guttmann, Raquel Sánchez-Barquilla, Carlos Morales, and Jan Ingo Flege — Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology Cottbus-Senftenberg, Cottbus 03046, Germany

Ni/ceria catalysts exhibit a high activity and selectivity for CO_2 methanation, making them very promising candidates for applications within a sustainable economy. The redox properties of cerium oxide allow it to readily switch between Ce^{4+} and Ce^{3+} states, facilitating CO_2 activation and conversion. We have studied the so-called strong metal-metal oxide interactions in the inverse catalyst configuration CeO_x/Ni(111) prepared by reactive molecular beam epitaxy in an oxygen atmosphere. Under specific growth conditions, the CeO_x (111)-oriented islands of different heights preferentially align in registry with the Ni(111) surface or are rotated azimuthally by ±10°, as observed by low-energy electron diffraction. Analysis by X-ray photoelectron spectroscopy reveals that during growth, partial oxidation of the Ni(111) surface leads to the formation of a NiO interface layer between the CeO_x islands and Ni substrate, resulting in a complex CeO_x(111)/NiO(111)/Ni(111) system with significant oxide-metal interactions. Finally, when we expose the system to H_2, O_2, and CO_2 atmospheres, we observe a complex behavior of the cerium and nickel oxidation states, which correlate with morphological changes in the oxide islands.

O 41.2 Tue 14:15 H8

Size-dependent nanoparticle sintering under catalytic reaction conditions — •Thomas Florian Keller[1,2], Christoph Seitz[1], Henning Runge[1], Vedran Vonk[1], and Andreas Stierle[1,2] — [1]Centre for X-ray and Nano Science CXNS, Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [2]University of Hamburg, Department of Physics, Hamburg, Germany

Catalytic metal nanoparticles applied in heterogeneous gas phase catalysis are known to change their shape during the conversion. We elucidate the evolution of the height to diameter aspect ratios of a substantial number of PtRh alloy nanoparticles exposed to mild and harsh catalytic CO oxidation reaction conditions by correlative atomic force- and scanning electron-microscopy. The preferentially (111) oriented Pt rich nanoparticles supported on a (0001) Al_2O_3 single crystal surface were imaged as grown and after the exposure to the catalytic conditions. We utilized an image-registration based approach combined with one-by-one nanoparticle correlation to overcome single nanoparticle studies and ensemble averages. This approach permitted us to shed light onto the active size dependent sintering mechanism as e.g., particle migration and coalescence, and Ostwald ripening. While for mild catalytic conditions the aspect ratio is rather independent of the lateral nanoparticle size, for harsh conditions particles above an initial threshold diameter of around 45 nm tend to extraordinary grow on the cost of the surrounding smaller particles.

O 41.3 Tue 14:30 H8

High-throughput photocatalytic screening of lead-free halide perovskites with bayesian optimization for surface photovoltage — •Astita Dubey[1,2], Mahshid Ahmadi[2], Vladimir Shvartsman[1], Sergei Kalinin[2], and Doru Lupascu[1] — [1]Institute for Materials Science and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Universitätsstr. 15, 45141 Essen, Germany — [2]Institute for Advanced Materials and Manufacturing, Department of Materials Science and Engineering, The University of Tennessee Knoxville, Knoxville, TN 37996, USA

The development of lead-free, stable, and efficient catalysts for energy conversion necessitates rapid materials discovery. In this study, we employed Bayesian optimization (BO) to investigate a one-dimensional binary combinatorial library of zero-dimensional lead-free halide perovskites (A3Bi2I9 types) synthesized using a high-throughput automated pipetting robot. Structural analysis revealed hexagonal P6*/mmc symmetry throughout the library with pronounced variations in the lattice parameter c. Gaussian process-based BO identified the optimal composition featuring 49% cesium substitution, which demonstrated the best photocatalytic activity and stability attributed to the enhanced surface photovoltage and optimized anion vacancies. This composition achieved complete degradation of rhodamine B and methylene blue dyes within 15 and 20 minutes,

respectively. The identified composition's stability, defect management and the most efficient photocatalytic activity among 96 compositions is promising for its further use in water splitting.

O 41.4 Tue 14:45 H8

Automatic Exploration of Catalytic Reaction Networks — •Hyunwook Jung, Johannes T. Margraf, Hendrik H. Heenen, and Karsten Reuter — Fritz-Haber-Institut der Max-Planck-Gesellschaft, Faradayweg 4-6, 14195, Berlin

The reaction network is a crucial element of first-principles microkinetics simulations, representing the connection between surface species and elementary reactions. Lacking systematic exploration methods, the reaction network is presently typically set up by human intuition. Especially for complicated processes such as syngas conversion, this is error prone and the absence of important species and reaction steps can be a source of sizable discrepancy between theoretical modeling and experiment. To address this problem, we introduce an automatic reaction network exploration scheme that starts with a fully enumerated, yet redundant reaction network, in which a reaction pathway is refined iteratively. The associated computational cost for extensive sampling of structures for both adsorption and activation energy calculations along the pathway is circumvented by simultaneously fine-tuning a MACE foundation model. Each trial reaction pathway is coupled with corresponding mean-field microkinetics and a detouring operation is attempted for the identified rate-limiting step. This procedure is repeated until user-defined criteria are reached. We demonstrate this automatic scheme on methanol synthesis at a Cu(111) surface.

O 41.5 Tue 15:00 H8

Functionalization of atomically defined Au step edges with N-heterocyclic carbenes for the electrocatalytic reduction of carbon dioxide — •Philipp Wiesener[1], Duong Tran[1], Ankita Das[2], Ying Pan[3], Nieves Lopez Salas[3], Frank Glorius[2], and Harry Mönig[1] — [1]Physikalisches Institut, Universität Münster, Münster, Germany — [2]Organisch-Chemisches Institut, Universität Münster, Münster, Germany — [3]Institut für Chemie, Universität Paderborn, Paderborn, Germany

N-Heterocyclic carbenes (NHCs) are versatile ligands allowing to tune the catalytic performance of metal surfaces and nanoparticles. In recent years, the understanding of molecular adsorption of a variety of NHC compounds on flat single crystalline surfaces has significantly advanced the knowledge about their extraordinary properties. In the present work, we use scanning tunneling microscopy (STM) and non-contact atomic force microscopy (nc-AFM) to investigate the adsorption of various NHCs on a Au(788) surface, featuring a high density of atomically defined step edges. Our results reveal that NHC nucleation is significantly more stable at the step edges than on flat terraces. Correlating sub-molecular imaging techniques with voltammetry, we demonstrate the formation of a macroscopically defined and catalytically active nanostructure for the CO_2 reduction reaction. Our results spotlight the important role and opportunities of step edge functionalization by NHC compounds to design highly efficient and selective catalysts with defined active sites.

A simple model of nonadiabatic energy loss during hydrogen scattering from a semiconductor — •Xuexun Lu, Nils Hertl, and Reinhard J. Maurer — University of Warwick, Coventry, UK

Experiments on hydrogen atom scattering from Ge(111) show bimodal energy loss distributions with two peaks. The first peak corresponds to low energy loss and can be quantitatively reproduced with classical molecular dynamics (MD) simulations. The second peak lies at energy losses equivalent to or above the band gap of Ge and arises from electronic transitions between the valence band and the conduction band. Here, we develop a simple and interpretable model for H/Ge(111) scattering to inform the development of new mixed quantum-classical dynamics simulation methods suitable for the description of such nonadiabatic effects in gas-surface scattering. Using density functional theory data and experimental quantities, we parametrize an effective one-dimensional analytical model based on the Newns-Anderson Hamiltonian. The model allows us to study the coupled electron-nuclear dynamics and their conjugate energy transfer using nonadiabatic molecular dynamics methods such as independent electron surface hopping (IESH), molecular dynamics with electronic friction (MDEF), and the Ehrenfest method. In particular, IESH dynamics qualitatively reproduce the nonadiabatic energy transfer channel observed in the experiment.

O 42.2 Tue 14:15 H11

Shaping Polarons in Hematite Fe_2O_3: From Creation to Charge Dynamics — •Sreehari Sreekumar[1], Llorenc Albons Caldentey[1], Jesus Redondo Redondo[1], Aji Alexander[1], Sarah Tobisch[2], Michele Riva[2], and Martin Setvin[1] — [1]Department of Surface and Plasma Science, Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic — [2]Institute of Applied Physics, Vienna University of Technology, Austria

The non-contact Atomic Force Microscopy (nc-AFM) technique has enabled breakthroughs in single-electron charge manipulation [1]. Here we use this capability to study polaron dynamics. Polarons are self-localized electrons or holes in ionic lattices that are crucial to material properties like conductivity, catalysis, and exotic phenomena such as high-temperature superconductivity and colossal magnetoresistance [2]. Polarons are studied in hematite at the single quasiparticle limit, focusing on the fundamental mechanisms involved in their injection, formation, migration, and interaction with defects [3].

O 42.3 Tue 14:30 H11

Observing the directed motion of a single molecule after dissociation on a surface — •Ilias Gazizullin[1], Matthew Timm[1], Matthias Krinninger[2], Friedrich Esch[2], and Leonhard Grill[1] — [1]Physical Chemistry Department, University of Graz, Austria — [2]Faculty of Chemistry, TU München, Germany

Unidirectional motion of single molecules on surface can be achieved via a rare interplay between the surface and the intramolecular chemical reaction [1]. An alternative approach to achieve controllable molecular motion on surface is to induce dissociation of a molecule, resulting in the recoiling motion of the products [2, 3].

Here, we show how orientation of functional groups of an adsorbed molecule can steer its motion after controlled dissociation of these groups. We study single organic molecules with azido groups adsorbed on Au(111) surface by low temperature scanning tunneling microscopy (STM). The azido group of the adsorbed molecule can be oriented in two possible directions. We applied voltage pulses from the STM tip onto the azido group to induce its dissociation and found that the molecule rotates after dissociation in a specific direction. This directionality clearly depends on the initial orientation of the dissociating azido group, opening new possibilities to induce controlled motion of single molecules on surfaces.

O 42.4 Tue 14:45 H11

Nonadiabatic quantum dynamics of molecules scattering from metal surfaces — •Riley Preston[1], Yaling Ke[2], Samuel Rudge[1], Nils Hertl[3], Raffaele Borrelli[4], Reinhard Maurer[3], and Michael Thoss[1] — [1]Institute of Physics, University of Freiburg — [2]Department of Chemistry and Applied Biosciences, ETH Zürich — [3]Department of Chemistry and Department of Physics, University of Warwick — [4]DISAFA, University of Torino

Nonadiabatic coupling between electrons and molecular motion at metal surfaces can strongly impact the dynamics of a scattering molecule [1]. We present a theoretical approach based on hierarchical equations of motion (HEOM) [2], which models the scattering of molecules from metal surfaces and incorporates all nonadiabatic and quantum nuclear effects due to the coupling of the molecular degrees of freedom to the electrons in the metal. The approach is exemplified by its application to NO scattering from Au(111), where we observe multi-quantum relaxation of the bond vibrational state due to coupling to electron hole pairs in the surface, in accordance with experiment. The data obtained by the HEOM approach is also used as a rigorous benchmark to assess various mixed quantum-classical methods, from which we derive insights into the validity range of each method [3].

O 42.5 Tue 15:00 H11

Nonthermal phonon distributions induced by hot electrons — •Tobias Held, Christopher Seibel, Markus Uehlein, Sebastian T. Weber, and Baerbel Rethfeld — Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern-Landau

When an ultrashort laser pulse irradiates a metal, the electrons initially absorb the energy and rapidly establish a hot Fermi distribution. Subsequently, on a

picosecond timescale, the electrons transfer energy to the phonon system. Electrons exhibit a stronger coupling to high-wavenumber phonons, leading to non-thermal phonon distributions induced by electron-phonon scattering.

In this study, we use the Boltzmann equation to examine the formation and subsequent relaxation of nonequilibrium phonon distributions. For our model system, we find that the majority of the energy is transferred within 10 ps, while a pronounced phonon nonequilibrium is induced. We observe "hot phonons" at the edge of the Brillouin zone, leading to a collapse of the electron-phonon energy transfer rate. Consequently, a finite temperature difference between electrons and phonons may persist significantly longer than the widely used two-temperature model would predict.

O 42.6 Tue 15:15 H11

Electronic friction simulations of laser-driven hydrogen evolution from copper. Just thermal desorption in a hurry? — •Alexander Spears, Wojciech G Stark, and Reinhard J. Maurer — University of Warwick, Coventry, UK

Ultrafast light pulses can induce energy transfer between light, electrons, and phonons at interfaces, leading to ultrafast dynamics such as light-driven hydrogen evolution from metal surfaces. Whether this energy transfer can drive photocatalysis through selective energy transfer into certain degrees of freedom remains an open question. Molecular dynamics simulations with electronic friction (MDEF) offer a quantum-classical description of electron-phonon coupling and have previously been used to model ultrafast surface dynamics. However, the effect of different electronic friction approximations on the final energy distributions has not been thoroughly investigated. We present MDEF simulations of light-driven hydrogen evolution from different copper surface facets, enabled by machine-learning surrogate models. For various laser fluences, we study desorption probabilities and final state distributions of desorbed molecules. Our results reveal that the choice of electronic friction approximation significantly affects desorption probabilities. However, the magnitude and nature of friction do not seem to affect the final vibrational, rotational, and translational energy distribution of molecular adsorbates. Within the electronic friction approximation, only the shape of the energy landscape determines these properties and no selective energy transfer occurs. This suggests that thermal and laser-driven desorption may yield similar outcomes.

O 43: Scanning Probe Microscopy: Light-Matter Interactions at the Atomic Scale II

Kinetics of nucleation and crystallization of sodium chloride based on frozen solution sample preparation apparatus — •Xinmeng Liu[1], Jiadong Guo[1], Yunzhe Jia[2], Sheng Meng[2], Enge Wang[1], and Ying Jiang[1] — [1]International Center for Quantum Materials, School of Physics, Peking University, Beijing, People's Republic of China — [2]Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing, People's Republic of China

Solution environment is ubiquitous and plays a vital role in various fields, especially in the nucleation and crystallization process. Here, we designed and built a new frozen solution sample preparation apparatus compatible with UHV environment, allowing atomic-scale SPM experiments. By utilization of this apparatus, we successfully transferred NaCl solution in glassy states onto the Au(111) substrate. The qPlus-based AFM with CO tip characterized the kinetics of ions nucleation and crystallization after annealing. We found that the ions tend to form disordered networks with water molecules at the initial stage of nucleation, and then adjust to ordered crystals. Furthermore, ions continue to crystallize on the formed island surface by way of chain growth. This is different from the previous view that NaCl nucleation follows the classical nucleation theory. In addition, we also captured the existence of a small crystal nucleus composed of several ions, which is surrounded by water molecules that help the nucleus to further grow. Our results provide new insights into solution process and will have significant effect on the mechanism of material synthesis.

O 43.2 Tue 14:15 H24

Wavefunction Reconstruction of Excitonic Edge States using Machine Learning — •Aritra Mishra, Sidhartha Nayak, and Alexander Eisfeld — Max Planck Institute for the Physics of Complex Systems

A typical problem in quantum mechanics is to reconstruct the eigenstate wave functions from measured data. In the case of molecular aggregates, the information about the excitonic eigenstates is important to understand the optical and transport properties [1]. The reconstruction of the wavefunction coefficients from the near field absorption spectra is shown for a linear and a 2D molecular arrangement [2].

Here, we consider the aggregates arranged in two sublattices in a 2D arrangement, each sublattice having a particular orientation of the molecular transition dipole moment, that shows topological edge states as described in [3]. We show the reconstruction of the excitonic wave function for $N = 50$ molecules and move to $N = 200$, in the presence of disorder in the molecular dipole orientations and noise in the spectra. We observe a better reconstruction for higher noises considering all the input spectra for the electric field polarisation of the nanotip along the x, y and z axes.

Probing topological Floquet states in graphene with ultrafast STM — •Nils Jacobsen[1,2], Melanie Müller[3], Michael Schüler[4,5], Martin Wolf[3], Angel Rubio[2,6], and Michael Sentef[1,2] — [1]ITP, University of Bremen, Bremen, Germany — [2]Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — [3]Fritz Haber Institute, Berlin, Germany — [4]Laboratory for Materials Simulations, Paul Scherrer Institut, Villigen, Switzerland — [5]Department of Physics, University of Fribourg, Fribourg, Switzerland — [6]Center for Computational Quantum Physics The Flatiron Institute, New York, USA

Floquet band engineering enables the control of solids via periodic laser driving. The light-induced quantum anomalous Hall effect (QAHE) in graphene with circularly polarized light [1] has been measured in ultrafast transport [2] and recently, Floquet replica bands under linearly polarized light have been reported in time-resolved photoemission spectroscopy [3]. Here, we explore the possibility of probing (topological) Floquet states in graphene with ultrafast scanning tunneling microscopy (USTM) as a complementary experimental technique [4]. Being highly sensitive to gap openings in the local density of states and the formation of edge states, USTM is a promising and versatile tool for probing light-induced topological states in quantum materials.

Theoretical Study of Electronic and Optical Properties in Edge-Modified Graphene Nanoribbons — •Jian Cheng Wong[1], Song Jiang[2], Sofia Canola[1], Alex Boeglin[2], Guillaume Schull[2], and Tomáš Neuman[1] — [1]Institute of Physics, Czech Academy of Sciences, Cukrovarnická 10, 16200 Prague, Czech Republic — [2]Université de Strasbourg, IPCMS, CNRS, UMR 7504, F-67000 Strasbourg, France

Graphene nanoribbon (GNR) exhibits electronic and optical properties tunable by its geometry. One such approach is to introduce localized electronic states by modifying the edge structure. A previous study [1] using scanning tunneling microscopy-induced luminescence (STML) revealed that the presence of localized single-particle end states in GNR contributed to the formation of localized optical excitations. Here we provide an extensive theoretical description of such excitations on the modified edge structure of GNRs, and how it interacts with the end states. To that end, we develop a many body model that incorporates ab initio electronic structure methods and elucidate the sequence of events involved that leads to the eventual light emission under STML. From this model, we compare the electroluminescence maps obtained with experimental results and show the microscopic details of the localized states probed by STML.

O 43.5 Tue 15:00 H24

Correlations between noise and electroluminescence in graphene nanojunctions — •Sascha Korn, Michael Krieger, and Heiko B. Weber — Lehrstuhl für Angewandte Physik, Friedrich-Alexander-Universität Erlangen-Nürnberg

Light emission in scanning tunneling microscopy is often explained by the granularity of charge and should be therefore correlated with shot noise. Also, hot electrons may create both noise and thermal luminescence [1,2]. Using planar graphene nanojunctions, we study the phenomenon of electroluminescence in the point contact regime in a simple and well controlled electromagnetic environment. A spectral analysis of such measurements perfectly follows Planck's law and unambiguously supports the thermal picture. We present experimental data that correlate electrical noise measurements and optical spectroscopy, providing an in-depth view into the microscopic processes.

Photon blockade in current-driven single-molecule emitters — Andrés Bejarano[1,2], •Moritz Frankerl[1], Rémi Avriller[2], Fabio Pistolesi[2], and Thomas Frederiksen[1,3] — [1]Donostia International Physics Center, Spain — [2]Univ. Bordeaux, CNRS, LOMA, France — [3]Ikerbasque, Bilbao, Spain

We consider photon emission from a single electronic level embedded in a strongly damped cavity, where photon emission is driven by electronic tunneling events. Using a Lindblad master equation approach we investigate the system dynamics, photon emission spectrum as well as the second-order coherence function $g^{(2)}(\tau)$ [1]. We demonstrate that many features observed in scanning tunneling microscopy light-emission experiments can be explained with this simple model. Specifically, restricting the applied bias to the first emission threshold, we find antibunching in the photon statistics irrespective of the coupling strength to the cavity [2]. Employing a higher bias leads to a excitation of states with a photon number greater than one and thus the system shows bunching behavior as well as an emergence of two distinct time scales in the dynamics of $g^{(2)}(\tau)$. O 43.7 Tue 15:30 H24

Attosecond charge transfer in atomic-resolution scanning tunnelling microscopy — •Katharina Glöckl[1], Simon Maier[1], Raffael Spachtholz[1], Carlos Bustamante[2], Korbinian Pürckhauer[1], Franz J. Giessibl[1], Franco Bonafé[2], Markus A. Huber[1], Angel Rubio[2], Jascha Repp[1], and Rupert Huber[1] — [1]Department of Physics & Regensburg Center for Ultrafast Nanoscopy (RUN), Universität Regensburg — [2]Max Planck Institute for the Structure and Dynamics of Matter, Hamburg

Scanning tunnelling microscopy (STM) driven with single-cycle terahertz pulses has afforded atomic-scale slow motion videos of single molecular orbitals. Driving tunnel currents with the carrier field of near-infrared light could improve the temporal resolution from ~100 fs down to attoseconds. Yet, competing multiphoton processes and thermal effects pose severe challenges in this spectral domain.

Here, we introduce an attosecond STM concept that is largely immune against thermal artifacts. By pulse synthesis, we periodically vary the waveform of single-cycle near-infrared pulses to drive tunnelling currents while keeping the thermal load on the tip constant. In a non-degenerate pump-probe scheme, we observe clear attosecond features in the sub-cycle currents and demonstrate atomic resolution by taking snapshot images of a single Cu adatom on a silver surface. Our results pave the way to recording the fastest relevant dynamics of electrons within atoms, molecules and quantum materials in actual attosecond atomic videography.

O 44.1 Tue 18:00 P2

The dynamic interaction of size-selected Pt clusters with CeO_2/Rh(111) — •Mina Soltanmohammadi, Johanna Reich, Barbara A.J. Lechner, and Friedrich Esch — Technical University of Munich, TUM School of Natural Sciences, Department of Chemistry, Germany

Recent studies on Pt clusters supported on ceria have revealed interesting cluster formation and redispersion processes that can be induced by cyclic redox treatments [1]. These catalysts' activity for combustion is linked to the verge of cluster formation. Here, we investigate the dynamic interaction of size-selected Pt clusters with CeO_2(111) thin films at the atomic scale, using a combination of scanning tunneling microscopy (STM) and X-ray photoelectron spectroscopy (XPS). We present a preparation protocol to obtain highly clean, crystalline and stochiometric CeO_2(111) thin films with extended terraces and well-defined monoatomic steps. Distinct oxygen vacancy distributions are obtained by either annealing in vacuum or reducing in a methanol atmosphere. We then systematically explore the interaction of Pt clusters with the support, particularly the mobility and sintering in dependence of the defect state. The influence of support stoichiometry and the parameters controlling the resulting cluster dispersion are presented. Finally, we present first studies of the Pt dispersion under cyclic oxidizing (O_2) and reducing (methanol) conditions at elevated temperatures, focusing on the resulting cluster configurations at the atomic scale.

O 44.2 Tue 18:00 P2

Search for crystalline SiO_2 on the wet chemically treated 6H-SiC(0001) surface — •Paul Schöngrundner[1], Igor Sokolovic[2], and Ulrike Diebold[2] — [1]Department of Physical Chemistry, University of Graz, 8010, Austria — [2]Department of Applied Physics, Technical University of Vienna, 1040, Austria

A 6H-SiC(0001) surface was found to host a crystalline superstructure consisting of SiO_2 after wet chemical treatment. This surface was envisioned as a model system for surface chemistry studies. In order to replicate and optimize this film, chemical and thermal treatments were investigated systematically. Using atomic force microscopy (AFM), x-ray photoelectron spectroscopy (XPS) and low energy electron diffraction (LEED), an improved cleaning methodology was established, resulting in contaminant-free surfaces (except adventitious C), but they were terminated with amorphous SiO_2 instead of a crystalline film. If the sample was treated by repeating the original cleaning technique, which was finished with Extran and milliQ sonication, without subsequent boiling in H_2O, the original surface termination could be re-prepared. However, this was accompanied by P and Cr contamination. It is hypothesized that P and/or Cr contamination were ultimately responsible for the crystalline silicon oxide overlayer.

O 44.3 Tue 18:00 P2

Pulsed laser deposition of epitaxial hematite α-Fe_2O_3 thin films on $Al_2O_3(1\bar{1}02)$ — •Sarah Tobisch, Giada Franceschi, Michael Schmid, Gareth Parkinson, Ulrike Diebold, and Michele Riva — Institute of Applied Physics, TU Wien, Vienna, Austria

Hematite α-Fe_2O_3 is a widely used support material for catalysis due to its abundance and high stability at ambient pressures. However, the insulating nature of the material poses major challenges, as it makes it difficult to achieve sufficient conductivity for techniques such as scanning tunnelling microscopy (STM). Samples commonly consist of natural crystals that can contain a variety of impurities as well as structural defects. The former problem is hardly controllable while the latter can lead to mechanical instabilities. While the conductivity can be improved by growing Ti-doped epitaxial films, the synthesis of hematite single crystals is still in its infancy and the size of these crystals is insufficient for many surface-analysis techniques. Therefore, new strategies to ensure the growth of flat and atomically defined doped films without the need of natural-crystal substrates are highly desired.

In this work, epitaxial growth of Ti-doped Fe_2O_3 on $Al_2O_3(1\bar{1}02)$ was investigated using a pulsed-laser-deposition (PLD) system with high-pressure reflection high-energy electron diffraction (RHEED) to optimize the growth conditions and monitor the growth behavior. The morphology and composition of the film's surface was characterized using x-ray photoelectron spectroscopy (XPS), atomic force microscopy (AFM), and STM.

O 45.1 Tue 18:00 P2

Scanning Tunneling Microscopy and Spectroscopy of YbPc2 Molecules — •Jonas Arnold[1], Kwan Ho Au-Yeung[1], Wantong Huang[1], Paul Greule[1], Christoph Sürgers[1], Wofgang Wernsdorfer[1], Mario Ruben[2], and Philip Willke[1] — [1]Physikalisches Institut, Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]Institute of Nanotechnology, Karlsruhe Institute of Technology, Karlsruhe, Germany

Individual molecules constitute excellent building blocks for quantum technologies thanks to their small size, reproducibility and the benefit of self assembly. A promising class are rare-earth bis-phythalocyanine complexes [1]. In this investigation, YbPc2 molecules are studied using scanning tunneling microscopy (STM) and spectroscopy (STS) to identify potential indicators of a magnetic signature. In the gas phase, the YbPc2 molecule is expected to exhibit a radical spin localized at its ligands as well as an f-shell electron spin S = 1/2 and a nuclear spin (I = 1/2 and 5/2) for certain isotopes. Thus, this system is a potential candidate for a spin cascade [1]. We perform measurements on self-assembled multilayer islands of YbPc2 on Ag(100) that reveal distinct orbital features which vary for the first, second and third molecular layer. Similarly, the orbital signatures

change when introducing a thin dielectric decoupling layer of MgO between the molecule islands and the electron bath. We discuss these results in the context of charge transfer between the molecular film and the underlying substrate [2].
[1] Wernsdorfer, W. et al., Advanced Materials 31, 1806687 (2019). [2] Hollerer, M. et al., ACS nano 11, 6252-6260 (2017).

O 45.2 Tue 18:00 P2

Magnetic adatom manipulation on monolayer transition metal dichalcogenides — •Daniel Jansen[1], Katharina Offermann[1], Tfyeche Tounsi[1], Affan Safeer[1], Jeison Fischer[1], Arkady Krasheninnikov[2], Nicolae Atodiresei[3], Thomas Michely[1], Hannu-Pekka Komsa[4], and Wouter Jolie[1] — [1]II. Physikalisches Institut, Universität zu Köln, Köln, Germany — [2]Institut für Ionenstrahlphysik und Materialforschung, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [3]Peter Grünberg Institut, Forschungszentrum Jülich, Jülich, Germany — [4]Faculty of Information Technology and Electrical Engineering, University of Oulu, Oulu, Finland

Two-dimensional materials are found to host a large variety of correlated phases. A promising approach towards understanding and controlling these phases is by means of atomic manipulation.
Here we compare two systems for atomic manipulation experiments: Fe on 1H-MoS_2 and Fe on 1H-TaS_2. We find that manipulation of Fe on 1H-MoS_2 results in point defects (sulfur vacancies) [1], which we investigate using scanning tunneling microscopy and spectroscopy. In contrast, we find that single Fe adatoms can be laterally moved on 1H-TaS_2, enabling construction of lattices consisting of tens of adatoms. We additionally report on the observation of two inequivalent adsorption sites for Fe, hollow and Ta-top sites, which manifest as differences in the adatom's apparent height.

O 45.3 Tue 18:00 P2

Investigating the origins of spin-polarization in Au(111) : experiments vs theory — •Sourour Ayari[1], Laurent Nicolaï[1], Aki pulkkinen[1], Ridha Eddhib[1], Saleem Khan[1], Trung Phuc[1], Ján Minár[1], and Mauro Fanciulli[2,3] — [1]New Technologies - Research Centre, University of West Bohemia, 301 00 Pilsen, Czech Republic. — [2]CY Cergy Paris University, France — [3]CEA Paris Saclay, France

This study explores the origins of spin polarization in semi-infinite Au(111), examining whether the observed spin polarization arises primarily from the system's initial states or solely through the Photoemission process. To address this, we will integrate both experimental and theoretical results to provide an understanding of this spin-polarization origins, we calculate the electronic band structure with and without the influence of Mott-Scattering, while isolating additional factors, such as the Rashba effect[1]. On the theoretical side the calculations are performed using the SPRKKR method [2,3] which is based on DFT calculations, which will account for fundamental effects, while the additional one-step model will account for the photoemission process.

O 45.4 Tue 18:00 P2

Coherent driving of interacting spins in single molecules — •Maria Steiner and Andrea Donarini — Institute for Theoretical Physics, University of Regensburg, Regensburg, Germany

The low energy spectrum of neutral closed shell molecules generically exhibits a set of singlet and triplet excited levels. The latter arises due to the exchange interaction between the unpaired electrons in singly occupied frontier orbitals. Moreover, the spatial anisotropy of these molecular states, combined with the spin-dipolar interaction, induces a zero-field splitting of the triplet. In recent AFM-ESR experiments on pentacene [1] Rabi oscillations between two of the split triplet states have been demonstrated. We now extend this concept to the full triplet space. By means of multiple frequency coherent driving, we investigate theoretically the rich dynamics of this molecular qutrit in search, for example, of the analogue of the dark states observed for Λ-systems in atomic physics.

O 45.5 Tue 18:00 P2

A molecular spin on a scanning probe tip enables quantum sensing at the atomic scale — Taner Esat[1,2], Dmitriy Borodin[3,4], •Jeongmin Oh[1,2], Andreas Heinrich[3,4], Stefan Tautz[1,2,5], Yujeong Bae[3,4], and Ruslan Temirov[1,2,6] — [1]Peter Grünberg Institute (PGI-3), Forschungszentrum Jülich; Jülich, Germany — [2]Jülich Aachen Research Alliance (JARA), Fundamentals of Future Information Technology; Jülich, Germany — [3]Center for Quantum Nanoscience (QNS), Institute for Basic Science (IBS); Seoul, South Korea — [4]Department of Physics, Ewha Womans University; Seoul, South Korea — [5]Experimentalphysik IV A, RWTH Aachen University; Aachen, Germany — [6]Faculty of Mathematics and Natural Sciences, Institute of Physics II, University of Cologne; Cologne, Germany

In this work, we fabricate a single-molecule quantum sensor on a scanning tunneling microscope (STM) tip by attaching Fe atoms and a PTCDA (3,4,9,10-perylenetetracarboxylic-dianhydride) molecule to the tip apex. The PTCDA molecule is a spin-1/2 system on the STM tip and serves as a two-level quantum system in a magnetic field. We probe this molecular spin system by electron spin resonance and achieve about 100 neV resolution in energy. The functionality of the quantum sensor we demonstrate by measuring the magnetic and electric dipole fields emanating from a single Fe atom and an Ag dimer on an Ag(111) surface with sub-angstrom spatial resolution [T. Esat, D. Borodin, J. Oh et al. Nat. Nanotechnol. 19, 1466 (2024)].

O 45.6 Tue 18:00 P2

Thermometry of a millikelvin scanning probe junction with spin-flip inelastic electron tunnelling spectroscopy — •Emilio Scontrino[1,3], Stefan Schulte[2,3], Taner Esat[3], Markus Ternes[1,3], Stefan Tautz[1,3], and Ruslan Temirov[2,3] — [1]RWTH Aachen — [2]Universität zu Köln — [3]Forschungszentrum Jülich, PGI-3, Germany

Organic molecules attached to the apex of a scanning probe tip have recently emerged as promising sensors for electric and magnetic fields at atomic scales [1, 2, 3]. Here, we functionalize the tip of a millikelvin scanning tunnelling microscope (STM) [4] with a 1,4,5,8-naphthalene tetracarboxylic dianhydride (NTCDA) molecule. We measure the inelastic spin-flip excitations of this molecular spin 1/2 system in an out-of-plane magnetic field of 7 T varying the temperature of the adiabatic demagnetization cryostat between 30 mK and 1.2 K. To perform thermometry of the STM junction we fit the temperature-dependent smearing of the spin-flip excitation spectra using the third-order perturbation theory in the Appelbaum-Anderson-Kondo framework [5].

O 45.7 Tue 18:00 P2

Investigation of the Kondo effect in complex, artificially built, single molecule structures — •Lars Pütz[1], Daria Sostina[1], Taner Esat[1,2], Stefan Tautz[1,2,3], Ruslan Temirov[1,4], and Markus Ternes[1,2,5] — [1]Peter-Grünberg-Institute for Quantum Nanoscience, Research Center Jülich, 52425 Jülich, Germany — [2]Jülich Aachen Research Alliance, Fundamentals of Future Information Technology, 52425 Jülich, Germany — [3]Institute of Physics IV, RWTH Aachen University, 52074 Aachen, Germany — [4]Institute of Physics II, University of Cologne, 50937 Cologne, Germany — [5]Institute of Physics IIB, RWTH Aachen University, 52074 Aachen, Germany

In engineered spin systems, strongly correlated many-body phenomena such as nontrivial topology, Kondo screening and highly correlated long-range states can be constructed and studied by site-selective measurements with scanning tunneling microscope (STM) tips [C. Zhao et al., Nat. Nanotech. 2024]. Here we show how many-body phenomena evolve by controlled manipulation of NTCDA molecules on Ag(111) using the tip of an STM. Building small clusters of 2-5 molecules and tuning their spatial geometry reveals complexly patterned Kondo resonances and, in addition, an electric field-dependent strong increase in conductance, which we attribute to the collapse of Kondo correlations [S. Arabi et al., arXiv 2022]. Single NTCDA molecules on the other hand show no detectable spin signature, despite the clear formation of Kondo resonances in clusters where their high symmetry with respect to the surface is broken.

O 45.8 Tue 18:00 P2

Investigation of the Yu-Shiba-Rusinov states arising from single Fe atoms on superconducting $2H$-NbS_2 — •Margarete Huisinga, Werner M.J. van Weerdenburg, Lisa M. Rütten, and Katharina J. Franke — Fachbereich-Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany

Magnetic adatoms on a superconductor give rise to states within the superconducting gap due to the interaction of the unpaired spin(s) with the Cooper pairs of the substrate. These so-called Yu-Shiba-Rusinov (YSR) states are therefore isolated from the rest of the electronic structure of the system, which makes them interesting building blocks for artificial molecules or the design of band structures, if the YSR states of multiple atoms hybridize. The YSR states are especially long range on 2D materials, which enables hybridization over a large spacing. Previous experiments on the hybridization of YSR states performed on $NbSe_2$ were limited by a charge density wave [1], which is not present in $2H$-NbS_2.
Using scanning tunneling microscopy and spectroscopy, we investigate single Fe atoms on superconducting $2H$-NbS_2. We find that Fe adsorbs in two different adsorption sites on the substrate, each with a distinct set of YSR states. We map the spatial distribution of these YSR states to determine their symmetry and find long-ranged YSR features extending up to 4 nm. Additionally, we observe a tip-induced shift in the energy of the YSR states for one adsorption site species.

O 45.9 Tue 18:00 P2

Hybridization of Yu-Shiba-Rusinov states in magnetic clusters on Pb(111) — •Katharina Biel, Bharti Mahendru, Werner M. J. van Weerdenburg, Lisa M. Rütten, and Katharina J. Franke — Fachbereich Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany

The unpaired spin of a magnetic impurity on a superconducting substrate interacts with the Cooper pairs via potential and exchange scattering. This leads to local in-gap bound states, so-called Yu-Shiba-Rusinov (YSR) states. The hybridization of close-by atoms can be described by linear combinations of the YSR states [1,2].

We investigated self-assembled manganese (Mn) and iron (Fe) clusters on superconducting lead (Pb(111)) by scanning tunneling microscopy and spectroscopy. While the topography essentially shows featureless protrusions, the differential conductance maps reflect characteristic shapes of the YSR states. We employ a phenomenological hybridization model [3] to simulate the observed shapes. In particular, we show atomic configurations which lead to chiral YSR patterns.

O 45.10 Tue 18:00 P2

Investigation of impurity states on the high-temperature superconductor $Bi_2Sr_2Ca_1Cu_2O_{8+x}$ via scanning tunneling microscopy — •Melvin Grumser, Verena Caspari, Werner M. J. van Weerdenburg, and Katharina J. Franke — Freie Universität Berlin, Department of Physics, Arnimallee 14,14195 Berlin, Germany

The interaction of magnetic impurities and superconductors gives rise to impurity states in the superconducting gap, which have been widely studied for s-wave superconductors [1]. For d-wave superconductors however, only few experiments addressing the interplay of local spins and Cooper pairs, governed by an anisotropic order parameter and non-vanishing density of states (DOS) in the superconducting gap have been reported [2,3].

Here, we investigated the interaction between the high-temperature d-wave superconductor $Bi_2Sr_2Ca_1Cu_2O_{8+x}$ and magnetic adatoms on the atomic scale using scanning tunneling microscopy. We present measurements conducted on scandium, iron and manganese adatoms, expected to display different amounts of in-gap states due to the different number of unpaired electrons. We find strong variations in the spectra that we ascribe to different adsorption sites and variations of the density of states across the substrate.

O 45.11 Tue 18:00 P2

Atomic-scale Josephson spectroscopy performed over magnetic clusters on Pb(111) — •Bharti Mahendru[1], Martina Trahms[1,2], Katharina Biel[1], Werner M. J. van Weerdenburg[1], Clemens B. Winkelmann[2], and Katharina J. Franke[1] — [1]Fachbereich Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany — [2]Université Grenoble Alpes, CNRS, Institut Neél, 25 Avenue des Martyrs, 38042 Grenoble, France

When two superconducting leads are brought in close proximity, they form a Josephson junction (JJ). In a JJ, quantum tunnelling of Cooper pairs occurs without an applied voltage between the two superconductors with a phase difference. To study the properties of Cooper-pair tunneling at the atomic scale, a scanning tunneling microscope is a powerful tool. A JJ forms by approaching the tip to the sample. Previously, it has been shown that a Josephson junction including a single magnetic adatom shows non-reciprocity in the retrapping current [1]. This expression of the Josephson-diode effect was ascribed to the broken particle-hole symmetry induced by the Yu-Shiba-Rusinov (YSR) states inside the superconducting energy gap. Here, we investigate the effect of hybridized YSR states of self-assembled Fe clusters on Pb(111). We find non-reciprocal retrapping currents that we correlate with the asymmetry in the YSR states and their spatial distribution. [1] Martina Trahms et al., *Nature* 615, (2023)

O 45.12 Tue 18:00 P2

Driving nuclear spin transitions on a single atom using ESR-STM — •Hester Vennema, Cristina Mier Gonzalez, Evert Stolte, Rik Broekhoven, Jinwon Lee, and Sander Otte — Delft University of Technology, The Netherlands

The spin of a single nucleus is a prime candidate for quantum information applications due to its weak coupling to the environment and subsequently longer coherence times [1]. Using the high energy resolution of electron spin resonance (ESR) in combination with the high spatial resolution of scanning tunneling microscopy (STM), it is possible to measure the hyperfine interaction between the nucleus and an electron for single atoms on a surface [2].

A recent effort has successfully resolved the coherent dynamics of a hyperfine-driven interaction between nuclear and electron spin [3]. Moreover, the lifetime of the nuclear spin has been measured to be in the order of seconds [4].

In this study we use a double resonance measurement scheme to resolve nuclear spin transitions of a single 47Ti isotope with a spin of I=5/2. Additionally, we are able to selectively drive multiple transitions directly.

Nanoscale Control of Quantum States in Radical Molecules on Superconducting Pb(111) — •Chao Li, Jung-Ching Liu, Outhmane Chahib, Thilo Glatzel, Rémy Pawlak, and Ernst Meyer — Department of Physics, University of Basel, Klingelbergstrasse 82, 4056 Basel, Switzerland.

Superconducting surfaces hosting magnetic impurities provide a promising framework for applications in quantum technology. Here, we demonstrate the manipulation of magnetic states in the radical molecule 4,5,9,10-tetrabromo-1,3,6,8-tetraazapyrene (TBTAP) deposited on a Pb(111) superconducting surface, utilizing low-temperature scanning tunneling microscopy. Tunneling spectroscopy reveals the presence of Yu-Shiba-Rusinov (YSR) states near the Fermi level for isolated TBTAP molecules. By varying the tip-molecule distance, we induce a quantum phase transition between singlet and doublet ground states. Furthermore, introducing a second TBTAP molecule enables tuning of the YSR state position through modifications in relative distance and orientation, with specific configurations leading to the splitting of YSR states. Extended molecular chains, up to pentamers, exhibit periodic patterns of charged and neutral molecules, where even-numbered chains form a distinct charged dimer structure at one terminus. This dimer position can be manipulated, allowing for information encoding within the chain.

O 45.14 Tue 18:00 P2

Exchange interactions of spin states in coupled triangular nanographenes — •Suyash Singh[1], Nils Krane[1], Elia Turco[1], Roman Fasel[1,2], and Pascal Ruffieux[1] — [1]Empa - Swiss Federal Laboratories for Materials Science and Technology, 8600 Dübendorf (Switzerland) — [2]Department of Chemistry and Biochemistry, University of Bern, 3012 Bern, Switzerland

Zigzag-edged triangular nanographenes (triangulenes) are promising realizations of spin qubits at a molecular level, with a total spin S scaling with the length of their edges. Chemical design and on-surface synthesis methods allow atomically precise engineering of carbon-based π–systems with strong spin-spin interactions, using triangulene units as building blocks. Exploiting the rules governing the exchange interactions, functional groups and spacer molecules, such as phenyl rings, can be used to tune the sign and magnitude of the exchange coupling between the triangulene units. We present the bottom-up fabrication of correlated spin platforms using the two smallest members of the triangulene family, the spin S=1/2 phenalenyl and S=1 [3]triangulene. We analyze the origin of spin-polarized states and spin excitations using a tight-binding and mean-field Hubbard Model for the π–orbital network. With an estimate of the couplings within the spin cluster, we describe it using an effective Heisenberg model. The spin excitations are then investigated experimentally using inelastic electron tunneling spectroscopy. Specifically, we summarize the results on dimers and trimers, where the exchange mechanisms can be investigated systematically by hydrogenation and selective re-activation of single spins.

O 45.15 Tue 18:00 P2

Properties of magnetic atoms on a hexagonal insulating lattice — •Johannes Schust, Henrik Lichtl, Julian Zeitler, Lukas Arnhold, Sebastian Loth, and Susanne Baumann — University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany

The symmetry of the immediate surrounding of an atom heavily influences its static properties and also governs its dynamics. For the exploration of atomic-scale systems by scanning tunneling microscopy (STM), the choice of a suitable thin film is thus key. While most preceding works take advantage of two- or four-fold underlying symmetries, we focus on the hexagonal surface of zinc oxide (ZnO) monolayers. Hexagonal substrates bear the potential for exploring spin frustration effects on a surface, realized by the assembly of magnetic nanostructures built atom-by-atom. ZnO, as a wide bandgap semiconductor [1], is employed to mitigate electron scattering between the Ag(111) substrate and the adsorbed species on the sample. We develop a reliable method to prepare the aforementioned substrate and carry out comprehensive characterization of cobalt (Co) and manganese (Mn) atoms in the present environment. These efforts provide the foundation for investigating novel dynamical aspects of frustrated systems on the atomic scale.

[1] A. Shiotari et al. J. Phys. Chem. (2014)

O 45.16 Tue 18:00 P2

Multiplet calculations of magnetic atoms on a hexagonal insulator — •Julian Zeitler[1], Johannes Schust[1], Henrik Lichtl[1], Lukas Arnhold[1], Sebastian Loth[1,2], and Susanne Baumann[1] — [1]University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany — [2]Center for Integrated Quantum Science and Technology (IQST), University of Stuttgart, Stuttgart, Germany

Novel designs for computational devices may offer improvements in energy efficiency, especially if they include a combination of storing and processing parts

in one unit. In such designs, the building blocks should enable slow and fast dynamics, and allow for precise control over the system. Atomic-scale frustrated spin systems combined with atom manipulation capabilities of a scanning tunneling microscope (STM) are a promising prospect in this field. Magnetic atoms placed on a thin hexagonal insulator, such as zinc oxide (ZnO), can potentially be used to realize such systems. As the magnetic atoms interact with their substrate, it is important to understand the substrate's influence on the atoms' characteristics. We use multiplet calculations to study the interactions of individual magnetic atoms with the ZnO substrate. With these calculations, we can make predictions about the magnetic characteristics of different atoms placed on top of this hexagonal substrate, in particular their orbital and spin moments. We are particularly interested in finding atomic-scale systems that, combined with atom manipulation capabilities of an STM, allow for further advancements in the field of atomic-scale frustrated spin systems.

O 45.17 Tue 18:00 P2

Exploiting YSR States for Driving Spin Transitions in a Magnetic Field — •Maneesha Ismail[1], Juan Carlos Cuevas[2], and Christian R. Ast[1] — [1]Max-Planck-Institute for Solid State Research, Stuttgart, Germany — [2]Universidad Autónoma de Madrid, Madrid, Spain

In recent years, advances in the field of atomic scale electron spin resonance (ESR-STM) have made it possible to manipulate single spins and observe their interaction [1,2]. In this work, we exploit the tip confinement of superconductivity in a magnetic field to explore a new candidate system, namely Yu-Shiba-Rusinov states. We present how the Zeeman-split states behave under microwave irradiation. Our theory, which is based on a Green's function approach, corroborates the idea that the presence of the YSR state can be used to detect a change in the spin population. A new sample system could open the path to observing new phenomena in the field of spintronics and quantum computing.

O 45.18 Tue 18:00 P2

Tuning the interaction between spin triplet states at the single-molecule level — Lorenz Meyer, •Maximilian Kögler, Robert Henninger, Nicolas Néel, and Jörg Kröger — Technische Universität Ilmenau, Ilmenau, Germany

In a scanning tunneling microscope junction, two molecular spins - one nickelocene (Nc) decorating the tip and another adsorbed on Pb(111) - are approached toward each other. Simultaneously, inelastic electron tunneling spectra reveal the evolution of spin excitations with increasing magnetic exchange interaction. An avoided energy level crossing occurs at the verge of the Nc-Nc contact. Modeling of the spectra hints at the exchange coupling of tunneling electrons to the Nc spins as the origin. Funding by the DFG through KR 2912/18-1 and KR 2912/21-1 and the BMBF through the ForLab initiative is acknowledged.

Electronic Properties of Interfaces between N-Heterotriangulene Donors and Strong Tetracyanoquinodimethane Acceptors — •Mohsen Ajdari[1], Jakob Roth[1], Ronja Pappenberger[1], Christian Walla[2], Ina Michalsky[3], Friedrich Maass[1], Milan Kivala[3], Andreas Dreuw[2], and Petra Tegeder[1] — [1]Physikalisch-Chemisches Institut — [2]Interdisziplinäres Zentrum für Wissenschaftliches Rechnen — [3]Organisch-Chemisches Institut, Heidelberg University

N-Heterotriangulenes (N-HTAs) are promising functional molecules with significant potential for optoelectronic applications, in particular, as electron donors in donor/acceptor (D/A) systems. This study explores the electron-donating properties of two N-HTAs, N-HTA 550 and N-HTA 557, at interfaces with well-known tetracyanoquinodimethane acceptors, TCNQ and F4TCNQ. Using high-resolution electron energy loss spectroscopy (HREELS) combined with quantum chemical calculations, we investigated the electronic properties of D/A interfaces adsorbed on Au(111) [1]. For all D/A combinations, low-energy electronic transitions (E<2.5 eV) associated with charge transfer (CT) states are identified. Quantum chemical calculations rule out the formation of ground-state CT complexes. Instead, CT in the excited state, in which an electron-stimulated CT from the N-HTAs to TCNQs is the underlying process, is proposed. The energies of the CT states are determined by the values of the ionization potential and electron affinity of the involved donor and acceptor.

O 46.2 Tue 18:00 P2

Self-assembly of magnetic complex on Cu (111) using scanning tunneling spectroscopy: probing Kondo resonance and decomposition effects — •Behzad Mortezapour[1], Torben Adam[2], Eike Kuhlemann[2], Felix Tuczek[2], and Richard Berndt[1] — [1]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, Germany — [2]Institut für Anorganische Chemie, Christian-Albrechts-Universität zu Kiel, Germany

The spin-crossover complex bis-(hydro-tris-(3-methyl-pyrazolyl)-borat)-Iron(II) on Cu (111) at ambient temperature was investigated with a scanning tunneling microscope (STM) under ultrahigh-vacuum conditions at a temperature of 4.6 K. The three-dimensional molecules self-assemble into ordered two dimensional arrays while some decomposition also occurs. The STM images of the intact molecules exhibit a significant dependence on the bias voltage and spectra of the differential conductance (dI/dV) show a zero-bias resonance that we tentatively attribute to the Kondo effect. Time series of the current reveal abrupt transitions that possibly are linked to spin switching. In addition, negative differential resistance is observed from decomposed molecules.

O 46.3 Tue 18:00 P2

stochastic spin-state switching of a Fe(II) complex on Cu (111) — •jasmeen jasmeen[1], sujoy karan[1], karl ridier[2], gaël reecht[1], and manuel gruber[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen, 47057 Duisburg, Germany — [2]LCC, CNRS and Université de Toulouse, UPS, INP, 31077 Toulouse, France

Spin-crossover (SCO) molecules exhibit different spin states that make them attractive for nanoscale memory applications. Using scanning tunneling microscopy (STM) at 4.5 K, we studied the [Fe(HB(1,2,4-triazolyl)3)2] complex adsorbed on a Cu (111) surface, focusing on the spin-state switching dynamics. Time traces of the tunneling current revealed switching in the order of milliseconds, which we investigated under a range of bias voltages and currents, providing insights into the stochastic response of this system.

Controlled switching of individual molecules induced by voltage pulses was successful, but also drove a pronounced neighborhood effect: switching a target molecule simultaneously influenced adjacent ones. These events suggest an intermolecular interaction acting on the neighboring molecules due to the conformational changes of the target molecule.

These findings help improving the understanding of electron-induced switching of SCO molecules. Funding from the CRC 1242 is acknowledged.

O 46.4 Tue 18:00 P2

STM Investigation of Molecular Double Motors — •Ken Kolar[1], Grant Simpson[1], Ben Feringa[2], and Leonhard Grill[1] — [1]Dept. of Physical Chemistry, University of Graz, Austria — [2]Stratingh Institute for Chemistry, University of Groningen, Netherlands

A molecular motor is a molecule with stator and rotor chemical groups which undergo directional motion relative to each other. They represent potential building blocks for nanoscale machinery and their motion on surfaces is of particular interest. With high-resolution imaging from a scanning tunnelling microscope (STM), we revealed distinct appearances of different conformers of a molecule containing two motor units. Furthermore, motion induced by voltage pulses from the STM tip was studied in detail, investigating unidirectionality. Finally, double motors with additional alkane chains attached to them were deposited, showing distinguishable appearances. The experiments showed that the alkane chain conformation can impact the motion of the molecules.

O 46.5 Tue 18:00 P2

Excited state alignment of molecular orbitals on the ferroelectric WTe2 bulk crystal — •Jannis Lessmeister[1], Ralf Hemm[1], Joohyung Park[2], Martin Aeschlimann[1], Oliver L.A. Monti[2], and Benjamin Stadtmüller[3] — [1]Rheinland-Pfälzische technische Universität Kaiserslautern-Landau and Research center OPTIMAS, Kaiserslautern, Germany — [2]University of Arizona, Tucson, USA — [3]Universität Augsburg, Augsburg, Germany

The interaction between organic molecules and ferroelectric domains on WTe_2 offers a promising pathway for tuning the electronic properties of hybrid systems. WTe_2, a layered transition metal dichalcogenide, exhibits ferroelectricity in its few-layer form due to broken inversion symmetry, resulting in switchable polarization domains. When organic molecules are deposited onto the surface, the local electronic environment created by these ferroelectric domains significantly influences molecular adsorption and electronic coupling.

Utilizing real- and momentum-space photoemission electron microscopy, we investigate how the ferroelectric properties of WTe_2 modulate the alignment of excited state energy levels at the FePc/WTe_2 interface. Our study elucidates the charge transfer behavior and interaction strength, exploring the role of local electric polarizations for tuning the energy level alignment in molecule-2D material heterostructures.

O 46.6 Tue 18:00 P2

Momentum space signatures of molecular orbitals on a ferromagnetic surface — •Martin Anstett[1], Lu Lyu[1], Martin Aeschlimann[1], and Benjamin Stadtmüller[1,2] — [1]Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Institute of Physics, University of Augsburg, 86135 Augsburg, Germany

The integration of organic molecules with ferromagnetic surfaces is a promising approach to advance spintronic applications. The spin functionalities depend not only on the molecular properties, but also on the energetics and spin polarization of so-called hybrid interface states, which arise due to the hybridization between molecular orbitals and substrate states.

This work focuses on momentum space imaging of the adsorption-induced modification of molecular orbitals on ferromagnetic surfaces at room temperature. This is challenging due to the lack of ordered or aligned molecules on highly reactive magnetic substrates, which is required for momentum space imaging using ARPES. This limitation can be overcome by using ultrathin cobalt films on Au(111) as a ferromagnetic platform. On this surface, we prepare long-range ordered superstructures using iron phthalocyanine molecules. We combine spin- and momentum-resolved photoemission spectroscopy with photoemission orbital tomography to study the characteristic emission pattern of the orbitals of the adsorbed molecules. Our analysis reveals how the molecules arrange on the cobalt surface, producing distinct photoemission signatures associated with individual molecular orbitals.

O 46.7 Tue 18:00 P2

Thermal-Driven Coordination Effect for Structural and Electronic Tailoring of a Metal-Organic Network — •Jonas Gödde[1], Lu Lyu[1,2], Benjamin Stadtmüller[2], and Martin Aeschlimann[1] — [1]Department of Physics and Research Center OPTIMAS, Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, Erwin-Schrödinger-Straße 46, 67663 Kaiserslautern, Germany — [2]Experimentalphysik II, Institute of Physics, Augsburg University, Universitätsstraße 2, 86159 Augsburg, Germany

Two-dimensional metal-organic porous networks (2D-MOPNs) have emerged as a unique material platform for designing structural tessellations and emergent electronic states on surfaces. The metal centre in a 2D-MOPN plays a vital role in bridging network and substrate. In this study, we investigate the cobalt-coordination effects in cyano-functionalized hexaaza-triphenylene-hexacarbonitrile (HATCN) on Ag(111). Scanning tunnelling microscopy (STM) reveals that HATCN self-assembles into a well-ordered porous network. A partially occupied LUMO state observed by angle-resolved photoemission spectroscopy (ARPES), indicates charge transfer from the substrate to the molecules. After cobalt deposition, the robust equilibrium, between intermolecular and substrate interactions, preserves the porous structure and molecular orbital states of HATCN, while trapping cobalt in the low-potential pores. Upon post-annealing the molecules coordinate with cobalt atoms, inducing a structural transition and creating distinct energy and momentum states. These results provide insights into tailoring 2D-MOPNs for applications in electronics and spintronics.

O 46.8 Tue 18:00 P2

Spectroscopic study of the interface between organic molecules and platinum telluride thin films — •Lorenz Klein, Hibiki Orio, Romana Ganser, Muthu P. T. Masilamani, Maximilian Ünzelmann, and Friedrich Reinert — Universität Würzburg, Experimentelle Physik VII & Würzburg-Dresden Cluster of Excellence, Würzburg, Germany

Van der Waals heterostructures of organic molecules and transition metal chalcogenides (TMCs) represent excellent model systems for the study of weak molecule-substrate interactions.

Here, we use two phases of metallic platinum telluride, which both host spin-polarized surface states in their electronic surface band structures. Using those as substrates, we deposit copper phthalocyanine (CuPc) and study the resulting atomic and electronic interface structure by means of x-ray (XPS) and angle-resolved photoemission spectroscopy (ARPES) as well as low-energy electron diffraction (LEED). On that basis, we discuss the differences in surface ordering, work function, and the binding energies of the observed molecular features.

O 46.9 Tue 18:00 P2

Fluorescence spectroscopy of linear trans-quinacridone (QA) on KCl/Ag(100): The influence of KCl layer thickness — •Morris E. L. Mühlpointner and Moritz Sokolowski — Clausius-Institut für Physikalische und Theoretische Chemie der Universität Bonn, Germany

The organic dye-molecule linear QA has attracted interest as a fluorescent probe molecule in STM luminescence (STM-LE) experiments [1]. We have performed fluorescence spectroscopy of multilayers on the bare Ag(100) surface and highly diluted layers of QA on an epitaxially grown thin KCl film on Ag(100) under UHV.

We find spectra that are reminiscent of solid state spectra for multilayers of QA on Ag(100). In addition, we see blue-shifted spectra for highly dilute QA layers (0.0005 ML – 0.1 ML) with a multitude of spectral features. We find that the stability of these spectral features under laser illumination varies depending on the thickness of the underlying KCl layer. Spectra are stable at 13 K for QA on 3-4 layers of KCl. However, on 6-8 layers of KCl, a spectral red-shift and a loss of FL-intensity is induced upon laser illumination at 13 K. We attribute these findings to a diffusion barrier of QA on KCl films that is dependent on the KCl-film thicknesses because the long-range interactions with the Ag(100) substrate are relevant [2].

O 46.10 Tue 18:00 P2

Field driven crossover of bonding and antibonding states in excitonic aggregates — •Amandeep Sagwal[1,2], Rodrigo Cezar De Campos Ferreira[1,3], Petr Kahan[1], Tomáš Neuman[1], and Martin Švec[1,3] — [1]Institute of Physics, Czech Academy of Sciences — [2]Faculty of Mathematics and Physics, Charles University; Czech Republic — [3]Institute of Organic Chemistry and Biochemistry, Czech Academy of Sciences

The present study aims to examine the effect of an electric field on the excitonic states of chromophore aggregates confined in optical nanocavity of a low-temperature SPM. Utilizing an optical configuration intended for near-field spectroscopies, tip-enhanced photoluminescence (TEPL) is used to investigate PTCDA molecules, deposited on a thin decoupling layer of NaCl on Ag(111) surface. A different energy shift is observed consistently between the bonding and antibonding excitonic emission lines in the spectra of dimer, trimer, and tetramer aggregates, in some cases even leading to a crossover. Typically, the antibonding states manifest a larger blue shift with increasing positive bias voltage applied on the gate electrode (substrate). We discuss the phenomenon using TD-DFT simulations and many-body state diagrams.

O 46.11 Tue 18:00 P2

Near-field spectroscopy of vibronic states of molecular aggregates — •Sidhartha Nayak[1], Fulu Zheng[2], and Alexander Eisfeld[1] — [1]MPIPKS, Dresden, Germany — [2]Department of Physics, Ningbo University, Ningbo, China

Strong dipole-dipole interactions between molecules give rise to delocalized electronic excited states in molecular aggregates, which determine their optical properties such as absorption. In near-field spectroscopy, the absorption spectrum of an aggregate is obtained when the molecules interact with electromagnetic radiation that is inhomogeneous across the length of the aggregate. Theoretically, by considering the near-field radiation from the apex of a metallic tip as a source of a localized field, it has been shown that the spectra of the aggregate reveal it's purely electronic states that are inaccessible through traditional far-field methods [1, 2]. In this contribution, we study aggregates composed of molecules with internal vibrational modes that are strongly coupled to electronic excitations, leading to non-Markovian phenomena. Using a local field method, which is numerically inexpensive, we observe that the vibronic states of aggregates are revealed in the near-field spectra and the spectra are comparable to those obtained by using a more accurate but computationally intensive method [3].

O 46.12 Tue 18:00 P2

The Luminescence of Rylene Derivatives — •Petr Kahan[1], Rodrigo Ferreira[1,2], Amandeep Sagwal[1], Jiří Doležal[2], and Martin Švec[1,2] — [1]Institute of Physics, Czech Academy of Sciences — [2]Institute of Organic Chemistry and Biochemistry, Czech Academy of Sciences

The exploration of single-molecule luminescence using scanning tunneling microscopy (STM) is a vividly developing area of research. A number of works using STM-PL/EL and TERS techniques addressing the photophysics at the true single-molecule limit have employed rylene dyes for their known luminescent properties [1,2]. However, up to this point, a thorough comparison investigating the absorption and luminescent characteristics of molecules that share similar rylene-based configurations has not been carried out. This study presents a comparative analysis with the tip-enhanced spectromicroscopy in STM nanocavity on isolated molecules such as NTCDA, PTCDA, and DBP [3]. The findings reveal surprisingly distinct characteristics of each species; notably of their photoluminescence (PL) fingerprints and photocurrent maps. This shows the versatility of chemically related species, which holds promise for tailoring custom opto-electronic functionality in molecular aggregates.

O 46.13 Tue 18:00 P2

Spin Hall Magnetoresistance as a Probe for Chiral-Induced Spin Selectivity — •Simon Sochiera[1], Ashish Moharana[1], Yael Kapon[2], David Anthofer[1], Fabian Kammerbauer[1], Akashdeep Akashdeep[1], Shira Yochelis[2], Mathias Kläui[1], Yossi Paltiel[2], and Angela Wittmann[1] — [1]Institute for Physics JGU, Mainz, Germany — [2]Hebrew University of Jerusalem, Jerusalem, Israel

Chiral molecules have gained significant attention in the spintronics community due to their ability to polarize electron spin angular momentum without any heavy metal atoms via the chiral-induced spin selectivity (CISS) [1] effect. Several optical and electrical methods confirmed the CISS effect. However, despite numerous theoretical approaches, the fundamental mechanisms of the CISS effect are still an open question. A recent experiment [2] reported a significant modulation of spin-to-charge conversion with chiral molecules in a spin-pumping experiment. Building on this result, we create a hybrid structure by combining a well-established spin Hall magnetoresistance (SMR) experiment with chiral molecules. The SMR relies on the reflection and absorption of spin currents at interfaces adjacent to a layer exhibiting an (inverse) spin Hall effect, such as a heavy metal. This allows for direct probing of the spin-to-charge conversion modulation by chiral molecules. Combined with the results established in the spin-pumping experiment, this paves the path toward designing new chiral-molecule-based spin-torque devices.

O 47: Poster Electron-driven Processes

Time: Tuesday 18:00–20:00 Location: P2

O 47.1 Tue 18:00 P2

Non-equilibrium electron distribution effects in ultrafast light-driven desorption dynamics — •Matthew Larkin, Henry Snowden, and Reinhard J. Maurer — University of Warwick, Coventry, UK

At metal surfaces, light excitation drives electronic states out of the (thermal) Fermi-Dirac distribution. The resulting non-equilibrium electronic distribution can induce coupled electron-nuclear dynamics that lead to ultrafast structural processes such as light-driven desorption of molecules. As non-equilibrium electron distributions in metals are short-lived, their role in the mechanics of light-driven surface dynamics remains insufficiently understood. In this work, we perform mixed quantum-classical dynamics simulations using a variant of the trajectory surface hopping method where electrons and nuclei are propagated simultaneously and electronic transitions between hundreds of electronic states can be captured. We describe light-generated non-thermal electron distributions as initial conditions to those dynamics. For simple 1D and 2D model systems of atomic and molecular desorption from metal surfaces, we study the role of non-thermal electrons by simulating light-driven desorption probabilities for comparable thermal and non-thermal electronic distributions and discuss the future applicability of this approach for high-dimensional dynamics.

O 47.2 Tue 18:00 P2

Spin effects in ultrafast non-equilibrium dynamics at surfaces — •Ash Baldwin and Reinhard J. Maurer — University of Warwick, Coventry, United Kingdom

Energy, charge, and spin transfer are important factors in modelling ultrafast gas-surface dynamics such as hyperthermal scattering and light-driven dynamics at surfaces. In particular, on metal surfaces, nonadiabatic energy dissipation is an important energy transfer channel in atomic and molecular dynamics at surfaces. In cases of adsorbates with unpaired spin, an additional question arises if and under which conditions the spin moment of the adsorbate survives the scattering event. The challenge lies in capturing the explicit electron correlation in the electronic structure and its effect on the coupled electron-nuclear motion, which mean-field dynamics methods cannot fully capture.

Here, we model the fate of adsorbate spin during scattering from a metal surface using the Newns-Anderson model. We go beyond previous works by simulating the nuclear dynamics beyond mean-field Ehrenfest dynamics, using stochastic trajectory surface hopping methods. Our model is applied to study the spin survival probability of hydrogen atoms on copper and platinum as a function of various model parameters and initial conditions such as the adsorbate kinetic energy and the adsorbate-metal coupling strength to identify the regime in which a finite spin survival probability can be measured.

O 47.3 Tue 18:00 P2

Adsorbate motors: toward tuning unidirectionality by chemical functionalisation — •Grant J Simpson[1], Mats Persson[2], and Leonhard Grill[1] — [1]University of Graz, Austria — [2]University of Liverpool, UK

The purpose of a molecular motor is to convert external energy into unidirectional motion. Feringa-type molecular motors, in which double-bond isomerisation leads to large geometric changes in the molecule, are known to undergo rapid unidirectional motion in solution but often have a reduced function when adsorbed on a surface. In contrast, recently discovered adsorbate motors [1] do not exhibit large structural changes and thus their motion is efficient and unidirectional when adsorbed on a metal surface. Using a scanning tunnelling microscope (STM), we track such motion at the single-molecule scale. The motion is triggered by an internal proton transfer reaction. We further show that, by altering the local chemical structure, this tautomerisation can be affected and may result in modulation of the unidirectional molecular translation.

O 47.4 Tue 18:00 P2

Creation, Displacement, and Dynamics of Individual Phasons on Si(001) — •Gaël Reecht, Michael Horn-von Hoegen, and Manuel Gruber — Universität Duisburg-Essen, Duisburg, Germany

The Si(001) surface, characterized by buckled dimers resulting from dangling bond pairing, exhibits a variety of structural configurations. The energetically favorable c(4x2) reconstruction can be manipulated into the p(2x2) configuration, differing by a glide of adjacent rows. The interface between these two phases is known as a phason [1]. Despite its significance in structural phase transitions, the mechanisms driving phason propagation remain poorly understood.

In this study, we employ low-temperature scanning tunneling microscopy to explore the diffusion of individual phasons under tip-induced excitation. We systematically examine the effects of tunneling current, bias voltage, and electric field on the formation and displacement of these structural defects. Phason motion below the STM tip results in stochastic jumps in tunneling current, which we analyze through time-resolved measurements. These findings shed light on the displacement dynamics of phasons and enhance our understanding of the underlying processes. We gratefully acknowledge funding from the CRC1242.

O 47.5 Tue 18:00 P2

Triplet exciton dynamics at the tetracene/a-Si/c-Si(111) interface — •Marvin Krenz[1,2], Simone Sanna[1], Wolf Gero Schmidt[2], and Uwe Gerstmann[2] — [1]Institut für Theoretische Physik, Justus-Liebig Universität Gießen, 35392 Gießen, Germany — [2]Lehrstuhl für Theoretische Materialphysik, Universität Paderborn, 33095 Paderborn, Germany

Exciton transfer is highly relevant for many physical, chemical, and biological processes. The transfer of triplet excitons across the tetracene-silicon interface in sensitized solar cells is a recent example in this context [1]: The excitons, generated by singlet fission in tetracene (Tc), promise to increase the cell efficiency from the single-junction limit of 29% to values as high as 35% [2]. In a previous work, we showed the significance of dangling bond (db) defects for the triplet transfer [3] at a model interface, where tetracene was bonded to an ideal c-Si(111) surface. Here, we present ab initio calculations for a more realistic structure, with a thin film of amorphous silicon (a-Si:H) in-between, resulting in a Tc/a-Si/c-Si model structure. We find that dbs are vital for the exciton transfer also in this case. Dbs at the a-Si/c-Si interface or in the a-Si interlayer itself affect the exciton transfer differently. Generally, it is found that the a-Si layer is energetically favourable for excitation transfer. However, the exciton electron tends to be trapped in a-Si conduction band tail states. Thus, the exciton transfer requires an external field to be completed. [1] M. Einzinger et al. Nature 571, 90*94 (2019). [2] A. Rao et al., Nat. Rev. Mater. 2, 17063 (2017). [3] M. Atomistic modeling of ultrafast laser induced structural changes in Bismuth — •Sahar Bakhshi Sangari, Jimiben Patel, Bernd Bauerhenne, and Martin Garcia — Institute of Physics, University of Kassel, Kassel, Germany

We present a temperature-dependent interatomic potential for laser-excited bismuth, $\Phi_{Bi}(Te)$, developed using a database of temperature-dependent density functional theory (DFT) calculations. Bismuth is a widely studied material in experiments, yet theoretical studies exploring its atomic dynamics following femtosecond laser excitation remain scarce. Our work compares the physical properties predicted by $\Phi_{Bi}(Te)$ with those obtained from ab initio simulations, demonstrating its reliability. We use $\Phi_{Bi}(Te)$ to describe, in the framework of a generalized two-temperature-model molecular dynamics (TTM-MD) method, laser induced thermal and nonthermal ultrafast structural changes in Bi. We compute the time evolution of selected Bragg peaks and directly compare them with experimental observations. This approach enables efficient and accurate modeling of complex material behaviors, providing a valuable alternative to computationally intensive temperature-dependent DFT simulations.

O 48.2 Tue 18:00 P2

Design and Characterization of Optical Cavities for Light-Induced Phase Transitions in Indium-Based Peierls Insulators — •Florian Spickmann[1,2], Sierra Randall Heinrich[1,2], Sebastian Zafra Koch[1,2], Murat Sivis[1,2], Hannes Boeckmann-Clemens[1,2], and Claus Ropers[1,2] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]4th Physical Institute, University of Göttingen, Germany

The integration of quantum materials into optical cavities enables active control of their properties through enhanced light-matter interactions. Low-dimensional materials, such as Peierls insulators, are particularly sensitive to external stimuli, making them ideal candidates for such studies [1]. This work focuses on designing and fabricating optical resonators on (111) silicon membranes, including slab waveguides, ridge waveguides, and ring resonators. The structures are created using focused ion beam (FIB) milling and electron beam lithography (e-beam), with light coupling achieved via integrated gratings. Characterization of the resonators is performed using Fabry-Pérot interferometry. Future studies will employ ultrafast low-energy electron diffraction (ULEED) to visualize light-driven phase changes in indium wires localized on these optical resonators, representing a promising model system for cavity-controlled light-matter interaction in condensed matter.

O 48.3 Tue 18:00 P2

Ultrafast LEED Study of Bismuth Thin Films on Silicon (001) — •Nandana V Uday[1], Felix Kurtz[1], Jonas Fortmann[3], Alp Akbiyik[1], Michael Horn-von-Hoegen[3,4], and Claus Ropers[1,2] — [1])Department of Ultrafast Dynamics, Max Planck Institute for Multidisciplinary Sciences, 37077 Göttingen, Germany — [2]4th Physical Institute ,Solids and Nanostructures, University of Göttingen, 37077 Göttingen, Germany — [3]University of Duisburg-Essen, 47057 Duisburg, Germany — [4]Center for Nanointegration (CENIDE), 47057 Duisburg, Germany

The interface between two materials in a heterostructure serves as a barrier to the diffusion of thermal energy, thereby hindering heat flow across the boundary. On the nanoscale, heat transport may further be modified. Recently, it was shown that the thermal transport from Bi film into a Si substrate is reduced for films thinner than the phonon mean free path, due to phonon trapping by total internal reflection [1]. To study the non-equilibrium phonon dynamics in this process, ultrafast low-energy electron diffraction (ULEED) is suitable and direct means providing ultrafast temporal and high momentum resolutions. By analyzing the momentum-resolved map of a transient inelastic scattering background [2], we aim to identify phonon trapping, depopulation, and thermalization. As a first step, we monitor the heat transfer by phonons through the thin film-substrate interface, extracting cooling times from the transient lattice temperature of the bismuth film.

O 48.4 Tue 18:00 P2

Predicting and modelling incommensurate charge density waves in 1H-$TaSe_2$ via downfolding approach — •Clara Pfister[1,2], Laura Pätzold[1], and Tim O. Wehling[1,2] — [1]I. Institute of Theoretical Physics, U Hamburg — [2]The Hamburg Centre for Ultrafast Imaging, Hamburg

Studying the emergence and thermodynamic behaviour of symmetry-broken phases such as charge density waves (CDWs) in solids is of great interest to deepen our understanding of collective phenomena and interactions between electrons and the crystal lattice. Incommensurate CDWs (ICCDWs) are especially intriguing because a realistic and efficient computational method to predict them has not been developed yet. To model ICCDW phases in the exemplary transition metal dichalcogenide material 1H-$TaSe_2$, we employed a downfolding approach that reduces the electronic degrees of freedom by retaining only the low-energy subspace relevant to CDW formation. This method achieves a computational speed-up of approximately five orders of magnitude compared to purely ab initio calculations [1], making it possible to simulate sufficiently large supercells efficiently. Our approach allows for modelling the ICCDW with reasonable accuracy, with the predicted temperature range for its occurrence agreeing well with experimental results of the ICCDW in undoped 2H-TaSe2 [2]. This suggests that our approach is applicable for the description of other materials exhibiting ICCDWs.

O 49: Poster Nanostructures at Surfaces

Time: Tuesday 18:00–20:00 Location: P2

O 49.1 Tue 18:00 P2

Au induced nanostructures on Si(110) — •Stephan Appelfeller — MAX IV Laboratory, Lund University, Sweden

The deposition and annealing of small amounts of Au on clean Si substrates often lead to enticing nanostructures showing, e. g., spin ordering on vicinal Si(111) substrates or self-doping by adatoms on planar Si(111). A curious case are Au induced nanostructures on Si(110) for which the phase diagram is known in the submonolayer to monolayer regime, but for which few detailed studies exist, although, quasi-1D metallicity has been proposed for one of the nanostructures.

Here, the various nanostructures and their evolution are studied in real space using scanning tunnelling microscopy measured in MAX IVs SPM Support Lab, with core-level and angle-resolved photoemission spectroscopy obtained at the FlexPES beamline of the MAX IV Laboratory. For lowest Au coverages, a 2x1 superstruture showing a distinct Au 4f core-level component forms. With increasing Au coverage, rows of 2x3 subunits develop leading to the formation of the 2x5 reconstruction with quasi 1D-metallicity and the two-domain (4,0)x(±1,3) high coverage phase, which shows a high stability and recoverability in UHV. This stability is shared with Au silicide nanowires, which grow in the mono- to multilayer Au coverage regime. Since there are no stable bulk Au silicides, the observation of Au silicide nanowires is a beautiful reminder that surfaces and interfaces in general are different and often deviate from bulk expectations.

XPS study of CuO, WO3 and CuWO nanoparticles-based films — •Michal Procházka[1], Kalyani Shaji[2], Stanislav Haviar[2], Eliška Benediktová[2], Radomír Čerstvý[2], Ján Minár[1], Petr Zeman[2], and Jiří Čapek[2] — [1]New Technologies - Research Centre, University of West Bohemia, Univerzitní 8, Plzeň, 301 00, Czech Republic — [2]Department of Physics and NTIS - European Centre of Excellence, University of West Bohemia, Univerzitní 8, Plzeň, 301 00, Czech Republic

Interest in clean and sustainable technologies is rapidly growing and hydrogen is widely used in this field. With this development, more emphasis is placed on hydrogen gas sensors as hydrogen poses significant risks due to its explosive nature and flammability [1]. Structural parameters and surface properties plays a significant role in interaction of gas with sensor material [2]. Therefore, the nanoparticles of various materials are more and more explored. To understand the surface evolution after annealing in the air we measured XRD, SEM and XPS of CuO, WO3 and CuWO nanoparticles-based films prepared by magnetron-based gas aggregation technique.

O 49.3 Tue 18:00 P2

Hydroxyl Groups on Different Metal Doped Co_3O_4 Particle Catalysts Observed by Sum Frequency Generation Vibrational Spectroscopy — •Furong Yan[1], Carsten Placke-Yan[2], Zhipeng Huang[1], Yujin Tong[1], and R. Kramer Campen[1] — [1]Faculty of Physics and Center of Nanointegration (CENIDE), University of Duisburg-Essen — [2]Faculty of Chemistry and Institute of Inorganic Chemistry, University of Duisburg-Essen

Metal-doped Co_3O_4 nanoparticles are promising catalysts for the electrochemical oxygen evolution reaction (OER), with surface Co-OH groups playing a critical role in the water oxidation cycle. However, the influence of metal doping on the behavior of surface OH groups and its subsequent effect on OER activity remains uncertain.

Here, we investigate the effects of metal doping (Mn and V) on the bonding of OH groups using sum frequency generation (SFG) vibrational spectroscopy. Our results reveal that Mn-doped Co_3O_4 exhibits stronger bonding between OH groups and the surface compared to both pristine Co_3O_4 and V-doped Co_3O_4, leading to a reduction in OER activity. We propose two mechanisms: (1) an excess of OH groups can block active sites and increase charge transfer resistance, and (2) the stronger Co-OH bonds in Mn-doped Co_3O_4 may hinder the cleavage of Co-OH bonds, thereby impeding the OER process. These findings provide valuable insights into how surface interactions with OH groups can be tailored to optimize OER catalytic performance.

O 49.4 Tue 18:00 P2

Coral-like structures on nickel surfaces obtained by nitrogen plasma treatment — •Christina Meinert, Timo Wagner, Felix Schaumburg, Moritz Sünner, Nicolas Wöhrl, and Axel Lorke — Faculty of Physics, University Duisburg-Essen

For electrochemical processes, nickel sheets are commonly used as electrode material because of their low cost and easy handling. Here we report on the use of a microwave induced remote nitrogen plasma to change the surface of the nickel, improving the electrochemical and mechanical properties of the nickel electrode. During this process the surface obtains coral-like nanostructures and a nitridation of the nickel can be detected. AFM is employed to characterize these evolved nanostructures. Furthermore, EDX, Raman Spectroscopy and XPS are used to identify the chemical composition of the surface. In addition, wettability is probed as this is important for the efficiency of electrolysis. The plasma process is also applied to more complex surfaces than nickel plates such as wires and meshes. This allows to investigate the feasibility and limitations of treating these substrates.

O 49.5 Tue 18:00 P2

Exploring Topological Boundary Modes in Atomically Assembled Quantum Structures — •Adrian Weindl, Christoph Setescak, and Franz J. Giessibl — Faculty of Physics, University of Regensburg, D-93053 Regensburg, Germany

Single-atom and single-molecule manipulation enables the construction of quantum simulators: artificial structures assembled atom-by-atom or molecule-by-molecule to emulate key properties of complex systems that are challenging or impossible to fabricate directly. Using scanning tunneling microscopy (STM) and atomic force microscopy (AFM), we create two atomic-scale structures from individual CO molecules on Cu(111): a 1D Su-Schrieffer-Heeger (SSH) chain and a 2D Kagome lattice.

The 1D SSH chain represents a fundamental system capable of hosting topological boundary modes. We investigate the interaction between these boundary modes and the AFM tip. As the boundary modes are spatially localized and pinned in energy, they are not expected to undergo chemical bonding, unlike the bulk states of the chain, which may exhibit such interactions.

The 2D Kagome lattice on Cu(111) was initially proposed as a higher-order topological insulator, a classification that remains under debate. Through STM and AFM measurements, we aim to contribute to this ongoing discussion by introducing defects and analyzing the bonding behavior of the purported topological corner modes.

O 49.6 Tue 18:00 P2

Au vs. Ag: How Does the Choice of Substrate Influence the Formation of SAMs with Carboxylic Head Groups? — •Verena Müller[1], Julian Picker[1], Daniel Hüger[1], Christof Neumann[1], Marco Gruenewald[2], and Andrey Turchanin[1] — [1]Friedrich Schiller University Jena, Institute of Physical Chemistry, Lessingstraße 10, 07743 Jena, Germany — [2]Friedrich Schiller University Jena, Institute of Solid State Physics, Helmholtzweg 5, 07743 Jena, Germany

Self-assembled monolayers (SAMs) enable modification of various solid substrates at the molecular level, providing a wide range of applications in nanoscience and nanotechnology, *e.g.*, photonics, organic electronics and biochemical sensing.

In this contribution, we present a systematic investigation of the formation of SAMs with carboxylic head groups (–COOH) on Ag and Au substrates. To this end, we analyze the results for three molecular precursors: a Ru^{II}-polypyridine complex photosensitizer, hexadecanoic acid and *p*-terphenyl-4-carboxylic acid. Complementary surface science characterization methods - including X-ray photoelectron spectroscopy (XPS), low-energy electron diffraction (LEED), scanning tunneling microscopy (STM) and polarization-modulation infrared reflection absorption spectroscopy (PM-IRRAS) - were employed to confirm the successful SAM formations. The obtained results are utilized to gain insight into the nature of the chemical interaction between the carboxylate and the metal surface.

O 49.7 Tue 18:00 P2

Phase Transitions of Naphthalene-2,3-carbonitride Steered by Solvent Effects and Metal Ion Concentration Variation — •Longnan Yu[1], Li Wang[2], and Xiaoqing Liu[3] — [1]KIT, Karlsruhe, Germany — [2]Nanchang University, Nanchang, China — [3]Nanchang University, Nanchang, China

This study explores the structural phase transitions of naphthalene-2,3-carbonitride (2,3-DCN) on highly oriented pyrolytic graphite (HOPG) influenced by varying solvents and Cu2+ ion concentrations. By combining scanning tunneling microscopy and density functional theory, it is revealed that in 1-nonanoic acid,Cu2+ ions coordinate with 2,3-DCN and other ligands (Cl- or 1-nonanoic acid), forming structures with a coordination number of 4 that depend on the 2,3-DCN to Cu2+ molar ratio. In contrast, in 1-heptanoic acid,Cu2+ ions do not coordinate with 2,3-DCN, and phase transitions occur solely through altered hydrogen bonding. This work highlights solvent-dependent metal organic coordination as a novel strategy for tailoring nanoarchitectures.

O 49.8 Tue 18:00 P2

Bottom-up realization of quasi-1D electronic states from Cs atoms on InSb(110) — •Niek Aarts, Annique Krieg, Emil Sierda, Danis Badrtdinov, Brian Kiraly, Elze Knol, Gerrit Groenenboom, Mikhail Katsnelson, Malte Rösner, Daniel Wegner, and Alexander Khajetoorians — Institute for Molecules and Materials, Radboud University, Nijmegen, The Netherlands

1D-electronic systems are predicted to exhibit very different physical phenomena compared to 2D and 3D systems. Scanning tunnelling microscopy (STM) and spectroscopy (STS) provide a way to study 1D electronic systems on surfaces in a bottom-up approach with atomic-scale precision by utilising atomic manipulation.

Here, we study the electronic states of quasi-1D structures that result from coupling individual Cs atoms adsorbed on InSb(110) using low-temperature STM and STS. When constructing chains of Cs atoms, we observe the formation of quantized electronic states in energy with a modulated charge density along the chain. We can tune these electronic states by changing the length and Cs density of the chain. Modifying the chain length, changes the spacing of the electronic states. Changing the density of Cs atoms, changes the onset energy of the electronic states. We ascribe these observations to a 1D-particle in a box behavior for the lowest electronic states. For the electronic states at higher energy, we observe deviations from the simple particle in a box description. These deviations could be due to the onset of states with a higher order orbital symmetry or due to a coupling of these states to a bath.

O 49.9 Tue 18:00 P2

Investigation of onset field variations in annealed and as-deposited NbTiN samples through field emission scanning microscopy — •Frederic Braun[1], Isabel Díaz-Palacio[2], Lea Preece[2], Florian Brockner[1], Robert Zierold[2], Marc Wenskat[2], Wolfgang Hillert[2], and Dirk Lützenkirchen-Hecht[1] — [1]Bergische Universtiät Wuppertal — [2]Universität Hamburg

Current superconducting radio frequency (SRF) cavities are predominantly constructed from high purity Niobium which is pushed to its theoretical limit. To enhance future cavity performance by minimizing operational power losses and increasing accelerating field strength, the focus of research must shift to alternative cavity materials. An effective strategy involves depositing superconducting thin films like NbTiN or Nb3Sn on the cavity inner walls. Heat treating NbTiN may further optimize film properties. In this study various samples, including as deposited NbTiN and annealed NbTiN are analyzed via a Field Emission Scanning Microscopy (FESM). Current-voltage-curves allow the determination of onset-fields for parasitic field emission . Mapping these fields at e.g., 1 nA reveals lateral variations due to thin film inhomogeneities, defects or surface contaminations Additionally, assessing long term surface stability through constant current measurements over an extended period is crucial for practical cavity applications.

O 49.10 Tue 18:00 P2

Surface Reconstructions and Photocatalysis of Thermally Reduced $LiNbO_3$ and $BaTiO_3$ Single Crystals — •Marta Macyk[1], Andrzej Jasicki[1], Llorenç Albons[2], Konrad Szajna[1], Martin Setvin[2], Dominik Wrana[1], and Franciszek Krok[1] — [1]Marian Smoluchowski Institute of Physics, Jagiellonian University, Krakow, Poland — [2]Department of Surface and Plasma Science, Charles University, Prague, Czech Republic

Perovskite oxides, such as $BaTiO_3$ (BTO) and $LiNbO_3$ (LNO), exhibit a wide range of different stoichiometries and crystal structures that make them ideal candidates for applications in optoelectronics and catalysis. Their properties can be tuned by the change of stoichiometry and the introduction of oxygen vacancies achieved by annealing under Ultra High Vacuum (UHV).

This poster presents a comparative study of surface reconstructions for tetragonal $BaTiO_3$(001) and hexagonal $LiNbO_3$(0001) after UHV annealing under low oxygen partial pressure. LEED analysis reveals a (1×1) to ($\sqrt{5}\times\sqrt{5}$)R26.6° transition for BTO, while LNO undergoes a (1×1) to ($\sqrt{3}\times6$)R30° transition, ending with (3 × 3) structure at temperatures near 1200°C. Morphological studies using SEM, STM, and AFM show the formation of nanowire structures aligned with the substrates' crystallographic directions, offering insights into controlled surface engineering. Furthermore, photocurrent measurements at variable temperature were performed on the thermally modified crystals to evaluate their photocatalytic and pyrocatalytic activity under ambient conditions.

O 49.11 Tue 18:00 P2

Freestanding thin film cryo-EM samples for electrospray ion beam deposition and molecular imaging — •Stephanie Stankard, Stephan Rauschenbach, Lukas Eriksson, and Jingjin Fan — Department of Chemistry, University of Oxford

Over the past decade, cryogenic electron microscopy (cryo-EM) has become the dominating method for imaging in structural biology, a method in which samples are conventionally made by plunge freezing.

Combining cryo-EM with soft landing, electrospray ion beam deposition (ESIBD) is a novel approach where intact, folded protein gas phase ions are landed onto the cryo-EM samples. For this, supported grids are required, which also need to be electron-transparent, and conductive. Often also ice needs to be grown on them after protein deposition.

Here, we present an analysis and optimisation of various thin, freestanding, amorphous carbon films for the purpose of application as a ESIBD and cryo-EM substrates.

O 50: Poster Organic Molecules on Inorganic Substrates: Adsorption and Growth

Time: Tuesday 18:00–20:00 Location: P2

Polymorphism of Naphthalene on Ag(111) in and out of thermodynamic equilibrium — •Lorenz Brill[1], Christoph Wachter[2], Roman Forker[1], Oliver T. Hofmann[2], and Torsten Fritz[1] — [1]Friedrich-Schiller-Universität, Jena, Germany — [2]Technische Universität, Graz, Austria

Even with a seemingly simple molecule like naphthalene, a rich polymorphism has been observed on Cu(111). Additionally, calculated phase diagrams predict multiple different structures of naphthalene on Ag(111), depending on the pressure and temperature during naphthalene deposition. In this poster, we present first experimental results of naphthalene structures formed in thermodynamic equilibrium obtained in our custom chamber specially designed to enable molecular growth in thermodynamic equilibrium. We compare our results to naphthalene structures grown using a conventional setup.

O 50.2 Tue 18:00 P2

Coverage-dependent assembly of functionalized helicenes — •Elise Fürch[1], Jonas Brandhoff[1], Fumi Nishino[2,3], Keisuke Fukutani[2,3], Marco Gruenewald[1], Maximilian Schaal[1], Felix Otto[1], Roman Forker[1], Takashi Hirose[4], Satoshi Kera[2,3], and Torsten Fritz[1] — [1]Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany — [2]Institute for Molecular Science, Myodaiji, 444-8585, Okazaki, Japan — [3]The Graduate University of Advanced Studies, Hayama-cho, 240-193 Kanagawa, Japan — [4]Institute of Chemical Research, Kyoto University, Uji, Kyoto 611-0011, Japan

Recently, the interest in chiral molecules has spiked. The chirality-induced spin selectivity (CISS) promises a high spin-polarizability for electrons traversing a chiral molecule. However, the CISS effect is yet not fully understood. To be able to probe the CISS effect with area averaging methods like photoelectron spectroscopy a well-defined chiral thin film, consisting of helical molecules, is needed. In this study the chiral molecule thiadiazole[9]helicene (TD[9]H) is investigated on Au(111) and Ag(111) surfaces. To understand how chirality from one single molecule evolves into a fully chiral overlayer, a coverage dependent study, showing different structural motifs of TD[9]H, was performed. This structural evolution was investigated using scanning tunneling microscopy (STM) and low-energy electron diffraction (LEED). In combination, these methods reveal a chiral lattice, and the role of the different molecule-molecule and molecule-substrate interactions will be discussed.

O 50.3 Tue 18:00 P2

Determining the Epitaxial Relations of Lead Phthalocyanine on Graphitic Surfaces — •Marco Gruenewald, Roman Forker, Matthias Spoddeck, and Torsten Fritz — Friedrich-Schiller-Universität Jena, Institut für Festkörperphysik, Helmholtzweg 5, 07743 Jena, Germany

The epitaxial relations between lead phthalocyanine (PbPc) layers and single-crystal graphite (SCG) as well as few-layer graphene/SiC(0001) are determined. Compared to previous reports, we obtain a clearly improved precision by combining the following concepts: [i] the use of distortion-corrected, calibrated low-energy electron diffraction (LEED), [ii] the complementary use of large-scale scanning tunneling microscopy (STM) with high resolution, [iii] the evaluation of multiple scattering features in LEED and Moiré spots in Fourier-transformed STM images, [iv] the simulation of those reciprocal-space patterns with an objective numerical fitting to the experimentally discernible spots, and [v] the analysis of the STM Moiré patterns in real space. Our independently determined LEED and STM results mutually confirm each other due to the remarkably similar structural parameters obtained. For all systems investigated we find noncommensurate, point-on-line coincident registries, and the epitaxial relations of PbPc layers on SCG and on graphene/SiC(0001) are found to be nearly identical despite the different compositions of those substrates. https://doi.org/10.1021/acs.cgd.4c01055

O 50.4 Tue 18:00 P2

Solvent-Free Fabrication of Supported Lipid Bilayers Incorporating Carbon Quantum Dots and Gramicidin A for Biosensing Applications — •Daniel A. Saavedra[1], Benjamín Ruz[1], Nicolás Moraga[1], Nancy Gomez-Vierling[1], Marcelo A. Cisternas[2], Susana D. Rojas[2], and Ulrich G. Volkmann[1] — [1]Instituto de Física, Pontificia Universidad Católica de Chile, Santiago, Chile — [2]Escuela de Ingeniería Industrial, Univ. de Valparaíso, Chile

This study employed two phospholipids for the formation of supported lipid bilayers (SLBs): DPPG, with a net negative charge for enhanced adsorption to surfaces and biomolecules, and DPPC, which is neutral. SLBs were fabricated using a solvent-free, dry, ultra-high vacuum (UHV) approach [1], designed for protein insertion and nanoscale biosensor development for Forster energy transfer (FRET) detection mechanism.

Gramicidin A, a stable ion-channel protein, was incorporated into SLBs via physical vapor deposition monitored by high-resolution ellipsometry, followed by thermal treatment to enhance stability. Carbon quantum dots (CQDs), synthesized through hydrothermal carbonization of chitosan, were added via spin-coating. CQDs were selected for their photostability, low toxicity, and tunable fluorescence [2].

O 50.5 Tue 18:00 P2

Long range ordering of molecular layers on Ag(110) — •Ravi Priya, Weishan Wu, and Peter Jakob — Department of Physics, Philipps University of Marburg, Germany

Single domain molecular layers have been explored on the non-hexagonal Ag(110) substrate in terms of their long-range ordering using SPA-LEED and vibrational signature using high-resolution FT-IRAS. The absence of rotational domains for fcc(110) metal substrates allows for growing layers with uniform azimuthal orientation of deposited molecules. We have investigated various molecules and configurations that may form single domain molecular layers (including mirror domains). Specifically, monolayers of PTCDA, NTCDA, and regio-selectively substituted pentacene species (pentacene (PEN), pentacene-quinone (P2O), pentacene-tetrone (P4O), quinacridone (QA)) were deposited on Ag(110) and examined in terms of their structure using SPA-LEED, and their vibrational signature using IR - spectroscopy. Among them, PTCDA, NTCDA, PEN, and QA have been found to form parallel-oriented, single domain structures. For QA two novel heterochiral phases are found after annealing, in addition to the single-domain homochiral phase present T < 500K. For P2O and P4O, steric hindrance and hydrogen bonding lead to the formation of 1D islands and 2D islands, respectively, at sub-monolayer coverages. Another finding refers to the increased molecule - metal interaction on Ag(110) vs. Ag(111) that leads to an extra energy (down)shift of the LUMO, thereby having a significant impact on interfacial dynamic charge transfer (IDCT) of vibrational modes.

O 50.6 Tue 18:00 P2

Structural and vibrational properties of mixed (CuPc + P4O) molecular layers on Ag(111) — •Yeondu Kim, Ravi Priya, and Peter Jakob — Department of Physics, Philipps University Marburg, Germany

Structural properties of mixed layers comprising CuPc and P4O on Ag(111) and their thermal evolution have been investigated by means of Fourier-transform

infrared absorption (FT-IRAS) and electron diffraction (SPA-LEED). For this material combination several long-range ordered phases at different relative ratios are found. Their formation and thermal stability have been analyzed in the temperature range 80 - 500 K, limited by thermal desorption and/or dissociation of the CuPc and P4O compounds at high temperature. Lateral interactions between CuPc and P4O within the mixed layers lead to characteristic frequency shifts of out-of-plane modes. In parallel, the intensities of in-plane vibrational modes of CuPc and P4O are strongly attenuated when adsorbed at nearby locations, indicating a major change in the associated interfacial dynamical charge transfer (IDCT). Specifically, IDCT that is quite prominent for the pure CuPc/Ag(111) and P4O/Ag(111) monolayers, is substantially attenuated for the mixed layers. This is ascribed to a through-metal charge transfer from CuPc to P4O that is associated with an upshift of the CuPc former LUMO and the correlated downshift of the P4O former LUMO. These correlated shifts lead to substantially lower density of states at the fermi level for both molecular species and thereby a weakening of IDCT induced bands.

O 50.7 Tue 18:00 P2

Structure and thermal Stability of (C60+P2O) and (C60+P4O) Heterolayers on Ag(111) — •Mohammed Suhail Ansari, Ravi Priya, Keda Jin, and Peter Jakob — Department of Physics, Philipps-Universität Marburg, Germany

This study investigates the interactions between C_{60} fullerene and two organic semiconductors, 6,13-pentacenequinone (P2O) and 5,7,12,14-pentacenetetrone (P4O), on Ag(111) substrates using IRAS, SPA-LEED, and TDS. The aim is to elucidate the structural properties and transformation processes of C_{60} and P2O/P4O under varying preparation conditions and thermal processing. Our findings reveal three different vertical arrangement scenarios of the heterostructures based on the deposition sequence and thermal treatments: (a) Formation of a well-defined bilayer on a pre-deposited monolayer corresponding to the deposition sequence, (b) a complete interlayer exchange of molecules, and (c) a partial interlayer exchange leading to mixed layers. Scenario (a) is observed with a P2O bilayer deposited on a well-defined C_{60} monolayer. Interestingly, P2O adsorbs in an inclined orientation on the C_{60}/Ag(111) monolayer. Scenario (b) is observed with deposition of a monolayer of P2O followed by a bilayer of C_{60} at room temperature that results in P2O migration to the second layer, emphasizing the weaker interaction of P2O with the substrate Scenario (c) is found for the combination of C_{60} and P4O and it involves migration of P4O to the second layer if it was deposited in the first layer, and vice-versa. We will discuss in detail the evolution of the grown heterolayers in terms of molecular orientations, interlayer exchange, and intermixing.

O 50.8 Tue 18:00 P2

Molecular self-assembly of BDA on $CsPbBr_3$(100) — •Hannah Loh, Andreas Raabgrund, and M. Alexander Schneider — Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

$CsPbBr_3$ is a promising alternative to organic-inorganic perovskites in solar cells and light emitting diodes [1]. In these devices, organic layers are often used as charge transport layers and hence interface properties are of particular interest. By choosing particular anchoring groups of organic molecules (here the carboxylic COOH-group) the interaction with the perovskite material may be tuned.

In this contribution we investigate the self assembly of 4-4-biphenyl dicarboxylic acid (BDA) on epitaxial $CsPbBr_3$ on Au(100) [2] by STM. For submonolayer coverage of BDA on $CsPbBr_3$ we find that upon deposition at 305 K molecules grow epitaxially in compact islands. The islands consist of chains with a V-structure inside the chains similar to the way BDA self-assembles on Cu(111) [3].

Structure and charge carrier dynamics of an organic donor/acceptor heterostructure: a LEEM/PEEM study — •Franz Niklas Knoop, Klaus Stallberg, and Winfried Daum — IEPT, TU Clausthal, Germany

We combine low-energy electron microscopy (LEEM) and two-photon photoemission electron microscopy (2P-PEEM) to study the relation between structure and charge carrier dynamics in well-ordered organic donor/acceptor (D/A) heterostructures of para-sexiphenyl (*p*-6P) and copper-hexadecaphthalocyanine (F_{16}CuPc). While *p*-6P monolayers deposited on SiO_2 exhibit structural order only on a nanometer scale, *p*-6P islands in the second layer comprise micrometer sized single-crystalline domains. Using microspot low-energy electron diffraction (μLEED) and dark-field LEEM, on many islands we observe two mirror domains which we attribute to different tilt angles of the *p*-6P molecules in the second layer. Using μLEED we confirm epitaxial growth of monolayer F_{16}CuPc on SiO_2/*p*-6P which results in a structurally well-defined organic D/A interface. Especially on *p*-6P bilayer regions, large single-crystalline F_{16}CuPc domains are observed. With 2P-PEEM we observe increased photoemission from SiO_2/F_{16}CuPc after optical pumping at 810 nm. In contrast, for SiO_2/*p*-6P/F_{16}CuPc the photoemission signal decreases. Also, the reflectivity for low-energy electrons changes upon optical pumping. We relate these long-lived pump-induced effects to intermolecular charge transfer which is more pronounced for bilayer-*p*-6P/F_{16}CuPc than for monolayer-*p*-6P/F_{16}CuPc.

O 51: Poster Electronic Structure of Surfaces: Spectroscopy, Surface States

Time: Tuesday 18:00–20:00 Location: P2

O 51.1 Tue 18:00 P2

Visualizing quantum states in fluorene-based organometallic quantum corrals — •Longfeng Huang[1], Wenchao Zhao[1], Ignacio Piquero-Zulaica[1], Johannes Barth[1], and Biao Yang[1,2] — [1]Physics Department E20, Technical University of Munich, 85748 Garching, Germany — [2]Institute of Functional Nano and Soft Materials (FUNSOM), Soochow University, 215123 Suzhou, China

Constructing well-defined and controllable quantum states holds promise for applications in quantum technology. As an exemplary quantum architecture, quantum corrals (QCs) which are considered as artificial atoms attract enormous attention.1, 2 Common strategies for manufacturing QCs have mainly involved atomic and molecular manipulations, molecular assembly, and on-surface synthesis.3-5 However, fabricating robust QCs simultaneously with a high yield and specific size still remains elusive. In this work, we realize stable QCs with a well-defined size via organometallic bonding between fluorine-based molecules and intrinsic Ag adatoms on Ag(111). In particular, we observe spatial quantum resonance states inside the QCs, which arise from the scattered two-dimensional electron gas. Additionally, stadium-shaped and triangular QCs exhibit intriguingly specific orbital-like quantum states in differential conductance maps. In addition, we tune the QCs by replacing the F to H atoms and tip manipulation. Our study provides new means to fabricate controllable exotic quantum states with atomically precise QCs, aiding in a rational design strategy towards materials with tailored electronic properties.

O 51.2 Tue 18:00 P2

Termination-dependent ARPES maps from novel magnetic Kagome metals GdV_6Sn_6 and $GdMn_6Sn_6$ — •Robin P. Forster[1], Honey Boban[1], Mohammed Qahosh[1], Xiao Hou[1], Yishui Zhou[2], Yixi Su[2], Claus M. Schneider[1], and Lukasz Plucinski[1] — [1]PGI-6 Forschungszentrum-Jülich — [2]JCNS Forschungszentrum-Jülich

The magnetic Kagome metals GdV_6Sn_6 and $GdMn_6Sn_6$ combine in a single material phenomena such as flat Kagome bands [1,2], local moments of the 4f electrons of Gd, and itinerant Mn or V 3d electrons [3], providing a platform to study their complex magentic and electronic interactions. We have performed termination-dependent micro-ARPES measurements with 20 μm real-space resolution at 20 K of paramagnetic GdV_6Sn_6 [4] and ferrimagnetic $GdMn_6Sn_6$ [5]. Surface and bulk states could be distinguished in the series of scans made over a range of photon energies. We have chosen $h\nu$ of 80 and 130 eV for GdV_6Sn_6 and 80, 112, 140, and 200 eV for $GdMn_6Sn_6$ for detailed ARPES scans. In addition, XPS measurements were conducted, which provide an insight into the measured terminations. Preliminary circular-dirchroic ARPES maps exhibit multiple sign inversions that stem from a combination of initial state orbital angular momenta and photoemission final state scattering [6]. [1] PRL 127, 266401 (2021) [2] PRB 104, 15122 (2021) [3] JPSJ 90, 124704 (2021) [4] JMMM 202, 519 (1999) [5] PRB 104, 235139 (2021) [6] *arXiv:2410.19652 (2024).

O 51.3 Tue 18:00 P2

Structural fingerprints in the reflectance anisotropy of P-rich and In-rich AlInP(001) — •Isaac Azahel Ruiz Alvarado[1], Mohammad Amin Zare Pour[2], Thomas Hannappel[2], and Wolf Gero Schmidt[1] — [1]Lehrstuhl für Theoretische Materialphysik, Universität Paderborn, 33095 Paderborn, Germany — [2]Grundlagen von Energiematerialien, Institut für Physik, Technische Universität Ilmenau, 98693 Ilmenau, Germany

The surface optical anisotropy of AlInP(001) surfaces is investigated through experimental and theoretical approaches. Comparison is made between spectra calculated for energetically favored AlInP(001) surface structures with data measured on epitaxially grown $Al_{0.52}In_{0.48}P$(001) epilayers lattice-matched to GaAs samples. The anisotropies for photon energies below 3 eV provide clear fingerprints for the structure of the outermost surface atomics layers. The negative anisotropies for P-rich AlInP(001) surfaces are related to transitions involving

surface states located at the top P-dimers. In contrast, In-rich AlInP(001) surfaces show anisotropies related to surface states localized on the In atoms of the In dimers of the second row. The spectral features at higher energies provide insight into the near surface bulk ordering of AlInP. In particular, optical anisotropies at the AlInP critical point energies are found to be related to the CuPt ordering in the material.

Next-Gen ARPES: AI-controlled beam polarization through Graphene — •Ridha Eddhib[1], Balasubramanian Thiagarajan[2], and Jan Minar[1] — [1]New Technologies-Research Centre, University of West Bohemia, 30100 Pilsen, Czech Republic — [2]MAX IV Laboratory, Lund University, Lund, 22100, Sweden

Angle-Resolved Photoemission Spectroscopy (ARPES) stands as a cornerstone technique in condensed matter physics, offering deep insights into electronic structures and quantum states. However, the precision of ARPES measurements critically depends on the exact calibration of the photon beam polarization, a challenge that often confronts experimentalists. This study introduces an innovative application of artificial intelligence (AI) to revolutionize ARPES experiments by enabling precise calibration and tuning of photon beam polarization through graphene ARPES cross section, aiming for the ideal of 100% circular polarization. At the heart of our methodology is a neural network model, meticulously trained on datasets generated by the sophisticated one-step model of the SPRKKR [1] (Spin-Polarized Relativistic Korringa-Kohn-Rostoker) code, renowned for its accurate ARPES simulation capabilities. This study leverages the ase2sprkkr package for streamlined interfacing with SPRKKR, enriching our AI model training data with high-fidelity simulations. By implementing this AI-driven methodology, researchers can dynamically adjust their ARPES setups, ensuring that each measurement is conducted under optimal polarization conditions. O 51.5 Tue 18:00 P2

The CD-ARPES study of intercalated transition metal dichalcogenide V1/3NbS2 — •Jyoti Kaswan[1], Laurent Nicolaï[1], Raphaël Salazar[1], Aki Ismo Olavi Pulkkinen[1], Sunil W Dsouza[1], Zdeněk Sofer[2], and Jan Minár[1] — [1]University of West Bohemia, Plzeň, Czech Republic — [2]University of chemistry and technology Prague, Czech Republic

Intercalated transition metal dichalcogenides (TMDCs) have recently garnered significant attention from the condensed matter community due to the demonstration of exotic phenomena that depend on the intercalated transition metal [1]. We investigate the electronic structure of V-intercalated TMDC, V1/3NbS2, using Circular Dichroic Angle-Resolved Photoemission Spectroscopy (CD-ARPES) in combination with the one-step model of photoemission as implemented in the SPR-KKR package [2].The intensity asymmetry in CD contains a well-known dichroism component related to the measurement geometry, as well as a component associated with magnetic ordering, complicating the extraction of spin information from CD-ARPES data. To address this challenge, our group has developed a model of dichroism based on the one-step model of photoemission (SPR-KKR code). By incorporating the measurement geometry, the ab initio calculations enable the separation of geometric and spin contributions to the CD signal [3,4]. [1] B. Edwards et al, Nature Materials 22, 459*465 (2023). [2] H. Ebert, D. Ködderitzsch and J. Minár, Rep. on Prog. in Phys. 74, 096501 (2011) [3] O. Fedchenko et al., Sci. Adv. 10, eadj4883 (2024) [4] S. Exploring novel scanning force microscopy schemes by stabilising unstable states — •Lukas Böttcher[1], Hannes Wallner[2], Niklas Kruse[2], Wolfram Just[2], Ingo Barke[1], Jens Starke[2], and Sylvia Speller[1] — [1]Universität Rostock, Institute of Physics — [2]Universität Rostock, Institute of Mathematics

Dynamic scanning Force Microscopy (SFM) is a versatile and popular method for investigation of surface properties on the nanoscale. When probing the surface with an oscillating cantilever bistabilities may occur [1, 2], which are a result of nonlinearities arising due to interaction between tip and sample. By implementing a control scheme, we track the unstable state arising between the two stable states [3]. These unstable states may enable ultra-sensitive imaging conditions and give access to virtually interaction free mapping of material parameters.

O 52.2 Tue 18:00 P2

Surface photovoltage spectroscopy for investigation of SiC surface quality — •Viktoriia Nikonova[1], Nadine Schüler[1], Steffen Fengler[1], Maaz Soomro[1], Knut Gottfried[2], Imme Ellebrecht[2], and Kay Dornich[1] — [1]Freiberg Instruments GmbH, Delfter Strasse 6, 09599, Freiberg, Germany — [2]ErzM-Technologies UG, Technologie-Campus 1, 09126, Chemnitz, Germany

The surface photovoltage (SPV) technique belongs to the advanced methods for studying charge separation and transfer processes in photoactive materials.

The measurements of the SPV signal amplitude and time constant maps for SiC wafers have been done using a compact HR-SPS tool with fixed energy excitation sources. It has a high flexibility, which for example enables the integration of up to four lasers in the measurement head, either for injection level dependent SPV measurements or extracting depth information by using different wavelengths. Presented method based on fixed capacitor approach, that is much faster and more sensitive than on Kelvin probe. Also it works for highly doped substrate for which microwave based methods are difficult.

The experiments show the difference in maps between surface quality of wafers: polished wafers, fine and coarse grinded surfaces. Thus, the presented technique can be used to make quantitatively based decisions on the goodness of surface treatment methods without damaging the samples and to improve production based on SiC and others wide bandgap materials.

ESEM Automation - Advanced Acquisition & Dual Magnification — •Maurits Vuijk[1], Annika Kubsch[1], Johannes Zeininger[2], Karsten Reuter[1], Thomas Lunkenbein[1], and Christoph Scheurer[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]TU Wien

In Environmental Scanning Electron Microscopy (ESEM) experiments, the acquisition parameters are generally kept constant throughout the collection of the data set. This requires human supervision and limits data collection to one data set at a time. We use a custom automation interface to minimize supervision and allow for the collection of multiple simultaneous data sets containing complementary information.

Slow oscillatory dynamics are observed on a Co surface under hydrogen and oxygen dosing conditions using traditional ESEM. With our automation interface, we can implement more advanced acquisition programs into the microscope that take advantage of different time scales of the surface dynamics. By using automation to change the settings of the acquisition after each frame, we are able to capture multiple interlaced views of the same process. In this case, we alternated between two different magnification values, allowing us to capture a low magnification overview of the propagation of the surface dynamics and a high magnification view of the ongoing local structural changes to a selected surface feature. Many acquisition parameters such as gun voltage, stage position or focus can be automatically adjusted in an intelligent fashion, allowing for more complex acquisition strategies to unravel complex dynamic processes.

Simultaneous Grazing Incidence Small Angle X-Ray Scattering (GISAXS) and Absorption Spectroscopy (XAS) of Liquid Surfaces — •Carlo Schneider, Lukas Voss, Frederic Braun, and Dirk Lützenkirchen-Hecht — Bergische Universität Wuppertal

A method combining Grazing Incidence Small Angle X-ray Scattering (GISAXS) and X-ray Absorption Spectroscopy (XAS) has been developed to investigate liquid surfaces. The approach employs a specialized reaction cell and detection systems, including a PILATUS 100k detector for scattering data and a PIPS detector for absorption spectra, paired with a Quick EXAFS (QEXAFS) monochromator. Solutions of nickel chloride, cobalt nitrate, and zinc acetate were analyzed to evaluate the feasibility of integrating time-resolved GISAXS with XAS. Results demonstrate the capability of the method to provide structural and compositional information on nanometer and angstrom scales simultaneously. Challenges, such as interference patterns potentially caused by instrumental effects, were identified and suggest areas for further refinement. The developed technique offers potential for applications in materials science and chemistry, enabling insights into liquid systems.

O 52.5 Tue 18:00 P2

Surface-Sensitive Analysis of Liquid Interfaces: Grazing Incidence X-Ray Absorption Spectroscopy with a Double-Mirror Setup — •Lukas Voss, Dirk Lützenkirchen-Hecht, Frederic Braun, and Carlo Schneider — Bergische Universität Wuppertal, NRW

Grazing incidence X-ray absorption spectroscopy (GIXAS) is a powerful technique for surface-sensitive investigations. While the study of solid materials can be easily performed by adjusting the sample orientation to vary the X-ray incidence angle, the examination of liquids requires a specialized experimental setup. To address this challenge, a double-mirror system was integrated into an existing reflectometer, enabling GIXAS measurements on liquid samples. This setup was utilized to study the melting behavior of gallium and the formation of sol-gel-derived germanium oxide nanoparticles.

Enhancing Efficiency of Bethe-Salpeter equation calculations including spin-orbit coupling — •Seokhyun Hong, Cecilia Vona, Sven Lubeck, and Claudia Draxl — Institut für Physik and IRIS Adlershof, Humboldt-Universität zu Berlin

Calculating optical excitations in materials with significant spin-orbit coupling (SOC) effects is challenging due to the computational costs. We propose a new method to compute optical spectra including excitonic effects within an all-electron framework. This method extends recently introduced second variation with local orbital (SVLO) method[1] towards the Bethe-Salpeter equation (BSE) framework. The SVLO method is based on the conventional second variation (SV) approach for density-funtional theory calculations. In SV, SOC is treated as a perturbation through a two-step procedure. By solving the scalar relativistic (SR) Hamiltonian, we first obtain eigenvalues and states without SOC. A subset of these SR Kohn-Sham states is used as basis functions for evaluating the SOC terms. For many materials, this approach can require all available states for convergence and thus may not capture SOC effects accurately without resorting to huge matrix sizes. In the SVLO method, local orbitals (LOs) are included in the SV step as additional basis functions. It could be shown that this enhances the computational efficiency tremendously[1]. Through this work, we have implemented an analogous scheme in the BSE framework. We demonstrate, how we overcome current limitations and achieve highly precise results for materials with strong SOC, such as lead iodide, perovskites, MoS2,etc.

O 53.2 Tue 18:00 P2

First-Principles Calculations of X-ray Absorption Spectra: Supercell Core-Hole Method versus Bethe-Salpeter Equation — •Ziyu Wang[1], Lu Qiao[1], Ronaldo Rodrigues Pelá[2], and Claudia Draxl[1] — [1]Physics Department and CSMB, Humboldt-Universität zu Berlin, Zum Großen Windkanal 2, 12489 Berlin, Germany — [2]Supercomputing Department, Zuse Institute Berlin (ZIB), Berlin, Takustraße 7, 14195 Berlin, Germany

Accurate simulations of X-ray absorption spectra (XAS) are essential for understanding core-level excitations and electronic structure. In this study, we compare two approaches for calculating XAS: the supercell core-hole (SCH) method based on density-functional theory and the Bethe-Salpeter equation (BSE) of many-body perturbation theory. In the SCH method, core excitations are simulated by removing a core electron from the system, thus treating electron-hole interaction on the DFT level. In contrast, excitonic effects are considered explicitly in the two-body Hamiltonian underlying the BSE. We apply the SCH method with various exchange-correlation (xc) functionals of DFT to calculate XAS in diverse materials (metals, semiconductors, and insulators) and absorption edges. By comparing them with XAS obtained from BSE, we evaluate in which cases the SCH method is appropriate to be applied.

Increasing the Transferability of Machine Learning Potentials by Learning Atomic Properties — •Johann Richard Springborn[1,2], Gunnar Schmitz[1,2], and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany

In the last decade, Machine Learning Potentials (MLPs) have become an established tool for describing potential energy surfaces (PESs) of complex systems. While they significantly speed up the evaluation of the energy and forces in comparison to *ab-initio* methods, they require high-quality reference data for training. Depending on the systems to be studied, generating this training data can become the computational bottleneck and it is of high interest to reduce the number of structures to be computed as well as their complexity. We propose to achieve this goal by training MLPs on atomic properties instead of global quantities such as the system's total energy. This approach aims to increase the transferability of the resulting MLPs to more complicated systems while still utilizing easily accessible reference data.

O 55: Poster Topology and Symmetry-protected Materials

Time: Tuesday 18:00–20:00 Location: P2

O 55.1 Tue 18:00 P2

Native Bi_2Se_3 bulk and surface defects calculated from first principles — •Juntao Kong[1], Timur Biktagirov[2], Uwe Gerstmann[3], and Wolf Gero Schmidt[4] — [1]Warburger Str. 100,33098 Paderborn,Germany — [2]Warburger Str. 100,33098 Paderborn,Germany — [3]Warburger Str. 100,33098 Paderborn,Germany — [4]Warburger Str. 100,33098 Paderborn,Germany

Bi_2Se_3 attracts great attention presently because it is a strong topological insulator with its surface state consisting of a single Dirac cone at Γ which is protected by timereversal symmetry. Defects in the bulk, such as selenium vacancies, may introduce charge carriers that interfere with these surface states and reduce the ability to isolate surface conduction, which is critical for applications in quantum computing and spintronic devices. Surface defects, on the other hand, may act as active sites for adsorbing gas molecules, enabling changes in electronic properties that can be used for gas sensing. Here, we present a first principles study of native point defects in Bi_2Se_3. In particular, the formation energies of vacancies, antisites and interstitials [1,2] are investigated in dependence on Fermi level position and preparation conditions.

O 55.2 Tue 18:00 P2

Exploring magnetism, topology, and magnetoresistance in rare-earth based compound GdAuSn: Ab initio study — •Sumit Mondal[1], Japsreet Singh[2], and Kanachana Venkatakrishnan[2] — [1]Central University of Haryana — [2]Indian Institute of Technology, Hyderabad

Among rare-earth intermetallics, Gd-based compounds have garnered particular interest due to their diverse magnetic ground states and interesting non-trivial topological properties. In the present work, we investigate the magnetic, electronic, and dynamical properties of the equiatomic ternary compound GdAuSn using first-principles calculations. We explore its crystal structure and analyse various magnetic configurations to determine the ground state. Our results indicate that the C-type antiferromagnetic configuration has the lowest energy. By correlating the spin configurations with the underlying Heisenberg spin model, we determine the exchange interactions and calculate the critical tempera- ture using the mean-field approximation. Additionally, we examine the electronic band structure and find evidences of nodal surface and Dirac points, indicative of non-trivial topology. Furthermore, we analyse the longitudinal and transverse magnetoresistance behaviour of GdAuSn under varying magnetic fields, observ-

ing intriguing trends that suggest a correlation between magnetic field strength and magnetoresistance. Finally, we assess the phonon dispersion of our compound and find the topological phononic states with nodal surfaces. Our findings shed light on the magnetism, topology, and transport properties in rare-earth-based intermetallic compound.

O 55.3 Tue 18:00 P2

Graphene intercalation of the large gap quantum spin Hall insulator bismuthene — •Lukas Gehrig[1,2], Cedric Schmitt[1,2], Bing Liu[1,2], Jonas Erhardt[1,2], Simon Moser[1,2], and Ralph Claessen[1,2] — [1]Physikalisches Institut, Universität Würzburg, D-97074 Würzburg, Germany — [2]Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, D-97074 Würzburg, Germany

Bismuthene, a honeycomb monolayer of bismuth atoms synthesized on a SiC(0001) substrate, is a topological insulator with a breakthrough bulk band gap of 800 meV due to giant spin-orbit coupling. The magnitude of this gap exposes bismuthene as a promising candidate for room temperature spintronic applications based on the quantum spin Hall effect. However, oxidation of bismuthene in air confines most experiments on this system to UHV conditions. Here we demonstrate the intercalation of bismuthene between SiC and a single sheet of graphene. This protective layer effectively prevents bismuthene from oxidation, while it fully conserves its structural and topological properties as we readily demonstrate by scanning tunneling microscopy and photoemission spectroscopy. This paves the way for ex-situ experiments and ultimately brings bismuthene closer to the fabrication of spintronic devices.

Topical Talk O 56.1 Wed 9:30 H24

trends and perspectives in on-surfece UHV synthesis — •Pavel Jelínek — Institute of Physics of the Czech Academy of Sciences, Cukrovarnicka 10, Prague 6, Czechia

On-surface synthesis in ultra-high vacuum conditions has demonstrated the capability to synthesize molecular structures that are not available through traditional methods in solutions [1]. For example, the synthesis of radical PAH molecules on metal surfaces and their subsequent characterization with the help of UHV SPM contributed significantly to the progress in pi-magnetism [2]. In this talk, we will discuss the current status and perspectives of the field. We will also review what makes the on-surface synthesis on metallic surfaces unique concerning synthesis in solution. This includes the 2D constraint imposed by the proximity of the surface as well as the essential catalytic role of single atoms diffusing on metal surfaces [3], so-called adatoms, at elevated temperatures has been pointed out [4].

O 57.1 Wed 10:30 H2

Imaging the subcycle dynamics of topological surface currents in two-dimensional momentum space — •Tim Bergmeier[1], Suguru Ito[1], Jens Güdde[1], and Ulrich Höfer[1,2] — [1]Fachbereich Physik, Philipps-Universität Marburg, Germany — [2]Fachbereich Physik, Universität Regensburg, Germany

Angle-resolved photoemission spectroscopy (ARPES), combined with THz-electric fields and subcycle temporal resolution, offers unique capabilites to explore light-matter interaction on timescales faster than the oscillation of a light-wave. With this approach, it is possible to directly observe the dynamics of lateral Dirac currents along the surface of topological insulators, as well as the ultrafast buildup and dephasing of Floquet-Bloch states. However, so far the momentum resolution of such experiments was restricted to only 1-dimensional cuts within the surface momentum space.

Here, we present first results on the subcycle dynamics of surface currents resolving the full Dirac cone of Bi_2Te_3. In our recently established setup in Marburg, a 200 kHz laser system allows for MV/cm field strengths by parametric amplification of frequency-tunable THz-pulses in the range of 20-40 THz, together with optimal focussing at large angles of incidence inside of the UHV chamber by astigmatism compensation. Combined with ultrashort 400nm two-photon probe pulses (<15 fs) and a Scienta DA30 photoelectron analyzer, we are able to measure the whole 2D-momentum space with subcycle resolution.

O 57.2 Wed 10:45 H2

Measuring the non-equilibrium electronic structure of phonon-driven 2D materials — •Niklas Hofmann and Isabella Gierz — University of Regensburg

Quasi-periodic driving of solids with tailored light fields has emerged as a promising pathway for non-equilibrium materials design. To bring this approach to the next level, tailored driving schemes targeting specific degrees of freedom need to be combined with ultrafast probes of the atomic and electronic structure. We combine pump pulses tunable all the way from the Terahertz to the visible spectral range with a time- and angle-resolved photoemission (trARPES) probe to gain access to the transient electronic structure of driven materials. We recently implemented a narrow-band, strong-field Terahertz source [1] that allows for the selective excitation of phonon modes in materials with strong spin-orbit coupling and extreme ultraviolet probe pulses with tunable pulse duration to trace band structure dynamics on sub-cycle as well as cycle-averaged time scales. In this talk we present proof-of-principle experiments on graphene and show the transient electronic structure of WS_2 driven at resonance to the E_{1u} phonon mode.

Invited Talk O 57.3 Wed 11:00 H2

Floquet engineering in black phosphorus — •Changhua Bao[1,2], Shaohua Zhou[2], Benshu Fan[2], Michael Schüler[3], Teng Xiao[2], Hui Zhou[4], Zhiyuan Sun[2], Peizhe Tang[5], Sheng Meng[4], Wenhui Duan[2], and Shuyun Zhou[2] — [1]Department of Physics, University of Regensburg, Regensburg, Germany — [2]Department of Physics, Tsinghua University, Beijing, China — [3]Laboratory for Materials Simulations, Paul Scherrer Institute, Switzerland — [4]Institute of Physics, Chinese Academy of Sciences, Beijing, China — [5]School of Materials Science and Engineering, Beihang University, Beijing, China

The time-periodic light field has emerged as a control knob for manipulating quantum states in solid-state materials, dubbed as Floquet engineering. In this talk, I will present our progress on the experimental realization of Floquet band engineering in a model semiconductor, black phosphorus. Driven by strong mid-infrared light fields, transient gap opening and band renormalization are directly resolved with exotic pseudospin selectivity. In addition to band-structure engineering, manipulation of symmetry properties through Floquet engineering is also explored, including ultrafast glide-mirror symmetry breaking and parity symmetry manipulation. This series of works provides a comprehensive understanding of Floquet engineering in semiconductors and important guidance for extending Floquet engineering into more materials.

Nat. Rev. Phys. 4, 33 (2022); Nature 614, 75 (2023); PRL 131, 116401 (2023); ACS Nano 18, 32038 (2024); Nat. Commun. in press

O 57.4 Wed 11:30 H2

Observation of Floquet states in graphene — •Marco Merboldt[1], Michael Schüler[2], David Schmitt[1], Jan Philipp Bange[1], Wiebke Bennecke[1], Karun Gadge[3], Salvatore R. Manmana[3], Sabine Steil[1], G. S. Matthijs Jansen[1], Daniel Steil[1], Michael Sentef[4], Marcel Reutzel[1], and Stefan Mathias[1] — [1]Georg-August-Universität Göttingen, I. Physikalisches Institut, Germany — [2]Department of Physics, University of Fribourg, Fribourg, Switzerland — [3]Georg-August-Universität Göttingen, Institut für Theoretische Physik, Germany — [4]Institute for Theoretical Physics, University of Bremen, Bremen, Germany

Recent advances in the field of condensed-matter physics have unlocked the potential to realize and control emergent material phases that do not exist in thermal equilibrium. One of the most promising concepts in this regard is Floquet engineering, the coherent dressing of matter via time-periodic perturbations. However, the broad applicability of Floquet engineering to quantum materials is in question, especially with respect to (semi-)metals and graphene in particular.

Here, we resolve this long-standing debate by using electronic structure measurements to provide direct spectroscopic evidence of Floquet effects in graphene [1]. We report light-matter-dressed Dirac bands by measuring the con-

tribution of Floquet sidebands, Volkov sidebands, and their quantum path interference to graphene's photoemission spectrum. Fully supported by experiment and theory, we demonstrate that Floquet engineering in graphene is possible.

[1] Merboldt *et al.*, arXiv:2404.12791 (2024)

O 57.5 Wed 11:45 H2

Theory of nonperturbative nonlinear transport in a Floquet-Weyl semimetal — •Juan Ignacio Aranzadi[1], Matthew Day[2,3], James McIver[2,3], and Michael Sentef[1,2] — [1]Institute for Theoretical Physics, University of Bremen/ Bremen Center for Computational Material Science, Bremen — [2]Max Planck Institute for the Structure and Dynamics of Matter, CFEL, Hamburg — [3]Department of Physics, Columbia University, New York, NY, USA

Weyl semimetals exhibit unique topological properties characterized by pairs of Weyl nodes with opposite chirality. While their transport properties have been extensively studied [1], their behavior under strong optical driving fields remains poorly understood. In this regime, the material response is governed by photon-dressed Floquet-Bloch states. Here, we investigate the photocurrent production mechanisms in Td-MoTe2, a type-II Weyl semimetal, under strong circularly polarized fields. Recent transport measurements in this material revealed a linear scaling of photocurrents at strong fields (<0.4 MV/cm) for the circular photogalvanic effect and the light-induced Hall effect [2]. We explore the microscopic theory underlying the photocurrent production in this system and disentangle its various contributing mechanisms. [1] J. Hu, S. Xu, N. Ni, Z. Mao, Annual Review of Materials Research (2019) 49:1, 207-252 [2] M. Day et. al. Nonperturbative nonlinear transport in a topological light-matter hybrid (2024)

O 57.6 Wed 12:00 H2

Hybrid Frenkel-Wannier excitons facilitate ultrafast energy transfer at a 2D-organic interface — •Wiebke Bennecke[1], Ignacio Gonzalez Oliva[2], Jan Philipp Bange[1], Paul Werner[1], David Schmitt[1], Marco Merboldt[1], Anna M. Seiler[1], Daniel Steil[1], R. Thomas Weitz[1], Peter Puschnig[3], Claudia Draxl[2], G. S. Matthijs Jansen[1], Marcel Reutzel[1], and Stefan Mathias[1] — [1]I. Physikalisches Institut, Georg-August-Universität Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany — [2]Physics Department and CSMB, Humboldt-Universität zu Berlin, 12489 Berlin, Germany — [3]Institute of Physics, NAWI Graz, University of Graz, 8010 Graz, Austria

The combination of two-dimensional transition metal dichalcogenides (TMDs) and organic semiconductors (OSCs) is a highly promising material platform for the realization of future optoelectronic devices. While the excitonic properties of their individual components have been intensively studied, much less is known about excitons at the hybrid interface. Here, we use ultrafast momentum microscopy and many-body perturbation theory to investigate the exciton landscape at the PTCDA/WSe_2 interface [1]. In particular, we find an exciton state formed via Förster resonant energy transfer, which is of hybrid nature: Concomitant intra- and interlayer electron-hole transitions within the OSC layer and across the TMD/OSC interface, respectively, give rise to an exciton wavefunction with mixed Frenkel-Wannier character.

[1] Bennecke *et al.*, arXiv:2411.14993 (2024)

O 57.7 Wed 12:15 H2

Characterization of Excitons for bulk Black Phosphorus — •Juan Felipe Pulgarin Mosquera[1,2], Geoffroy Kremer[2,3], Claude Monney[2], and Michael Schueler[1,2] — [1]PSI Center for Scientific Computing, Theory and Data, 5232 Villigen PSI, Switzerland — [2]Department of Physics, University of Fribourg, CH-1700 Fribourg, Switzerland — [3]Institut Jean Lamour, CNRS-Université de Lorraine

Excitons (coupled electron-hole pairs) in semiconductors can form collective states that exhibit spectacular nonlinear properties and possible applications in future optoelectronic devices. We present here some theoretical methods and a workflow for determining the excitonic wave functions and the corresponding excitonic binding energies for bulk Black Phosphorus. We solve the Bethe-Salpeter equations for coherent and incoherent excitations. The theoretical/numerical results are compared to the experimental ones of angle resolved photoemission spectroscopy (ARPES), by analyzing the spectra produced after including non-equilibrium electron-phonon dynamics; solving the time-dependent Boltzmann equation. These results allow us to understand the nature and characteristics of these two-particle bound states, together with some scattering effects, being challenging due to the stronger screened potential for 3D materials, resulting in short time excitations.

O 57.8 Wed 12:30 H2

Momentum-resolved valleytronic dynamics in TMDC monolayers — •Sarah Zajusch[1], Lasse Münster[2], Marcel Theilen[1], Marleen Axt[1], Yaroslav Gerasimenko[2], Jens Güdde[1], Robert Wallauer[1], and Ulrich Höfer[1,2] — [1]Fachbereich Physik, Philipps-Universität Marburg — [2]Fachbereich Physik, Universität Regensburg

The lack of inversion symmetry allows to access the valley degree of freedom in TMDC materials. With circular polarized light, time-resolved momentum microscopy enables us to trace the formation of a rich variety of bright and dark excitons typical for these materials on an ultrafast timescale and throughout the whole Brillouin zone.

We performed measurements on both $MoSe_2$ and WS_2. In WS_2, we observe a valley depolarization at room temperature within 100 fs, whereas in $MoSe_2$, this happens on a slower timescale, with a slight polarization that is still visible long after 100 fs. There are mainly two proposed leading mechanisms for this relaxation process, exciton-phonon scattering and electron-hole exchange interaction, which are differently pronounced in W- and Mo-based TMDCs due to the differences in their excitonic energy landscapes. As the ultrafast formation of dark KK'- and KΣ-excitons in WS_2 shows, mainly exciton-phonon scattering contributes to the valley relaxation here. This process is strongly temperature-dependent.

O 57.9 Wed 12:45 H2

Formation and thermalization of non-equilibrium excitonic occupations — •Paul Werner[1], Jan P. Bange[1], Wiebke Bennecke[1], Giuseppe Meneghini[2], David Schmitt[1], Marco Merboldt[1], Anna Seiler[1], AbdulAziz AlMutairi[3], Samuel Brem[2], Junde Liu[1], Daniel Steil[1], Stephan Hofmann[3], R. Thomas Weitz[1], Ermin Malic[2], Stefan Mathias[1], and Marcel Reutzel[1] — [1]I. Physikalisches Institut, Georg-August Universität Göttingen, Germany — [2]Fachbereich Physik, Philipps-Universität Marburg, Germany — [3]Department of Engineering, University of Cambridge, United Kingdom

Semiconducting transition metal dichalcogenides (TMDs) host a rich landscape of Coulomb-correlated electron-hole pairs, which makes them ideal candidates for future optoelectronic applications. After an initial optical excitation of bright excitons, it is known that subsequent scattering into optically dark excitons takes place [1]. However, these processes must involve non-thermal exciton distributions that thermalize to a quasi-equilibrium [2]. In this work we use time-resolved momentum microscopy to directly access these non-thermal exciton distributions in optically excited homobilayer MoS_2. We identify the exciton landscape and relaxation pathways, and we find clear signatures of the non-equilibrium exciton distributions that are involved in the thermalization process. We compare our data with a full microscopic model calculation that confirms our experimental findings.

O 58.1 Wed 10:30 H4

Step Bunching Instability and its Effects in Electrocatalysis on Platinum Surfaces — •Francesc Valls Mascaró[1], Marc T. M. Koper[2], and Marcel J. Rost[3] — [1]Departement of Physical Chemistry, University of Innsbruck — [2]Leiden Institute of Chemistry, Leiden University — [3]Huygens-Kamerlingh Onnes Laboratory, Leiden Institute of Physics, Leiden University

The atomic-scale surface structure plays a major role in the electrochemical behaviour of a catalyst. The electrocatalytic activity towards many relevant reactions, such as the oxygen reduction reaction on platinum, exhibits a linear dependency with the number of steps until this linear scaling breaks down at high step densities. In this work we show, using Pt(111)-vicinal surfaces and in situ electrochemical scanning tunnelling microscopy, that this anomalous behaviour at high step densities has a structural origin and is attributed to the bunching of closely spaced steps. While Pt(554) presents parallel single steps and terrace widths that correspond to its nominal, expected value, most steps on Pt(553) are bunched. Our findings challenge the common assumption in electrochemistry that all stepped surfaces are composed of homogeneously spaced steps of monoatomic height and can successfully explain the anomalous trends documented in the literature linking step density to both activity and potential of zero total charge [1].

O 58.2 Wed 10:45 H4

ALD coatings on 1D and 3D structures for electrochemical applications — •Siow Woon Ng — Department of Chemistry and Pharmacy, Friedrich-Alexander-Universität Erlangen Nürnberg, Egerlandstraße 3, 91058 Erlangen, Germany

Atomic layer deposition (ALD) utilizes self-limiting surface reactions to construct ultrathin films layer by layer. Among many deposition techniques, ALD

uniquely offers conformal deposition and excellent coating thickness control. Hence, the technique is particularly attractive for depositing structures with complex geometries, such as spheres, foams, 1D nanostructures, and 3D structures. This presentation discusses the preparation of 1D nanostructure and 3D-printed structures, followed by ALD inorganic and semiconductor coatings on these scaffolds. The influence of surface properties on the ALD coatings, and how the coatings enhance the electrical, mechanical, optical, and chemical properties or introduce new functionalities to the host structures will be presented. In particular, we will demonstrate that thin coatings in nanometer thicknesses are optimized for sensing and photo- and electrocatalytic applications.

O 58.3 Wed 11:00 H4

echemdb - a Database for Electrochemical and -catalytic Data of Metal Single-Crystal Electrodes — •Johannes Hermann[1], Julian Rüth[2], Nicolas G. Hörmann[3], Nicolas Bergmann[3], Karsten Reuter[3], Timo Jacob[1], and Albert K. Engstfeld[1] — [1]Institute of Electrochemistry, Ulm, DE — [2]Julian Rüth GmbH, DE — [3]Fritz-Haber-Institut der MPG, Berlin, DE

Over the last decades and still today, electrochemical and catalytic studies on metal single-crystal electrodes form the basis of our fundamental understanding of atomic-scale processes on such electrodes and more complex catalyst materials, such as supported nanoparticles, found in applications. So far, experimental data and information on the data are mostly only available as traces and plain text in published works, which limits the FAIR (findable, accessible, interoperable, and reusable) use of the data in further experimental and theoretical works. To mitigate this issue, we present an open-source community approach to store such data and metadata in a structured way in a dedicated database, using the frictionless framework combined with a simple metadata standard. We illustrate the challenges associated with setting up such a system for the underlying data types, highlight tools that allow recovering data from published works and storing new data from experimental and theoretical works similarly. We demonstrate that these tools are equally applicable to other research areas. Finally, we provide some examples of using such a database in daily routines (finding and comparing experimental and theoretical data) and system-specific studies (reusability).

O 58.4 Wed 11:15 H4

The direct comparison of Pt and Cu particles on a TiO_2 photocatalyst in the hydrogen evolution reaction — •Lucia Mengel[1], Pieter van den Berg[2], Martin Tschurl[1], Neill Goosen[2], and Ueli Heiz[1] — [1]Chair of Physical Chemistry, School of Natural Sciences & Catalysis Research Center, Technische Universität München, Lichtenbergstr. 4, 85748 Garching, Germany — [2]Department of Process Engineering, Stellenbosch University, Banghoek Rd, Stellenbosch Central, Stellenbosch, 7599, South Africa

Anatase TiO_2 loaded with a metal co-catalyst is a well-known photocatalyst for hydrogen evolution. Fundamental studies on this system often employ photoreforming of alcohols as model reaction, utilizing noble metals such as platinum as a co-catalyst. The hole-mediated photooxidation reaction of the alcohol yields hydrogen next to valuable organic compounds such as aldehydes. Recent efforts aim at a replacement of platinum as co-catalyst by the more abundant and less expensive copper. In our work, we focus on the evolution of hydrogen on copper-loaded anatase by performing ethanol photoreforming in the liquid phase in oxygen- and water-free conditions. We study the hydrogen evolution reaction under excitation with UV-light and compare the photoactivity of the system to a common platinum-loaded catalyst and discuss possible scenarios for the interpretation of the reaction behavior.

O 58.5 Wed 11:30 H4

Microkinetic Modeling of the Hydrogen Evolution Reaction in Alkaline Conditions — •Dipam Patel and Georg Kastlunger — Technical University of Denmark

The Hydrogen Evolution Reaction (HER) in alkaline media is distinguished from the acidic case by the source of H. Significant theoretical work has investigated and diagnosed activity in acidic conditions, but this understanding does not necessarily correspond to alkaline. The implications of the stronger O-H bond in H2O compared to that in H3O+ are not yet fully understood. Using constant-potential electrochemical barriers, we developed a microkinetic model of alkaline HER activity on a selection of close-packed metallic surfaces. By accounting for the different potential responses of catalysts, we are able to reproduce the relative rates and tafel slopes seen in experiment. By relating the calculated activities to electrochemical descriptors, we show that the application of solely hydrogen binding descriptors, as in acidic HER, does not fully explain HER activity in alkaline.

O 58.6 Wed 11:45 H4

Predicting Charge Effects at Electrified Solid/Liquid Interfaces — •Nicolas Bergmann[1], Nicéphore Bonnet[2], Nicola Marzari[2], Karsten Reuter[1], and Nicolas G. Hörmann[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Laboratory of Theory and Simulation of Materials, EPFL, Lausanne

Computational modeling of electrified solid-liquid interfaces must account for capacitive contributions at potentials beyond the point of zero charge (PZC) [1]. These contributions can approximately be obtained from first-principles calculations at constant charge, employing a second-order Taylor expansion that involves the surface's free energy, the work function, and the interfacial capacitance at the PZC [2]. Machine learning (ML) surrogate models have already successfully been employed to predict the PZC energies at significantly reduced computational costs. Here, we extend this by presenting a ML model for work functions and apply this to two standard electrode modeling setups. By including the derivatives of the atomic forces with charge, we stabilize our model and predict the atomic effective charge. As an outlook, we show how this methodology could be utilized to run molecular dynamics simulations at charged conditions and electrochemical barrier calculations.

O 58.7 Wed 12:00 H4

Dynamics at metal-water interfaces for catalytic hydrogenation — Tien Le[1], Shoutian Sun[1], and •Bin Wang[1,2] — [1]University of Oklahoma, Norman, Oklahoma, US — [2]Max Planck Institute for Sustainable Materials GmbH, Düsseldorf, Germany

The presence of water has been shown to enhance hydrogenation of polar chemical functional groups, such as C=O and N=O bonds, through proton shuttling. To demonstrate such rather sophisticated reaction pathways, explicit solvent models with dynamic change of local solvent structures should be considered. Beyond what we reported previously for water-promoted C=O hydrogenation in furfural, in this presentation, we will highlight how the dynamics of the local water structures within the first solvation shell may affect the hydrogenation kinetics. Specifically, we find that the activation barriers correlate well with some collective variables that determine the local configuration and relative positions of surface hydrogen and water. We further show that such dynamics of the metal-water interfaces can be manipulated by different approaches to tune the reaction kinetics. Our findings thus provide fundamental insights of this dynamic transformation at the solid-liquid interface and its impact on catalytic activity and selectivity.

O 58.8 Wed 12:15 H4

Rough Choice: Comparing 1- and 2D Representations of Electrocatalyst Morphology in Multiscale Models — •Hemanth S. Pillai, Hendrik H. Heenen, Karsten Reuter, and Vanessa J. Bukas — Fritz Haber Institute der MPG, Berlin

While electrocatalyst morphology is often used to tune product selectivity in electrochemical systems, the precise mechanism underpinning this relationship still remains elusive. Recently, we highlighted the role of morphology impacting product selectivity through a "Desorption–Re-adsorption–Reaction" mechanism [*Nat. Catal.* 7, 847*854 (2024)]. In particular, the catalyst morphology steers the competition between two elementary steps: either the desorption and diffusion of an intermediary byproduct or its re-adsorption and further reaction. Within such a model, morphology is captured in an effective manner via a surface roughness descriptor, however some systems may require a more explicit representation of the catalyst morphology. To assess this we employ a transport coupled kinetic model and systematically improve the representation of the catalyst from an effective one-dimensional descriptor to an explicit two-dimensional catalyst morphology. We find that deviations between the two descriptions are governed by morphological and transport parameters, i.e. diffusion length, particle size, shape, and interparticle distance. To conclude, we demonstrate that detailed morphological descriptions are only necessary within a narrow parameter window, thus providing guidance for selecting appropriate representations.

O 58.9 Wed 12:30 H4

Atomistic Simulation of Platinum-Water Interface: Deep Potential Molecular Dynamics (DP-MD) — •Muhammad Saleh[1], Alexander Lozovoi[2], Riccardo Martina[1], Matthew Darby[2], Clotilde Cucinotta[2], and Marialore Sulpizi[1] — [1]Theoretical Physics of electrified liquid-solid interface, Ruhr-University Bochum, Germany — [2]Department of Chemistry, Imperial College London, UK

The interaction between platinum surfaces and water holds significant importance due to its extensive applications in catalysis and electrochemical reactions. However, investigating these interactions at the atomistic level presents considerable experimental challenges. Moreover, accurately modeling such systems demands a substantial number of atoms (exceeding 1000), which can impede computational efficiency, particularly when using high-quality methods. In this study, we utilize the capabilities of machine learning potentials, specifically Deep Potential Molecular Dynamics (DP-MD), to overcome these challenges and achieve comprehensive simulation trajectories. This approach allows for an in-depth analysis, providing valuable insights into the surface properties.

O 58.10 Wed 12:45 H4

Preparation and Electrochemical Characterization of Metal Bicrystal Electrodes — •Nadine Wölfel, Albert K. Engstfeld, and Timo Jacob — Institute of Electrochemistry, Ulm, DE

The activity of a metal-based electrocatalyst strongly depends on its structural properties, where grain boundaries (GB) can play a significant role. One approach to study the impact of GBs is by varying the grain size of a material, which changes the GB density. In our study we aim at gaining fundamental insights into the atomic scale electrochemical and -catalytic processes at a GB, separating two surfaces with specific crystallographic orientation. We demonstrate how such electrodes can be prepared from Pt wires using the controlled atmosphere flame fusion method [1]. Here, poly-oriented single crystals are formed from two wires, crystallizing as a poly-oriented bicrystal from a common melt. By carefully polishing the poly-oriented crystal along the surface orientation of interest, a planar bicrystal surface with a single GB can be created. The structural properties of the prepared electrodes are determined by Laue X-ray diffraction, scanning electron microscopy (SEM), and electron backscatter diffraction (EBSD) spectroscopy. Electrochemical measurements, such as cyclic voltammetry (CV) are presented, which, based on the features in the CV, provide insights into the available facets and defects. The local electrocatalytic activity of the GB can be elucidated by scanning electrochemical microscopy (SECM) measurements.

O 59: Spins on Surfaces at the Atomic Scale I

Time: Wednesday 10:30–13:00 Location: H6

O 59.1 Wed 10:30 H6

Quantum spin engineering in bottom-up assembled molecular nanostructures — •Taner Esat[1,2], Dmitriy Borodin[3,4], Jeongmin Oh[1,2], Andreas Heinrich[3,4], Stefan Tautz[1,2,5], Yujeong Bae[3,4], and Ruslan Temirov[1,2,6] — [1]Peter Grünberg Institute (PGI-3), Forschungszentrum Jülich, Germany — [2]Jülich Aachen Research Alliance, Germany — [3]Center for Quantum Nanoscience, Institute for Basic Science, South Korea — [4]Ewha Womans University, South Korea — [5]RWTH Aachen University, Germany — [6]University of Cologne, Germany

Scanning tunneling microscopy (STM) is a powerful technique for fabricating and studying artificial nanostructures with purpose-engineered quantum states. Using the manipulation capabilities of the STM, we place aromatic molecules in an upright geometry on a pedestal of two transition metal atoms on the surface [1] and on the STM tip. These nanostructures carry electron spins that are well decoupled from the metallic substrate [2]. Based on this, we fabricate a single-molecule quantum sensor at the apex of the STM tip and address it by electron spin resonance. We use this sensor to measure the magnetic and electric dipole fields emanating from a single atom with sub-angstrom spatial resolution [3]. Finally, we show that varying the transition metal atoms in the pedestal alters the spin state of the molecular nanostructures, leading to exceptionally long spin lifetimes of up to several minutes. [1] Esat et al., Nature 558, 573 (2018) [2] Esat et al., Phys. Rev. Research 5, 033200 (2023) [3] Esat et al., Nat. Nanotechnol. 19, 1466 (2024)

O 59.2 Wed 10:45 H6

Tuning the Kondo temperature of Porphyrin molecules via adsorption configurations. — •Xiangzhi Meng[1], Jenny Möller[2], Rodrigo Menchón[3], Alexander Weismann[1], Daniel Sánchez-Portal[3], Aran Garcia-Lekue[3], Rainer Herges[2], and Richard Berndt[1] — [1]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität, 24098 Kiel, Germany — [2]Otto-Diels-Institut für Organische Chemie, Christian-Albrechts-Universität, 24098 Kiel, Germany — [3]Donostia International Physics Center (DIPC), 20018 Donostia-San Sebastián, Spain

Magnetic molecules may serve as building blocks for spintronic devices at the ultimate limit of miniaturization. This sort of application requires an understanding of their spin properties. An important example is the Kondo effect that originates from the exchange interaction between a localized magnetic moment and the conduction electrons of the host metal. The interaction strength is reflected by a characteristic temperature, the Kondo temperature TK. In this work, we will show the Kondo effect of cobalt(II)-5,15-bis(4'-bromophenyl)-10,20-bis(4'-iodophenyl)porphyrin (CoTPPBr2I2) molecules on an Au(111) surface with a low-temperature STM. In comparison with the molecules reported before, the Kondo temperature of CoTPPBr2I2 can be tuned over a much broader range (8 K to 250 K) by switching their configurations. Additionally, we show that surface reconstruction plays a crucial role in modulating the molecular Kondo effect.

O 59.3 Wed 11:00 H6

Fock-Darwin states in tunable artificial atoms with high spin-orbit coupling — •Julian H. Strik, Hermann Osterhage, Kira Junghans, Niels P.E. van Mullekom, Emil Sierda, Anna M.H. Krieg, Danis Badrtdinov, Daniel Wegner, Mikhail I. Katsnelson, Malte Rösner, and Alexander A. Khajetoorians — Institute for Molecules and Materials, Radboud University, Nijmegen, The Netherlands

Quantum simulators are a pathway to study novel physical phenomena which are difficult to predict or observe in synthesized materials. To date, there is still a lack of viable platforms for quantum simulation to study confined electrons in strong magnetic fields, namely in the limit that the magnetic length is on the order of the Bohr radius. For typical crystals, this corresponds to field strengths that are unattainable in a laboratory.

In this talk I will discuss the magnetic response of atomic-scale quantum dots based on individual Cs atoms on the semiconducting surface of InSb [1]. Using low-temperature scanning tunnelling microscopy and spectroscopy, we pattern quantum dots of various sizes and geometries, by sculpting the potential of the underlying 2DEG. We then study the LDOS of these various structures to an external magnetic field. We relate this to the Fock-Darwin model of atomic states [2]. We review the experimental results in this context and discuss the role of structure size, symmetry and spin-orbit coupling.

O 59.4 Wed 11:15 H6

Nickelocene-functionalized tips as a molecular spin sensor — •Diego Soler-Polo[1], Ana Barragán[2], Andrés Pinar Solé[1], Manish Kumar[1], Oleksandr Stetsovych[1], Ben Lowe[1], Elena Pérez-Elvira[2], Koen Lauwaet[2], Pavel Jelínek[2], and José Ignacio Urgel[2] — [1]Institute of Physics of the Czech Academy of Sciences, Prague, Czech Republic — [2]IMDEA Nanoscience, Cantoblanco, Madrid, Spain

Polyradicals nanographenes with low-lying spin excitations have almost degenerate states with different spins. Even Many-Body methods such as CASSCF and NEVPT2 might not provide enough accuracy to determine the spin of the real ground state. Here, we demonstrate that scanning probe microscopy with a nickelocene-functionalized tip can distinguish between nearly degenerate spin states of single molecular π-magnets. The nickelocene molecule has a spin 1 and a small magnetic anisotropy of 4 meV that interacts with the molecular spins of the sample. The spectroscopic patterns as we the tip is approached can be related to the number of radicals and their couplings. Such patterns are well reproduced by simple spin models and the corresponding simulated inelastic current. First, the molecular radicals are fitted to a spin hamiltonian, which is then coupled to the S=1 modelling the nickelocene. A cotunneling formalism adapted to spin hamiltonians provides the dIdV maps comparable with the experimental measurements, thus revealing the spin of the sampled system.

O 59.5 Wed 11:30 H6

Vibrational excitations in magnetic triangular nanographenes — Nils Krane[1], •Elia Turco[1], Annika Bernhardt[2], Michal Juríček[2], Roman Fasel[1,3], and Pascal Ruffieux[1] — [1]Empa - nanotech@surfaces Laboratory, 8600 Dübendorf, Switzerland — [2]University of Zurich, Zurich, Switzerland — [3]University of Bern, Bern, Switzerland

Inelastic electron tunneling spectroscopy has become a powerful tool for the investigation of excited states in single molecules and other quantum dot systems. These excited states can be of various origins, notably from higher energy spin states but also from vibrational modes. Especially in the case of carbon-based molecules, featuring π-magnetism with strong exchange coupling, both excitation mechanisms can be found within one system. Here, we present a simple method to distinguish between these two mechanisms by spatial map-ping of the excited states without any need for high magnetic fields. As a model system, we investigate the spin $S = 1/2$ phenalenyl radical on Au(111) and observe the featuring of two excited states via inelastic tun-neling spectroscopy. Comparison with DFT calculations proofs the vibrational origin of the observed inelastic features and allows us to assign them to distinct vibrational modes.

O 59.6 Wed 11:45 H6

Realization of separation of time scales in a heterogeneous atomic Boltzmann machine — •Kira Junghans, Hermann Osterhage, Werner M. J. van Weerdenburg, Niek M. M. Aarts, Anna M. H. Krieg, Tren Jacobs, Niels P. E. van Mullekom, Ruben Christianen, Eduardo J. Domínguez Vázquez, Hilbert J. Kappen, and Alexander A. Khajetoorians — Radboud University, Nijmegen, The Netherlands

The Boltzmann machine (BM) describes an energy-based neural network formed by coupled, fluctuating Ising spins [1]. A material realization of the Boltzmann machine was constructed using the complex stochastic dynamics of coupled Co atoms on the surface of black phosphorus (BP) [1]. Neurons and synapses were realized by a separation of time scales exploiting the anisotropic electronic structure of BP [1]. Using the anisotropy of the substrate is a limita-

tion in scaling this concept.
Here, we study the coupled dynamics of different types of atoms on BP, which exhibit orbital memory [2,3]. We study the influence of the coupling on stochastic dynamics in heteroatomic dimer and trimer configurations with scanning tunneling microscopy (STM). Further, we discuss how the multi-well energy landscape can be influenced by an applied AC signal.

O 59.7 Wed 12:00 H6

Spin-surface interactions of S=1/2 molecular magnets on superconductors — •Susanne Baumann[1], Lukas Arnhold[1], Nicolaj Betz[1,2], Matteo Briganti[3], Andrea Sorrentino[4], Giulia Serrano[4], Federico Totti[3], Roberta Sessoli[3], and Sebastian Loth[1,2] — [1]University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany — [2]Center for Integrated Quantum Science and Technology, Stuttgart, Germany — [3]Department of Chemistry 'Ugo Schiff', University of Florence, Italy — [4]Department of Industrial Engineering, University of Florence, Italy

The interaction between magnetic molecules and superconducting surfaces critically depends on the electronic properties of the surface and the molecules' binding configuration, which determines the wave function overlap between molecule and surface. Using scanning tunneling microscopy (STM), we study the organometallic molecule ((η8-cyclooctatetraene)(η5-cyclopentadienyl)titanium) (CpTicot) on two different superconducting surfaces. On lead (Pb) nanoislands on Si(111), CpTicot exhibits multiple binding orientations with varying surface coupling strengths, that can be strong enough to generate Yu-Shiba-Rusinov bound states within the superconducting gap. Conversely, on vanadium (V(100)), the molecules adsorb in a single orientation with minimal coupling to the superconductor. Their spin states remain largely decoupled from the substrate, preserving their S=1/2 properties. These findings offer valuable insights into chemical design principles for molecular qubits where individual adressability and decoupling from superconducting substrates is desired.

O 59.8 Wed 12:15 H6

Edge states in bottom-up designed spin chains on a superconducting Rashba surface alloy — •Harim Jang, Khai That Ton, Lucas Schneider, Jens Wiebe, and Roland Wiesendanger — Department of Physics, University of Hamburg, Hamburg, Germany

The experimental quest for topological superconductors and emergent Majorana modes (MMs) at their edges have attracted significant interest recently in both directions of fundamental understanding of topology-driven quantum states and their potential applications in quantum computation leveraging the robustness by topological protection. A spin chain on a conventional superconductor in the presence of spin-orbit coupling is one of the promising platforms for realizing topologically non-trivial Yu-Shiba-Rusinov (YSR) bands, which can show signatures of MMs at the chain boundaries in the form of zero-energy states [1]. In this talk, we report on bottom-up designed Fe chains on the Rashba surface-alloy $BiAg_2$ grown on Ag(111)/Nb(110) and the detailed investigation of prominent states near the Fermi level at both chain ends, which are studied using scanning tunneling spectroscopy at sub-Kelvin temperatures. The atomically constructed Fe chains on the $BiAg_2$ alloy with proximity-induced superconductivity originating from the bulk Nb substrate show YSR bands with minigaps on the verge of our energy resolution inside the chain and edge states near the Fermi level at the chain's ends. The results are systematically compared to chains composed of other 3*d* transition metals, Mn and Co, on the same surface, revealing the absence of edge states for both cases. [1] S. Rachel and R. Wiesendanger, Phys. Rep. 1099, 1 (2025)

O 59.9 Wed 12:30 H6

Second harmonic driving of paramagnetic resonance of molecular spin through non-linear transport phenomena — •Stepan Kovarik[1], Richard Schlitz[1], Jose Reina-Gálvez[2,3], Aishwarya Vishwakarma[1], Dominic Ruckert[1], Nicolas Lorente[4,5], Christoph Wolf[2,3], Pietro Gambardella[1], and Sebastian Stepanow[1] — [1]ETH Zurich, Switzerland — [2]QNS, Seoul, Korea — [3]Ewha Woman University, Seoul, Korea — [4]CFM, Donostia-San Sebastian, Spain — [5]DIPC, Donostia-San Sebastian, Spain

The second harmonic excitation of electron paramagnetic resonance (EPR) originates from nonlinear processes. In this talk, I will demonstrate the presence of second and higher harmonic driving of a single spin in a pentacene molecule on 2ML MgO on Ag(001) when applying a radio-frequency electric field in an STM. Comparing our results to a theory considering EPR driven by a periodic modulation of the tunneling barrier [1] yields qualitative agreement, indicating the presence of higher harmonic driving. The key observation is that the barrier modulation can introduce nonlinearities to the electronic transport, leading to the excitation of magnetic resonance at the driving frequency [2] and at its multiples. Our work enhances the capabilities of EPR measurements in STM by introducing the frequency upconversion mechanism, showcasing the key role of electronic transport in driving the EPR. The presented findings apply also to other quantum transport systems, where the electrons are transported through discrete energy levels. References: [1]J. Reina-Gálvez et al., Phys. Rev. B 107, 235404 (2023)., [2]S. Kovarik et al., Science 384, 1368-1373 (2024).

O 59.10 Wed 12:45 H6

A quantum simulator to study electronic structure of matter in the Hofstadter limit — •Hermann Osterhage, Julian H. Strik, Kira Junghans, Niels P. E. van Mullekom, Anna M. H. Krieg, Emil Sierda, Danis Badrtdinov, Daniel Wegner, Mikhail I. Katsnelson, Malte Rösner, and Alexander A. Khajetoorians — Radboud University, Nijmegen, The Netherlands

The Hofstadter limit describes electronic structure in strong magnetic fields, where the magnetic length is on the order of the periodicity of the crystal. In this limit, the electronic structure shows self-similarity, namely fractal behavior. Experimentally, it is challenging to reach this limit for conventional crystals due to the high required field strengths. Therefore, one solution is to investigate structures with effectively larger periodicities. [1]. However, finding platforms that allow to study this limit with control over orbital and lattice symmetries is a current challenge.

Here, I will present a quantum simulator based on patterning Cs atoms on the surface of InSb(110) by scanning tunneling microscopy [2]. Cs atoms can be patterned into nanostructures that exhibit multi-orbital wavefunctions reminiscent of an artificial atom, and can be coupled to each other. We detail how the electronic spectrum evolves in magnetic field, and discuss the role of finite size effects and temperature, as well as link this to the expected spectra in the Hofstadter limit.

O 60: Plasmonics and Nanooptics: Fabrication, Characterization and Applications I

Time: Wednesday 10:30–12:45 Location: H8

O 60.1 Wed 10:30 H8

Infrared beam-shaping via geometric phase metasurfaces with the plasmonic phase-change material In_3SbTe_2 — •Lukas Conrads, Florian Bontke, Matthias Wuttig, and Thomas Taubner — I. Institute of Physics (IA), RWTH Aachen University

Conventional optical elements are bulky and limited to specific functionalities, contradicting the increasing demand of miniaturization and multifunctionalities. Optical metasurfaces enable tailoring light-matter interaction at will, especially important for the infrared spectral range which lacks commercially available beam-shaping elements. While the fabrication of those metasurfaces usually requires cumbersome lithography techniques, direct laser writing promises a simple and convenient alternative. Here, we exploit the non-volatile laser-induced insulator-to-metal transition of the plasmonic phase-change material In_3SbTe_2 (IST) [1] for optical programming of large-area metasurfaces for infrared beam-shaping. We tailor the geometric phase of metasurfaces with rotated crystalline IST rod antennas to achieve beam steering, lensing, and beams carrying orbital angular momenta. Finally, we investigate multi-functional and cascaded metasurfaces exploiting enlarged holography, and design a single metasurface creating two different holograms along the optical axis. Our approach facilitates fabrication of large-area metasurfaces within hours, enabling rapid-prototyping of customized infrared meta-optics for sensing, imaging and quantum information.[2] [1] Heßler et al. *Nat. Com.* **12**, 924 (2021) [2] Conrads et al. *arXiv:2408.05044* (2024)

O 60.2 Wed 10:45 H8

Investigation of lithiated carbon as active plasmonic material system — •Valentin Maile, Mario Hentschel, and Harald Giessen — 4th Physics Institute, University of Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart, Germany

Active plasmonic structures are integral to recent advancements in optical technologies due to their ability to confine and manipulate light on the nanoscale, enabling the miniaturization of optical devices. A pivotal aspect of future devices is the switchability and tunability of their optical resonances. However, only very few material systems can intrinsically switch the ability of the individual resonator to support plasmonic resonances via a metal-to-insulator transition.

Here, we introduce a novel concept based on lithium-intercalated carbon, a material system widely studied in battery research. The electrically driven, re-

versible lithium intercalation in the carbon lattice leads to an increase in charge carrier density and a corresponding shift in the optical material properties, visibly changing its color from black to golden. This unique optical modulation demonstrates its potential for integrating dynamic plasmonic functionalities.

In this work, lithiated forms of carbon and their change in optical reflectance are investigated as a switchable material system for plasmonics. Furthermore, we explored multiple fabrication techniques for nanostructuring the material, demonstrating that the nanostructures can be electrically switched while maintaining their structural integrity. This approach promises to expand the toolkit of active plasmonic structures for metasurfaces and nano-optics.

O 60.3 Wed 11:00 H8

Hybrid resonant metasurfaces combining dielectric nanocup metasurfaces and plasmonic networks — Jelena Wohlwend, Anna Hilti, Claudiadele Polinari, Ralph Spolenak, and •Henning Galinski — Laboratory for Nanometallurgy Department of Materials ETH Zurich, 8093 Zurich, Zurich Switzerland

State-of-the-art dielectric metasurfaces commonly consist of geometric primitives, such as cylinders or nanofins, and their integration into hybrid systems is fundamentally limited as confinement of light occurs only in their interior. In this talk, we report on a simple fabrication scheme that unlocks a new degree of freedom in the optical design space, as it enables the design of complex metasurfaces that break the out-of-plane symmetry [1]. We showcase the versatility of this approach on the specific example of nanocup metasurfaces made of amorphous silicon. We outline the extraordinary modal properties of these resonant sub-wavelength structures including confinement of light in air, lattice resonances and optical non-reciprocity. Creating complex hybrid metasurfaces, which combine such ordered silicon nanocups and disordered plasmonic networks [2, 3], we demonstrate that the generation of configurable structural colors can be tailored by the local near-field coupling between the ordered and disordered optical elements.

Optical programming of Hyperbolic Phonon Polariton Resonators with the plasmonic phase-change material In_3SbTe_2 — •Aaron Moos, Lina Jäckering, Lukas Conrads, Matthias Wuttig, and Thomas Taubner — I. Institute of Physics (IA), RWTH Aachen University, Germany

Tailoring light at the nano scale is mandatory for creating new nanophotonic devices and is achievable with polaritons. Hexagonal Boron Nitride (hBN), a 2d van der Waals material, hosts Hyperbolic Phonon Polaritons (HPPs) featuring high volume-confinement and low losses [1]. Restricting HPPs to resonators enables ultra-confined resonances, but their fabrication requires cumbersome etching processes [2]. Instead, resonators can be fabricated via optical programming of a phase-change material like In_3SbTe_2 (IST) with a metallic and a dielectric state in the infrared enabling rapid fabrication and reconfigurability. IST resonators combined with surface polaritons on bulk SiC were exploited before [3]. Here, we show optical programming of circular IST resonators below 2d hBN and investigate the HPP mode structures with scattering-type scanning near-field optical microscopy (s-SNOM). Influences of hBN thickness and resonator-size on resonances are studied. Furthermore, we show focussing of free propagating HPPs launched by a crystalline IST structure with tuneable focal length by reconfiguring. Our results enable rapid prototyping of confined polariton resonators for infrared nanophotonics. [1] Dai et al., *Science* **343**, 1125-1129 (2014), [2] Sheinfux et al., *Nat. O 60.5 Wed 11:30 H8

Optical Response of High-refractive Index Nanodisk Arrays with Hyperuniform Disorder — •Davy Tesch, Koundinya Upadhyayula, Bodo Fuhrmann, Alexander Sprafke, and Ralf Wehrspohn — Martin Luther University Halle-Wittenberg, 06120 Halle, Germany

Light-scattering metasurfaces with tailored disorder, in particular hyperuniform disorder (HUD), have recently attracted interest in the photonics community. HUD promises several properties that were previously associated only with either periodic or random structures. The combination of the strong diffraction of periodic structures and the broadband spectral response of disordered structures holds promise for tailored light scattering.

In this work, we use a scalable fabrication process to experimentally fabricate HUD nanodisk arrays using hydrogenated amorphous silicon (a-Si:H) optimised for low absorption as the nanodisk material. Optical measurements of such fabricated samples show a strong dependence of the scattering response on the form factor of the individual scatterers and their HUD arrangement, given by the structure factor. By tuning these quantities, we were able to tailor the scattering response. One of the most striking results is the ability of the fabricated samples to suppress scattering at small angles (below 45°) due to the HUD arrangement and to enhance scattering at large angles (up to 80°) due to the dominance of electric dipoles in single a-Si:H scatterers.

We have also studied a more complex system: nanodimers consisting of two stacked nanodisks, separated by a spacer layer.

O 60.6 Wed 11:45 H8

Edge-state imaging of high-precision plasmonic SSH chains — Benedikt Schurr[1], Luisa Brenneis[2], Philipp Kessler[2], Jin Qin[1], Victor Lisinetskii[2], •Matthias Hensen[2], Ronny Thomale[3], Tobias Brixner[2], and Bert Hecht[1] — [1]NanoOptics & Biophotonics Group, Experimental Physics 5, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany — [2]Institut für Physikalische und Theoretische Chemie, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany — [3]Institute for Theoretical Physics and Astrophysics, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany

Topological nanophotonics offers the possibility to precisely control nanoscale light–matter interaction via states that are topologically protected from disorder and impurities. A prominent example are Su–Schrieffer–Heeger (SSH) chains, in which the staggered nearest-neighbor coupling strength leads to topologically protected and localized edge states. Here, we present plasmonic SSH chains of nanoslot dipole antennas fabricated by helium ion-beam milling in a single-crystal Au micro-platelet. The chains are characterized by individual antenna distances down to 12 nm, strong coupling amplitudes, and negligible next-nearest-neighbor coupling. Furthermore, the near-field distribution of plasmonic eigenmodes is consistent with the amplitude distribution of the eigenfunctions of a quantum mechanical SSH model. We prove the existence of topological edge states experimentally by imaging corresponding mode patterns with aberration-corrected photoemission electron microscopy (PEEM) under wide-field excitation.

O 60.7 Wed 12:00 H8

Analytical study of Mie void resonances — Timothy J. Davis[1,2], •Julian Schwab[1], Harald Giessen[1], and Mario Hentschel[1] — [1]4th Physics Institute, Research Center SCoPE, and Integrated Quantum Science and Technology Center, University of Stuttgart, Germany — [2]School of Physics, University of Melbourne; Parkville Victoria 3010, Australia

The preferential light scattering at particular wavelengths by mall particles is a well know phenomenon since the introduction of an analytical theory by Gustav Mie in 1908. Over the decades, this theory has helped in understanding, designing, and optimizing a multitude of plasmonic and dielectric nanophotonic systems. Just recently it was shown that Mie scattering can also be observed from voids in high-index dielectric media, such as silicon or gallium arsenide. This phenomenon is particularly counterintuitive as the void sizes are on the order of the resonant wavelength, rendering full-wave simulations and thus a deeper understanding challenging. Here, we present a new analytical model to study and understand the resonance properties of Mie voids. In particular, we derive analytical expressions of the electric field distribution based on solutions of Maxwell's equations for cylindrical holes in the substrate. These solutions are used in a simple three-layer model of the void that gives predictions of the void resonances, the observed spectra, as well as the microscopic appearance. Our model will aid in the future design of Mie-void based systems and applications, such as nanophotonic sensors, metasurfaces, and nanoscale detection.

O 60.8 Wed 12:15 H8

In-situ Plasmonic Sensing of Surfactant Structures — •Esmée Berger[1], Narjes Khosravian[1], Ferry Nugroho[2], Joakim Löfgren[3], Christoph Langhammer[1], and Paul Erhart[1] — [1]Department of Physics, Chalmers University of Technology, Gothenburg, Sweden — [2]Department of Physics, Universitas Indonesia, Depok, Indonesia — [3]Department of Applied Physics, Aalto University, Espoo, Finland

Surfactants play an important role in many areas of chemistry and have immense technological relevance. Their functionality is dictated by their frequently complex phase diagrams, which are very difficult to probe, especially *in situ*. Here, by combining experiment and multi-scale modeling, we demonstrate that the structure and dynamics of surfactant layers can be very efficiently probed using plasmonic sensing. Considering a prototypical surfactant-surface system (CTAB on silica), we show that the plasmonic response not only reveals changes in the structure of the surfactant layer as the CTAB concentration varies but also provides access to the kinetics of the phase transition. The approach demonstrated in the present work is minimally intrusive, efficient, and widely applicable. It thus constitutes a very powerful tool for exploring surfactant-surface structures, representing a large step forward in understanding these systems of enormous scientific and technological importance.

O 60.9 Wed 12:30 H8

Optical Sieve for Nanoplastic Detection — •Dominik Ludescher[1], Lukas Wesemann[2], Julian Schwab[1], Julian Karst[1], Shaban B. Sulejman[2], Monika Ubl[1], Ann Roberts[2], Harald Giessen[1], and Mario Hentschel[1] — [1]4th Physics Institute and Research Center SCoPE, University of Stuttgart, Germany — [2]ARC Center of Excellence for Transformative Meta-Optical Systems (TMOS), The University of Melbourne, Australia

Micro- and nanoplastics contaminate marine ecosystems and endanger aquatic life, even in remote locations. These minute synthetic fragments, persisting for

hundreds of years, infiltrate the food chain, posing potential health risks due to toxic chemicals. Besides improving the quality of plastic disposal and reducing plastic production, determining the existence of micro- and nanoplastics in aqueous environments like water or blood is essential for biological studies. We present an optical sieve for nanoplastic detection based on the recently discovered Mie void resonances. Our devices are able to detect, size, and count nanoplastic particles by observing apparent color changes of the emitted light in the presence of a sphere in the void. The proposed method profits from its simplicity and only requires a conventional microscope setup with CMOS RGB imaging sensor.

O 61: 2D Materials: Electronic Structure and Exitations II (joint session O/HL/TT)

Time: Wednesday 10:30–12:45 Location: H11

O 61.1 Wed 10:30 H11

The Bell-Shaped Component in Diffraction from 2D Materials — •Birk Finke[1], Christian Brand[1], Karim Omambac[1,2], Pascal Dreher[1], Hannah Kohler[1], Frank-J. Meyer zu Heringdorf[1,3,4], and Michael Horn-von Hoegen[1,3] — [1]Universität Duisburg-Essen — [2]Polytechnique Montréal Canada — [3]Center for Nanointegration Duisburg-Essen — [4]Interdisciplinary Center for Analytics on the Nanoscale

In 2D materials, the formation of moiré superlattices with graphene or hBN on crystalline surfaces alters electronic, vibrational, and chemical properties. Here we analysed an unusual broad diffraction background observed in low energy electron diffraction from 2D material systems, which is called the bell-shaped component (BSC). Employing SPA-LEED, LEEM, and μ-LEED we propose the origin to be the inelastic scattering of the low energy electrons at the vertically polarized ZA-phonons of the weakly bound graphene and hBN layers on Ir(111) and SiC(0001). For these systems the ZA-phonon branch exhibits a parabolic dispersion with a finite phonon frequency of a few meV at the Γ point. This results in a high phonon density at low energy, but high momentum causing the strong intensity of the BSC in diffraction. In the framework of kinematic scattering theory, we performed simulations of the inelastic diffuse scattering which quantitively confirm our proposal.

O 61.2 Wed 10:45 H11

Combining DFT and ML to Explore the Electronic Properties of Nanoporous Graphene — •Bernhard Kretz and Ivor Lončarić — Institut Ruder Bošković, Zagreb, Croatia

Nano-porous graphene (NPG) holds great potential in electronics due to its tunable electronic properties. However, establishing a comprehensive understanding of how structural parameters influence these properties remains a challenge. This work employs density functional theory (DFT) calculations combined with machine learning (ML) to systematically investigate both static and dynamic electronic properties across a set of 460 NPG structures derived from four distinct templates.

Our DFT results reveal correlations between structural features and band gaps within subsets of our NPG structures. Notably, we identify certain NPG configurations exhibiting band gap behavior analogous to armchair graphene nanoribbons. To predict the dynamic response of our NPG structures, we train two distinct ML networks: one for predicting forces and total energies, and another one for predicting band gaps. Using the former allows us to perform temperature-dependent molecular dynamics simulations for all 460 NPG structures, while the latter enables us to predict band gap evolution under varying operating temperatures, a crucial factor for semiconductor device performance. Our findings identify several NPG structures exhibiting band gaps suitable for semiconductor applications while demonstrating sufficient thermal stability to function effectively at typical operating temperatures.

Invited Talk O 61.3 Wed 11:00 H11

Polaritons in two-dimensional materials and hybrids probed by electron beams — •Nahid Talebi — Institute for Experimental and Applied Physics, Kiel University, Leibnizstr. 19, 24118 Kiel

Polaritonic quasiparticles in two-dimensional (2D) materials have garnered significant attention in recent years, emerging as a promising platform for studying novel photon- and phonon-mediated correlations between various material excitations. In this work, we employ electron beams to investigate exciton and plasmon polaritons in diverse 2D materials, including transition-metal dichalcogenides, perovskites, hexagonal boron nitride, borophene, and hybrid systems. By comparing cathodoluminescence and photoluminescence spectroscopy, we uncover differences in the selection rules governing the excitation of quasiparticles by coherent light versus electron beams. Furthermore, leveraging a recently developed method that utilizes electron-driven photon sources inside an electron microscope for Ramsey-type spectroscopy, we examine the coherence of cathodoluminescence emitted by exciton polaritons (Nature Physics 19, 869 (2023)) and defects in hexagonal boron nitride (arXiv:2404.09879). These results provide new insights into the temporal coherence of the radiation from 2D materials excited by coherent and incoherent excitations.

O 61.4 Wed 11:30 H11

Electron-phonon interaction in polar two-dimensional materials — •Gerrit Johannes Mann, Thorsten Deilmann, and Michael Rohlfing — Institute of Solid State Theory, University of Münster, Germany

Electron-phonon interaction is a crucial effect in solid state physics, in particular in two-dimensional materials. We recently developed a generally applicable ab-initio implementation on top of density functional theory that combines finite differences calculations with the perturbative Allen-Heine-Cardona framework in order to calculate the temperature-dependent renormalization of the electronic bandstructure due to electron-phonon interaction using a basis set of localized Gaussian orbitals. Our implementation circumvents the limiting problems of previous implementations and allows to evaluate Debye-Waller contributions beyond the rigid-ion approximation, which are usually neglected [1].

Incorporating effects from macroscopic electric fields into our implementation allows us to extend our calculations to the class of polar materials. In this presentation we discuss our results for two-dimensional transition-metal dichalcogenides, where the renormalization of the electronic bandstructure due to electron-phonon interaction can be as large as several hundreds of meV.

[1] Mann et al., Phys. Rev. B **110**, 075145 (2024)

O 61.5 Wed 11:45 H11

Structural modulations of unidirectional charge density waves in rare earth tellurides — •Eunseo Kim[1], Sanghun Lee[1], Junho Bang[1], Hyungryul Yang[1], Jongho Park[2], Changyoung Kim[2], Dirk Wulferding[2], Doohee Cho[1], Makoto Hashimito[3], Donghui Lu[3], and Sunghun Kim[4] — [1]Department of Physics, Yonsei University, Seoul 03722, Republic of Korea — [2]Department of Physics and Astronomy, Seoul National University, Seoul 08826, Republic of Korea — [3]Stanford Synchrotron Radiation Lightsource, SLAC National Accelerator Laboratory, Menlo Park, CA 94025, USA — [4]Department of Physics, Ajou University, Suwon 16499, Korea

Charge density waves (CDWs) in rare earth tellurides (RTe_3) provide a unique platform for exploring the interplay between lattice deformations and electronic order. Using scanning tunneling microscopy and spectroscopy (STM/S), we investigate unique surface features in two different materials, $GdTe_3$ and $DyTe_3$, that influence the CDW behavior. In $GdTe_3$, twin domain boundaries provide a static platform for observing the spatial "melting" of unidirectional CDWs and the emergence of bidirectional CDWs. Our spatial lock-in analysis demonstrates the attenuation of CDW order parameters and the proliferation of topological defects at these boundaries, correlating with enhanced local density of states near the Fermi level. In $DyTe_3$, nanowrinkles act as topological interfaces, hosting phase-winding CDWs and confining one-dimensional metallic states. These findings emphasize the role of local structural distortions in shaping CDW phenomena, offering insights into manipulating quantum states via lattice engineering.

O 61.6 Wed 12:00 H11

Ultrafast Charge Separation on the Nanoscale Induced by a Uniform Field — •Jan-Philip Joost and Michael Bonitz — Kiel University, Institute for Theoretical Physics and Astrophysics, 24098 Kiel, Germany

When illuminated by white light, atoms, molecules, and materials absorb only certain characteristic energy contributions based on their absorption properties. Here, we show that this effect can be translated from energy to space: a spatially uniform laser pulse can create strongly localized carrier excitations and spatial charge separation on the sub-nanometer scale within a few femtoseconds, possibly opening new avenues for nanoelectronics. A promising candidate are small graphene heterostructures, which exhibit a pronounced space dependence of the DOS with strongly localized topologically protected states [1]. Direct evidence for this effect is presented by performing extensive NEGF simulations for these systems that take into account strong coupling and dynamical screening [2]. Further, we demonstrate multiple ways to excite targeted areas of the nanostructures, such as a proper choice of the laser energy, polarization, or carrier-envelope phase. Moreover, we find that the observed effects greatly benefit from surface screening, while in free-standing systems the targeted charge excitation is restricted by strongly bound excitons. The findings are expected to be applicable for a broad class of nanoscale monolayer clusters of graphene or TMDCs.

[1] J.-P. Joost et al., Nano Lett. **19**, 9045 (2019)

[2] J.-P. Joost et al., Phys. Rev. B **105**, 165155 (2022)

O 61.7 Wed 12:15 H11

Two-dimensional breathing Kagome lattice of antimony atoms on a SiC substrate — •Bing Liu[1], Kyungchan Lee[1], Jonas Erhardt[1], Manish Verma[1], Stefan Enyner[1], Cedric Schmitt[1], Philipp Kessler[1], Lukas Gehrig[1], Chris Jozwiak[2], Aaron Bostwick[2], Martin Kamp[1], Eli Rotenberg[2], Jörg Schäfer[1], Simon Moser[1], Giorgio Sangiovanni[1], and Ralph Claessen[1] — [1]Physikalisches Institut, Universität Würzburg, 97074 Würzburg, Germany — [2]Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA

The Kagome lattice, characterized by flat electronic bands, which represents a class of candidate materials for charge order, time-reversal symmetry-breaking and exotic superconductivity. In this work, we report the successful synthesis of a breathing Kagome lattice of Sb on SiC surface. Band mapping reveals a significant gap opening at the K point near the Fermi level, driven by different hopping parameters within the breathing Kagome lattice. Scanning tunneling microscopy measurements of this phase confirm a well-ordered 2x2 lattice reconstruction, consistent with the breathing Kagome unit cell. Furthermore, DFT calculations elucidate the role of the Sb p-orbitals. Specifically, near the Fermi level the physics is dominated by px and py orbitals, which are sensitive to hopping and possibly electron correlation, giving rise to an energy gap, and by their splitting reflect the breathing Kagome lattice situation. Our findings demonstrate a pathway for constructing two-dimensional Kagome lattices on semiconductor surfaces, and are encouraging further research into their spin and electronic properties.

O 61.8 Wed 12:30 H11

Ultrafast lattice dynamics of monolayer ReS_2 — •Victoria C. A. Taylor[1], Yoav W. Windsor[1,2], Samuel Lai[3], Hyein Jung[1,2], Fang Lui[3], and Ralph Ernstorfer[1,2] — [1]Fritz-Haber-Institut der Max-Planck-Gesellschaft, 14195 Berlin, Germany — [2]Technische Universität Berlin, 10623 Berlin, Germany — [3]Stanford University, Stanford, CA 94305, USA

Within the transition metal dichalcogenide (TMDC) material family, TMDCs containing rhenium stand out due to their low crystal symmetry. Instead of the common hexagonal structure, ReS_2 exhibits in-plane 1D chains of rhenium ions due to a Peierls-like distortion. This highly anisotropic crystal structure results in a range of material properties, such as anisotropic effective carrier masses, polarization dependent optical absorption, and extremely weak interlayer coupling.

We present femtosecond electron diffraction (FED) measurements of monolayer ReS_2. FED is a direct probe of photoexcited lattice dynamics, providing quantitative information on coherent and incoherent atomic vibrations on femtosecond timescales. In ReS_2 monolayers we observe a strong and complex lattice response to photoexcitation. In particular, we observe a rapid (<1 ps) collective response, indicative of a concerted change in ionic positions within the unit cell. We measure the fluence dependence of this response and investigate the effect of the pronounced polarization dependence of the optical excitation, which results from the material's in-plane anisotropy.

O 62: Focus Session Molecular Nanostructures on Surfaces: On-Surface Synthesis and Single-Molecule Manipulation III

This focus session aims to discuss recent advances in the on-surface synthesis, manipulation, characterization, and understanding of complex molecular architectures on surfaces. The interest in surface-confined molecular nanostructures emerges from their prospective applications in nanoscale (opto-) electronics, spintronics, solar cells, energy storage devices, and other fields. The bottom-up fabrication of surface-supported nanostructures can be based on molecular self-assembly utilizing non-covalent intermolecular interactions, covalent on-surface synthesis, or the direct manipulation of molecules. Molecular self-assembly usually leads to highly ordered nanostructures, controlled by non-covalent interactions, adsorbate-substrate interactions, as well as thermodynamic and kinetic factors. On-surface synthesis by covalent coupling of reactive precursors adsorbed on metallic, semiconducting, or even insulating surfaces has emerged as a powerful method that has opened new possibilities in exploring new routes towards the synthesis of complex low-dimensional nanostructures with unprecedented material properties, often via novel chemical reactions not available in conventional organic chemistry. Finally, the direct manipulation of molecules with the tip of a scanning probe microscope allows for unprecedented chemical transformations or structural modifications, as envisioned by the pioneers of nanotechnology. This focus session is intended to provide a platform for addressing current trends in these closely linked fields from various perspectives in experiment and theory.

O 62.1 Wed 10:30 H24

Selective On-Surface Synthesis of Isokekulene Facilitated by Strong Molecule-Substrate Interaction — Qitang Fan[1], Alexander Reichmann[2], Zilin Ruan[1], Faming Kang[1], Tim Naumann[1], Simon Werner[1], Olaf Kleykamp[1], Jose Martinez[3], Felix Lüpke[3], François C. Bocquet[3], Christian Kumpf[3], Serguei Soubatch[3], Jörg Sundermeyer[1], Peter Puschnig[2], F. Stefan Tautz[3], J. Michael Gottfried[1], and •Sabine Wenzel[1,3] — [1]Fachbereich Chemie, Philipps-Universität Marburg — [2]Institute of Physics, University of Graz — [3]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich

The role of different facets of metal nanoparticles in steering reaction pathways is crucial for the design of heterogeneous catalysts with superior selectivity. Transition-metal-catalyzed C-H bond activation is widely used for the synthesis of different chemicals. Here, we report orthogonal selectivity in intramolecular cyclodehydrogenation of a nonplanar cyclic precursor steered by different facets of a copper single crystal. On Cu(110), the previously unknown cycloarene isokekulene is formed with a high selectivity of 92 %, while reaction on Cu(111) is known to result in kekulene (> 99 %). Combining scanning tunneling microscopy with CO-functionalized tips and density functional theory, we identify two adsorption geometries of the precursor which react to the respective products. The isokekulene molecule appears in two nonplanar adsorption configurations and shows a strong molecule-substrate interaction including charge transfer, which accounts for the more favorable energetics of isokekulene on Cu(110).

O 62.2 Wed 10:45 H24

On-surface synthesis and characterization of long azaacenes — •Zilin Ruan[1], Liping Ye[2], Jakob Schramm[3], Tim Naumann[1], Faming Kang[1], Ralf Tonner-Zech[3], Michael Mastalerz[2], and J. Michael Gottfried[1] — [1]Department of Chemistry, Philipps-Universität Marburg, 35037 Marburg, Germany — [2]2Organisch-Chemisches Institut, Ruprecht-Karls-Universität Heidelberg, 69120 Heidelberg, Germany — [3]Wilhelm Ostwald Institute of Physical and Theoretical Chemistry, Universität Leipzig, 04103 Leipzig, Germany

Introducing electronegative nitrogen into the backbone of acenes yields azaacenes, enabling fine-tuning of the energy alignment of frontier orbitals while enhancing resistance to oxidation, photodegradation, and dimerization. Here, we demonstrate the on-surface synthesis of tetraazanonacene and hexaazatridecacene, the latter being the longest azaacene known to date and here reported for the first time via atom-manipulation-induced dissociation of a triethenobridged precursor on a Au(111) surface in UHV. The geometric and electronic structures of the generated azaacenes were investigated by combined scanning tunneling microscopy/spectroscopy and non-contact atomic force microscopy. For tetraazanonacene, we observed an increase of the frontier orbital gap compared to pristine nonacene, attributed to a more pronounced downshift of occupied states. Meanwhile, hexaazanonacene exhibited an open-shell singlet ground state with a singlet-triplet gap of 110 meV, slightly smaller than that observed for long acenes.

O 62.3 Wed 11:00 H24

On-surface synthesis and characterization of polyynic carbon chains — •Wenze Gao[1,2], Wei Zheng[1], Luye Sun[1], Faming Kang[1], Zheng Zhou[1], and Wei Xu[1] — [1]Interdisciplinary Materials Research Center, School of Materials Science and Engineering, Tongji University, Shanghai, China — [2]Empa-Swiss Federal Laboratories for Materials Science and Technology, Dübendorf, Switzerland

Carbyne, an elusive sp-hybridized linear carbon allotrope, has fascinated chemists and physicists for decades. Due to its high chemical reactivity and extreme instability, carbyne was much less explored in contrast to the sp2-hybridized carbon allotropes such as graphene. Herein, we report the on-surface synthesis of polyynic carbon chains by demetallization of organometallic polyynes on the Au(111) surface; the longest one observed consists of 60 alkyne units (120 carbon atoms). The polyynic structure of carbon chains with alternating triple and single bonds was unambiguously revealed by bond-resolved atomic force microscopy. Moreover, an atomically precise polyyne, C14, was successfully produced via tip-induced dehalogenation and ring-opening of the decachloroanthracene molecule (C14Cl10) on a bilayer NaCl/Au(111) surface at 4.7 K, and a band gap of 5.8 eV was measured by scanning tunnelling spectroscopy, in a good agreement with the theoretical HOMO-LUMO gap (5.48 eV).

O 62.4 Wed 11:15 H24

The odd-number cyclo[13]carbon and its dimer, cyclo[26]carbon — •Florian Albrecht[1], Igor Rončević[2], Yueze Gao[2], Fabian Paschke[1], Alberto Baiardi[3], Ivano Tavernelli[3], Shantanu Mishra[1], Harry L. Anderson[2] und Leo Gross[1] — [1]IBM Research Europe - Zurich — [2]Department of Chemistry, Oxford Univeristy — [3]IBM Quantum, IBM Research Europe - Zurich

Using CO-functionalized tips, we generate the odd-numbered cyclocarbon molecule cyclo[13]carbon (C13) on an ulatra-thin insulating film by applying voltage pulses to a stable precursor molecule. The geometric and electronic properties of C13 were characterized experimentally as well as theoretically, determining the electronic ground state to be an open-shell triplet. In addition to the C13 monomer, we also generated its dimer, cyclo[26]carbon, from two precursor molecules [1].

Invited Talk O 62.5 Wed 11:30 H24

On-Surface Synthesis with Hydrogen Atoms — •Szymon Godlewski — Jagiellonian University, Krakow, Poland

In recent years the on-surface manipulation and chemical reactions created a playground for atomically precise synthesis and development of new atomic and molecular nanostructures. However, the abilities to produce desired systems are limited, among others, by relying on the catalytic role of the substrate in initiating selected reactions. Therefore striving for the generation of desired systems forces the search of new reaction pathways and catalytic transformations.

In this talk I will demonstrate our approach based on the application of hydrogen atoms in the on-surface experiments. First, I will discuss the synthesis of the acene series based on the application of *extra* hydrogen atoms. The application of atomic hydrogen in on-surface transformations will be exemplified by organometallic hybrids and graphene nanoribbons.

While the surface assisted synthesis approach has proven its effectiveness in the precise formation of new organic compounds on metallic surfaces one of the most challenging limitations arises from the dependence on the catalytic activity of the substrate. This makes the direct transfer to the non-metallic surfaces extremely challenging. In this talk I will present our pathway for the synthesis of new molecular compounds on non-metallic surfaces with prospects for circumventing the need to exploit the catalytic role of metallic substrates.

This work was supported by the National Science Center, Poland (2019/35/B/ST5/02666)

O 62.6 Wed 12:00 H24

On-Surface Synthesis of Hydrogen-Substituted γ-Graphdiyne with High Efficiency — •Faming Kang[1,3], Wei Zheng[1], Luye Sun[1], Wenze Gao[1], Lina Shang[1], Lifeng Chi[2], and Wei Xu[1] — [1]Interdisciplinary Materials Research Center, School of Materials Science and Engineering, Tongji University, 201804 Shanghai, China — [2]Institute of Functional Nano & Soft Materials (FUNSOM), Jiangsu Key Laboratory for Carbon-Based Functional Materials and Devices, Joint International Research Laboratory of Carbon-Based Functional Materials and Devices, Soochow University, 215123 Suzhou, China — [3]Department of Chemistry, University of Marburg, 35032 Marburg, Germany

Graphyne-family structures, a group of hybrid carbon allotropes with sp- and sp2-hybridized carbon atoms, are expected to have unique features, including a natural direct bandgap, unlike graphene. Here, we developed and synthesized precursors with one and three tribromoethenyl groups. In mild conditions, metal-free dimer and network (HsGDY) products were synthesized in big scale and good quality. The geometric structure of synthesized dimer and network products was accurately characterized by scanning tunneling microscopy and non-contact atomic force microscopy. The electronic structures of produced hydrogen-substituted graphdiyne were studied using DFT calculations. Our research may motivate theoretical and experimental efforts to create more sensitive two-dimensional carbon nanostructures with sp-hybridized carbon atoms.

O 62.7 Wed 12:15 H24

Tip-induced nitrene generation — •Leonard-Alexander Lieske[1], Aaron Oechsle[1], Ilias Gazizullin[2], Matthias Krinninger[3], Igor Rončević[4], Florian Albrecht[1], Leonhard Grill[2], Friedrich Esch[3], and Leo Gross[1] — [1]IBM Research Europe - Zurich, Rueschlikon, Switzerland — [2]Physical Chemistry Department, University of Graz, Graz, Austria — [3]Chair of Physical Chemistry and Catalysis Research Center, Department of Chemistry, TUM School of Natural Sciences, Technical University of Munich, Garching, Germany — [4]Department of Chemistry, University of Manchester, Manchester, United Kingdom

We have successfully generated mono-, di- and trinitreno-*s*-heptazine by tip-induced chemistry from the precursor 2,5,8-triazido-*s*-heptazine[1,2] on bilayer NaCl and on bare Au(111). The precursor's azide groups are cleaved off sequentially in a controlled manner, demonstrating the generation of single molecules with one, two and three nitrene moieties, which are highly reactive.[3] We characterized the mono-, di- and trinitrene species by high-resolution atomic force microscopy with CO functionalized tips[4] and by scanning tunneling microscopy. Broken-symmetry density functional theory and multi-reference complete active space calculations of inter- and intra-nitrene exchange couplings J and J^* suggest a high-spin (S = 3) ground state for trinitreno-*s*-heptazine. O 62.8 Wed 12:30 H24

On-Surface Synthesis and Reactivity of Biphenylene Network on Au(788) — •Ye Liu, Yingling Zhang, Zilin Ruan, Tim Naumann, Faming Kang, Ulrich Koert, and J. Michael Gottfried — Department of Chemistry, University of Marburg, 35032 Marburg, Germany

The recently synthesized biphenylene network (BPN), a new sp2-hybridized carbon allotrope comprising four-, six-, and eight-membered rings, significantly differs from graphene in its electronic and chemical properties. Theoretical studies predict that BPN features a multiradical ground state, with its open-shell character predominantly localized at the four-membered rings. However, experimental confirmation of these predictions has been hindered by the limited quality of the material currently available. To address this challenge, we employed Au(788), a surface characterized by narrow terraces, and designed an extended molecular precursor to promote the formation of the desired structure. For comparison, we also investigated interpolymer dehydrofluorination (HF-zipping) reactions of the precursor on Au(111). Scanning probe microscopy (SPM) analysis revealed that pure BPN fused chains formed on Au(788) exhibit superior structural quality compared to those synthesized on Au(111). These findings provide a solid experimental foundation for probing the theoretically predicted properties of BPN, opening avenues for the further exploration of its distinctive electronic and chemical behavior.

O 62.9 Wed 12:45 H24

Incorporating Nonhexagonal Polygons into Carbon-Based Nanostructures via On-Surface Synthesis — •Dong Han[1], Jakob Schramm[2], Zilin Ruan[1], Tim Naumann[1], Konstantin Y. Amsharov[3], Ralf Tonner-Zech[2], and J. Michael Gottfried[1] — [1]Department of Chemistry, Philipps-Universität Marburg, Marburg, Germany — [2]Faculty of Chemistry and Mineralogy, Wilhelm Ostwald Institute for Physical and Theoretical Chemistry, Universität Leipzig, Leipzig, Germany — [3]Institute of Chemistry, Organic Chemistry, Martin-Luther-Universität Halle-Wittenberg, Halle, Germany

The incorporation of nonhexagonal rings offers a powerful strategy for designing novel carbon-based nanostructures with unique physicochemical properties. Herein, we report the on-surface synthesis of: (1) Quasi-planar, furan-containing cycloparaphenylenes (CPPs): Synthesized via Ullmann coupling and cyclodehydrogenation on Au(111), these CPPs show a decreasing energy gap with increasing size. Orbital confinement at edges and pores is observed, which is associated with the slower wave function decay above the CPP plane. (2) Carbon nanoribbons (CNRs) embedded with nonbenzenoid rings: Zigzag nanoribbons bearing 5-6-7 membered rings and linear nanoribbons containing 4-5-6-8 carbon polygons are formed through the lateral fusion of polymer chains on Au(111). Low-temperature scanning tunneling microscopy/spectroscopy (STM/STS) reveals their geometric and electronic properties, and X-ray photoelectron spectroscopy (XPS) unravels the reaction process.

O 63.1 Wed 10:30 H25

Unravelling the Photocatalysis of Alcohol on Rutile(110) — •Philip Petzoldt, Lucia Mengel, Anna Lemperle, Moritz Eder, Martin Tschurl, and Ueli Heiz — Chair of Physical Chemistry, School of Natural Sciences & Catalysis Research Center, Technische Universität München, Lichtenbergstr. 4, 85748 Garching, Germany

Heterogeneous photocatalysis is a promising tool for the environmentally benign production of chemical fuels such as hydrogen. However, the structural complexity of state-of-the-art materials makes mechanistic investigations and, in consequence, the targeted design of new catalysts extremely challenging. We employ surface science methods to explore fundamental mechanisms in photocatalysis. In this contribution, we focus on the photocatalytic hydrogen evolution from alcohols over rutile(110) loaded with Pt cluster co-catalysts. Our experimental evidence reveals a new reaction mechanism, which substantially differs from the generally assumed model of independent redox reactions. By changing active sites for both the alcohol oxidation and the hydrogen evolution reaction, we further show that the overall photoactivity strongly depends on the equilibrium of a reaction network of several elementary photo- and thermal reaction steps. Our results provide new mechanistic insights into the photocatalytic hydrogen evolution from Pt loaded titania and illustrate the importance of a comprehensive understanding of the photocatalysts (surface) chemistry.

O 63.2 Wed 10:45 H25

Characterization of rhodium single atoms as dicarbonyls on TiO_2(110) — •Moritz Eder, Faith Lewis, Panukorn Sombut, Johanna Hütner, David Rath, Jan Balajka, Jiri Pavelec, and Gareth Parkinson — Institute of Applied Physics, TU Wien, Austria

Single-atom catalysts (SACs) have garnered significant attention in recent years due to their potential to minimize noble metal usage by isolating active atoms on metal (oxide) surfaces. However, stabilizing these single atoms remains a major challenge. Ligands, such as carbon monoxide, can stabilize single atoms by transforming them into surface-bound metal complexes, closely resembling the well-defined species in homogeneous catalysis. In this contribution, we present a comprehensive characterization of a ligand-stabilized single atom: a rhodium gem-dicarbonyl ($Rh(CO)_2$) bound to rutile TiO_2(110). Using XPS, TPD, scanning probe, and a newly developed IRRAS apparatus, we provide a detailed analysis of these sites. Our findings are contextualized through comparisons with theoretical models and insights from powder catalyst studies in the literature. This work demonstrates that multi-technique approaches are essential for the accurate characterization of single-atom catalysts, offering a deeper understanding of their structure and stability.

O 63.3 Wed 11:00 H25

Desorption of water from microcline (001) — Tobias Dickbreder[1,2], Florian Schneider[1], Lea Klausfering[1], Kim Noelle Dreier[1], Franziska Sabath[1,3], Adam S. Foster[4], Ralf Bechstein[1], and •Angelika Kühnle[1] — [1]Bielefeld University, 33615 Bielefeld, Germany — [2]University of Vienna, 1090 Vienna, Austria — [3]Max Planck Institute for Polymer Research, 55128 Mainz, Germany — [4]Aalto University, Finland and Kanazawa University, Kanazawa 920-1192, Japan

Feldspar minerals are highly abundant in the Earth's crust. They play a significant role in a plethora of geochemical processes, including, e.g., weathering and ice nucleation. For many of these processes, the interaction of water with the feldspar surface is decisive. However, little is known about binding and desorption of the first water layer on feldspar. Here, we present temperature-programmed desorption (TPD) experiments of water desorbing from the thermodynamically most stable cleavage plane of potassium-rich feldspar, microcline (001). From the interplay of these experimental data with density-functional theory (DFT) results we shed light onto the binding of the first water layer. Our work confirms previous theory results from literature and provides molecular-scale insights into the binding of water onto microcline (001).

O 63.4 Wed 11:15 H25

Cleaved feldspar surfaces under dry and humid conditions: an AFM study — •Luca Lezuo[1], Sandra Boigner[1], Rainer Abart[2], Michael Schmid[1], Ulrike Diebold[1], and Giada Franceschi[1] — [1]Inst. of Applied Physics, TU Wien, 1040 Wien, Austria — [2]Dep. of Lithospheric Research, Universität Wien, 1090 Wien, Austria

The Earth's surface is largely shaped by the interaction between water and the minerals of its crust. Feldspars, the most common aluminosilicates, are made of a framework of corner-sharing silica and alumina tetrahedra, enclosing cations such as potassium (K^+), sodium (Na^+), and calcium (Ca^{2+}). The chemical reactions at the feldspar-water interface contribute to geological processes such as erosion and weathering [1], clay formation [2], and ice nucleation [3], with implications for geology, agriculture, atmospheric chemistry, and climate science.

We exposed cleaved surfaces of different feldspars to air and Ar with defined humidity and examined the evolution of their mesoscale morphology with atomic force microscopy (AFM). Overlayers with distinct patterns develop over time. They remain stable after rinsing the surface with ultrapure water, suggesting a permanent alteration of the surface morphology. We attribute the distinct patterns to local chemistry differences and different cation leaching rates [1].

O 63.5 Wed 11:30 H25

Tracking the redox cycle of CeO_2 by Infrared spectroscopy via a titration of the defect states by O_2 adsorption. — •Lachlan Caulfield, Eric Sauter, Hicham Idriss, and Christof Wöll — Karlsruhe Institute of Technology

CeO_2 is probably the most stable reducible metal oxide known. It is the main component of automobile three-way catalysts and is the chief prototype for the thermochemical water splitting to H_2 and O_2 reaction as well as for CO_2 thermal reduction to CO. This is largely due to the relative stability of the $Ce4f_1$ electron formed upon the removal of surface oxygen atoms during the reduction process. While these are commonly studied by photoelectron spectroscopy (XPS Ce3d or UPS Ce4f), less attention in general has been given to the Ce^{3+} (2F5/2 to 2F7/2) spin orbit transition of this process that appears in infrared spectroscopy at ca. 2150 cm^{-1}. In this work we have monitored the formation of these transition on reduced polycrystalline CeO_2 exposed to molecular O_2 as a function of temperature using the DRIFT technique. Results have shown that there is a linear relationship between the disappearance of the observed electronic transition at ca. 2130-2160 cm^{-1} and the IR signal of the superoxo (O^{2-}). species upon exposure of the reduced surface to different partial pressures of O_2. Moreover, it was found that the oxidation process is irreversible: the spin-orbit transition signal does not recover upon the removal of adsorbed oxygen species. Work in progress to track the catalytic activity of these adsorbed O_2 species and spin-orbit transition by probe molecules suitable for the redox cycle.

O 63.6 Wed 11:45 H25

Nucleation of TMDAH on CoO nanoislands on Au(111) — •Jonas Hauner, Nikolai Sidorenko, Hanna Bühlmeyer, and Jörg Libuda — Interface Research and Catalysis, Friedrich-Alexander-Universität Erlangen-Nürnberg, Egerlandstraße 3, 91058 Erlangen, Germany

Atomic layer deposition (ALD) has recently received considerable attention as a promising method to precisely grow thin films of a wide variety of materials. This work focuses on the ALD of HfS_2 on oxide substrates. In specific, we report on the nucleation behavior of the ALD precursor tetrakis(dimethylamido)hafnium(IV) (TMDAH) on cobaltoxide nanoislands on Au(111). The samples were prepared by deposition of Co in oxygen atmosphere and subsequent deposition of TMDAH. We investigated the adsorption of TMDAH by scanning tunneling microscopy (STM) and infrared absorption reflection spectroscopy (IRAS). At 300 K, TMDAH nucleates at OH groups at the CoO surface by means of a Brønsted acid-base reaction. At 400 K, the mechanism changes and involves a Lewis acid-base reaction due to the lack of OH groups on the substrate. Presaturation of the substrate with H_2O further modifies the reaction mechanism of nucleation.

O 63.7 Wed 12:00 H25

Maghemite (γ-Fe_2O_3): From Bulk Phases to (001) Oriented Surfaces — •Muhammad Munawar[1,2] and Rossitza Pentcheva[1] — [1]Department of Physics and Center for Nanointegration (CENIDE), Universität Duisburg-Essen, Lotharstr. 1, 47057 Duisburg, Germany — [2]International Max Planck Research School on Sustainable Metallurgy, Max-Planck-Straße 1, 40237, Düsseldorf, Germany

Maghemite (γ-Fe_2O_3) finds applications across a wide range of fields, including spintronics, magnetic recording, and nano-medicine, to name a few. It can be derived from the magnetite (Fe_3O_4) structure by introducing Fe vacancies in the B layers containing octahedral Fe ions and oxygen. A stoichiometric phase is achieved by tripling the cubic cell along the c-axis, resulting in a charge-transfer insulator with band gap of 1.90 eV. Phonon dispersion indicates that the cubic structure is stable without imaginary frequency modes. *Ab initio* molecular dynamics (AIMD) simulations confirm the stability at 300 K. Additionally, we explore the stability of the (001) surface within the framework of *ab initio* thermodynamics. The A and B layer terminations are favored at oxygen-poor and oxygen-rich conditions, whereas at intermediate oxygen chemical potentials, a 0.5A layer termination is stabilized. While the A termination exhibits only a minor band gap change, a significant decrease occurs for the B-layer termination due to reduction of magnetic moments and Fe-O bonds up to 0.21 Å. These surfaces serve as a starting point to explore the mechanism of hydrogen adsorption and reduction of the material in view of green steel production.

O 63.8 Wed 12:15 H25

New insights into CO adsorption on TiO_2(110): Enhanced IRAS characterisation — •Nail Barama, Moritz Eder, Igor Sokolović, Michele Reticcioli, David Rath, Michael Schmid, Ulrike Diebold, Jiri Pavelec, and Gareth Parkinson — Institute of Applied Physics, TU Wien, 1050 Vienna, Austria

TiO_2(110) serves as a model system for investigating surface reactivity and catalytic behavior, with CO adsorption commonly employed as a probe molecule. While previous IR spectroscopy studies identified two distinct adsorption sites for low coverages, regular Ti sites, and Ti sites near oxygen vacancies[1,2], recent work based on DFT and microscopy suggests the existence of additional adsorption configurations influenced by the polaronic nature of the substrate[3]. In this contribution, we present experimental results obtained using our custom-built reactivity and infrared reflection absorption spectroscopy (IRAS) setup[4]. This design, optimized for detecting small concentrations of adsorbates on metal oxide surfaces, delivers high-resolution spectra with a high signal-to-noise ratio, allowing us to observe new features. Our data reveal multiple CO adsorption configurations on TiO_2(110), which agrees with STM observations from a recent study[3]. References: [1] Xu, M. et al. Angew. Chem. Int. O 64: Focus Session Atomic Scale Investigation of Magnetic 2D Materials

The rapid expansion of the family of magnetic two-dimensional (2D) materials led to the observation of various types of magnetic order in the 2D limit, such as (anti-)ferromagnetism, noncolinear structures, and magnetic moiré effects. On the fundamental level, there are various open questions regarding the mechanisms that underlie these ground states, as well as the understanding of the role of the interface and dimensionality.

Epitaxial growth of 2D magnetic materials on inert substrates under ultrahigh vacuum conditions and respective in situ investigation allows direct and unambiguous comparison between experimental findings and theoretical calculations. Experimentally, (spin-polarized) scanning tunneling microscopy methods are ideal to explore the electronic structure and magnetic properties of emerging 2D magnetic phases with ultimate real-space and energy resolution at low temperatures. These results are often corroborated by averaging techniques such as X-ray magnetic circular dichroism or magneto-optic Kerr effect. Theoretically, the use of model Hamiltonians requires atomically well-defined systems to precisely predict the electronic and magnetic properties. Combining these complementary approaches helps to elucidate the role of the substrate, defects, and the coupling between quasiparticles in stacked heterostructures.

This focus session aims at highlighting recent progress in the growth and characterization of magnetic states in epitaxial 2D materials and 2D heterostructures on metal substrates, bringing together experts from the fields of scanning probe techniques and first-principles calculations. The overall goal of the session is to gain fundamental insights into the driving mechanisms of 2D magnetic phases.

Organized by Jeison Fischer, University of Cologne, Germany and Wouter Jolie, University of Cologne, Germany.

Invited Talk O 64.1 Wed 15:00 H2

Topological spin structures in two-dimensional van der Waals magnets and heterostructures — •Stefan Heinze — Institute of Astrophysics and Theoretical Physics, University of Kiel, Germany

Two-dimensional (2D) van der Waals (vdW) magnets offer exciting opportunities for topological magnetism due to high-quality interfaces, the possibility of single-atomic layer systems, and easy control of magnetism via external stimuli [1]. Here, we explore nano- and atomic-scale topological spin structures in 2D vdW magnets and heterostructures based on first-principles calculations and atomistic spin simulations. A focus is given to heterostructures based on the 2D vdW magnet Fe_3GeTe_2 which is experimentally accessible and exhibits favorable properties such as a high transition temperature. An essential pre-requisite to apply topological spin states such as skyrmions in future applications is a sufficient stability which we quantify by calculating their lifetime using transition-state theory [2,3]. All-electrical skyrmion detection is proposed via the tunneling anisotropic and non-collinear magnetoresistance considering both a scanning tunneling microscopy geometry and a planar tunnel device structure [4]. Finally, the all-magnetic vdW heterostructure $Fe_3GeTe_2/Cr_2Ge_2Te_6$ is studied and the stability of bimerons in $Cr_2Ge_2Te_6$ is discussed [5].

Invited Talk O 64.2 Wed 15:30 H2

Ferromagnetic Order in 2D Layers of Transition Metal Dichlorides — Andrea Aguirre[1], Andres Pinar[2], Diego Soler[2], Carmen Gonzalez-Orellana[1], Jon Ortuzar[3], Oleksandr Stesovych[2], Celia Rogero[1], Jose Ignacio Pascual[3], Pavel Jelinek[2], Maxim Ilyn[1], and •Martina Corso[1] — [1]Centro de Fisica de Materiales, San Sebastian, Spain — [2]Institute of Physics, Czech Academy of Sciences, Prague, Czech Republic — [3]CIC NanoGUNE, San Sebastian, Spain

Transition metals dihalides are an ideal class of van der Waals materials that enable the study of magnetic phases as function of the transition metal and halide composition as predicted by theory. Here, we characterize the magnetic and electronic properties of 2D magnets based on metallic dichlorides. The materials form flat epitaxial layers on Au(111) with semiconducting character. By X-Ray Magnetic Circular Dichroism (XMCD) measurements we find that single layers of FeCl2 and NiCl2 are soft ferromagnets on Au(111) and their magnetization can be switched from out-of-plane to in-plane by substituting the metal ion from Fe to Ni. Using low temperature scanning tunnelling microscopy with tips functionalized with a nickelocene molecule as magnetic sensor, we confirm the magnetic order of the materials at the atomic scale even at zero applied magnetic field. We thus established a correlation between the mesoscopic magnetic properties probed by XMCD and the atomic spins. Our results suggest that these 2D semiconducting magnets could be implemented in van der Waals heterostructures for applications in spintronics and opto-spintronics.

Invited Talk O 64.3 Wed 16:00 H2

Tailoring spin lattice in van der Waals monolayer crystals — •Ying-Shuang Fu — Huazhong University of Science and Technology, Wuhan, Chinaina

Spin lattices in monolayer van der Waals (vdW) crystals provide a paradigm for exploring both fundamental spin physics at the 2D limit and miniaturized spintronic applications. Here, we present our recent research in the construction of spin lattices with molecular beam epitaxy and addressing their spin states with both spin-averaged and spin-polarized scanning tunneling microscopy. We explored artificial Kondo lattices in monolayer vdW crystals aiming to emulate protocol heavy fermion systems. We realized quasi-1D Kondo lattice in monolayer stripe-phase 1T-NbSe2 and superconducting 2D Kondo lattice in monolayer VSe2 grown on NbSe2. We also investigated intrinsic magnetic order in monolayer vdW crystals using spin-polarized scanning tunneling microscopy. We identified an antiferromagnetic order in monolayer CrTe2, unraveling the indispensable role of interlayer coupling in determining the magnetic order. Based on that finding, we further fabricated Janus CrTeSe monolayer, and regulates the magnetic anisotropy energy via the symmetry breaking introduced from the Janus structure. Our study resolves intrinsic magnetism with atomic-scale resolution down to monolayer limit, opening up an avenue for studying the unusual spin excitations.

Invited Talk O 64.4 Wed 16:30 H2

Spin excitations in 2D heterostructures from realistic fermionic models — •António Costa — Center of Physics of the University of Minho, Braga, Portugal — International Iberian Nanotechnology Laboratory

Spin excitations dominate the magnetic response of ferromagnetic two-dimensional crystals. The interplay between low dimensionality, reduced symmetry and spin-orbit coupling endows spin excitations in those materials with intriguing properties, such as non-trivial topology and non-reciprocity. Moreover, spin-orbit coupling connects spin and charge degrees of freedom, opening up paths to electrical control and detection of magnetic states. I will present a microscopic description of the spin response of nanostructured materials based on Hamiltonians for itinerant fermions, derived from DFT calculations. This approach incorporates spin-orbit coupling, does not rely on postulated spin models, and can be applied to insulating or conducting 2D heterostructures, with any kind of magnetic order. I will discuss the properties of magnons in insulating and metallic van der Waals ferromagnets, as well as in 2D molecular crystals. I will also discuss the proximity effect in a heterostructure formed by a 2D ferromagnet and graphene.

O 64.5 Wed 17:00 H2

Monolayer Multiferroic - Superconductor van der Waals Heterostructures — •Büşra Gamze Arslan, Mohammad Amini, Ziying Wang, Robert Drost, and Peter Liljeroth — Department of Applied Physics, Aalto University, P.O. Box 15100, 00076 Aalto, Espoo, Finland

Topological superconductivity, a quantum phase hosting robust edge modes like Majorana zero modes (MZMs), holds promise for fault-tolerant quantum computation due to its stability against disturbances. Stacked van der Waals materials offer a promising platform to engineer topological superconductors, as they arise from the interactions between superconductors and magnetic materials. With its helical magnetic order and intrinsic spin-orbit coupling, multiferroic NiI_2 is an excellent component for heterostructures realising topological superconductivity.

Here we present our study on monolayer NiI_2 grown on superconducting bulk $NbSe_2$. This system is characterized using scanning tunneling microscopy (STM) and spectroscopy (STS). The effect of doping due to the growth of NiI_2 on different substrates is investigated. Our observations revealed that NiI_2 does not show ferroelectricity, likely due to the charge transfer from the $NbSe_2$ substrate. In addition, we have investigated the edges of the NiI_2 islands, where we found clear signatures of edge modes in the $NiI_2/NbSe_2$ system. Whether these arise from topological effects remains to be seen in future studies. Our results show that combining 2D materials can create custom materials with relevant properties.

O 64.6 Wed 17:15 H2

Engineering the electronic and magnetic properties of MPS_3 (M=Fe, Ni, Co, Mn) materials through alkali metal doping — Jonah Nitschke[1], •Preeti Bhumla[2], Till Willershausen[1], Patrick Merisescu[3], Lasse Sternemann[1], Valentin Mischke[1], Michele Capra[1], Mira Arndt[1], David Janas[1], Giovanni Zamborlini[4], Silvana Botti[2], and Mirko Cinchetti[1] — [1]TU Dortmund — [2]Research Center Future Energy Materials and Systems, ICAMS, Ruhr University Bochum — [3]University of Bath — [4]Universität Graz

Transition metal phosphorus trichalcogenides, MPX_3 (where M represents a transition metal and X represents a chalcogen), have emerged as promising candidates for exploring two-dimensional (2D) magnetism. In this study, we focus particularly on MPS_3 (M = Fe, Ni, Co, Mn) materials, both above and below the Néel temperature TN. We investigate the electronic and magnetic properties of these materials using micrometer-scale angle-resolved photoelectron spectroscopy (ARPES) and density functional theory (DFT+U) calculations. We observe an increase in the band gaps and shifts in the M d and S p states below TN in the antiferromagnetic (AFM) phase. The density of states reveals the orbital character of the observed bands, and the strong hybridization between the M d and S p orbitals suggests that the superexchange mechanism, in which the S atom mediates the magnetic interaction between neighboring M ions, is relevant for these materials. Further, we examine the effect of alkali metal doping on the magnetic properties of these transition metal phosphorus trichalcogenides.

O 64.7 Wed 17:30 H2

Conflicting magnetic anisotropy in 2D metal-organic networks — •Diego Radillo[1,2], Céline Hensky[1,2], Quy Hien Le[1,2], Manfred Parschau[3], Egzona Isufi Neziri[3], Christian Wäckerlin[1,2], and Pierluigi Gargiani[4] — [1]EPFL, Switzerland — [2]PSI, Switzerland — [3]Empa, Switzerland — [4]ALBA, Spain

This talk presents insights into the properties of 2D metal-organic coordination networks embedded with atoms of conflicting magnetic anisotropies. In particular, we look into the coordination networks of tetracyanoethylene with Ni atoms (NiTCNE), Fe atoms (FeTCNE) and a mixture of both (NiFeTCNE), on a gold(111) surface. NiTCNE is known to be a ferromagnet with an out-of-plane easy axis of magne- tization. Whereas, for the conflicting in-plane ferromagnet, we propose FeTCNE as a suitable candidate. In our mixed-network experiments, where the magnetic exchange energy enforces that the preferences of the two metal ions cannot be perfectly satisfied, we observe that the magnetization along the out-of-plane and in-plane axes at the Ni and Fe centers mutually influence each other in a rather rational way. This interaction suggests the potential for fine-tuning the magnetization axis and highlights the importance of investigating spin alignment at the per-atom scale. Scanning probe microscopy (SPM) and non-contact atomic force microscopy (AFM) are employed to inspect the morphology of the networks, while X-ray absorption spectroscopy (XAS) and X-ray mag- netic circular dichroism (XMCD) were utilized to analyze the magnetic properties.

O 64.8 Wed 17:45 H2

Non-van der Waals 2D Materials: Magnetic State Control — •Tom Barnowsky[1,2] and Rico Friedrich[1,2,3] — [1]TU Dresden — [2]Helmholtz-Zentrum Dresden-Rossendorf — [3]Duke University, Durham, USA

Non-van der Waals (non-vdW) 2D materials – exfoliated from non-layered bulk structures [1] – offer unique opportunities for exploring magnetic properties and their surface-assisted manipulation.

In recent data-driven studies [2,3], we predict several dozen exfoliable candidates. Many of these materials exhibit intrinsic magnetism, notably due to magnetic surface cations, which lead to strong surface spin polarization. Furthermore, the exposed "dangling" bonds at their surfaces – created by bond breaking during exfoliation from the bulk – enable passivation that can significantly modify their electronic and magnetic properties [4]. This passivation-based tuning can, for example, switch the magnetic state of these materials, *i.e.*, alter their local spin symmetry. Most notably, non-vdW 2D $CdTiO_3$ – a diamagnetic compound in its pristine form – becomes ferromagnetic upon hydrogenation. Using data mining and autonomous density functional theory, we demonstrate the potential of these materials as a powerful platform for magnetic state control, opening new possibilities for spintronics.

O 65: Solid-Liquid Interfaces: Reactions and Electrochemistry III

Time: Wednesday 15:00–17:45 Location: H6

O 65.1 Wed 15:00 H6

Potential Pulsed CO2 Reduction Reaction on Polycrystalline Copper Electrodes Studied with Operando Plasmonic Interface Analysis — •Hagen Übele, Katharina Krischer, and Moritz Josef Feil — Chemische Physik fern des Gleichgewichts Technische Universität München, München, Deutschland

This contribution highlights the use of polished polycrystalline Cu electrodes for the CO2 reduction reaction. By applying time-periodic potential pulses, long-term stability and enhanced selectivity towards hydrocarbon products like methane, ethylene, and ethanol are achieved. These methods rival the performance of nano-structured oxide-derived catalysts or Cu single crystal electrodes while improving electrode longevity.

Operando monitoring is conducted using a plasmonic interface analysis technique with a time resolution of 100 ms. This enables real-time tracking of the Cu oxidation state and the nano-morphology of the electrode surface during potential pulses. The study demonstrates that optimized pulsing protocols can significantly extend the stability of Cu electrodes without the need for premanufactured nanostructures.

O 65.2 Wed 15:15 H6

Au(111) in the Ionic Liquid [MPPip][TFSI]: Corrosion, Reconstruction and Other Surface Restructuring Phenomena — •Maren-Kathrin Heubach[1] and Timo Jacob[1,2,3] — [1]Institute of Electrochemistry, Ulm University, Ulm, Germany. — [2]Helmholtz-Institute-Ulm (HIU), Ulm, Germany. — [3]Karlsruhe Institute of Technology, Karlsruhe, Germany.

In fundamental electrochemistry, Au single-crystals are a good benchmarking standard because of the ease of their preparation and high chemical stability.[1-4] Nevertheless, the morphological stability of Au under measurement conditions is rather limited. In this study, we utilize *in situ* scanning tunnelling microscopy (STM) to investigate the stability of a Au(111) electrode in the ionic liq-

uid *N*-methyl-*N*-propylpiperidinium bis(trifluoromethane)sulfonimide ([MPPip][TFSI]). We will provide an overview of the observed surface structures and the corresponding potential ranges in which they remain stable.

O 65.3 Wed 15:30 H6

The relationship between composition, structure and activity of well-defined Pt-Ru alloys during electroreduction of acetone — •Robert Hübsch[1], Pankaj Kumar Samal[2], Frederike Jäschke[1], Tomáš Skála[2], Nataliya Tsud[2], Josef Mysliveček[2], Olaf Brummel[1], Yaroslava Lykhach[1], and Jörg Libuda[1] — [1]Interface Research and Catalysis, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — [2]Department of Surface and Plasma Science, Charles University, Prague, Czech Republic

The isopropanol/acetone couple can be used as an electrochemically active liquid organic hydrogen carrier (EC-LOHC). PtRu-based alloys are the state-of-the-art catalysts for the electrooxidation of isopropanol. We have investigated the reverse reaction, i.e. electrochemical reduction of acetone, on well-defined PtxRu1-x alloys by means of cyclic voltammetry (CV), synchrotron radiation photoelectron spectroscopy (SRPES) coupled with an ex-situ emersion electrochemical cell, electrochemical infrared reflection absorption spectroscopy (EC-IRRAS), and differential electrochemical mass spectrometry (DEMS). In a systematic study, we established structure-activity relationships for well-ordered PtxRu1-x alloys and surfaces subjected to dealloying in pure and acetone-containing electrolyte. We found that the active state of the catalyst corresponds to the presence of ultra-small Pt aggregates supported on partially oxidized Ru(0001). While Pt(110) forms propane as reduction product, the dealloyed catalysts form the target product isopropanol and suppress propane formation.

O 65.4 Wed 15:45 H6

Electrochemical XPS for probing the electrified solid-liquid interface of tungsten carbide — Christoph Griesser, Toni Moser, Sergio Diaz-Coello, and •Julia Kunze-Liebhäuser — Institute of Physical Chemistry, University of Innsbruck, Innsbruck, Austria

A profound understanding of the solid/liquid interface is central in electrochemistry and electrocatalysis, as the interfacial properties determine the electroreactivity of the system. This study reveals the in-situ surface chemistry evolution of tungsten carbide (WC) powders during electrochemical polarization. WC is known for its platinum-like properties and its high activity towards the hydrogen evolution reaction (HER), but prone to passivation upon air or electrolyte exposure. It is found that the unpreventable surface passivation layer on WC dissolves into the electrolyte under HER conditions, which explains the typically measured high HER electrocatalytic activity of this compound material. The electrochemical (EC-)XPS data provide profound chemical understanding of the electrode/electrolyte interface during operation. This enables fundamental contribution to bottom-up electrocatalyst development, and thus to the advancement of energy conversion and storage technologies.

We thank the FWF for financial support within the Cluster of Excellence MECS.

O 65.5 Wed 16:00 H6

Degradation of TiO_2/Pt catalyst interfaces during operation — •Sergej Levashov[1], Tim Rieth[1,2], Ian D. Sharp[1,2], and Johanna Eichhorn[1] — [1]TUM School of Natural Sciences — [2]Walter Schottky Institut

Photoelectrochemical (PEC) water splitting is a promising approach for generating green fuels. However, photosystems often degrade in the harsh chemical environment required for PEC water splitting. To overcome this limitation, understanding the starting point of the degradation and the exact degradation mechanism at the nanoscale is required. In this work, we study TiO_2 thin films grown by atomic layer deposition (ALD) combined with Pt catalyst layers, deposited by sputtering and two different ALD processes, by in-situ/operando atomic force microscopy and elucidate their changes in topography and mechanical properties under operation conditions. The main difference between the Pt is the growth mechanics: while sputtering yields a continuous film, the ALD growth results in Pt islands. On the macroscale, the ALD grown Pt catalysts show similar onset potentials and saturation current densities as the sputtered ones. At the nanoscale, we observe that the ALD Pt films are more stable than sputtered Pt under operation conditions. Complementary, we performed X-ray photoelectron spectroscopy (XPS) before and after PEC operation to reveal chemical changes. Overall, ALD grown Pt catalysts improve the system performance compared to sputtered Pt. These measurements provide important insights into the underlying reaction mechanism and the role of surface restructuring and delamination of catalyst interfaces.

O 65.6 Wed 16:15 H6

TiO2 passivation of GaInP(100) surfaces — •David Ostheimer[1], Julius Kühne[2,3], Sahar Shekarabi[1], Agnieszka Paszuk[1], Mohammad Amin Zare Pour[1], Ian D. Sharp[2,3], Wolfram Jägermann[4], and Thomas Hannappel[1] — [1]TU Ilmenau, Inst. of Physics, Fundamentals of Energy Materials, Ilmenau, Germany — [2]TU Munich, Walter Schottky Institute, Garching, Germany — [3]TU Munich, Physics Department, TUM School of Nat. Sciences, Garching, Germany — [4]TU Darmstadt, Surface Science Lab, Darmstadt, Germany

GaInP is widely used in III-V-based photoelectrochemical devices as a top photoabsorber or charge-selective contact, achieving high solar-to-fuel conversion efficiencies. To enhance stability under HER conditions, a thin TiO2 protection layer can be applied. This study investigates the electronic structure of the TiO2/GaInP(100) interface. TiO2 was deposited via atomic layer deposition (ALD) on p-type GaInP(100) grown on GaAs(100) substrates. Two surfaces were prepared: a phosphorus-rich (P-rich) (2x1)-like surface transferred contamination-free under ultra-high vacuum (UHV) and a naturally oxidized surface. X-ray and UV photoelectron spectroscopy revealed a slightly thinner interfacial oxide in the UHV-transferred sample. Initial ALD cycles formed an oxide nearly stoichiometric to the native oxide, but both samples exhibited strong Fermi level pinning, resulting in similar band alignments. These findings highlight the influence of initial oxides on interface control in III-V semiconductors.

O 65.7 Wed 16:30 H6

Influence of pH and Electrolyte Flow on the Oxidation of Ni anodes at High Overpotentials — •Justus Leist[1], Timo Jacob[1,2,3], and Albert K. Engstfeld[1] — [1]Institute of Electrochemistry, Ulm, Germany — [2]Helmholtz-Institute-Ulm (HIU), Ulm, Germany — [3]Karlsruhe Institute of Technology, Karlsruhe, Germany

The electrocalalytic splitting of aqueous electrolytes is typically impeded by the sluggish kinetics of the oxygen evolution reaction (OER). Ni-based catalysts are considered as cost-effective alternatives to the currently used rare metal oxides, such as Ir or Ru. While the fundamental properties of Ni have been studied intensively usually at or around the onset potential for the OER, here we study the OER activity at high overpotentials, which are more closely related to application.

The OER characteristics are studied by means of cyclic voltammetry and polarization curves using Ni electrodes in alkaline solutions. Depending on the experimental conditions, electrolyte pH and flow, the current voltage traces show several features at high overpotentials, which can be attributed to the pH-dependent change in OER kinetics. Based on additional in-situ Raman spectroscopy and electrochemical quartz crystal microbalance measurements we discuss possible structures formed and the degradation of the Ni electrodes under these conditions.

O 65.8 Wed 16:45 H6

DFT Study of Aldehyde Oxidation and Hydrogen Evolution on Flat and Stepped Gold Surfaces — •Samuel Mattoso[1], Stefan Wipperman[1,2], Mira Todorova[1], and Jörg Neugebauer[1] — [1]Max-Planck-Institut für Nachhaltige Materialien, Max-Planck-Straße 1, 40237 Düsseldorf — [2]Philipps-Universität Marburg, Renthof 5, Marburg, 35032, Germany

Significant investments are being made in the development of greener industrial processes, with heterogeneous electrocatalysis playing a major role. Gold is known as a catalyst, which selectively oxidizes aldehydes to carboxylic acid. It may also catalyze the hydrogen evolution reaction (HER). These chemical reactions take place at the solid-liquid interface, where the role of step sites, pH, adsorption of intermediates, solvation and applied bias are largely unknown but may be relevant to understand in order to improve performance. We employ DFT simulations to provide mechanistic insights into this system, by probing the interaction of Au(111) and Au(331) surfaces with H, OH and acetaldehyde. The adsorption energies and work function changes as a function of H and OH coverage for different observed patterns will be reported for the two surfaces. In addition, we find that surface imperfections such as step edges are essential for the HER and aldehyde oxidation to proceed, as they dissociatively bind the aldehyde, leading to adsorbed H.

O 65.9 Wed 17:00 H6

On the pH-dependence of the H_{upd} peak in cyclic voltammograms of Pt-group nanoparticles — •Hedda Oschinski[1,2], Simeon Beinlich[1,2], Karsten Reuter[1,2], and Nicolas Hörmann[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Technische Universität München, München

Understanding the electrochemical behavior of hydrogen adsorption at Pt-group metal surfaces, particularly in the context of non-well-defined nanoparticle surfaces, is crucial for advancing electrocatalytic applications such as the hydrogen evolution reaction (HER). To this end, we provide insights into the non-Nernstian pH shifts observed for underpotential deposited H_{upd}-like cyclic voltammetry (CV) peaks on Pt, Ir, Pd, and Rh nanoparticles. Utilizing density-functional theory, we explore the potential-dependent stability of H and OH adsorbates at undercoordinated surface sites, emphasizing the role of non-ideal electrosorption valencies in these shifts. This identifies direct H-OH replace-

ment as predominant mechanism behind the CV peaks and reveals a primary influence of partial charge transfer. The theoretical predictions show good agreement with experimental observations across various Pt-group metals, even over various surface coordinations, and provide insights into cation-specific effects at Pt across the entire pH scale. This work not only clarifies the origin of the H_{upd}-like peak shift within the water stability region, but also suggests the interfacial capacitance as a main descriptor for cation effects in the HER, paving the way for more detailed analyses of cation type, concentration, and interfacial solvent structure.

O 65.10 Wed 17:15 H6

From model to realistic copper sulfide electrocatalyst — •Roser Fernandez Climent, Jesus Redondo, and Martin Setvín — Charles University, Prague, Czech Republic

Copper sulfide is a widely studied material in electrocatalysis. In this study, we synthesized copper sulfide thin films electrochemically under inert conditions, enabling precise control of material properties and minimizing contamination risks. The films were transferred in-vacuum for surface characterization using X-ray photoelectron spectroscopy (XPS), low-energy electron diffraction (LEED), and scanning transmission electron microscopy (STEM).

O 65.11 Wed 17:30 H6

Stability of Pd-Rh core-shell electrocatalysts supported on Co3O4(111) in alkaline environment — Alexander Simanenko[1], Jan Škvára[2], Pankaj Kumar Samal[2], Evanie Franz[1], Robert Hübsch[1], Tomáš Skála[2], Nataliya Tsud[2], Sascha Mehl[3], Viktor Johánek[2], Josef Mysliveček[2], Olaf Brummel[1], •Yaroslava Lykhach[1], and Jörg Libuda[1] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — [2]Charles University, Prague, Czech Republic — [3]Elettra-Sincrotrone Trieste SCpA, Basovizza-Trieste, Italy

The electronic metal-support interaction (EMSI) is considered as an efficient strategy to stabilize the noble metal nanoparticles against sintering, but its consequences under the electrochemical conditions remain elusive. We investigated the effect of the EMSI on the stability of bimetallic Pd@Rh and Rh@Pd core@shell nanoparticles supported on well-ordered Co3O4(111) films in alkaline electrochemical environment by means of synchrotron radiation photoelectron spectroscopy (SRPES) coupled with ex-situ emersion electrochemical cell. We found that the EMSI promotes strong oxidation of Rh metal. The extent of Rh oxidation strongly depends on the specific metal/oxide interface configuration below the core@shell nanoparticles. Our study suggests that decoupling the Rh metal and the Co3O4(111) substrate by constructing the Pd/Co3O4(111) interface below Pd@Rh core@shell nanoparticles reduces the effect of the EMSI and improves the stability of the electrocatalyst toward oxidation.

O 66: Vacuum Science Technology: Theory and Applications

Time: Wednesday 15:00–18:00 Location: H8

Invited Talk O 66.1 Wed 15:00 H8

Unveiling the crucial role of kinetic modeling of gas flows in vacuum and fusion technologies — •Christos Tantos and Thomas Giegerich — Institute for Technical Physics, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, 76344, Germany

Accurate and reliable modeling of non-equilibrium flows is not only of academic interest within the scientific community, including the field of vacuum gas dynamics, but is also crucial for the design and enhancement of engineering processes, such as those in vacuum and fusion technologies. In these applications, the flow is characterized by molecular mean free paths that are comparable to the reference characteristic length, making a particle-based description of the flow field essential. This requires the use of the Boltzmann equation and widely accepted numerical methods for solving it, such as the stochastic Direct Simulation Monte Carlo (DSMC) and the deterministic Discrete Velocity Method (DVM).

This talk discusses key aspects of rarefied gas dynamics in vacuum and fusion technologies, emphasizing the link between theory and practice. It is divided into two parts. The first covers recent advances in modeling multicomponent transport phenomena in vacuum technology using DSMC and DVM methods, with a focus on gas separation in multicomponent flows. The second part analyzes vacuum gas dynamics in fusion systems, presenting numerical simulations (2D and 3D) of pumping systems in fusion machines and highlighting their design impact.

Invited Talk O 66.2 Wed 15:30 H8

Advances in traceable vacuum and outgassing rate measurements — •Matthias Bernien[1], Annas Bin Ali[1], Thomas Bock[1], Tom Rubin[1], Janez Setina[2], Perrin Waldock[3], Kirk Madison[3], and Karl Jousten[1] — [1]PTB, Abbestr. 2-12, 10587 Berlin — [2]IMT, Lepi pot 11, 1000 Ljubljana, Slovenia — [3]University of British Columbia, 6224 Agricultural Road, Vancouver, B.C. V6T 1Z1, Canada

For the pressure range from 10 mPa to 130 Pa, a fully automated static expansion system made of aluminum has been set up and validated. Its principle involves transferring a fixed amount of gas from a smaller volume to a larger one, creating a well-defined lower pressure, provided that the initial pressure and the volume ratio are accurately known. Relative standard measurement uncertainties between 0.08% and 0.012% are achieved. Primary standards utilizing cold atom traps offer a promising new approach for realizing the pascal in the UHV range by measuring the loss rate caused by collisions with gas molecules. To establish these standards, the University of British Columbia and PTB have carried out a comparison between a mobile standard based on cold atoms and a continuous expansion system for N_2, Ar and H_2. In the semiconductor industry, outgassing from components in vacuum must be well controlled. Contaminants are monitored using QMSs which lack stability. This is particularly problematic when maximum levels of contaminants must be agreed between manufacturers and suppliers. To improve the comparability of outgassing rate measurements, reference samples for dodecane and water have been developed suitable for in-situ calibration of QMSs.

O 66.3 Wed 16:00 H8

BeamPipes4ET: Innovative On-Site Production and Welding of the Einstein Telescope Vacuum Tubes — Charlotte Benning, •Robert Joppe, Oliver Pooth, and Achim Stahl — III. Physikalisches Institut B, RWTH Aachen

The Einstein Telescope will be the first gravitational wave detector of the third generation. It requires about 120 km of vacuum tubes with a diameter of 1 m to achieve the design sensitivity and reduce scattered light. BeamPipes4ET introduces an innovative production concept for vacuum pipes, incorporating a new welding technology and adapting existing flange and T-section production methods. This approach enhances reliability, significantly reduces labor, welding, and finishing efforts. By manufacturing pipes on-site from coils of sheet metal in a continuous process, transportation needs are minimized, and pipe connections are eliminated. Additionally, the project pioneers laser beam welding under mobile vacuum and transfers advanced pipe feature integration technologies to further streamline production.

This talk presents the current status and ongoing activities in the BeamPipes4ET project.

O 66.4 Wed 16:15 H8

Aluminum fiber optical vacuum feedthroughs for challenging environments — •Christoph Bartlitz, Kristian Kirsch, Marco John, Marcel Hannemann, Andreas Trützschler, and Klaus Bergner — VACOM Vakuum Komponenten & Messtechnik GmbH, In den Brückenäckern 3, 07751 Großlöbichau, Germany

Fiber optical components are used in a wide variety of places, both in scientific experiments and in production processes in vacuum systems. In principle, these components enable interference-free transmission of the finest measurement signals over long distances, robust sensor technology and maximum transmission speed. Hermetic optical fiber feedthroughs based on stainless steel, ceramics and quartz glass have become established for coupling light signals to vacuum- and process chambers.

We designed and tested a novel optical fiber feedthrough whose metallic components are made entirely of aluminum.

These technologies enable the application of optical fibers as in-vacuum diagnostic within challenging environments. Thereby, the diagnostic is driven by fiber Bragg gratings (FBGs) in the optical fiber itself. The application of FBGs as an in-vacuum temperature sensor is demonstrated, where an optical fiber containing a bunch of several FBGs becomes a compact, stable, robust, and flexible network of local sensors at different positions in vacuum with up to km-length signal path.

O 66.5 Wed 16:30 H8

Comparative Measurements of Ion Pump pumping speed according to ISO/DIS 3556 and DIN 28429 — •Marcel Herrmann, Kristian Kirsch, Marco John, Christoph Bartlitz, Andreas Trützschler, and Klaus Bergner — VACOM Vakuum Komponenten & Messtechnik GmbH, In den Brückenäckern 3, 07751 Großlöbichau

Sputter Ion Pumps (SIP) offer an appealing strategy to efficiently maintain ultra-high and extremely-high vacuum conditions in a vacuum chamber. The pumping speed, i.e. the volume flow of gas extracted from the vacuum in a specific

period of time, can be determined according to various standards. However, recorded pumping speeds may vary severely, depending on the standard chosen and the detailed procedure applied. This talk compares experimentally obtained pumping speeds of several SIPs, acquired according to the most commonly applied standards, DIN 28429:2014 05 and ISO/DIS 3556 1.2(1992).

O 66.6 Wed 16:45 H8

Performance and future of the KATRIN experiment after 6 years of tritium operation — •Joachim Wolf — Karlsruher Institut für Technologie (for the KATRIN Collaboration)

The Karlsruhe Tritium Neutrino experiment (KATRIN) searches for the effective electron neutrino mass with electrons from the β-decay of tritium with an unprecedented sensitivity of <0.3 eV/c2. The β-electrons are guided magnetically through the 70-m long setup, moving from the gaseous tritium source through a differential pumping section (DPS) and a cryogenic pumping section (CPS) to the high-resolution spectrometer. In the spectrometer, the kinetic energies of the decay electrons are analysed in an electrostatic high-pass filter (MAC-E-filter). Background considerations require a very good vacuum in the order of 10-11 mbar in the large spectrometer vessel (volume 1240 m^3, surface: 1222 m^2). A combination of NEG pumps and turbo-molecular pumps reliably provides the necessary pumping speed since more than 10 years. In addition, a very clean surface and low outgassing rates are mandatory.

After several years of engineering runs, the experiment started full tritium operation in March 2019, searching for the effective mass of electron-antineutrinos. These measurements will finally end in December 2025, followed by hardware upgrades and a new physics program. This talk reports on the performance of the components, after almost 20 years of R&D and 6 years of tritium operation with special emphasis on vacuum-related issues, followed by a description of future plans for the KATRIN setup.

O 66.7 Wed 17:00 H8

Miniaturized Pirani vacuum sensor with active heat-loss compensation — •Julian Eiler[1], Stefan Weber[2], Peter Gerlesberger[2], Heinz Plöchinger[2], and Rupert Schreiner[1] — [1]Faculty of Applied Natural Sciences and Cultural Studies, OTH Regensburg, D-93053 Regensburg, Germany — [2]Thyracont Vacuum Instruments GmbH, D-94036 Passau, Germany

Pirani sensors measure the thermal conductivity of the residual gas in a vacuum by creating a thermal gradient between a heated sensor element and a heat sink. The heat flux from the sensor element to the heat sink over the residual gas is a measure of the vacuum and can be determined by the electrical power applied.

In addition to the heat flux over the gas, there are further energy losses from the heating structure due to radiation and parasitic heat fluxes via the suspensions of the sensor element. These losses reduce the sensitivity of the sensor.

For this reason, a Micro-Pirani sensor in the shape of a micro-hotplate was developed that actively compensates the heat flux via the suspensions. This was achieved by placing additional heating structures on the suspensions, which interrupt the heat flow from the sensor element via the suspensions during operation. This active compensation improves the sensitivity at low pressures, enabling vacuum measurements from atmospheric pressure down to 10e-6 mbar.

O 66.8 Wed 17:15 H8

Feasibility Study on Laser-Based Real-Time Monitoring of Hydrogen Atom Beams — •Tobias Geier, Alexander Marsteller, and Robin Grössle — Karlsruher Institute for Technology, IAP-TLK, for the KAMATE Collaboration

Through the observation of neutrino oscillations, it has been shown that there are three different neutrino mass eigenstates. Current measurements of the oscillation length of the flavor states yield a lower limit for the effective electron neutrino mass of ~ 0.05 eV (inverted ordering) or ~ 0.01 eV (normal ordering). The sensitivity of the KATRIN experiment is limited to ~ 0.3 eV. Therefore, future experiments which aspire to achieve inverted ordering or better need new technologies. For the next generation of experiments aiming at the direct determination of the neutrino mass using high-resolution beta spectroscopy on tritium, atomic tritium is to be used. The advantage over the currently used molecular tritium (T_2) lies in the avoidance of molecular excitations in the $^3HeT^+$ daughter molecule, which lead to a smearing of the beta spectrum, thus limiting the maximum achievable resolution. In order to employ atomic tritium for beta spectroscopy, it is essential to cool it to a few mK and trap it magnetically. A method for contactless real-time analysis of the beam is required to monitor and control the operation of the atomic source. This talk presents a method for characterizing the beam profile based on Rayleigh scattering of a laser beam. By measuring the intensity with a sensitive camera, the particle density can be mapped. In this contribution, the results of a first experimental feasibility study are presented.

O 66.9 Wed 17:30 H8

Challenging tasks in modern vacuum technology applications — •Kristian Kirsch, Andreas Trützschler, Christoph Bartlitz, Marcel Herrmann, Marco John, and Klaus Bergner — VACOM Vakuum Komponenten & Messtechnik GmbH In den Brückenäckern 3 07751 Großlöbichau / Germany

Cutting-edge technology from the field of particle accelerators, quantum technology applications and lithography is pushing the limits of vacuum technology. In general, off-the-self" products are not sufficient for that. In this context, product developers and scientists need to find a joint language to deal with this task. The focus of this talk is to explain needs and challenges of today's cutting edge technology applications related to vacuum requirements. Therefore, we address different state-of-the-art applications. One focus is the fundamental difficulty to fulfill demanding vacuum conditions in one compact system. On the other hand, we address the complex and demanding task of isolating quantum objects within a quantum application like quantum computing, quantum gravimetry, and quantum metrology. Based on this, benefits and drawbacks of different vacuum technology solutions to all of these requirements are shown within the transition from customized single components to standardized and industrial ready serial components.

O 66.10 Wed 17:45 H8

Different Approaches to Vacuum System Performance Improvement for the Einstein Telescope — •Charlotte Benning, Robert Joppe, Maike Kühler, Stefan Krischer, Oliver Pooth, and Achim Stahl — III. Physikalisches Insitut B, RWTH Aachen

The Einstein Telescope will be the next European gravitational wave detector. It requires about 120 km of vacuum tubes in tunnels with a diameter of 1 m for a laser beam to achieve the design sensitivity. The required pressure of less than 10^{-11} mbar introduces the need for innovations that help with performance improvement and cost reduction. The current baseline concept of the vacuum system includes passive sections of stainless steel welded inside the tunnels and connected to pumping stations. Achieving ultra-high vacuum (UHV) in these tubes requires high pumping capacities and long bake-out times of the tubes, which are associated with high energy and equipment costs.

This talk discusses two possible improvements over the baseline design: Integrating non-evaporable getter (NEG) surfaces into the inside of the tubes to reduce costs and aiming for a more homogeneous distribution of pumping power (distributed pumping). Furthermore, forming seamless flanges from the pipe material eliminating the need for welding is presented, which is especially relevant for the underground environment of the Einstein Telescope.

O 67: Ultrafast Electron Dynamics II

Time: Wednesday 15:00–17:45 Location: H11

O 67.1 Wed 15:00 H11

Polaron formation in NiO analysed by transient absorption spectroscopy — •Mahendra Kabbinahithlu[1], Björn Sothmann[1], Fred Hucht[1], Sergey Kovalenko[2], Tobias Lojewski[1], Nico Rothenbach[1], Katharina Ollefs[1], Heiko Wende[1], Uwe Bovensiepen[1], Julia Stähler[2], and Andrea Eschenlohr[1] — [1]Universität Duisburg-Essen, Fakultät für Physik und Center for Nanointegration (CENIDE), Lotharstraße 1, 47057 Duisburg, Germany — [2]Humboldt-Universität zu Berlin, Institut für Chemie, Brook-Taylor-Straße 2, 12489 Berlin, Germany

Polaron formation is the process by which free electrons in a material find a lower energy localized state by distorting their surrounding lattice. The polaron formation timescales and its fluence dependent dynamics in nickel oxide (NiO) from time-resolved optical absorption studies is discussed here.

NiO is pumped above the band gap with 3.98 eV energy photons, and is probed using a time-delayed supercontinuum. The time-resolved absorption spectrum shows negative ground state bleach and positive excited state absorption and in addition, a time-delayed and energy separated appearance of a positive feature at 3.35 eV that is discussed as the signature of polaron formation. With increasing fluence,the build-up time of this 3.35 eV signature decreases from 4 ps down to 1.1 ps, indicating the transition from isolated polarons to the formation of a polaron band. The spectrally distinct transition between low fluence and high fluence regimes is used to estimate the polaron size and the dynamics is modelled by coupled rate equations.

O 67.2 Wed 15:15 H11

Sharp Exciton Mott Transition in WS_2 and its Ultrafast Decay — •Subhadra Mohapatra[1], Lukas Gierster[1], Samuel Palato[1], Nicholas Michael Olsen[2], Xiaoyang Zhu[2], and Julia Stähler[1] — [1]Humboldt-Universität zu Berlin, Institut für Chemie — [2]Columbia University

The excitonic Mott transition (EMT) in transition metal dichalcogenides is reported to be either discontinuous [1] or continuous [2]. To resolve the ambiguity,

here we study the optical response of WS_2 across the Mott density. Using a complex lineshape analysis, we separate the optical response in the photo-excited part of the sample from the unexcited regimes. In agreement with a continuous EMT, a gradual increase in the bleach of the sample-averaged absorption is observed. However, the lineshape analysis unveils a sharp discontinuity in the transient dynamics of the A and B exciton resonances above a critical photoexcitation density. This is attributed to plasma formation followed by band gap renormalization. The plasma decays with a laser fluence-independent time constant of 0.65 ps which is attributed to phase separation into excitonic and plasma regions, in agreement with the literature [3,4]. This work not only provides the first detailed experimental investigation of the EMT close to the critical limit but also highlights the role of spatial inhomogeneous charge carrier distribution for the widely used transient optical spectroscopies of 2D materials. O 67.3 Wed 15:30 H11

Ultrafast formation of electron polarons in rutile TiO_2(110) — •Xiang Zhang, Lukas Gierster, and Julia Stähler — Humboldt-Universität zu Berlin, Institut für Chemie

The electron dynamics at TiO_2 surfaces are widely studied, mainly focusing on the defect-induced electronic states [1,2]. Additionally, recent calculations suggest that upon across-bandgap excitation, electron polarons form within 25 fs by trapping of photoexcited electrons inside the deformed lattice [3]. Using time-resolved photoelectron spectroscopy, we observe the instrument response-limited (<30 fs) rise of a photoinduced electron population at 0.3 eV below E_F. To elucidate whether this feature originates from polaron formation, experiments are conducted with different laser fluences, photon en- ergies and under varying surface conditions. Based on this, competing mechanism as exciton formation, surface photovoltage effects and band gap renormalization can be excluded. Our results suggest that photoexcitation of the rutile TiO_2(110) surface creates small sub-surface polarons within only 30 fs.

O 67.4 Wed 15:45 H11

Time-resolved two-photon photoemission of antiferromagnetic $LaFeO_3$ — •Friederike Wührl, Antonia Rieche, Anne Oelschläger, Kathrin Dörr, and Wolf Widdra — MLU Halle-Wittenberg

Basic quantities as band gaps or the lifetime of electrons at the conduction band minimum are of strong interest for optoelectronic devives. In this context, strongly correlated oxides are rarely studied. One such example is NiO, which shows a remarkable short lifetime of < 10 fs at the conduction band minimum, relaxing in a many-body in-gap state, which couples to the antiferromagnetic spin system [1].

We present time-resolved two-photon photoemission (2PPE) data on above band gap excitation of electrons in $LaFeO_3$, a charge-transfer insulator with antiferromagnetic order, which exhibits weak ferromagnetism through spin canting. The band gap opens between hybridized O 2p – Fe $3d_\uparrow$ and minority Fe 3d $t_{2g\downarrow}$ states. Thin films of 9 nm $LaFeO_3$ were prepared on $SrRuO_3$/$DyScO_3$ substrates using pulsed laser deposition. Low-energy electron diffraction confirmed the formation of single crystalline layers with a c(2x2) superstructure, indicative for the long-range magnetic ordering. In one-colour and two-colour UV-UV pump-probe experiments ($h\nu$ = 3.4 eV and 4.2 eV) we find three unoccupied states at 0.3, 1.3, 2.1 eV above E_F, the middle one being resonantly pumped from Fe $e_{g,\uparrow}$ states and exhibiting a short lifetime of 22 fs. At the conduction band minimum we observe a biexponential decay with lifetimes of 40 fs and 1.1 ps.

O 67.5 Wed 16:00 H11

Photo-induced charge-transfer renormalization in NiO — •T. Lojewski[1], D. Golez[2,3], K. Ollefs[1], L. Le Guyader[4], L. Kämmerer[1], N. Rothenbach[1], R. Y. Engel[5], P. S. Miedema[5], M. Beye[5,6], G. S. Chiuzbaian[7], R. Carley[4], R. Gort[4], B. E. Van Kuiken[4], G. Mercurio[4], J. Schlappa[4], A. Yaroslavtsev[4,8], A. Scherz[4], F. Döring[9], C. David[9], H. Wende[1], U. Bovensiepen[1,10], M. Eckstein[11], P. Werner[12], and A. Eschenlohr[1] — [1]Univ. Duisburg-Essen & CENIDE — [2]Jozef Stefan Inst. — [3]Univ. of Ljubljana — [4]European XFEL — [5]DESY — [6]Stockholm Univ. — [7]Sorbonne Univ. — [8]MAX IV Lab. — [9]PSI — [10]Univ. of Tokyo — [11]Univ. of Hamburg — [12]Univ. of Fribourg

For strongly correlated materials, like the charge transfer insulator NiO, the interplay between the interaction-based localization and the itinerant behaviour of electrons is essential in determining the electronic properties. In these materials, resonant photoexcitations result in convoluted dynamics involving dynamical screening induced band shifts, charge redistributions and *d-d* type excitations. By combining fs time-resolved X-ray absorption spectroscopy and dynamical mean-field theory, we disentangle the intertwined dynamics. We find long-lived redshifts of the Ni *L* and O *K* edges (> 10 ps), arising from a combination of Hartree shifts and renormalization of local interactions. We also identify a short-lived Ni L_3 pre-edge feature (< 1 ps) related to photo-induced *d-d* transitions [1]. Financial support by DFG through SFB 1242 is acknowledged. - [1] T. Lojewski et al., Phys. Rev. B, in press (ArXiv:2305.10145)

O 67.6 Wed 16:15 H11

Non-equilibrium carrier dynamics and band structure of graphene on 2D silicon — •Maria-Elisabeth Federl[1], Theresa Glaser[1], Niclas Tilgner[2], Thomas Seyller[2], and Isabella Gierz[1] — [1]University of Regensburg — [2]Technical University Chemnitz

Confinement heteroepitaxy, where novel 2D structures are stabilized at the interface between epitaxial graphene and SiC substrate, provides a pathway to engineer proximity-coupling between the massless carriers in graphene and the carriers in the underlying layer. If the latter is a Mott insulator, exotic electronic properties might emerge due to hybridization between itinerant and localized electrons. The Si-rich (3x3) structure on the surface of SiC(0001) was proposed to be Mott insulating with a bandgap of 1eV [1]. We used confinement heteroepitaxy to prepare a graphene monolayer on top of this putative 2D Mott insulator [2] and searched for indications of interlayer hybridization using time- and angle-resolved photoemission spectroscopy (trARPES). Our findings are consistent with the occurrence of ultrafast charge transfer between graphene and the Si-rich surface structure that we attribute to interlayer hybridization in agreement with predictions from density functional theory [2].

O 67.7 Wed 16:30 H11

Direct view on ultrafast charge transfer between C60 molecules and graphene — •Michael Herb, Maria-Elisabeth Federl, and Isabella Gierz — University of Regensburg

Interfacing 0D molecules with 2D materials holds great potential for various applications in materials science, electronics, and nanotechnology. For example, C60/graphene hybrids have been proposed to serve as supercapacitors or sensitive UV-visible photodetectors. We use time- and angle-resolved photoemission spectroscopy (trARPES) to investigate the interfacial non-equilibrium charge carrier dynamics of a sub-monolayer C60 film deposited on single-layer graphene. Upon excitation below the HOMO-LUMO gap of C60, we observe a shift of the graphene Dirac cone towards higher binding energies and a concurrent shift of the C60 molecular levels towards lower binding energies. These shifts indicate a photoinduced hole doping of graphene that persists for several picoseconds. Based on these findings we propose a possible microscopic pathway for ultrafast charge transfer across the C60-graphene interface.

O 67.8 Wed 16:45 H11

Light-induced hidden state studied by ultrafast angle-resolved photoemission spectroscopy — •Junde Liu[1], Pei Liu[3], Liu Yang[3], Sung-Hoon Lee[4], Mojun Pan[2], Famin Chen[2], Jierui Huang[2], Bei Jiang[2], Mingzhe Hu[2], Yuchong Zhang[2], Zhaoyang Xie[3], Gang Wang[3], Mengxue Guan[3], Wei Jiang[3], Huaixin Yang[2], Jianqi Li[2], Chenxia Yun[2], Zhiwei Wang[3], Sheng Meng[2], Yugui Yao[3], Tian Qian[2], and Xun Shi[3] — [1]University of Göttingen, I. Physikalisches Institut, Germany — [2]Institute of Physics, Chinese Academy of Sciences, Beijing, China — [3]Beijing Institute of Technology, Beijing, China — [4]Kyung Hee University, Yongin, Republic of Korea

The non-volatile and ultrafast optical manipulation of material properties offers profound insights into light-matter interactions and holds great potential for optoelectronic applications. However, the discovery of such transitions is often serendipitous, and their practical implementation remains limited, underscoring the need for systematic investigation. In this talk, I will focus on laser-induced nonvolatile phase transitions in transition metal dichalcogenides (TMDs), highlighting the critical role of interlayer order in the formation of hidden states. By employing ultrafast laser excitations (single-pulse writing, pulse-train erasing and pulse-pair control), systematic angle-resolved photoemission spectroscopy (ARPES) characterizations, and comparative density functional theory (DFT) calculations, I aim to unravel the mechanisms that form and stabilize these hidden states, paving the way for novel methods to optically control low-dimensional materials.

O 67.9 Wed 17:00 H11

A machine-learning approach to understanding ultrafast carrier dynamics in the 3D Brillouin zone of $PtBi_2$ — Paulina Majchrzak[1], Charlotte Sanders[2], Yu Zhang[2], Andrii Kuibarov[3], Oleksandr Suvorov[3], Tami Meyer[1], Gesa Siemann[1], Emma Springate[2], Iryna Kovalchuk[3,4], Saicharan Aswartham[3], Grigory Shipunov[3], Bernd Büchner[3], Sergey Borisenko[3], and •Philip Hofmann[1] — [1]Department of Physics and Astronomy, Aarhus University, DK — [2]Central Laser Facility, Harwell, UK — [3]IFW Dresden, Germany — [4]Kyiv Academic University, UA

We examine the electron dynamics of the type-I Weyl semimetal $PtBi_2$ by time- and angle-resolved photoemission spectroscopy. By varying the probe photon energy over a wide range, we are able to explore differences throughout the three-

dimensional Brillouin zone. For these experiments, the photoemission intensity is measured as a function of emission angle, electron kinetic energy, time delay and probe photon energy. In order to discover trends in this multi-dimensional data set, we apply k-means, an unsupervised machine learning technique. This reveals k_z-dependent differences in dynamics–in particular, we observe dynamics that are faster in the parts of the Brillouin zone that host most of the bulk Fermi surface than in parts close to the Weyl points.

O 67.10 Wed 17:15 H11

Tracing thermal and athermal electrons in laser-excited metals — •Markus Uehlein[1], Henry Snowden[2], Christopher Seibel[1], Tobias Held[1], Sebastian T Weber[1], Reinhard J Maurer[2,3], and Baerbel Rethfeld[1] — [1]Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern-Landau, Germany — [2]Department of Chemistry, University of Warwick, United Kingdom — [3]Department of Physics, University of Warwick, United Kingdom

Understanding the energy- and time-resolved electronic properties in metals at the initial athermal stage after femtosecond laser irradiation is of fundamental importance for many applications in surface science. In the time domain, where no electron temperature is defined, the non-equilibrium dynamics are usually described with microscopic methods, such as the Boltzmann equation. However, especially when investigating ballistic transport processes, a description with full Boltzmann collision integrals [1] is challenging due to the numerical effort.

We present a model that describes the athermal carriers efficiently. To that end, we consider thermal and athermal electrons separately. We use a temperature-based approach for the thermal electrons and the phonons, while we trace the distribution of the athermal electrons explicitly. Such a separation allows to conserve particles and energy even when a relaxation time approach is applied. We show the energy-resolved dynamics and find good agreement with time-resolved two-photon photoemission spectroscopy measurements [2].

O 67.11 Wed 17:30 H11

Influence of carbon buffer layer on non-equilibrium carrier dynamics of epitaxial graphene on SiC(0001) — •Johannes Gradl[1], Leornard Weigl[1], Neeraj Mishra[2,3], Stiven Forti[2], Camilla Coletti[2,3], and Isabella Gierz[1] — [1]University of Regensburg, Germany — [2]Istituto Italiano di Tecnologia, Pisa, Italy — [3]Istituto Italiano di Tecnologia, Genova, Italy

The carbon buffer layer resting at the interface between epitaxial graphene and SiC(0001) substrate is believed to be electronically dead with two non-dispersing bands located well below the Fermi level [1]. We use time- and angle-resolved photoemission spectroscopy (trARPES) to show that this picture breaks down away from thermal equilibrium and on ultrafast time scales. We find that photodoping of the graphene - buffer layer heterostructure increases the carrier concentration inside the Dirac cone. Supported by pump fluence and pump wavelength dependent measurements we attribute this transient charging to direct electronic transitions between the buffer layer and the graphene layer and subsequent relaxation of the non-equilibrium charge carrier distribution.

O 68: Focus Session Molecular Nanostructures on Surfaces: On-Surface Synthesis and Single-Molecule Manipulation IV

This focus session aims to discuss recent advances in the on-surface synthesis, manipulation, characterization, and understanding of complex molecular architectures on surfaces. The interest in surface-confined molecular nanostructures emerges from their prospective applications in nanoscale (opto-) electronics, spintronics, solar cells, energy storage devices, and other fields. The bottom-up fabrication of surface-supported nanostructures can be based on molecular self-assembly utilizing non-covalent intermolecular interactions, covalent on-surface synthesis, or the direct manipulation of molecules. Molecular self-assembly usually leads to highly ordered nanostructures, controlled by non-covalent interactions, adsorbate-substrate interactions, as well as thermodynamic and kinetic factors. On-surface synthesis by covalent coupling of reactive precursors adsorbed on metallic, semiconducting, or even insulating surfaces has emerged as a powerful method that has opened new possibilities in exploring new routes towards the synthesis of complex low-dimensional nanostructures with unprecedented material properties, often via novel chemical reactions not available in conventional organic chemistry. Finally, the direct manipulation of molecules with the tip of a scanning probe microscope allows for unprecedented chemical transformations or structural modifications, as envisioned by the pioneers of nanotechnology. This focus session is intended to provide a platform for addressing current trends in these closely linked fields from various perspectives in experiment and theory.

Organized by Sabine Wenzel (University of Marburg) and Christian Wagner (Forschungszentrum Jülich)

Time: Wednesday 15:00–17:45 Location: H24

O 68.1 Wed 15:00 H24

On-surface Synthesis of Aza-Coronoids — •Tim Naumann[1], Zilin Ruan[1], Olaf Kleykamp[1], Alix Kaczmarek[2], Linus Pohl[2], Andreas Achazi[2], Eugen Sharikow[1], Doreen Mollenhauer[2,3,4], Jörg Sundermeyer[1], and J. Michael Gottfried[1] — [1]Philipps-Universität Marburg, Hans-Meerwein-Str. 4, 35032 Marburg, Germany — [2]Justus Liebig Universität Gießen, Heinrich-Buff-Ring 17, 35392 Gießen, Germany — [3]Helmholtz-Institut für Polymere in Energieanwendungen, Lessingstr. 12-14, 07743 Jena, Germany — [4]Institut für Technische Chemie und Umweltchemie, Friedrich Schiller University Jena, Philosophenweg 7a, 07743 Jena, Germany

The properties of nanographenes can be tailored by altering the topology, introducing defect sites like vacancies, or doping with heteroatoms. Coronoids represent a versatile sub-class of the nanographenes and can be regarded as benzenoids featuring a cavity. In-solution synthesis of extended coronoids has shown to be challenging due to their low solubility. To gain access to various aza-coronoids, we combined in-solution and on-surface techniques. By modification of the precursor's substituents, the edge termination of the coronoids is controlled. Besides planar armchair-edge and zigzag-edge terminated coronoids, a curved coronoid was synthesized. Nitrogen functionalization of the cavity allows for hosting a metal atom, giving rise to the formation of coronoid-metal complexes. The electronic and geometric properties of the nanostructures were investigated by low temperature scanning tunneling microscopy/spectroscopy (STM/STS) and non-contact atomic force microscopy (nc-AFM) and supported by DFT calculations.

O 68.2 Wed 15:15 H24

Sequential on-surface synthesis of planar and curved fused anthracenyl-porphyrins — •Miloš Baljozović[1], Joffrey Pijeat[2], Stéphane Campidelli[2], and Karl-Heinz Ernst[1,3,4] — [1]Empa, Dübendorf, Switzerland — [2]Université Paris-Saclay, CEA, Gif-sur-Yvette, France — [3]University of Zürich, Zürich, Switzerland — [4]The Czech Academy of Sciences, Prague, Czech Republic

On-surface synthesis has lately provided means for C-C bond formation that would otherwise hardly be accessible by conventional solution chemistry. Porphyrins are of particular interest in this regard, due to the ability to fine tune their physical and chemical properties via central metal incorporation or peripheral functionalization. Nevertheless, the formation of π-extended porphyrins bearing unsubstituted anthracenyl moieties was so far not achieved.

In this contribution we demonstrate temperature controlled (cyclo)dehydrogenation of bis- and tetra-anthracenyl Zn(II) porphyrins on a Au(111) substrate. Notably, on-surface dehydrogenation is not limited to the first dehydrogenation step involving fusion of anthracenyl units to the macrocycle. Sequential dehydrogenation with temperature elevation is leading to novel planar and curved porphyrin products beyond ones obtained by wet synthesis that could be identified in our combined STM, XPS and ToF-SIMS study.[1]

Support by Swiss National Science Foundation and University of Zürich Research Priority Program LightChEC is gratefully acknowledged.

[1] Baljozović, M. et al. J. Am. Chem. Soc. - just accepted.

O 68.3 Wed 15:30 H24

On-surface synthesis of porphyrin-capped carbon nanocones — Nemanja Kocic[1], Andreas Dörr[1], Moritz Villmow[1], Kevin Dhamo[2], Michael Ruppel[2], Norbert Jux[2], Bernd Meyer[2], and •Sabine Maier[1] — [1]Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — [2]Department of Chemistry and Pharmacy, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany

We demonstrate the surface-assisted transformation of porphyrin-based precursor molecules into bowl-shaped nanographenes through cyclization reactions on an Au(111) surface. The structures are visualized by scanning probe techniques with submolecular resolution, directly revealing intramolecular bonding and compared to density-functional theory calculations. Distinct configurations that suggest bowl-to-dome inversion are identified on the surface. Additionally, we report the accompanying metallation of the macrocycle with Au substrate adatoms. This combination of porphyrin and nanographene with a periphery solely consisting of six-membered all-carbon rings might serve as a seed for growing porphyrin-doped graphene sheets.

O 68.4 Wed 15:45 H24

Relating Radical Delocalization, Charge Transfer and Magnetic Ground State in Open-Shell Molecules — Tao Wang[1], Sergio Salaverria[2], Fernando Aguilar-Galindo[3], Javier Besteiro-Saez[4], Luis M. Mateo[4], Paula Angulo-Portugal[5], Jonathan Rodriguez-Fernandez[6], Dolores Perez[4], Martina Corso[1,5], Diego Peña[4], and •Dimas G. de Oteyza[1,2] — [1]Donostia International Physics Center, San Sebastián, Spain — [2]Nanomaterials and Nanotechnology Research Center (CINN), El Entrego, Spain — [3]Universidad Autónoma de Madrid, Madrid, Spain — [4]CiQUS, Santiago de Compostela, Spain — [5]Centro de Fisica de Materiales, San Sebastián, Spain — [6]University of Oviedo, Oviedo, Spain

At the same time as our capabilities to synthesize open-shell carbon-based materials are rapidly growing with the development of on-surface synthesis under vacuum conditions, the interest in pi-magnetism is rising due to its excellent prospects for potential applications. As a result, increasing efforts are being focused on the detailed understanding of open-shell carbon nanostructures and all the parameters that determine their spin densities and magnetic ground states. Here we present a facile route to synthesize different open-shell acene derivatives with closely related structures. A systematic comparison allows us to draw conclusions on the role of the functional groups, their number and distribution, as well as on the role of the radical state delocalization in relation with the presence or absence of charge transfer at interfaces, which consequently impacts the molecules pi-magnetism.

O 68.5 Wed 16:00 H24

A route toward the on-surface synthesis of organic ferromagnetic quantum spin chains — •Fabian Paschke[1], Ricardo Ortiz[2], Shantanu Mishra[1], Manuel Vilas-Varela[3], Florian Albrecht[1], Diego Peña[3], Manuel Melle-Franco[2], and Leo Gross[1] — [1]IBM Research Europe - Zurich, 8803 Rueschlikon, Switzerland — [2]CICECO - Instituto de Materiais de Aveiro, 3810-193 Aveiro, Portugal — [3]CiQUS and Department of Organic Chemistry, 15782 Santiago de Compostela, Spain

Engineering a sublattice imbalance is an intuitive way to induce high-spin ground states in bipartite polycyclic conjugated hydrocarbons. Such high-spin molecules can be employed as building blocks of quantum spin chains, which are outstanding platforms to study many-body physics and fundamental models in quantum magnetism [1].

In contrast to antiferromagnetism, demonstration of ferromagnetic coupling between polycyclic conjugated hydrocarbons has been scarce. Here, we demonstrate the on-surface synthesis of short ferromagnetic spin chains based on dibenzotriangulene, a polycyclic conjugated hydrocarbon with a triplet ground state. We achieve a direct majority-minority sublattice coupling between adjacent units, which leads to a global sublattice imbalance in the chains and therefore a ferromagnetic ground state with a strong intermolecular ferromagnetic exchange. By means of scanning probe measurements and quantum chemistry calculations, we confirm quintet and septet ground states in dimers and trimers, respectively.

O 68.6 Wed 16:15 H24

Atomically Precise Control of Topological State Hybridization in Conjugated Polymers — Alejandro Jiménez-Martín[1,2], Zdenka Sosnová[2], Diego Soler[2], Benjamin Mallada[1], Héctor González-Herrero[1], Shayan Edalatmanesh[1,2], Pavel Jelínek[1,2], and •Bruno de la Torre[1,3] — [1]Regional Centre of Advanced Technologies and Materials, Czech Advanced Technology and Research Institute (CATRIN), Palacký University, 78371 Olomouc, Czech Republic — [2]Institute of Physics of the Czech Academy of Sciences, 16200 Prague, Czech Republic — [3]Nanomaterials and Nanotechnology Research Center (CINN), CSIC-UNIOVI-PA, 33940 El Entrego, Spain

Realization of topological quantum states in carbon nanostructures has recently emerged as a promising platform for hosting highly coherent and controllable quantum dot spin qubits. However, their adjustable manipulation remains elusive. Here, we report the atomically accurate control of the hybridization level of topologically protected quantum edge states emerging from topological interfaces in bottom-up-fabricated π-conjugated polymers. Our investigation employed a combination of low-temperature scanning tunneling microscopy and spectroscopy, along with high-resolution atomic force microscopy, to effectively modify the hybridization level of neighboring edge states by the selective dehydrogenation reaction of molecular units in a pentacene-based polymer and demonstrate their reversible character.

O 68.7 Wed 16:30 H24

On-surface encapsulation of azafullerene radicals: towards 2D spin networks — •Marion A. van Midden Mavrič[1], Bastien Anézo[1,2], Gregor Kladnik[3,4], Luca Schio[4], Gregor Bavdek[4,5], Yuri Tanuma[1,6], Ruben Canton-Vitoria[7], Ioanna K. Sideri[7], Nikos Tagmatarchis[7], Jannis Volkmann[8,9], Herman A. Wegner[8,9], Andrea Goldoni[10], Chris Ewels[2], Alberto Morgante[4,11], Luca Floreano[4], Erik Zupanič[1], Dean Cvetko[1,3,4], and Denis Arčon[1,3] — [1]Jožef Stefan Institute, Ljubljana, Slovenia — [2]IMN, Nantes University, France — [3]FMF, University of Ljubljana, Slovenia — [4]CNR-IOM, Trieste, Italy — [5]PF, University of Ljubljana, Slovenia — [6]CAREM, Hokkaido University, Sapporo, Japan — [7]T.P.C.I., Athens, Greece — [8]Center for Materials research, Giessen, Germany — [9]Justus Liebig University, Giessen, Germany — [10]Elettra Sincrotrone Trieste S.C.p.A., Italy — [11]Phys. dept., University of Trieste, Italy

While organic radicals on surfaces are a promising platform for realizing and controlling qubits, they are usually highly reactive. Here we present on-surface encapsulation of azafullerene $C_{59}N^{\bullet}$ into [10]cycloparaphenylene ([10]CPP) nanohoops on Au(111) as an efficient strategy to form supramolecular complexes with long-term spin protection. By vacuum depositing $C_{59}N^{\bullet}$ on a pre-deposited template layer of [10]CPP, extended networks of spin 1/2 radicals in a hexagonal lattice are formed. We find compelling evidence for electronic coupling between both molecular species, show that [10]CPP protects $C_{59}N^{\bullet}$ against dimerization and inhibits coupling to the Au(111) substrate.

O 68.8 Wed 16:45 H24

Remote debromination on ultrathin insulating film — •Tzu-Chao Hung[1], Lucía Gómez-Rodrigo[2], Lennart Moritz[1], Manuel Vilas-Varela[2], Leo Gross[3], Diego Peña[2], and Jascha Repp[1] — [1]Institute of Experimental and Applied Physics, University of Regensburg, Germany — [2]Centro Singular de Investigación en Química Biolóxica e Materiais Moleculares (CiQUS) and Departamento de Química Orgánica, Universidade de Santiago de Compostela, Spain — [3]IBM Research Europe, Zurich, Switzerland

Open-shell carbon-based structures are widely studied in recent years not only owing to their potential applications in spintronics and as quantum devices, but they can also serve as a platform to investigate electron-correlation phenomena. One way to study open-shell molecules despite their large reactivity, is to create them from a suitable precursor in a scanning probe microscope (SPM) under ultra-high-vacuum and low-temperature conditions. Here, we demonstrate a particularly efficient debromination reaction resulting in an open-shell molecule by means of SPM manipulation on ultrathin NaCl film on Cu(111). The debromination even works remotely with the tip being up to ~10 nm away from the molecule for both voltage polarities. Based on our observation, possible reaction mechanisms will be discussed.

Invited Talk O 68.9 Wed 17:00 H24

On-Surface Synthesis of Porphyrins and BN-Substituted Carbon Scaffolds — •Willi Auwärter — Technical University of Munich, Garching, Germany

On-surface synthesis protocols provide elegant routes to individual molecular complexes, oligomers, and other carbon-based nanomaterials on metal supports [1]. The resulting structural, physical, and chemical properties can be controlled by heteroatom-substitution. The talk will report on our activities employing thermally induced reactions on coinage metal surfaces, affording heteroatom-doped porphyrins and BN-substituted carbon scaffolds. Specifically, a route to peripherally O-doped porphyrins is addressed [2]. Furthermore, we will discuss the use of functionalized borazine precursors yielding covalent carbon networks with $(BN)_3$ motifs. These include random sheet-like BNC structures [3], which can be transferred to Si waver dices, and covalent organic frameworks (COFs) on Ag(111) and Au(111). The comprehensive characterization by scanning probe microscopy, complemented by theoretical modelling, reveals that COFs with distinct $(BN)_3$ densities, pore sizes, and electronic structures can be achieved. The findings open pathways to new O- and BN-substituted carbon-based nanoarchitectures on surfaces. [1] Grill, L.; Hecht S. Nat. Chem. 12, 115 (2020). [2] Deyerling, J. et al. Angew. Chem. Int. Ed., e202412978 (2024). [3] Tömekce et al., Chem. Eur. J., e202402492 (2024).

O 68.10 Wed 17:30 H24

An electrically controlled molecular spin switch — •Kwan Ho Au-Yeung[1], Wantong Huang[1], Paul Greule[1], Máté Stark[1], Christoph Sürgers[1], Wolfgang Wernsdorfer[1], Roberto Robles[2], Nicolas Lorente[2,3], and Philip Willke[1] — [1]Physikalisches Institut, Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]Centro de Física de Materiales CFM/MPC (CSIC-UPV/EHU), 20018 Donostia-San Sebastián, Spain — [3]Donostia International Physics Center, 20018 Donostia-San Sebastián, Spain

Precise control of spin states and spin-spin interactions in atomic-scale molecular complexes is key to developing multi-spin systems on surfaces for instance for applications in quantum technologies. This has been realized in a variety of systems, for instance in spin-crossover molecules. In this study, we explore the spin coupling and tunability of molecular dimer complexes on an insulating magnesium oxide film: When brought close to a single Fe adatom, a FePc molecule interacts with the Fe forming an interacting spin system. The calculated adsorption geometries by density functional theory (DFT) shed light on the two adsorption configurations of the two bistable states. The two states of the Fe-FePc complex can be successfully and reversibly switched using STM voltage pulses. Subsequently, by using scanning tunneling spectroscopy, we show that this is accompanied by an alteration of the total spin state and spin coupling in the complex. We further illustrate how the complex can be used to shift the resonance frequency of a nearby FePc in single spin resonance experiments, which demonstrates that this complex can function as a magnetic spin switch.

O 69: Nanostructures at Surfaces II

Time: Wednesday 15:00–17:30 Location: H25

O 69.1 Wed 15:00 H25

Thermally-activated molecular rotors organised by porous networks on Au(111) — •Vishakya Jayalatharachchi[1], Roberto Robles[2], Milan Kivala[3], Nicolás Lorente[2,4], Meike Stöhr[1,5], and Sabine Maier[1] — [1]Department of Physics, Friedrich- Alexander-Universität Erlangen-Nürnberg, Germany — [2]Centro de Física de Materiales CFM/MPC (CSIC-UPV/EHU), Donostia-San Sebastián, Spain — [3]Institute of Organic Chemistry, University of Heidelberg, Germany — [4]Donostia International Physics Center (DIPC), San Sebastián, Spain — [5]University of Applied Sciences of the Grisons, Switzerland

Gaining insights into the precise control of molecular rotation on surfaces is crucial for making progress in nanoscale device innovation. In this study, we investigate the thermally triggered rotational motion of bromine-functionalized decacyclene (Br-DC) molecules, which are confined within a host-guest network of 4,4',4"-nitrilotribenzoic acid (H3NTB) on Au(111). With scanning tunneling microscopy (STM) experiments at variable temperatures, we could determine both the onset of molecular rotation (around 110 K) and the barrier for rotation. Importantly, the Br-DC molecules do not possess a predefined intrinsic rotation axis. Instead, the rotational motion is facilitated by the attractive interactions between the Br-DC guests and the H3NTB host network. Computational simulations support our findings and provide further insights into the energetics. Our strategy provides greater flexibility and versatility compared to traditional confinement approaches based on precise size matching of rotor and host networks.

O 69.2 Wed 15:15 H25

Examination and Modification of Self-organized Nanostructures in the Ternary System Au/Co/Ge(001): Chain Growth and the Observation of a Zero-Bias Anomaly — •Nico Kubetschek, Till-Jakob Stehling, Ulrike Kürpick, Marcel Schlesag, Johann Tonhäuser, and René Matzdorf — Institute of Physics, University of Kassel, Heinrich-Plett-Str. 40, Kassel D-34132, Germany

The twofold symmetric reconstruction of the Ge(001) surface provides a template for the self-organized formation of various transition metal nanostructures [1]. We employed scanning tunnelling microscopy (STM) and spectroscopy (STS) at 77 K and 5 K to examine the nucleation, chain growth, and subsequent modification of hexagonal cobalt nanostructures embedded in Ge(001) [2] through the introduction of gold-induced defects [3]. Moreover, the introduction of additional amounts of Au resulted in the formation of previously unobserved nanorods [4]. The electronic properties of these rods were examined by STS, which revealed a zero-bias anomaly (ZBA) in the tunneling spectra. The formation of nanorods with high aspect ratios was subjected to a systematic statistical investigation.

[1] J. Schäfer et al. 2009, New J. Phys. 11 125011, [2] H. J.W. Zandvliet et al. 2011, Surface Science 605,1129, [3] J. Tonhäuser et al. 2022 Phys. Rev. B 106, 115404, [4] M. Schlesag et al. 2024 Phys. Rev. B 110, 195412

O 69.3 Wed 15:30 H25

Electrical Modulation of a Plasmonic Single Particle Resonance — Luka Zurak[1], Christian Wolff[2], Jessica Meier[1], René Kullock[1], •Asger Mortensen[2], Bert Hecht[1], and Thorsten Feichtner[1] — [1]Nano-Optics and Biophotonics Group, Experimentelle Physik 5, Universität Würzburg, 97074 Würzburg, Germany — [2]POLIMA Center for Polariton-driven Light-Matter Interactions, University of Southern Denmark, DK-5230 Odense M, Denmark

Acitive modulation of plasmonic resonances is a promising route towards optical switches smaller way that than the diffraction limit. However, due to the difficulties to directly electrically connect a single resonator most experiments in this direction have been performed on large scales and/or in electrochemical environments – hampering interpretation and application.

Here, we demonstrate fast modulation of the plasmonic resonance of a single electrically connected gold nano-rod [1]. We employ a lock-in amplifier to measure the relative change of scattering signal $\Delta S/S_0$ in the spectral range from 500 to 900 nm, while driving our structure with up to 50 kHz in frequency and up to 40 V in voltage amplitude. Results are of the expected order of magnitude according to existing theories. We discuss some of the theories in detail, like classical surface currents or the introduction of Feibelman parameters to account for non-classical electron spill-out at metal surfaces.

[1] Zurak, L., et al. (2024). Modulation of surface response in a single plasmonic nanoresonator. Science Advances, 10(36), eadn5227.

O 69.4 Wed 15:45 H25

On-surface induced fitting and mobility of conformationally flexible molecules inside nanometer-sized quantum confinements — Aisha Ahsan[1,2], •Aaron Oechsle[2,1], Luiza Buimaga-Iarinca[3], Lutz H. Gade[4], and Thomas A. Jung[2,1] — [1]Department of Physics, University of Basel, 4056 Basel, Switzerland — [2]Laboratory for Micro and Nanotechnology, Paul Scherrer Institute, 5232 Villigen, Switzerland — [3]CETATEA, National Institute for Research and Development of Isotopic and Molecular Technologies, 400293 Cluj-Napoca, Romania — [4]Institute of Inorganic Chemistry, University of Heidelberg, 69120 Heidelberg, Germany

Host-guest architectures provide ideal systems to investigate site-specific physical and chemical effects. Condensation events in nanometer sized confinements are particularly interesting for the investigation of inter-molecular and molecule-surface interactions. They may be accompanied by conformational adjustments representing induced-fit packing patterns. Here, we report that the symmetry of small clusters of cycloalkane molecules, formed by condensation, their registry with the substrate, their structure as well as their adsorption height is characteristically modified by their packing in confinements. While cyclopentane and cycloheptane display cooperativity upon filling of the hosting pores, cyclooctane and to a lesser degree cyclohexane diffusively re-distribute to more favored adsorption sites. The site-specific modification of the interaction and behavior of adsorbates in confinements plays a crucial role in many applications of porous materials, e.g., as gas storage agents or catalysts and biocatalysts.

O 69.5 Wed 16:00 H25

Areas of lower local contact potential difference in the wetting layer in the system Pb/Si(111)-(7x7) — •Paul Philip Schmidt[1], Felix Hartmann[1], Ralf Metzler[1,2], Janet Anders[1,3], and Schmidt Hoffmann-Vogel[1] — [1]University of Potsdam, Institute of Physics and Astronomy, Germany — [2]Asia Pacific Center for Theoretical Physics, Pohang 37673, Republic of Korea — [3]Department of Physics and Astronomy, University of Exeter, Stocker Road, Exeter EX4 4QL, UK

The description of the diffusion of Pb atoms on Si(111)-(7x7) is highly nontrivial. Previous studies show that although Pb grows in the Stranski-Krastanov mode, it exhibits explosive island growth and ultrafast mass transport [1,2]. The developing wetting layer plays a special role [3]. We have investigated this system using non-contact scanning force microscopy and Kelvin probe force microscopy. We have worked under ultrahigh vaccum conditions at variable temperatures between 120K and 300K. Our studies show inhomogeneities of the work function in the wetting layer. The areas with different work function seem to be related to the position of the islands and the step edges of the Si(111). We assume that the different work function values are caused by different Pb concentrations in the wetting layer, which are probably related to the preferred direction of growth of the islands, so that in certain areas Pb is extracted from the wetting layer with varying effectiveness. [1] M. Hupalo et. al. Phys. Rev. B, 23 (2007), [2] K. L. Man et al. Phys. Rev. Lett., 101 (2008), [3] M. T. Hershberger et al. Phys. Rev. Lett. 113 (2014)

O 69.6 Wed 16:15 H25

Pyridyl-functionalized tripod molecules on Au(111): Inter-play between hydrogen bonding and metal coordination — •Sajjan Mohammad[1], Neeta Bisht[2], Anjana Kannan[1], Anne Brandmeier[2], Christian Neiss[2], Andreas Görling[2], Meike Stöhr[1,3], and Sabine Maier[1] — [1]Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — [2]Department of Chemistry and Pharmacy, Chair of Theoretical Chemistry, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — [3]University of Applied Sciences of the Grisons, Switzerland

Two-dimensional metal-organic coordination networks (MOCNs) offer rich opportunities for fabricating materials with potential applications in catalysis and molecular electronics. We investigated the self-assembly of pyridyl-functionalized triazine (T4PT) on Au(111) using low-temperature scanning tunneling microscopy (STM) complemented by density functional theory (DFT) calculations. T4PT forms a well-ordered, close-packed structure stabilized by hydrogen bonds upon adsorption at 300 K. Upon post-deposition annealing, the assemblies are additionally stabilized by metal-ligand bonding between the pyridyl ligands and native Au adatoms. Further post-deposition annealing to 473 K led to the breaking of the N-Au bonds, with the molecular assemblies transforming into a second close-packed hydrogen-bonded structure. Above 503 K, few covalently linked dimers formed, likely as a result of CH-bond activation. Our findings highlight the challenge of predicting and controlling 2D structure formation for porous MOCNs on metal surfaces due to competing interactions.

O 69.7 Wed 16:30 H25

Active manipulation of interface electronic structures by two-dimensional metal-organic coordination on metallic substrates — •Lu Lyu[1,2], Jonas Gödde[2], Martin Anstett[2], Martin Aeschlimann[2], and Benjamin Stadtmüller[1] — [1]Experimentalphysik II, Institute of Physics, Augsburg University, 86159 Augsburg, Germany — [2]Department of Physics, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany

Designing two-dimensional metal-organic coordination networks (2DMOCNs) on metallic substrates provides a unique approach for engineering interface electronic structures. To achieve this goal, we first investigate a protocol of pyridine-functionalized T4PT molecules with Co coordination (Co-T4PT) adsorbed on Au(111). In this system, the surface state electrons are bound to the Co metal centers, and charge transfer occurs between the Co and the substrate. By substituting the Co center with a Cu atom, the surface state electrons in the Cu-T4PT coordination exhibit weaker binding to the Cu centers and are partially confined within the pores surrounded by the molecular potentials. Additionally, replacing T4PT with cyano-functionalized DCA enhances the coordination between Co and DCA, resulting in altered charge transfer within the Co-DCA plane. Consequently, the orbital states of DCA undergo modifications in both energy and momentum space. Our study demonstrates that the manipulation of coordinated metals and functionalized molecules can actively tailor electronic structures at a 2DMOCN-metal interface.

O 69.8 Wed 16:45 H25

Unveiling hybrid electronic bands in 2D metal-organic frameworks: insights from density functional theory and photoemission spectroscopy — Dominik Brandstetter[1], Simone Mearini[2], Yan Yan Grisan Qiu[2], Daniel Baranowski[2], Andreas Windischbacher[1], Claus Michael Schneider[2,3], Vitaliy Feyer[2,3], and •Peter Puschnig[1] — [1]Institute of Physics, University of Graz, Austria — [2]PGI-6, FZ-Jülich, Germany — [3]Faculty of Physics and CENIDE, University of Duisburg-Essen, Germany

Two-dimensional metal-organic frameworks are atomically thin materials that combine properties of organic molecules with the characteristics of crystalline inorganic solids. The strong bonding between the organic linkers and transition metal centers may result in new electronic states with hybrid organic/inorganic character, from which two-dimensional, dispersing electronic bands emerge. However, until recently no experimental proof for such hybrid bands could be given and the requirements for efficient hybrid band formation remained unknown. Here, we combine density functional theory calculations with experimental angle-resolved photoemission spectroscopy to reveal the nature of the interaction between the transition metal atoms and the organic linker. On the example of the Ni-TCNQ network supported on Ag(100) and by employing photoemission orbital tomography, we observe how the molecular orbitals hybridize with the Ni d-states of appropriate symmetry. Our findings are not only based on electronic structure theory, but are also confirmed by the experimental photoemission fingerprints of the involved molecular orbitals.

O 69.9 Wed 17:00 H25

Atomic size effects in 1D metal-coordination polymers on silver — •Pengfei Zhao[1], Hongxiang Xu[1,3], Joachim Reichert[1], Anthoula C. Papageorgiou[1,2], and Johannes V. Barth[1] — [1]Technical University of Munich, Germany — [2]National and Kapodistrian University of Athens, Greece — [3]Peking University, China

Supramolecular coordination on solid surfaces provides a versatile approach to synthesize one-dimensional metal coordination polymers (1D-CPs), where the atomic size of metals plays a crucial role in determining the final structures and properties. Here, we systematically investigate 1H,1'H-2,2'-bibenzo[d]imidazole (H_2bbim) on silver substrates under ultra-high vacuum. Using scanning probe microscopy, we find that the shape of 1D-CPs can be steered by metal-coordination templating with different metal atom sizes. Specifically, H_2bbim molecules and cobalt atoms on Ag(100) allow the formation of micrometer-sized 1D-CPs with porphyrinoids formed by covalently fused H_2bbim dimers, which is distinct from its counterpart of holmium-coordinated chains of monomers. This suggests that size-tuned metal templating is a good strategy for tailoring the formation of 1D-CPs, demonstrating its potential for next-generation electronic devices.

O 69.10 Wed 17:15 H25

An insight into the thermally activated organometallic-to-covalent transition in novel Graphdiyne Molecular Wires Frameworks — •Alice Cartoceti[1], Simona Achilli[2], Paolo D'Agosta[1], Alessio Orbelli Biroli[3], Guido Fratesi[2], Valeria Russo[1], Andrea Li Bassi[1], and Carlo Spartaco Casari[1] — [1]Department of Energy, Politecnico di Milano, I-20133 Milano, Italy — [2]Department of Physics, Università degli Studi di Milano, I-20133 Milano, Italy — [3]Department of Chemistry, Università di Pavia, I-27100 Pavia, Italy

Graphdiynes (GDYs) are novel carbon allotropes with mixed sp-sp^2 hybridization, characterized by tunable optoelectronic properties. This study investigates the temperature-dependent atomic-scale structure and vibrational properties of 1,4-bBEB-based GDY molecular wires frameworks synthesized via Ullmann coupling on Au(100) and Au(111) surfaces. Scanning Tunnelling Microscopy revealed the transition from ordered frameworks of densely packed and oriented 1D organometallic wires (OMF) at room temperature, to progressively more disordered covalent frameworks (COF) at high temperatures. Density Functional Theory calculations and in situ Raman spectroscopy measurements tracked the OMF-to-COF transition, assigning specific Raman features to both phases. Raman spectroscopy also revealed that surface orientation influences the wires-gold interaction, resulting in a lower temperature for the OMF-to-COF transition on Au(100) than on Au(111).

Nitrogen Doping of Cuprous Oxide Films: A Surface Science Perspective — Mina Soltanmohammadi and •Niklas Nilius — Carl-von-Ossietzky University, Institute of Physics, D-26111 Oldenburg, Germany

Nitrogen doping of Cu_2O films grown on Au(111) and Pt(111) supports was explored by a variety of surface-science techniques, including electron-diffraction, X-ray photoelectron-spectroscopy (XPS), scanning tunneling microscopy and photoluminescence spectroscopy (PL). The films were prepared by Cu vapor deposition and high-pressure oxidation at 50 mbar O_2. Nitrogen was inserted by adding N_2 to the reactive gas or via sputter doping. Only the latter resulted in a clear N1s signal in XPS, compatible with the insertion of N-atoms at O substitutional sites. The N-doping caused an overall degradation of the oxide lattice and suppressed the formation of the $(\sqrt{3} \times \sqrt{3})R30^\circ$ surface reconstruction observed on pristine $Cu_2O(111)$. Moreover, the oxide Fermi level shifted from the valence-band top into the band gap, indicative for a reduced p-type conductivity of the sample upon doping. The N-dopants featured low thermal stability and largely desorbed at 500 K, leaving behind a pronounced 850 nm PL peak due to O vacancy emission. Our findings indicate that the N-atoms initially occupy O substitutional sites but get removed easily at moderate temperature, casting doubts whether N-doping is a suitable pathway to improve the conductance and luminescence behavior of Cu_2O.

Large area writing of In_3SbTe_2 metasurfaces for polarization optics and complex orbital angular momentum beams — •Maike Kreutz[1], Lukas Conrads[1], Andreas Mathwieser[2], Matthias Wuttig[1], Robert Schmitt[2], and Thomas Taubner[1] — [1]I. Institute of Physics (IA), RWTH Aachen — [2]Fraunhofer IPT

Optical metasurfaces enable tailoring light-matter interaction for miniaturized optical elements with customized functionalities.The non-volatile reversible switching of phase-change materials (PCMs) has been applied for tunable optical metasurfaces [1]. The plasmonic PCM In_3SbTe_2 (IST) switches from an amorphous dielectric to a crystalline metallic state. IST has been exploited for the direct laser writing of metallic nanoantennas in a dielectric surrounding [2] and for geometric phase metasurfaces [3] including orbital angular momentum (OAM) beams with single singularities. Here, we investigate optical metasurfaces fabricated with the Nanoscribe Photonic Professional GT to shape OAM beams with multiple singularities. We show preliminary results regarding the optical programming of these OAM beams for possible applications in optical communications [4]. Additionally, metasurface polarization optics are explored, enabling plasmonic quarter-wave plates with large bandwidths in the infrared range. This work paves the way towards creating tailored reconfigurable metaoptics for the infrared without cumbersome fabrication techniques. [1] Wuttig et al., Nat. Photon. 11, 465 (2017), [2] Heßler et al., Nat. Commun. 12, 924 (2021), [3] Conrads et al. arXiv:2408.05044 (2024), [4] Shen, Y. et al. Light. Sci. Appl. 8, 90 (2019)

Investigation of the plasmonic phase-change material In_3SbTe_2 in the near-infrared range — •Hristiyana Kyoseva, Lukas Conrads, Rebecca Rahmel, Gero von Plessen, and Thomas Taubner — I. Institute of Physics (IA), RWTH Aachen University

Phase-change materials (PCMs) provide a suitable platform for active nanophotonics and reconfigurable metasurfaces by enabling reversible switching between two phases with contrasting optical properties [1]. In_3SbTe_2 (IST) is a novel plasmonic PCM which can be switched between an amorphous (dielectric) and a crystalline phase (metallic in the whole infrared (IR) spectrum) with precise laser pulses [2]. The direct writing of micrometer-sized structures into a thin IST film with resonances in the mid-IR (above 5 μm) has been extensively demonstrated [3]; however, smaller structures have not been explored yet due to their challenging fabrication process. Here, we examine the smallest achievable sizes of structures written in IST by spatially overlapping crystallization and amorphization pulses. We investigate the resonances of sub-micrometer rod antenna arrays as they shift to shorter wavelengths (below 4 μm) with decreasing size. We also aim to identify its lower limit set by the refractive index of the surrounding media. Our work paves the way towards sophisticated antenna structures with resonances at shorter wavelengths, broadening the applications of IST as a versatile platform for active nanophotonics. [1] Wuttig et al. *Nat. Photon.* **11**, 465 (2017) [2] Heßler et al., *Nat. Com.* **12**, 924 (2021) [3] Heßler, Conrads et al., ACS Photon. **9**, 5 (2022).

O 71.3 Wed 18:00 P2

Laser pulse front tilt effects in the observation of SPPs using photoemission electron microscopy — •Hanno Christiansen[1], Tobias Eul[1], and Michael Bauer[2] — [1]Institute of Experimental and Applied Physics, Kiel University, 24098 Kiel, Germany — [2]Kiel Nano, Surface and Interface Science KiNSIS, Kiel University, 24118 Kiel, Germany

In recent years, PEEM has become an established technique for the investigation of surface plasmon polaritons (SPP). This technique allows, for example, the study of the propagation dynamics of these collective surface excitations with femtosecond resolution or the measurement of their dispersion relations with high spatial resolution. The characteristic signal measured in PEEM results from the coherent superposition of the exciting laser field and the emitted SPP. Based on simulations and experimental data we show in this contribution that the plasmonic PEEM signal is very sensitive to the pulse front tilt of the exciting laser pulse and thus represents a sensor for this often overlooked laser parameter.

Surface plasmon polariton neuronal cell — •Emily Kruel[1], Christopher Weiss[1], Tobias Eul[2], Mario Pfeiffer[1], Benjamin Stadtmüller[3], and Martin Aeschlimann[1] — [1]Department of Physics and Research Center OPTIMAS, University of Kaiserslautern- Landau, Germany — [2]Institute of Experimental and Applied Physics, University of Kiel, Germany — [3]Institute of Physics, University of Augsburg, Germany

Today, the classical electronic computer architecture is one of the limiting factors for fast and energy-efficient data processing. This has triggered the search for alternative hardware architectures to overcome these limitations. For instance, neuromorphic photonics has emerged as a novel research field for new classes of information processing devices that incorporate photonically integrated neural networks [1].

The hybrid nature of surface plasmon polaritons (SPPs) offers a concept for integrating neuromorphic photonics by combining photonic advantages such as high bandwidth and speed with strong electronic interactions. Here, we present an experimental approach to constructing essential components of an artificial neuron based on SPP interactions. We optimized the dimensions of individual components through a combination of finite-difference time-domain (FDTD) simulations and iterative experimental adjustments. The resulting plasmonic responses are imaged using a photoemission electron microscope (PEEM).

O 71.5 Wed 18:00 P2

Investigating Gel Electrolyte Compositions for Enhanced Switching Speed in PEDOT:PSS Electrochromic Devices and Switchable Metasurfaces — •Hoorieh Fallah[1], Dominik Ludescher[1], Jonas Herbig[1], Mario Hentschel[1], Andy Steinmann[1], Klaus Dirnberger[2], Junqi Lu[2], Semi Kim[2], Aldilene Santos Franca[2], Sabine Ludwigs[2], and Harald Giessen[1] — [1]4th Physics Institute and Research Center SCoPE, University of Stuttgart — [2]Institute of Polymer Chemistry, University of Stuttgart

Switchable metasurfaces using the conductive polymer PEDOT:PSS have gained substantial interest over the last years. PEDOT:PSS can be switched from metallic to dielectric state for wavelengths > 1.3 μm using electrochemistry, with CMOS compatible voltages between -1V to +1V. Here, we report on the preparation and characterization of gel electrolytes for PEDOT switching with varying ratios based on polyethylene oxide (PEO), polyvinyl alcohol polymers (PVA), acetonitrile, and lithium perchlorate ($LiClO_4$). Our gel electrolytes are integrated with PEDOT:PSS, coated onto ITO substrates to evaluate their performance in electrochromic switching applications. By applying alternating voltage and laser light, we analyze the dynamic switching speed of the PEDOT layer as it transitions from a conductive to an insulating state. Our approach explores how PEO- and PVA-based electrolytes impact high-frequency, low-voltage switching in PEDOT:PSS systems. We have achieved switching rates up to 100 Hz. The results aim to enhance our understanding of the influence of the electrolyte composition on switching behavior.

Time: Wednesday 18:00–20:00 Location: P2

O 72.1 Wed 18:00 P2

Implementation of a fiber-based cathodoluminescence detector system for a scanning electron microscope — •Filip Majstorovic[1], Paul H. Bittorf[1], and Nahid Talebi[1,2] — [1]Institute for Experimental and Applied Physics, Kiel University, Leibnizstraße 19, D-24118 Kiel, Germany — [2]Kiel Nano, Surface and Interface Science KiNSIS, Kiel University, Christian-Albrechts-Platz 4, D-24118 Kiel, Germany

Cathodoluminescence (CL) is the light emitted from materials irradiated with the electron beam, within the infrared to ultraviolet spectral range. CL recently has gained a major interest in analyzing quantum materials and emitters, thanks to its high spatial and temporal resolutions. In our study, inside a scanning electron microscope (SEM) high energy and broad bandwidth electron beams are generated. The CL emission is then collected with a detector, consisting of a multimode fiber attached to piezo stages, which allows for nanometer precision movement of the fiber near the sample. We present the variety of possible measurements such a system allows. One component of this is obtaining the spectrum of the emitted light, that for example enables the investigation of plasmonic resonances. Further this detector system provides a way to measure the emission profile by scanning the fiber three-dimensionally along the sample. Such emission profiles give information about the processes responsible for this radiation and show if coherent or incoherent CL are more dominant. Moreover, higher-order correlations unravel a superbunching effect in CL generated from semiconducting samples.

O 72.2 Wed 18:00 P2

Comprehensive Probing of Electron and Phonon Systems by Raman Scattering — •Jan Kutschera[1], Marc Herzog[1], Wouter Koopman[1], Felix Stete[1], and Matias Bargheer[1,2] — [1]Institut für Physik & Astronomie, Universität Potsdam, Potsdam, Deutschland — [2]Helmholtz Zentrum Berlin, Berlin, Deutschland

Inelastic processes in light-matter interactions are crucial for understanding energy transport within solid-state materials, where energy is distributed between electron and phonon systems. Investigating these interactions provides deeper insights into fundamental processes relevant to plasmonics, optoelectronics, and optoacoustics. However, knowledge about the energy transfer dynamics within each system is also essential for a complete picture. By extending Raman spectroscopy to ultrashort timescales, we aim at analyzing the transient population dynamics of phonon modes and the interplay of different electronic bands to ultimately establish ultrafast Raman Spectroscopy which directly probes electron-electron, electron-phonon, and phonon-phonon interactions. Here, we present an intraband emission of the conduction band electrons in gold nanoparticles, which is excited by interband absorption and appears as a continuous background in static Raman experiments. Pump-probe experiments can help further examine the origin of this emission and the interaction of different electronic subsystems. Moreover, we investigate the phonon modes of HfN and other materials as potential candidates for the catalysis of light-driven reactions.

O 72.3 Wed 18:00 P2

Adiabatic focusing of propagating Surface plasmon polaritons at gold nanotriangles — •Gregor Stockmann, Felix Stete, and Matias Bargheer — Institut für Physik und Astronomie, Universität Potsdam, Deutschland

Surface plasmon polaritons (SPPs) are the collective oscillations of surface-near charges at a dielectric-metallic interface. Due to the Coulomb force, these oscillations can propagate along the surface. This effect can be utilized to spatially separate the laser excitation and a chemical reaction site. In this work, we use gold nano-triangles, to focus SPPs from a μm-sized excitation spot to the tip at the nanometer scale. We investigate the influence of different parameters on the propagation behavior of SPPs. Key parameters are the particle dimensions, excitation wavelength and the light polarisation.

O 72.4 Wed 18:00 P2

Plasmon assisted catalysis of Ferricyanide by Gold-Nanoparticles with different sizes and light intensities. — •Kyra Peikert, Wouter Koopman, and Matias Bargheer — Institut für Astronomie und Physik Universität Potsdam, Potsdam, Deutschland

In recent years plasmonic catalysis emerged as promising new field in photocatalysis. However, to improve its efficiency, a better understanding of its governing principles is required. In this study we investigate the reaction kinetics of the light driven reduction of ferricyanide catalyzed by gold nanoparticles of different sizes. To refill the holes generated by electron transfer to ferricyanide the hole scavenger Ethanol (EtOH) is added to the solution. We compare this situation to reactions in a purely aqueous solution. The kinetics under different light intensities including dark conditions help to understand the mechanisms. The results show indications of a charging effect of the particles due to the presence of the hole scavenger, which speeds up the reaction rate.

O 72.5 Wed 18:00 P2

Single particle sample with gold nanorods for micro-spectroscopy — •Alexandra Faber — Institut für Physik und Astronomie, Universität Potsdam, Deutschland

Nobel metal nanostructures show great potential for photocatalytical applications due to their broadband plasmonic absorption across the visible spectrum. Chemical reactions taking place at surfaces can be accelerated by several effects, including charge transfer and local heating. As one important factor, the accumulation of charges on the particle during a reaction process, is expected to have a large influence on the charge transfer process. In order to better understand the effects of photocharging of gold nanorods (GNR), possible electron transfer between individual GNRs and the substrate, single nanoparticles are studied by optical micro-spectroscopy. The samples are investigated by dark-field as well as scanning electron microscopy and must therefore fulfill different requirements. This includes that the sample must provide the necessary criteria such as conductivity and light transmission in order to be observed with both microscopy methods. At the same time, it should be possible to rediscover individual GNRs and the distance between the particles has to be large enough to allow spectroscopy of individual GNRs. We show the development and improvement of the sample preparation procedure as well as first recorded dark-field scattering spectra and fluorescence spectra of single GNRs.

O 72.6 Wed 18:00 P2

Size effects on the plasmon resonance in silver cluster anions studied by energy-resolved photoemission — •Norman Iwe[1], Klara Raspe[1], Franklin Martinez[1], Lutz Schweikhard[2], Karl-Heinz Meiwes-Broer[1,3], and Josef Tiggesbäumker[1,3] — [1]Institute of Physics, University of Rostock, Germany — [2]Institute of Physics, University of Greifswald, Germany — [3]Department of Life, Light and Matter, University of Rostock, Germany

Numerous applications ranging from efficient solar cells to cancer treatment profit from the interaction between nanoparticles and light. In the case of metal clusters, one often takes advantage of collective resonances of the valence electrons, which lead to a strong increase of the cross section at a certain wavelength. Previous studies already showed, that the resonance energy can be tuned via size and charge state of the nanoparticles. However, systematic measurements to explore the development of the plasmonic resonance in free metal clusters so far concentrate on small sizes.

We conduct photoelectron spectroscopy on anionic silver clusters Ag_N^- in a size range $N = 7 - 300$. By extracting photodetachment cross sections, we gain insights into the collective resonances. At $N = 55$, we observe a transition from a blueshift to a general redshift of the plasmon energies with decreasing cluster size. However, the resonance energies for sizes below N = 55 are oscillating whereby the maxima are found at known electronic shell closures. On top, a splitting of the resonance is observed at a few smaller cluster sizes, hinting on a deformation of the particle.

O 72.7 Wed 18:00 P2

Anisotropic photoelectron emission from individual Ag nanoparticles on silicon — •Waqas Pervez[1,2], Kevin Oldenburg[1,2], Sylvia Speller[1,2], and Ingo Barke[1,2] — [1]Institute of Physics, University of Rostock, Germany — [2]Department of Life, Light & Matter, University of Rostock, Germany

Laser excitation of localised plasmons in nanoparticles can give rise to a vastly enhanced photoemission yield [1, 2]. Here we study detailed characteristics of the photoelectron emission process of size-selected nanoparticles with diameters around 10 nm, deposited from the gas phase onto silicon. To this end we employ femtosecond laser excitation with wavelengths around 800 nm and 400 nm, respectively, in a photoemission electron microscope (PEEM). The spatially resolved electron yield is investigated as a function of laser wavelength and polarisation. Furthermore, we report on photoelectron emission from individual, supported nanoparticles in reciprocal space. Upon resonant plasmon excitation we observe anisotropic electron yield that depends on the laser polarisation. The observed photon order, ranging from 2PPE to 5PPE, and the underlying excitation and emission mechanisms are discussed in view of the local near field distribution and the effect of the substrate.

O 72.8 Wed 18:00 P2

Near-field Fano spectroscopy of MaPbI3 nanoparticles — Jinxin Zhan[1], Tom Jehle[1], Sven Stephan[1], •Sam Nochowitz[1], Ekaterina Tiguntseva[2], Sergey Makarov[2], Juanmei Duan[1], Petra Gross[1], and Christoph Lienau[1] — [1]Universität Oldenburg, D-26129, Germany — [2]St. Petersburg, Russia

Semiconducting halide perovskite nanoparticles support Mie-type resonances that confine light on the nanoscale in localized modes with well-defined spatial field profiles yet unknown near-field dynamics. We introduce an interferometric scattering-type near-field microscopy technique [1] to probe the local electric field dynamics at the surface of a single MAPbI3 nanoparticle [2]. The amplitude and phase of the coherent light scattering from such modes are probed in a broad spectral range and with high spatial resolution. In the spectral domain, we uncover a Fano resonance with a 2π phase jump. In the near-field dynamics, this Fano resonance gives rise to a destructive interference dip after a few femtoseconds. Mie theory suggests that the interference between electric quadrupole and magnetic dipole modes of the particle, with spectra affected by resonant interband absorption of MAPbI3, lies at the origin of this effect [3]. Our results open up a new approach for probing local near-field dynamics of single nanoparticles.

[1] Zhan, J., et al. Advanced Photonics 2020, 2 (04)
[2] J. Zhan et al., Nano Lett. 2024
[3] Tiguntseva, E. Y., et al. Nano Lett. 2018, 18 (2), 1185-1190.

O 72.9 Wed 18:00 P2

Energy and momentum distribution of surface plasmon-induced hot carriers — •Ellen Brennfleck[1], Christopher Weiss[1], Jannis Lessmeister[1], Tobias Eul[2], Benjamin Stadtmüller[3], and Martin Aeschlimann[1] — [1]Department of Physics and Research Center OPTIMAS, University of Kaiserslautern-Landau, Germany — [2]Institute of Experimental and Applied Physics, University of Kiel, Germany — [3]Institute of Physics, University of Augsburg, Germany

Are the spectroscopic properties of plasmon- and photon-induced carriers fundamentally different? This question is crucial for advancing plasmonic energy conversion. Initial studies have suggested characteristic energy and momentum distributions for the photoemission of both bulk plasmon resonances and surface plasmons. For surface plasmons, however, the separation of plasmon and photon-induced emission patterns by their inherent spatial and dynamics remains challenging [1].

To further characterize the electron emission pattern of surface plasmons, we combine a femtosecond laser system with a spatial light modulator to generate a

vector vortex beam to excite surface plasmon polaritons at an annular structure. Our photoemission electron microscope enables us to compare the spectroscopic properties of photoemitted electrons and those generated by plasmonic emission at the center of the structure, providing valuable insights into the distinct emission mechanisms.

O 72.10 Wed 18:00 P2

Self-organized plasmonic particles configurations in front of mirror — •Aleksei Overchenko and Frank Cichos — Leipzig University, Peter Debye Institute for Soft Matter Physics, Linnéstr. 5, 04103 Leipzig

Plasmonic particles and their field enhancement properties found wide applications in various fields. For example, they are used in Surface-Enhanced Raman Spectroscopy (SERS), plasmon-enhanced fluorescence, Photothermal Therapy and energy conversion. Field enhancement can be achieved by bringing two spheres into close proximity, placing a sphere on a mirror, fabricating bowtie antennas, or designing hybrid structures like particle-dielectric-mirror systems. In most cases, surface functionalization often requires complicated modification methods such as lithography and chemical binding, e.g., of DNA origami which leads to complicated and non-reconfigurable systems. Here, we deliberately manipulate induvial as well as multiple gold particles in front of a gold mirror by local laser-induced temperature fields generating thermo-osmotic flow. Multiple particle trapping is performed by focused laser that can divide in multiple independent beams via AOD. We characterize the resulting single, dimeric and higher order clusters, their plasmonic coupling and the coupling of the particles to a thin gold film by scattering spectroscopy. The distance between the film and particles is around 10 nm due to the second minimum of the DLVO-theory. Enhancement is described by sensing of biomolecules. The system is reconfigurable as no binding is required and analytes may be bound to the film to enable spatially resolved SERS.

O 72.11 Wed 18:00 P2

Optical resonance tuning of micro- and nanoparticles with phase change materials in the near-infrared and visible range — •Rebecca Rahmel, Hristiyana Kyoseva, Jonathan Müller, Lukas Conrads, Thomas Taubner, and Gero von Plessen — I. Institute of Physics (IA), RWTH Aachen University

Micro- and nanoparticles with scattering and absorption resonances promise interesting optical behaviour. These resonances are highly sensitive to the particle size, shape, and configuration, as well as the dielectric properties of both particle and surrounding medium [1]. Phase-change materials (PCMs) show high optical contrast when switched between their amorphous and crystalline phases [2], facilitating antenna resonance tuning based on a change in refractive index [3]. The novel plasmonic PCM In_3SbTe_2 (IST) can be locally optically switched between the dielectric amorphous and the metallic (in the infrared) crystalline phase, enabling a sign change in permittivity [4]. While antenna resonance tuning with PCMs has been studied extensively, locally addressing PCMs below single particles has not been demonstrated yet. Here, we investigate the optical response of single polysterene micro- and gold nanoparticles placed on thin films of IST and other PCMs and locally switch the PCMs to tune the particle resonances. Our work paves the way towards mode selection of nanoparticles beneficial for tuning of emitters and sensing applications.

Analytical Theory of the Optical Inter- and Intraband Response in Noble Metals — •Robert Lemke, Andreas Knorr, and Jonas Grumm — Institut für Theoretische Physik, Nichtlineare Optik und Quantenelektronik, Technische Universität Berlin, Berlin, Germany

The optical response of plasmonic noble metal nanostructures can be attributed to the interplay of electronic intra- and interband processes described by coupled Boltzmann-Bloch equations. In this set of coupled equations, the specific properties of the noble metal are addressed by an anisotropic electronic dispersion relation expanded in the vicinities of the X and L high symmetry points.

In order to address the dephasing of the inter- and intraband polarizations we consider near equilibrium electron-phonon scattering rates in random phase approximation to estimate relaxation timescales. Our approach allows to connect spectroscopic signatures directly to microscopic processes, not possible with simple Drude-Lorentz models.

O 72.13 Wed 18:00 P2

Kinetics of hydrogen molecules on Ag(111) by tip-enhanced Raman spectroscopy — Shuyi Liu[1,2], Jun Yoshinobu[3], Martin Wolf[1], Takashi Kumagai[4], and •Akitoshi Shiotari[1] — [1]Fritz-Haber Institute of the Max-Planck Society, Berlin, Germany — [2]Huazhong University of Science and Technology, Wuhan, China — [3]University of Tokyo, Kashiwa, Japan — [4]Institute for Molecular Science, Okazaki, Japan

Surface diffusion is the first step for adsorbates to undergo characteristic chemical and physical phenomena such as self-assembly, catalytic reactions, and low-dimensional molecular transport. However, the characterization of highly diffusive molecules, such as physisorbed molecules, has been challenging even with scanning tunneling microscopy and its related techniques. In this study, we use tip-enhanced Raman spectroscopy (TERS) to sensitively detect hydrogen molecules physisorbed on Ag(111) at low temperatures around 10 K. Strong Raman peaks were observed only when the diffusive molecule entered the plasmonic tip-sample junction, while the peaks decayed by thermal desorption at higher temperatures. By monitoring the peak intensities and investigating its temperature dependence, we successfully analyzed the kinetics of hydrogen molecules on the surface. This demonstrates that TERS is useful for evaluating the dynamics of diffusive molecules.

Time: Wednesday 18:00–20:00 Location: P2

O 73.1 Wed 18:00 P2

In-situ tritium contamination and decontamination of fusion-relevant materials — •Elizabeth Paine[1], Dominic Batzler[2], James Braun[2], Robin Grössle[2], Philipp Haag[2], Marco Röllig[2], Marie-Christine Schäfer[2], Marius Schaufelberger[2], and Kerstin Trost[2] — [1]Eindhoven University of Technology, The Netherlands — [2]Tritium Laboratory Karlsruhe, Karlsruhe Institute of Technology, Germany

Nuclear fusion could offer a solution to the growing global demand for clean, sustainable and abundant energy. The deuterium-tritium fusion reaction offers a high energy yield and feasibility at achievable temperatures. However, the scarcity and radioactive nature of tritium pose significant challenges for its handling in fusion reactors. Tritium adsorption onto surfaces leads to challenges in licensing, process control and maintenance. Ozone is a known decontaminant and may provide a viable solution for the decontamination of these tritiated surfaces. Due to its strong oxidising nature, ozone reacts with the adsorbed tritium, which can then be evacuated. This study aims to investigate tritium accumulation and decontamination on the fusion-relevant materials: beryllium, EUROFER97 and tungsten. These are selected for their critical roles in reactor components and tritium-processing systems. The findings will provide insights into the behaviour of tritium in these materials and assess the potential of ozone-based decontamination techniques compared to established methods. This contributes to the development of effective strategies for tritium handling, decontamination and inventory management in future fusion reactors.

O 73.2 Wed 18:00 P2

Role of the surface for adsorbate motors — •Bensu Günay Ramovic[1], Grant Simpson[1], Mats Persson[2], and Leonhard Grill[1] — [1]Department of Physical Chemistry, University of Graz, 8010 Graz, Austria — [2]Department of Chemistry, University of Liverpool, Liverpool L69 3BX, United Kingdom

Molecular motors have the ability to perform uni-directional rotation or translation. In addition to such motors in nature, for instance kinesin, artificial molecular motors have seen great developments in the last decades. They have been studied intensely in solutions by averaging methods, but these cannot resolve individual motors. We have studied molecular motors on metal surfaces by scanning tunneling microscopy under ultrahigh vacuum and cryogenic temperatures, allowing us to track the motion of single molecules. Metallic surfaces generally play an important role for physical/chemical processes in molecular adsorbates. Here, we investigate adsorbate motors [1] on different metal surfaces in order to elucidate the role of the substrate for the molecular motion. It turns out that even rather small differences - maintaining the same surface symmetry, but changing the elemental composition - strongly affects the molecular configuration and motion.

O 73.3 Wed 18:00 P2

Poisoning resistance of GaPt SCALMS model systems — •Christoph Wichmann[1,2], Michael Moritz[2], Haiko Wittkämper[2], Tzung-En Hsieh[3], Johannes Frisch[3], Macus Bär[2,3,4], Hans-Peter Steinrück[2], and Christian Papp[1] — [1]FU Berlin, Germany — [2]FAU Erlangen, Germany — [3]Helmholtz-

Zentrum Berlin, Germany — [4]Helmholtz Institute Erlangen-Nürnberg Germany

Supported catalytically active liquid metal solutions (SCALMS) are a novel concept, where low amounts of a catalytically active transition metal is dissolved in another low melting metal, which acts as a matrix. The highly dynamic surface provides an interesting system offering high activity and remarkable stabilities for dehydrogenation reactions. For industrial applications, different challenges have to be met. One of them is the presence of catalytic poisons in the catalytic feed such as sulfur compounds. Therefore, a model system of a macroscopic GaPt droplet with a low Pt content (1 at.%) and nanoscopic GaPt particles were investigated during the exposure to thiophene as catalyst poison using X-ray photoelectron spectroscopy (XPS) under ultra-high vacuum and near-ambient pressure (0.1-0.2 mbar) conditions. The formation of Ga-sulfides at the surface of the catalyst is observed, leading to an accumulation of Pt in / under this layer. For higher temperatures (>650 K), the dissolution of the formed Ga-sulfides into the liquid metallic Ga-matrix is observed. In all cases, no Pt-sulfide was formed, indicating a resistance of the active Pt sites towards sulfur poisoning of SCALMS.

O 73.4 Wed 18:00 P2

An XPS and molecular beam study of olefin adsorption on ultrathin ionic liquid films on Pt(111) — •Laura Ulm, Cynthia C. Fernández, Leonhard Winter, Florian Maier, and Hans-Peter Steinrück — Lehrstuhl für Physikalische Chemie II, Friedrich-Alexander-Universität Erlangen-Nürnberg

Solid catalysts with ionic liquid layer (SCILL) promise improvements for a wide range of applications, e.g. an enhanced selectivity of the 1,3-butadiene hydrogenation to 1-butene by coating a heterogeneous catalyst with thin ionic liquid (IL) films. We studied hydrocarbon adsorption as central step of this reaction by X-ray photoelectron spectroscopy combined with a supersonic molecular beam. Ultrathin films of three different ionic liquids with thicknesses below 1 nm were deposited onto a Pt(111) crystal in UHV by physical vapor deposition and characterized with XPS. These films were exposed to 1,3-butadiene or 1-butene from a supersonic molecular beam at 180 K. The coverage-dependent sticking coefficients of the two olefins were measured using the King-and-Wells method. With increasing IL pre-coverage, the total amounts of adsorbed olefins decreased until further adsorption was completely suppressed by the IL layer. The minimum IL coverage needed for complete suppression of adsorption and the differences between the ionic liquids will be discussed in the context of IL-induced selective 1,3-butadiene hydrogenation.

Supported by the DFG through SFB 1452 (Project ID: 431791331).

O 73.5 Wed 18:00 P2

N heteroatom effects in large aromatic physisorbed adsorbates on metal surfaces: azabenzopyrene on Cu(111) — •Henry Thake[1], Matthew Stoodley[1,2], David A. Duncan[2,3], and Reinhard J. Maurer[1] — [1]University of Warwick, UK — [2]Diamond Light Source, UK — [3]University of Nottingham, UK

Conjugated molecules at metal surfaces are bound by a subtle balance of short- and long-range interactions including charge transfer and dispersion interactions. As such, they represent a challenging opportunity to improve approximations to density functional theory (DFT) where accurate structural and spectroscopic benchmark measurements exist. Accurate structural predictions of the large aromatic molecules naphthalene and pyrene have shown weak adsorption in a flat geometry on Cu(111). Here, we present a combined computational and experimental study of a closely-related molecule featuring a single nitrogen heteroatom - azabenzopyrene on Cu(111). Based on DFT calculations, x-ray standing wave (XSW) structural characterisation, x-ray photoelectron (XPS) and near-edge adsorption fine structure (NEXAFS) spectroscopy simulations, we study the effect of the heteroatom on the adsorption of the conjugated molecule. We develop a structural model consistent with XSW structure determination and simulate XPS and NEXAFS signatures of the sole nitrogen species in the molecule. Nitrogen 1s XPS and K-edge NEXAFS spectra present multiple coexisting chemical environments for the nitrogen species, for which we present a model hypothesis.

O 73.6 Wed 18:00 P2

Surface Charge Modification of Silver Substrates for Enhanced SERS Selectivity — •Georgiana Ion, Stefania Dana Iancu, and Nicolae Leopold — Faculty of Physics, Babes-Bolyai University, 400084, Cluj-Napoca, Romania

Surface-enhanced Raman spectroscopy (SERS) uses the plasmonic properties of metallic nanoparticles for sensitive detection in complex matrices. A key challenge is controlling the detection of specific species. This study developed solid-state SERS substrates with optimized surface properties for selective detection of anionic and cationic analytes.

Citrate-capped silver nanoparticles (cit-AgNPs) were synthesized via the Lee-Meisel method, while hydroxylamine-reduced silver nanoparticles (hya-AgNPs) followed the Leopold-Lendl method. Concentrated nanoparticles were dried into 2 μL droplets on cover glass to create solid substrates. Raman spectra were obtained by immersing the substrates in 2 mL analyte solutions (Nile Blue, Crystal Violet, fumaric acid) using a 532 nm laser.

We found that adding $Ca(NO_3)_2$ only impacts selectivity when added to the colloidal form before drying, making it crucial for developing both substrate types. This optimized cit-AgNPs for anionic detection, while hya-AgNPs, covered with Cl^- ions, selectively detected cationic analytes. Cationic detection can also occur on cit-AgNPs by adding NaCl to the solution. This work highlights how surface modifications enhance SERS substrate selectivity and provide a pathway for tailored systems for specific analyte detection in complex environments.

O 73.7 Wed 18:00 P2

Water adsorption on Bi(111) surfaces calculated from first principles — •Yingjie Xie, Adriana Bocchini, Uwe Gerstmann, and Wolf Gero Schmidt — Universität Paderborn, Paderborn, Deutschland

Bismuth is a semimetal with unique electronic properties, including a strong spin-orbit coupling. Water adsorption on bismuth surfaces is interesting from both a scientific and technological point of view, since the material has numerous electrode applications ranging from analytical chemistry, environmental monitoring, and energy storage to seawater desalination. Surprisingly, relatively little and partially contradiction information is available on the interaction between Bi and water [1,2]. In the present contribution, density-functional theory is used to calculate the adsorption of single water molecules, water clusters and water thin films on Bi(111). We analyze in detail the molecule-molecule and molecule-substrate interaction and provide information on the diffusion characteristics. The calculations are discussed in the context of previous theory and experimental data.

O 73.8 Wed 18:00 P2

Investigation of Na^+ ion solvation on the Cu(111) surface by STM — •Anna Shugai and Karina Morgenstern — Physical Chemistry I, Ruhr-Universität Bochum, Bochum, 44801, Germany

Sodium-ion (Na^+) batteries offer great potential as an energy storage, making them an attractive alternative to the lithium-ion batteries. However, the practical realization is currently restricted due to the instability of the electrode-electrolyte interface. To reveal the reasons for it, we need to understand the underlying mechanisms that govern the process of Na^+ ion on-surface solvation. In this project, we use low-temperature scanning tunneling microscopy (STM) to get the locally resolved structure of D_2O-solvated Na^+ ions that are supported on the Cu(111) surface. First, the small D_2O clusters, containing 10 to 20 molecules, were prepared on the Cu(111) surface. We compare them to the D_2O clusters deposited on the Na^+-pre-covered Cu(111) surface. The results show that there is strong interaction between the Na^+ ion and the D_2O solvent molecules. Accordingly, the solvation behaviour of Na^+ is more similar to that exhibited by the Li^+ ion, than to that of the Cs^+ ion.

O 73.9 Wed 18:00 P2

Adsorption of bifunctional methoxy butene on Si(001): the multiplicity of non-selective adsorption — •Jannick Peters, Sophie Göbel, and Michael Dürr — Institut für Angewandte Physik and Zentrum für Materialforschung, Justus-Liebig-Universität Giessen, Germany

Both, ether group and C=C double bond, adsorb on Si(001) via an intermediate state and with high reactivity. When combining these two functional groups in a bifunctional organic molecule, a variety of different adsorption configurations can be envisioned. However, selective adsorption via the ether group was found for allyl ethers on the Si(001) surface [1]. In the case of methoxy butene (MeBut), the functional groups are separated by an additional CH_2 group when compared to allyl ethers. Despite this seemingly small change in the molecules' structure, major differences in the reactivity on Si(001) were observed. At surface temperatures between 90 and 450 K, no selective reaction but a large variety of different adsorption configurations, which are bound either via ether cleavage, the C=C double bond, or both functional groups, was observed when studying intermediates and final products by means of XPS. Depending on the final configuration, the reactivity of the ether group was found to be either enhanced or reduced, which results in an increased temperature window for the reaction from intermediate to final state.

Steel Mesh-Supported SNW-1/CsPbBr3 Nanocomposite: Photocatalyst for Sustainable Ammonia Production — •Negin Khosroshahi and Vahid Safarifard — Iran University of Science and Technology, Tehran 16846-13114, Iran

The conversion of solar energy into chemical energy through photocatalysis is an important field of interest in green energy generation and environmental improvement. Nevertheless, its effectiveness currently falls short of expectations, primarily due to the issue of charge recombination. To address this challenge, the photocatalytic effect has become an optimistic approach for enhancing processes. In this research, we have developed a Steel Mesh-Supported

SNW-1/CsPbBr3 nanocomposite by combining covalent-organic frameworks with metal halide perovskite. To gauge their effectiveness, the heterostructure was assessed by employing multiple characterization methods including XRD, IR, FESEM, DRS, EDX, VSM, PL, EIS, Zeta, and BET. After the composite's preparation and characterization, we examined its photocatalytic activity in nitrogen reduction. The SNW-1/MHP/Steel mesh nanocomposite exhibited exceptional performance in ammonia generation. These findings suggest that the SNW-1/MHP/Steel mesh nanocomposite holds promise as an environmentally friendly and cost-effective photocatalyst, capable of addressing the challenges of sustainable ammonia production. This study presents a promising method for identifying effective photocatalytic materials using mesh substrates to address environmental concerns.

Time: Wednesday 18:00–20:00 Location: P2

O 74.1 Wed 18:00 P2

Lithium adsorption on Cu(111) for anodeless lithium ion batteries — •Darius Hübner — Universität Ulm, Institut für theoretische Chemie, Oberberghof 7, 89081 Ulm

Anodeless batteries in which the anode is created upon the first charging are of strong current interest as they avoid processing and cost concerns as well as lead to an increased safety. In order to contribute to the understanding of the the viability of copper charge collectors in anodeless Lithium ion batteries, we studied the deposition of lithium on a Cu(111) substrate using periodic density functional theory calculations.

We find that the lattice mismatch between lithium and copper leads to the formation of a fcc lithium structure with fewer atoms per layer than the copper substrate. Additionally, this lithium structure shows remarkably lower surface diffusion barriers compared to a standard bcc lithium surface. As an enhanced surface mobility is supposed to suppress dendrite growth, this suggests a reduced formation of dendrites in the initial steps of the anode formation.

O 74.2 Wed 18:00 P2

Spin-State Switching of Indium-Pthalocyanine on Pb(100) — Niklas Ide, Arnab Banerjee, •Alexander Weismann, and Richard Berndt — Institut für Experimentelle und Angewandte Physik, Kiel, Deutschland

Indium(III) phthalocyanine chloride, deposited on Pb(100), is investigated using a scanning tunnelling microscope at cryogenic temperatures. The chloride ions dissociate, leaving behind indium phthalocyanine (InPc), which is observed in two distinct configurations: the metal ion oriented either towards (↓) or away from (↑) the substrate. The study reveals isolated molecules and islands which exhibit a $\sqrt{65}\times\sqrt{65}$, R ± 30° superstructure, characterized by a unit cell containing four inequivalent molecules, one in the InPc↑ state and three in the InPc↓ state at different sites. Variations in the conductance spectra of the lowest unoccupied molecular orbital are observed, depending on the adsorption sites and azimuthal orientations of the complexes. Notably, only the InPc↑ molecules within the islands exhibit Shiba states, signifying the presence of a localized spin. Electron extraction allows for the conversion of both isolated complexes and molecules in islands from the InPc↑ to InPc↓ state. This transition is accompanied by a change in their spin state, as evidenced by the disappearance of the Shiba states.

O 74.3 Wed 18:00 P2

On-surface fabrication of cesium tin halide nanostructures deviating from the perovskite ABX_3 structure — Madad Abbasli, Dina Wilks, Carsten Busse, and •Robin Ohmann — University of Siegen, Siegen, Germany

We demonstrate that evaporation of the precursor molecules CsBr and $SnBr_2$ onto an atomically clean gold surface not only leads to the expected stoichiometric $CsSnBr_3$ structure, but also yields a range of other distinct structures. The experiments were conducted in ultra-high vacuum and investigated by scanning tunneling microscopy (STM) and low-energy electron diffraction (LEED). When deposited on Au(111), we observe a flower structure with hexagonal symmetry tentatively assigned to Cs_2SnBr_6, a ladder structure, a stripe pattern, a honeycomb structure, and a large square structure. The emergence of these structures depends on surface coverage - either submonolayer or multiple monolayers - and on the relative proportions of the two precursor molecules. In contrast, on Au(100) these structures are not observed, suggesting that the interface is playing a crucial role. The structures are compared with those formed by depositing either CsBr or $SnBr_2$ on Au(111). While a honeycomb structure can also be formed with $SnBr_2$ alone, the other structures bear no resemblence to either pure component. Thus, they are assigned to structures involving specific ratios of Cs, Sn and Br deviating from the standard ABX_3 structure. The structural variability underscores the importance of precise deposition conditions and interface selection in the fabrication of perovskite materials.

O 74.4 Wed 18:00 P2

Band alignment at InP/TiO_2 interfaces from density-functional theory — Isaac Azahel Ruiz Alvarado[1], Christian Dressler[2], and •Wolf Gero Schmidt[1] — [1]Universität Paderborn, Germany — [2]TU Ilmenau, Germany

The natural band alignments between indium phosphide and the titanium dioxide polymorphs rutile, anatase and brookite as well as amorphous titania are calculated from the branch point energies of the respective materials. Type-I alignment is predicted, irrespective of the type of titania interfacing with InP. The actual band offset may differ, however, from the natural band alignment depending on the microscopic structure of the interface. Supercell calculations are performed for the interface between P-rich InP(001) surface and amorphous titania thin films. The valence band offset increases substantially compared to the natural band alignment, while the conduction band offset is reduced, resulting in nearly aligned conduction bands. Depending on the interface properties, both type-I and type-II interfaces are observed in the simulations. The results show that with careful control of the microscopic interface structure and the atomic order of the titania film a very wide range of band alignments becomes accessible.

O 74.5 Wed 18:00 P2

Structure of tellurium phases on Ni(111) and Ni(111)-(1 × 1)-2C (graphene) — •Alexander Wegerich, Gwyn R. Thomas, Andreas Raabgrund, and M. Alexander Schneider — Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

Using quantitative LEED-IV analyses, STM and DFT, we examine Te on Ni(111) to understand the interactions and emerging structures. For Θ_{Te} = 0.33 ML a $\left(3\times\sqrt{3}\right)_{rect}$-2Te superstructure is identified. For Θ_{Te} = 0.40 ML this changes to a $\left(5\times\sqrt{3}\right)_{rect}$-4Te superstructure. As LEED-IV analyses reveal, these superstructures are identical to those that can be observed for the Te/Cu(111) system [1], albeit with different stacking and reduced Te-Metal bond length.

In addition, we also present our first results regarding Te on the well-known Ni(111)-(1 × 1)-2C (graphene) structure [2, 3]. The presence of Te reduces the thermal stability of the graphene on Ni(111). At annealing temperatures above 570 K the graphene begins to dissolve and structures for the Te/Ni(111) system emerge. In the course of our studies, we also determined the Ni(111)-(1 × 1)-2C (graphene) structure by LEED-IV analysis and obtained picometer accuracy by virtue of a low Pendry R-factor of R = 0.10.

An atomistic analysis of the carpet growth of KCl across Ag(111) step edges — •Anna Juliana Kny[1], Adam Sweetman[2], and Moritz Sokolowski[1] — [1]Clausius Institut für Physikalische und Theoretische Chemie, Universität Bonn, Germany — [2]School of Physics and Astronomy, University of Leeds, UK

Thin alkali halide (AH) films of 2-3 atomic layer thickness, grown on metal substrates, are widely used for studying decoupled molecules by scanning tunneling microscopy. For many combinations of AH and metal surface, a continuous growth of the AH layer across step edges of the substrate is observed, which is called carpet growth. Here, we report a first atomistic analysis of the layer distortions in the carpet growth region of KCl layers at Ag(111) step edges.[1] STM measurements were performed at room temperature and with Cl anions decorated W-tips which yield a high atomic resolution. We find that the AH layer distorts locally and in a non-uniform manner within a short lateral distance of four unit cells, when it grows across the Ag step. Furthermore, we find that the Ag(111) surface adapts to the AH layer, as the carpet growth is accompanied by a straightening of the Ag steps along the <110> direction and a splitting of higher Ag steps into multiple mono-atomic ones. These mono-atomic Ag steps allow for the carpet growth if the distance between them is larger than 13 Å, while a carpet growth across higher or closer Ag steps was not observed.[1]

Supported by the DFG through the research training group 2591, the Royal Society, and the ERC.

O 74.7 Wed 18:00 P2

Epitaxial growth of bismuthene-based transition metal compounds — •Holger Diehm, Bing Liu, Simon Moser, Jörg Schäfer, and Ralph Claessen — Würzburg-Dresden Cluster of Excellence ct.qmat and Physikalisches Institut, Universität Würzburg, D-97074 Würzburg, Germany

This work explores the fabrication of alloy phases between bismuthene - a fully planar honeycomb structure of bismuth atoms on a silicon carbide (0001) sub-

strate - and 3d transition metals (TMs).

Bismuthene is a promising candidate for quantum spin Hall (QSH) effect at room-temperature [1] that shows interacting 1D spin-polarized electrons in a metallic edge channel [2]. While topological protection of the edge channels can be lifted by edge coupling [3], interfacing it with ordered TM-rich phases could locally introduce magnetic moments. This provides a novel platform to explore the effects of broken time-reversal symmetry and its potential impact on the topological phase.

Our work focusses on epitaxially grown bismuthene, garnished with manganese, chromium or cobalt. While bismuthene on silicon carbide shows a rt(3) x rt(3) surface reconstruction in low energy electron diffraction (LEED), incorporation of transition metals causes an additional 3 x 3 phase. In addition, scanning tunneling microscopy (STM) is used to analyze the surface structure on an atomic level.

This study paves the way for both fundamental research and application-oriented development in spintronics.

O 75: Poster Focus Session Chemical Imaging for the Elucidation of Molecular Structure (joint session O/BP)

Time: Wednesday 18:00–20:00 Location: P2

O 75.1 Wed 18:00 P2

Imaging of structure, conformation, and assembly of biological molecules by scanning probe microscopy (SPM) — •Joshua Holloway, Márkó Grabarics, Banjamin Mallada, Alejandro Lynch Gonzalez, Lukas Eriksson, and Stephan Rauschenbach — University of Oxford, Oxford, UK

Direct imaging of (bio)molecules by scanning probe microscopy (SPM) is a powerful approach for molecular structure elucidation. Sample preparation presents a challenge: an analyte must be taken into the gas phase, and intactly deposited on the sample surface. Because many biological molecules we wish to study are incompatible with sublimation, we employ electrospray ion beam deposition (ES-IBD). A novel, custom-built deposition stage extending a commercial mass spectrometer (Thermo Fisher Q Exactive UHMR) allows for mass-filtered, soft-landed deposition onto atomically flat metal crystals for high-performance SPM imaging.

Here we present the workflow of mass spectrometry, selection, deposition, and imaging for several examples of biological molecules. In particular we explore the imaging of molecular assemblies of biomolecules with large and small ligands, formed in the gas-phase and/or on the surface.

O 76: Poster Focus Session Atomic Scale Investigation of Magnetic 2D Materials

Time: Wednesday 18:00–20:00 Location: P2

O 76.1 Wed 18:00 P2

Unconventional magnetic response in epitaxial-grown single-layer Cr_2S_3-2D — •Affan Safeer[1], Calisa Carolina Oliveira[2], Mahdi Ghorbani-Asl[3], Jörg Schöpf[1], Wouter Jolie[1], Amilcar Bedoya-Pinto[2], Arkady V. Krasheninnikov[3], Thomas Michely[1], and Jeison Fischer[1] — [1]Universität zu Köln, Köln, Germany — [2]University of Valencia, Paterna, Spain — [3]Institute of Ion Beam Physics and Materials Research, Dresden, Germany

We studied the magnetic ordering in epitaxially-grown single-layer Cr_2S_3-2D on Gr/Ir(110) using X-ray magnetic circular dichroism (XMCD), scanning tunneling microscopy (STM) and spectroscopy (STS). Prior characterization of the 2D material structure via low-energy electron diffraction (LEED), STM, and density functional theory (DFT) calculations confirmed that single-layer Cr_2S_3-2D has a NiAs-type structure. DFT calculations further predicted that the ground state could be either A-type antiferromagnetic or ferromagnetic, depending on the Hubbard parameter. Differential conductance STS measurements as a function of the out-of-plane magnetic field at 1.7 K show a hysteresis behavior with a switching field of about 4T, indicating a ferromagnetic ordering. In contrast, XMCD measurements on the same sample revealed no signal, indicating zero net magnetic moment, suggesting antiferromagnetic behavior.

O 76.2 Wed 18:00 P2

Atomically thin $MnBr_2$ grown by molecular-beam epitaxy on graphene/Ir — Oktay Güleryüz, Affan Safeer, Nicolas Georgopoulos, Thomas Michely, and •Jeison Fischer — II. Physikalisches Institut, Universität zu Köln, Zülpicher Straße 77, 50937 Köln, Germany

We report on the growth of potentially magnetic manganese dibromide ($MnBr_2$) films on graphene/Ir substrates using molecular-beam epitaxy. $MnBr_2$ is evaporated as a single compound from an effusion cell onto the graphene/Ir. Low-electron energy diffraction analysis reveals that the hexagonal lattice constant of $MnBr_2$ amounts to 0.390 ± 0.005 nm, consistent with calculated 0.3885 nm and bulk 0.3873 nm values.

Our scanning tunneling microscopy study reveals that the best growth conditions to form large, compact monolayers involve deposition at elevated temperatures (400 K). Growth at low temperature on graphene/Ir(110) leads to the formation of small islands with a distribution of orientations. A new moiré superstructure is formed, which reflects the interaction of the $MnBr_2$ lattice with the corrugated graphene/Ir(110) moiré.

Low-temperature scanning tunneling spectroscopy at 1.7 K of monolayer $MnBr_2$ further reveals a significant band gap of approximately 5 eV. Additionally, isolated polarons are observed, which can be manipulated, created, and destroyed by the STM tip.

O 76.3 Wed 18:00 P2

The Nickelocene as an STM Atomic-Spin Sensor via cotunnelling theory — •Andres Pinar Sole[1,2], Manish Kumar[1], Diego Soler-Polo[1], Oleksandr Stetsovych[1], and Pavel Jelinek[1] — [1]Czech Institute of Physics, Cukrovarnicka 10, Prague 6, 16200 (Czech Republic) — [2]Center for Quantum Nanoscience (QNS) Research Cooperation Building Ewha Womans University, 03760 Seoul, (Republic of Korea)

Functionalization of a scanning microscopy probe with a single nickelocene attached to the tip allows reproducible spin-sensitive measurements of magnetic systems on surfaces. As a S=1 molecule, the triplet ground state of the nickelocene tip gives rise to a inelastic electron spin-flip excitation which changes upon interactions with spin systems on the surface. Some advantages of nickelocene functionalization compared to spin-polarized tips include tip passivation, enabling data acquisition at close tip-sample distances and well defined spin and tip apex. These features enable us to determine the local spin moment on the surface with atomic-scale precision.

While the interactions between the nickelocene spin and the magnetic centers has been modelled using a two-site Heisenberg Hamiltonian, we complement it to include the tunnelling current as an electronic transport phenomenon via cotunneling theory. It allows understanding the absence of transitions that are not allowed according to the selection rules or have relatively weaker intensity. We cover S = 1/2, 1, and 3/2 systems, as well as 2D magnetic materials and compare the simulations with experimental results.

O 77: Poster Vacuum Science Technology: Theory and Applications

Time: Wednesday 18:00–20:00 Location: P2

O 77.1 Wed 18:00 P2

An apparatus of preparing frozen solution samples for ultra-high vacuum experiments — •Jiadong Guo, Xinmeng Liu, and Ying Jiang — International Center for Quantum Materials, School of Physics, Peking University, Beijing, China

Here we develop an apparatus for preparing frozen solution samples, which can be characterized by surface science techniques under ultra-high vacuum (UHV) condition. When a temperature-variable substrate is approached to contact the frozen solution at 77 K, the surface of the frozen solution is locally melted and then refreeze with the substrate. By detaching the substrate from the frozen so-

lution in high vacuum, the frozen solution is cleaved and transferred onto the substrate. Applying this method, we demonstrate transferring NaCl and $LiNO_3$ frozen solutions onto the Au substrate, and directly image the crystallization of NaCl and $LiNO_3$ using atomically resolved atomic force microscopy (AFM) in UHV at 5 K.

This apparatus provides a new approach to transfer solution samples in their glassy states into the UHV environment while maintaining the cleanliness of the samples, laying the foundation for further research related to solution environment, such as crystallization, hydration, chemical reaction, materials synthesis and bioimaging.

O 77.2 Wed 18:00 P2

Investigating Nanoscale Hydrophobic Polymer Coatings for the use in the Einstein Telescope — •Maike Kühler, Achim Stahl, Charlotte Benning, and Oliver Pooth — III. Physikalisches Institut B, RWTH Aachen

With 120 km pipes of 1m diameter, the ultra-high vacuum (UHV) system of the Einstein Telescope is going to be one of the largest vacuum systems in existence. It will need an enormous input of innovation and optimization. This work explores superhydrophobic coatings for the vacuum chambers of the Einstein Telescope. Hoping to achieve faster pumpdown times and eventually lower bake out temperatures to reach sufficient pressure regimes. This poster presents a coating based on reactive silyl anchor units and functionalised with a long perfluoropolyether/organofluorine chain. The coating has been investigated for its performance and compatibility with UHV conditions. Its compatibility with the vacuum system of the Einstein Telescope was evaluated through molecular flow simulations.

O 77.3 Wed 18:00 P2

Tritium Induced Exchange Reaction of Hydrogen Isotopes — •James O'Callaghan, Robin Grössle, Simon Niemes, and Robin Holzwarth — Tritium Laboratory Karlsruhe (TLK), Institute of Astroparticle Physics (IAP), Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany

Tritium (T), the heaviest isotope of hydrogen, is used for experiments in astroparticle physics and is essential as fuel for fusion reactors. It comes with many challenges due to its radioactivity. Isotopic exchange is one such challenge, Hydrogen-1 (H) and Deuterium (D) can be left in an idealised vessel and will practically not react with each other; the concentrations of H2, D2 and HD will remain unchanged and will not reach the thermal equilibrium in practical time scales. This is not the case with tritium. In the presence of tritium, the radioactive decay induces chemical reactions and therefore the concentrations will shift towards the chemical equilibrium. Most prominently in a fusion reactor context, starting with mixtures of homonuclear molecules (H2, D2, T2), the production of potentially undesirable heteronuclear molecules (HD, HT and DT) up to the chemical equilibrium is facilitated by the decay of tritium. This needs to be understood for designing fuel cycle components for a fusion reactor. In this contribution first efforts for a data driven development of an empirical model to describe the reactions rates in tritiated mixtures is given.

O 78: Overview Talk Manish Garg

Time: Thursday 9:30–10:15 Location: H24

Topical Talk O 78.1 Thu 9:30 H24

Imaging Electronic and Atomic Motion in Molecules — •Manish Garg — Max Planck Institute for Solid State Research, Heisenbergstrasse 1, Stuttgart 70569

The capability to capture electronic and atomic motions at their natural length (Ångstrom-scale) and time-scales (attoseconds to femtoseconds) is a long-standing goal in modern science. In my talk, I will show you how electron dynamics in molecules can be locally probed with angstrom-scale spatial resolution and sub-femtosecond temporal resolution simultaneously, at the single orbital-level with the help of a scanning tunnelling microscope (STM), defying the previously established fundamental space-time limits [1-3].

Quantum decoherence of the excited electronic states and dipole-dipole interactions between molecules can now be imaged in real-space and real-time. We have recently imaged electronic excitation transfer dynamics between donor and acceptor kind of molecules. Excitons locally excited in a donor molecule exchanges energy by coherent dipole-dipole interaction with a neighboring acceptor molecule [4].

Atomic motions in a single molecule can be directly imaged by realizing coherent anti-Stokes Raman spectroscopy in an STM [5-8]. These recent developments pave the way towards direct real space-time imaging of chemical reactions and phase transformations in two-dimensional materials.

O 79: Ultrafast Electron Dynamics III

Time: Thursday 10:30–12:30 Location: H2

O 79.1 Thu 10:30 H2

Hybrid Exciton Orbital Tomography in 2D-organic interfaces — •Christian Simon Kern[1], Michele Capra[2], Marco Gruenewald[3], Torsten Fritz[3], Mirko Cinchetti[2], Peter Puschnig[1], and Giovanni Zamborlini[1] — [1]Institute of Physics, University of Graz, Austria — [2]Department of Physics, TU Dortmund University, Germany — [3]Institute of Solid State Physics, Friedrich Schiller University Jena, Germany

Organic molecules adsorbed on semiconducting 2D substrates pose an interesting class of interfaces for optoelectronic applications. Here we investigate the interface of pentacene and a transition metal dichalco-genide layer with many-body perturbation theory. In particular, we compare those results to optical spectroscopy and demonstrate the connection of excitons to their experimentally observable photoemission signatures in pump-probe spectroscopy. The latter approach— exciton photoemission orbital tomography [1]—especially allows for the unambiguous characterization of the excitons' hole and electron configuration, and is extended to the case of hybrid interlayer excitons.

[1] C. S. Kern, A. Windischbacher, and P. Puschnig, Photoemission orbital tomography for excitons in organic molecules, PRB 108, 085132 (2023)

O 79.2 Thu 10:45 H2

Ultrafast table-top three-dimensional photoemission orbital tomography — •G. S. Matthijs Jansen[1], Wiebke Bennecke[1], Thi Lan Dinh[2], Jan Philipp Bange[1], David Schmitt[1], Marco Merboldt[1], Lennart Weinhagen[1], Bent van Wingerden[1], Fabio Frassetto[3], Luca Poletto[3], Marcel Reutzel[1], Daniel Steil[1], D. Russell Luke[2], and Stefan Mathias[1] — [1]University of Göttingen, I. Physikalisches Institut, Göttingen, Germany — [2]University of Göttingen, Institute of Numerical and Applied Mathematics, Göttingen, Germany — [3]Institute for Photonics and Nanotechnologies CNR-IFN, 35131 Padova, Italy

In photoemission orbital tomography (POT), molecular orbitals can be imaged with femtosecond resolution. Also, when combined with photon-energy-dependent measurements, POT is, so far, the only method that can probe the orbitals of adsorbed molecules in 3D. However, the study of, e.g., hybridization in organic/inorganic heterostructures [Bennecke *et al.*, arXiv:2411.14993 (2024)] by 3D-POT is extremely challenging due to the demanding nature of the experiment. Here, we present a table-top approach for 3D POT: By combining a photoelectron momentum microscope with a pulse-preserving monochromator for laser-generated extreme ultraviolet light, we speed up data acquisition. Moreover, we developed a new reconstruction algorithm that reduces the sampling requirements by about an order of magnitude [Dinh *et al.*, New J. Phys. 26 043024 (2024)]. Our first results achieved on PTCDA/Ag(110) highlight the potential for ultrafast femtosecond time-resolved 3D-POT.

O 79.3 Thu 11:00 H2

Exciton wave function signatures from time-resolved photoemission tomography of an organic molecular layer — •Siegfried Kaidisch[1], Marcel Theilen[2], Monja Stettner[3], Eric Fackelman[3], Galit Cohen[4], Amir Kleiner[4], Christian Simon Kern[1], Andreas Windischbacher[1], Sivan Refaely-Abramson[4], Frank Stefan Tautz[3], Ulrich Höfer[2], and Peter Puschnig[1] — [1]Institute of Physics, University of Graz, Austria — [2]Fachbereich Physik, Philipps-Universität Marburg — [3]PGI-3, FZ Jülich & RWTH Aachen University — [4]Weizmann Institute of Science, Israel

Oriented layers of organic molecules adsorbed on passivated metal surfaces are a promising class of interfaces for studying electron dynamics at femtosecond timescales. In particular, time-resolved photoemission tomography promises to reveal information about the electron distribution in optically excited states. Using the example of sexithiophene (6T) multilayers adsorbed on Cu(110)-p(2x1)O, we observe photoemission patterns for the low-energy excited states. These measured momentum maps exhibit signatures that cannot be explained by a mere population of the lowest unoccupied molecular orbital of 6T. To analyze the source of these features, we perform GW/BSE (Bethe-Salpeter equation)

calculations on multiple levels of theory (gas-phase, cluster, embedded and periodic calculations). Using the framework of photoemission orbital tomography for excited states, we also simulate the photoemission patterns and thereby shed light on the nature of the exciton wave function of the lowest optically allowed state.

O 79.4 Thu 11:15 H2

Quenching Strong-Field Recollisions at Nanotapers with Strong Bias Fields — •Rasmus Lampe, Germann Hergert, and Christoph Lienau — Institut für Physik, Carl-von-Ossietzky Universität, 26129 Oldenburg, Germany

Recollisions of intensively accelerated electrons with the parent are a well-known effect in strong-field photoemission of electrons, leading to photoemission spectra showing a recollision plateau with a cut-off energy of ten times the ponderomotive energy. It has recently been demonstrated that such a recollision plateau also arises in multiphoton photoemission from metallic nanostructures, showing that recollisions are much more fundamental to photoemission than anticipated [1].

We analyze electron recollisions from strongly biased tungsten nanotapers illuminated by few-cycle near-infrared laser pulses. We demonstrate significant changes in the photoelectron spectra in the strong-field regime by applying static electric fields on the order of the optical near-field driving the photoemission. A continuous transition of a horizontal recollision plateau into triangularly shaped spectra is observed.

Stronger static fields increase the acceleration of the electrons away from the apex, such that the ponderomotive acceleration by the near-field is not sufficient to drive the electrons back to the surface, ultimately suppressing recollisions. This enables the control of the electron motion with bias fields, which has an immediate importance for ultrafast low-energy electron microscopy allowing to maintain few fs time resolution of the electron beam over mesoscopic distances.

[1] B. Bánhegyi et al., Phys. Rev. Lett. 133, 033801 (2024)

O 79.5 Thu 11:30 H2

Time-resolved photoemission orbital tomography of 6T on Cu(110)-(2×1)O — •Marcel Theilen[1], Monja Stettner[2], Eric Fackelman[2], Francois C. Bocquet[2], Alexa Adamkiewicz[1], Sarah Zajusch[1], Siegfried Kaidisch[3], Christian Kern[3], Robert Wallauer[1], Peter Puschnig[3], F. Stefan Tautz[2], and Ulrich Höfer[1,4] — [1]Fachbereich Physik, Philipps-Universität Marburg — [2]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich — [3]Institut für Physik, Universität Graz — [4]Fachbereich Physik, Universität Regensburg

For ordered molecular layers, photoemission orbital tomography (POT) is a powerful technique for imaging the electron distribution of molecular orbitals in momentum space. When combined with laser pump-probe techniques, time-resolved photoemission orbital tomography (tr-POT) offers the ability to track the population dynamics of the excited molecular states on a femtosecond time scale[1].

In this talk, I will discuss our recent results obtained through tr-POT for three distinct, well-ordered layers of sexithiophene (6T) on a Cu(110)-(2×1)O surface: a monolayer, a bilayer and a multilayer. The focus will primarily be on the dynamics of the populated 6T LUMO via an optically HOMO-LUMO transition. For instance, a comparison between the individual layers reveals a significant extension of the LUMO lifetime with increasing layer thickness. Specifically, we find that the lifetime for the monolayer is less than 50 fs, while it increases to more than 600 fs for the multilayer.

[1] R. Wallauer *et al.*, Science **371**, 1056 (2021).

O 79.6 Thu 11:45 H2

Understanding the ultrafast electron dynamics and CDW transition in $LaTe_3$ using machine learning — •Gesa Siemann[1], Davide Curcio[1], Paulina Majchrzak[1], Charlotte Sanders[2], Jenny Rigden[2], Yu Zhang[2], Deepnarayan Biswas[3], Leslie Schoop[4], Emma Springate[2], and Philip Hofmann[1] — [1]Department of Physics and Astronomy, Aarhus University, DK — [2]Central Laser Facility, Harwell, UK — [3]Diamond Light Source, UK — [4]Department of Chemistry, Princeton University, USA

The rare-earth tritelluride $LaTe_3$ hosts a unidirectional charge density wave (CDW) with a high transition temperature of 670 K. Recently, it has been suggested that exposing the system to a short light pulse not only suppresses this primary CDW but also induces a second CDW in the perpendicular direction[1]. An open question is, how these structural dynamics affect the electronic structure, and if fingerprints of the second CDW can be found in corresponding data obtained by time- and angle-resolved photoemission spectroscopy. Here, we explore this question, studying the frequency-dependent coherent response of the system, and the time-dependent evolution of the Fermi surface topology, which we compare to predictions by a simple tight-binding model. We support our analysis using k-means clustering, a machine learning technique, in order to identify different dynamics throughout the Brillouin zone. This reveals varying relaxation times across the Fermi surface, as well as multiple frequencies that can be ascribed to coherent excitations. [1]A. Kogar *et al.*, *Nat. Phys.* 16, 159*163 (2020).

O 79.7 Thu 12:00 H2

Following charge-transfer between plasmonic NPs and adsorbed molecules by time-resolved IR spectroscopy — •Daniel Sandner[1], Katrin Schulz[1], Andrei Stefancu[2], Reinhard Kienberger[1], Emiliano Cortes[2], and Hristo Iglev[1] — [1]Lehrstuhl für Laser- und Röntgenphysik E11, TUM, James-Franck Str 1, 85748 Garching — [2]Fakultät für Physik, LMU München

Plasmonic Nanoparticles can efficiently convert light in a broad range into hot charge carriers, which can be subsequently transferred to molecules or semiconductors for photocatalytic processes. The role of charge-carrier-mediated or thermal reaction pathways is still under debate. Here, we use time-resolved IR spectroscopy between 1200-3000 cm-1 as a sensitive probe for free charges and study the dynamics of different molecules attached to silver NPs. Charge transfer is only observed for resonant excitation of the plasmon resonance and in the presence of attached molecules. Furthermore, we find a correlation between the lifetime of transferred charges and the chemical reactivity.

O 79.8 Thu 12:15 H2

Ultrafast Photoexcitation of Semiconducting Photocathode Materials: An Ab Initio Study — •Hilde Bellersen, Michele Guerrini, and Caterina Cocchi — Carl von Ossietzky Universität Oldenburg, Institute of Physics, 26129 Oldenburg, Germany

Cs-based semiconductors like Cs_3Sb and Cs_2Te are currently used as photocathode materials in particle accelerators. Their performance as electron sources critically depends on their response to the intense laser radiation impinging them. In this work, we investigate from first principles the time-dependent response of Cs_3Sb and Cs_2Te to ultrafast laser pulses of varying intensities, ranging from 1 GW/cm^2 to 100 TW/cm^2. Nonlinear effects, including high harmonic generation and multiphoton absorption, emerge at thresholds of 400 GW/cm^2 for Cs_3Sb and 500 GW/cm^2 for Cs_2Te. Beyond these intensities, the energy uptake and number of excited electrons saturate, with renewed increases observed beyond 10 TW/cm^2. These findings provide new insights into the nonlinear optical properties of Cs_3Sb and Cs_2Te, contributing to the optimization of these materials for the development of next-generation photoinjectors.

CISS in single heptahelicene molecules on Fe bilayers on W(110) — •Daniel E. Bürgler[1], Mohammad Reza Safari[1], Frank Matthes[1], Karl-Heinz Ernst[2], and Claus M. Schneider[1] — [1]Peter Grünberg Institut, Forschunschungszentrum Jülich, Germany — [2]Empa, Swiss Federal Laboratories for Materials Science and Technology, 8600, Dübendorf, Switzerland

We reproduce and extend our single-molecule studies of CISS [1,2] to an alternative substrate system. Heptahelicene molecules are sublimed onto a multidomain Fe bilayer film on W(110) instead of single-domain Co bilayer nanoislands on Cu(111). Using spin-polarized low-temperature scanning tunneling microscopy, the current flow through single *(M)*-enantiomers chemisorbed on neighboring and oppositely magnetized domains of the Fe bilayer film is mapped in the constant-height mode, where the tip is scanned at constant height above the Fe surface. The CISS magnetoresistance reaches up to 18% at 5 K and shows a strong dependence on the bias voltage. A comparison is drawn with the data obtained on Co nanoislands.

O 80.2 Thu 10:45 H4

STM topography and photoluminescence of three different Eu complexes — •Adrian Ebert[1], Lukas Gerhard[1], Julia Feye[2], Senthil Kumar Kuppusamy[3], Mario Ruben[3], Peter Roesky[2], and Wulf Wulfhekel[1] — [1]Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]Institute for Organic Chemistry, Karlsruhe Institute of Technology, Karlsruhe, Germany — [3]Institute of Nanotechnology, Karlsruhe Institute of Technology, Karlsruhe, Germany

We explore the self-assembly and luminescence properties of three distinct Europium (Eu) complexes *Eu(tta)$_3$(H$_2$O)$_2$, Eu(btfa)$_3$(bpy), and Eu(tta)$_3$(bpy)* on a Au(111) surface. Utilizing Scanning Tunneling Microscopy (STM), we explore the molecular topography and the ordered structures formed by these complexes, providing insight into their surface interactions. The Europium Eu^{3+} ion, a member of the lanthanide series, is renowned for its unique photophysical properties, particularly its sharp emission lines and long-lived luminescence, which make it a valuable component in light-emitting devices, bio-imaging, and sensing applications.

O 80.3 Thu 11:00 H4

First-Principles Modeling of Mixed-Dimensional Heterostructures: A Path Forward — •Jannis Krumland and Caterina Cocchi — Carl von Ossietzky Universität Oldenburg

Inorganic/organic interfaces between transition-metal dichalcogenides and organic adsorbates are promising candidates for future opto-electronic applications, leveraging and combining the unique strengths of the two different types of materials. The first-principles description of such interfaces, however, remains challenging because methods based on density-functional theory are unreliable for their simulation [1]. This is a result of the mixed dimensionality of the interface, with molecules being zero-dimensional while surfaces are two-dimensional. The mixed dimensionality moreover poses challenges in the analysis of the results, as molecules are usually described in terms of energy levels, whereas surfaces are characterized by band structures. Here, we present a methodological study establishing pragmatic yet accurate simulation approaches for the calculation of energy-level alignments [2]. In addition, we highlight unfolding techniques as a key tool for gaining a deeper understanding of the interactions and hybrid-state formation occurring at such interfaces [3].

O 80.4 Thu 11:15 H4

Photo-induced force microscopy of organic molecules on thin van der Waals substrates — •Markus Kratzer[1], Mohamad Khan[1], Simon Leitner[1], Aleksandar Matkovic[1], Olivier Siri[2], Conrad Becker[2], and Christian Teichert[1] — [1]Chair of Physics, Montanuniversität Leoben, Franz-Josef Straße 18, 8700 Leoben, AUT — [2]Aix Marseille Univ., CNRS, Cinam, 13288 Marseille, FGrance

Photo-induced force microscopy (PiFM) is an atomic force microscopy based technique for obtainiung infrared spectroscopic data with a spatial resolution down to a few 10 nm. Here, we utilized PiFM to investigate nano and microstructures comprising small organic molecules like para-hexaphenyl or dihydrotetraaza-acene (DHTA7) on exfoliated thin layers of van der Waals materials as hexagonal boron nitride (hBN). It is notices that the PiFM spectra systematically vary with van der Waals substrate thickness. Further PiFM spectra of upright standing molecular structures and flat lying structures are copared. PiFM turned out to be sensitive even for single molecular layers, which are only about 2 nm thick. Similarities and differences between thin film and bulk infrared data are discussed.

O 80.5 Thu 11:30 H4

Engineering Optical Properties through Polymorphism — •Nina Kainbacher[1,2], Peter Puschnig[1], and Oliver T. Hofmann[2] — [1]Institute of Physics, University of Graz, Austria — [2]Institute of Solid State Physics, Graz University of Technology, Austria

Molecular monolayers on a supporting substrate can order in different configurations, i.e. polymorphs. Owing to variations of the intermolecular coupling between the transition dipole moments, we expect that different polymorphs exhibit also distinctly different optical properties due to changes in transition energies and oscillator strengths. In this study, we computationally study the impact of polymorphism of organic molecular monolayers on optical absorption spectra. Specifically, we investigate influencing factors, such as geometric distortions upon adsorption, interactions between transition dipole moments, changing selection rules due to the symmetry of different polymorphs, and particularly, effects arising from the potential delocalization of the wave functions. As an example, we predict the polymorphism of the dipolar organic molecule nitropyrene-amine on NaCl(100) using machine learning-based structure search and calculate its optical properties based on density functional theory and the RPA approximation. Specifically, we find two distinctly different polymorphs, where the excitation energies differ by approximately 0.2 eV which we attribute to a combination of the above-mentioned effects.

O 80.6 Thu 11:45 H4

Imaging the occupied states of multilayers of α-sexitiophene (6T) on Cu(110)-p(2x1)O using orbital tomography — •Monja Stettner[1,2], Andrey Matetskiy[1], Eric Fackelman[1,2], Siegfried Kaidisch[3], Serguei Soubatch[1], François C. Bocquet[1], Peter Puschnig[3], Christian Kumpf[1,2], and F. Stefan Tautz[1,2] — [1]Peter Grünberg Institut (PGI-3), FZ Jülich, Germany — [2]RWTH Aachen University, Germany — [3]Institute of Physics, University of Graz, Austria

Deposition of α-sexithiophene (6T) on an oxygen-reconstructed Cu(110)-p(2x1)O surface results in a well ordered, close-packed monolayer structure, and at higher coverages in layer-by-layer growth. Note that even beyond a monolayer, 6T retains its orientation along the [001] direction of Cu. We investigated samples with coverages of up to eight layers using ARPES and - in particular - orbital tomography. For the latter, experimental momentum maps are compared to simulated maps which are calculated for a single free molecule and for extended layers of 6T. We found a good resemblance for several occupied molecular states, e.g., the HOMO. However, in the binding energy range of several deeper orbitals, the momentum maps clearly show signatures of a sizable intermolecular dispersion that cannot be explained by a superposition of the single gas phase maps. The orbitals rather form dispersing bands, which indicates a significant intermolecular hybridization.

O 80.7 Thu 12:00 H4

Electronic structure of molecular and crystalline benzene on an MoS_2 monolayer — •Jan-Phillip Topmöller and Michael Rohlfing — Institute of Solid State Theory, University of Münster, Germany

TMDCs show great potential in terms of their applicability in optical electronics. Due to their large surface, molecules can easily bind to the TMDC and affect its electronic properties. Here we investigate molecular benzene and its bulk crystal as prototypical systems.

We use DFT (GGA) and DFT-D3 to determine the most stable adsorption position of both the molecule and the bulk crystal on MoS_2. Subsequently, we use many body perturbation theory to calculate the electronic spectrum of the adsorbate system and its individual components (MoS_2 and the benzene molecule/crystal) in order to investigate the effect of the molecule on the MoS_2 electronic and optical spectrum.

O 80.8 Thu 12:15 H4

Contact-dependent electronic properties of anthracene-MoS_2 heterostructures — •Hsin-Mei Ho and Peter Kratzer — Faculty of Physics, University of Duisburg-Essen, Lotharstr. 1, 47057 Duisburg, Germany

Flexible nanodevices composed of atomically thin layers have revolutionized fundamental and applied sciences. Based on density functional theory (DFT), we consider the organic-inorganic heterostructures: anthracene molecules adsorbed on monolayer MoS_2. Our investigations of the adsorption geometries and the energy band dispersions demonstrate that the contact between the organic and inorganic layers greatly affects the electronic properties. Anthracene thin films give rise to different shifts of the frontier energy levels, and consequently, variations in the band alignments when the molecules are in the perpendicular and parallel orientations on MoS_2. As anthracene is known for ordered structures when grown on substrates, we find in the present study that the bandgap of an anthracene film reduces when the interactions between molecules increase. This suggests that how the molecules are packed also plays a critical role. Our study provides detailed insights regarding the advances of oligoacene-TMDs layers for both theoretical and experimental sides.

Cu Oxide Nanoparticles for Virus Inactivation — •Daniel Silvan Dolling[1,2], Miguel Blanco Garcia[1,2], Mona Kohantorabi[1], Mohammad Ebrahim Haji Naghi Tehrani[1,2], Jan-Christian Schober[1,2], Ming-Chao Kao[1,2], Jagrati Dwivedi[1], Arno Jeromin[1], Thomas F. Keller[1], Olof Gutowski[3], Dimitry V. Novikov[3], Andreas Stierle[1,2], and Heshmat Noei[1] — [1]Centre for X-ray and Nano Science CXNS, Deutsches Elektronen-Synchrotron DESY, Notkestr. 85, 22607 Hamburg, Germany — [2]Fachbereich Physik, Universität Hamburg, Jungiusstraße 11, 20355 Hamburg, Germany — [3]Deutsches Elektronen-Synchrotron DESY, Notkestr. 85, 22607 Hamburg, Germany

TiO_2 is known to inactivate SARS-CoV-2 photocatalytically under UV light. Recently, it has been shown that Cu oxide on Titania shifts the photoactivty into the visible light region. The specific oxidation state of Cu is paramount for the photocatalyst efficiency. Here, we use single crystalline TiO_2 to investigate the effects of growth conditions of Cu nanoparticles (NPs). To this cause, we em-

ploy X-ray diffraction (XRD) and scanning electron microscopy (SEM), revealing a temperature-dependent morphology. Subsequently, we analyze the short- and long-term oxidation behavior with X-ray photoelectron spectroscopy (XPS) and scanning Auger microscopy (SAM). Finally, we investigate the interaction of the NPs with asparagine amino acid using reflection-absorption infrared spectroscopy (IRRAS) and grazing-incidence small-angle scattering (GISAXS).

O 81.2 Thu 10:45 H6

Charting Catalysis: Unveiling Regime Boundaries in Kinetic Phase Spaces Through Concentration Profiles — •Maryke Kouyate, Gianmarco Ducci, Frederic Felsen, Christian Kunkel, Karsten Reuter, and Christoph Scheurer — Fritz-Haber-Institut der MPG, Berlin

In an industrial context, optimizing process variables is a critical step in ensuring optimal performance of catalytic reactors. Selecting the relevant process variables not only aids in meeting precise requirements but also in streamlining reactions and thus saving time and costs. Robust kinetic rate laws capable of accurately describing experimental data allow for predictive modelling in reactor design, optimization, and control. Specialized profile reactors efficiently yield the required data to derive kinetic models by providing access to spatio-temporally resolved chemical information along the reactor axis. Depending on the range of experimental conditions and the catalytic reaction, the kinetic phase space can exhibit sub-regions of smooth kinetic behavior, separated by transitional regions characterized by sudden qualitative changes of the kinetic behavior. These kinetic phase transitions carry important information about the catalytic reaction network. To pinpoint distinct sub-regions and corresponding models within a kinetic phase diagram, we propose an automated system capable of systematically exploring the design space. This algorithm manages the experimental reactor and iteratively suggests new experiments through model-based design of experiments.

O 81.3 Thu 11:00 H6

Mechanistic Probes for Photocatalysis: Gas Phase Reactions of Tertiary Alcohols on Titania in a Micro-Photoreactor — •Martin Tschurl[1], Clara Aletsee[1], Paula Neumann[1], Ib Chorkendorff[2], and Ueli Heiz[1] — [1]Chair of Physical Chemistry, School of Natural Sciences & Catalysis Research Center, Technische Universität München, Lichtenbergstr. 4, 85748 Garching, Germany — [2]SurfCat Section for Surface Physics and Catalysis, Department of Physics, Technical University of Denmark, 2800 Kgs Lyngby, Denmark

The lack in mechanistic understanding still hinders the rational design of efficient photocatalyst for various applications. To gain more comprehensive insights into the fundamental effects in photocatalysis, we analyze the gas phase photoreactions of tertiary alcohols on titania powder in a micro-photoreactor in a well-defined environment under the exclusion of oxygen. The parallels of the observed reaction properties to studies performed on a rutile single crystal in vacuum suggest similar mechanistics, which is in contrast to the generally assumed reaction model under such conditions. Furthermore, the time resolution of the micro-reactor setup allows the determination of the alcohol surface coverage, which excludes the existence of liquid films and evidences a gas phase reaction. In addition to the scientific insights on photocatalysis on titania, these results demonstrate the use of tertiary alcohols as suitable probe reactants for mechanistic studies.

O 81.4 Thu 11:15 H6

Selectivity trends in CO hydrogenation over transition metal surfaces — •David Degerman[1,2], Patrick Lömker[1], Markus Soldemo[1], Fernando Garcia-Martìnez[3], Robin Yoël Engel[1,2], Martin Beye[1,2,3], and Anders Nilsson[1,2] — [1]Department of Physics, Stockholm University, 114, 21, Stockholm, Sweden — [2]WISE - Wallenberg Initiative Materials Science for Sustainability, Department of Physics, Stockholm University, 114, 21, Stockholm, Sweden — [3]Deutsches Elektronen Synchrotron, DESY, Photon Science, Notkestraße, 22607, Hamburg, Germany

Understanding the selectivity of heterogeneously catalyzed CO hydrogenation is increasingly important for the transition towards a sustainable chemical industry. While theoretical studies yielded a model based on the competition of various elementary surface reactions, we need experimental observation of the surface's chemical state to verify the mechanistic origin of the selectivity. Here, we compare in-situ x-ray photoelectron spectra over operating single crystal catalysts (200 to 325 °C, 150 mbar) of Fe, Rh, Ni, Co and Cu and infer from the observed trends which mechanistic steps decides the product distribution for each material. In particular, we find that the chemisorption energies of C and O (commonly used descriptors for activity and selectivity) qualitatively predicts the rate-limiting step of catalysts, but fails when the reaction mechanism of Ni and Fe is fundamentally altered due to reaction-induced carburization. This work emphasizes that the complete chemical overview provided by photoemission spectroscopy is required to understand the selectivity of CO hydrogenation.

O 81.5 Thu 11:30 H6

Exploration of Explicit Solvation Effects in Heterogeneous Catalysis Using Machine Learning Interatomic Potentials — •Maciej Baradyn and Johannes T. Margraf — University of Bayreuth

The presence of solvent affects many aspects of modeling elementary reactions involved in heterogeneous catalysis, such as stabilization of adsorbed species, the nature of interaction with the surface, as well as energetics and reaction rates, to name just a few. Unfortunately, treating solvent effects in atomistic simulations is a great challenge, since the solvent adds many additional degrees of freedom to the calculation. In first-principles calculations, implicit solvation models are often used to approximately include these effects with moderate computational effort. However, they do not take into account the explicit solvent-surface and solute-solvent interactions, and are therefore known to fail, e.g. when hydrogen bonding is important. More importantly, the solvent molecules can sometimes play a decisive role in the reaction's mechanism (e.g. as proton shuttles), which cannot be captured by implicit models, where solvent is treated as a continuous medium. In this contribution, we explore the efficiency of machine learning potentials based on the MACE-MP-0 foundation model for describing explicit solvation at catalytic interfaces. These potentials are used to capture the kinetic and thermodynamic parameters of small organic molecules interacting with metallic surface in an explicit water bath. Implications for our understanding of the underlying catalytic reaction network and improved design of catalysts will be discussed.

O 81.6 Thu 11:45 H6

Reducibility of Sm-doped ceria islands on Ru(0001) — •Raquel Sanchez-Barquilla, Rudi Tschammer, Lars Buss, Carlos Morales, and Jan Ingo Flege — Applied Physics and Semiconductor Spectroscopy, BTU Cottbus-Senftenberg, Germany

The interaction between metal and oxide is critical when considering the hydrogenation of CO_2 to hydrocarbons. In this context, the inverse oxide/metal catalysis architecture allows for achieving better catalytic performance due to strong oxide-metal interactions. In particular, in cerium-based inverse catalyst systems, the Ce^{3+} cations have been demonstrated to play an active role in methanol synthesis, suggesting that the activity can be enhanced by promoting those through alloying with trivalent, catalytically active rare-earth metals, such as Sm. Here, we present a low-energy and X-ray photoemission electron microscopy (LEEM/XPEEM) investigation that shows how the reducibility of CeO_2(111) islands on Ru(0001) is highly enhanced when doped with Sm. After post-annealing with Sm, intensity-voltage (I-V) LEEM curves show an immediate reduction of the islands at the surface. Exposure to low H_2 pressures efficiently reduces the islands to a (3×3) superstructure formed by ordered oxygen vacancies, as evidenced by characteristic IV-LEEM spectra and low-energy electron diffraction patterns. Furthermore, annealing at high temperatures shows the further reduction of the Sm-ceria islands, with features characteristic of the hexagonal Ce_2O_3(0001) phase. While this reduction takes about one hour for pure ceria, this transition is virtually immediate for the Sm-doped ceria islands at comparable conditions.

O 81.7 Thu 12:00 H6

Interaction of single cobalt co-catalyst atoms with the $SrTiO_3$(001) surface — •Aji Alexander[1], Pankaj Kumar Samal[1], Llorenç Albons[1], Jan Škvára[1], Dominik Wrana[2], Viktor Johánek[1], Josef Myslivecek[1], and Martin Setvin[1] — [1]Department of Surface and Plasma Science, Charles University, Prague, Czech Republic — [2]Marian Smoluchowski Institute of Physics, Jagiellonian University, Krakow, Poland

Perovskite surfaces attract attention in the catalysis community due to their promising chemical properties, ability to separate electron-hole pairs for light harvesting, and ferroelectricity in various phases. Understanding metal clusters, specifically their electronic structure and atomic utilization efficiency, is crucial for developing more efficient and sensitive catalysts.

This work focuses on the atomic structure of doped $SrTiO_3$(001) perovskite surface and the potential to modify its catalytic activity by the presence of extrinsic metals, with the main focus on cobalt. Combined STM/AFM, LEED, and XPS show a combination of cobalt clustering and dispersion within an ordered reconstruction. We will highlight how cobalt interacts with perovskite surfaces at different reducing conditions and explain the various phases of the supported cobalt as a function of temperature.

The work was supported by projects MSMT LL2324, GACR 20-21727X, and GAUK 10/252122. The work was supported by projects GAUK 10/252122, GACR 20-21727X, and GAUK Primus/20/SCI/009.

Machine Learning Assisted Realistic Description of Mo-V Mixed Oxide Surfaces — •Kyeonghyeon Nam, Y. Song, L. Masliuk, T. Lunkenbein, A. Trunschke, K. Reuter, and C. Scheurer — Fritz-Haber-Institut der MPG, Berlin

The activity and selectivity of realistic heterogeneous catalysts can be noticeably altered by subtle changes in factors such as bulk composition, dopants, defects, and reaction conditions. These effects are intricately interrelated. To systematically unravel them, we aim to understand their impact on the evolution of catalyst surfaces. Specifically, we focus on the M1 structural modification of $(Mo,V)O_x$ and $(Mo,V,Te,Nb)O_x$ as selective catalysts for the oxidative dehydrogenation of ethane to ethylene.

The large primitive cell of the M1 catalyst poses challenges for a detailed study of its surface terminations using conventional first-principles calculations. To overcome this, we trained machine learning interatomic potentials (MLIPs) using a staged training method from motifs to surfaces. By combining density-functional tight-binding (DFTB) calculations with simulations employing MLIPs, such as molecular dynamics and *ab initio* thermodynamics (AITD), we elucidated the influence of niobium and tellurium doping on enhanced surface structure stability and catalytic activity during the thermal activation. This was supported by experimental *quasi-operando* scanning transmission electron microscopy (STEM) images.

O 82: Plasmonics and Nanooptics: Fabrication, Characterization and Applications II

Femtosecond Direct Laser Writing of Conductive and Electrically Switchable PEDOT:PSS Optical Nanostructures — •Dominik Ludescher[1], Pavel Ruchka[1], Leander Siegle[1], Yanzhe Huang[2], Philipp Flad[1], Monika Ubl[1], Sabine Ludwigs[2], Mario Hentschel[1], and Harald Giessen[1] — [1]4th Physics Institute and Research Center SCoPE, University of Stuttgart, Germany — [2]IPOC - Functional Polymers, Institute of Polymer Chemistry, University of Stuttgart, Germany

Conducting polymers, exemplified by PEDOT:PSS, exhibit distinctive electronic and polymeric attributes. When subjected to CMOS-compatible voltages (-3 V and +2 V), PEDOT:PSS transitions between insulating and metallic states via an intrinsic electrochemical redox reaction. Consequently, this conducting polymer is suited perfectly for AR/VR applications, advanced display technologies, dynamic sensors, and integration with printed optics. The latter application requires a robust foundation in fabrication and the ability to combine 3D printed optics with switchable materials to open the route to dynamic miniaturized optics. We present an alternative fabrication method based on the photon-induced solubility modulation that combines conventional, static photopolymer structures (IP-S) with the dynamic behavior of PEDOT:PSS. Additionally, we demonstrate that the electrical, optical, and dynamic material properties remain even after structuring based on direct laser writing, present the resolution limit at 400 nm structure width, and investigate the switching speed and sample longevity.

O 82.2 Thu 10:45 H8

Revolutionizing OLED Performance and Efficiency with Core-Shell Nanoparticles in HTL and Carbon Dots in ETL Layers — •Zoi Georgiopoulou[1,2], Apostolis Verykios[1], Theodoros Triadis[1], and Maria Vasilopoulou[1] — [1]Institute of Nanoscience and Nanotechnology, National Center for Scientific Research *Demokritos* — [2]Solid State Physics Section, Department of Physics, National and Kapodistrian University of Athens

The development of efficient organic light-emitting diodes (OLEDs) is essential for advancing modern displays and flexible electronics. This presentation explores two methodologies to enhance OLED performance through innovative material integration. The first involves incorporating core-shell nanoparticles into the hole transport layer (HTL). Metal nanoparticles (M-NPs) are encapsulated in a tungsten polyoxometalate (POM) compound and embedded in the PEDOT:PSS layer, leveraging the Localized Surface Plasmon Resonance (LSPR) effect. Analyses, including UV-Vis spectroscopy, atomic force microscopy, and electrical measurements, reveal enhanced optoelectronic properties with POM-M-NP integration. The second approach enhances OLED efficiency by combining carbon dots and a porphyrin layer in the electron transport layer (ETL). Carbon dots improve electron mobility and reduce recombination losses, while the porphyrin layer facilitates charge injection and blocks backflow. This synergy optimizes charge balance, lowers operating voltage, and improves luminous efficiency. These strategies underscore the importance of advanced material engineering in OLED development

O 82.3 Thu 11:00 H8

Engineered disorder metasurfaces for near-field light shaping — •Luca Schmid[1], Julian Schwab[1], Chi Li[2], Stefan Maier[2], Harald Giessen[1], Haoran Ren[2], and Mario Hentschel[1] — [1]4th Physics Institute and Research Center SCoPE, University of Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart, Germany — [2]School of Physics and Astronomy, Monash University, Clayton, Victoria, Australia

Plasmonic and dielectric nanophotonic building blocks allow for shaping the flow of light at boundaries and interfaces. They have opened the field of metasurfaces, which until now mostly allow for the creation of nearly arbitrary far-field intensity distributions in the far field. Drawing inspiration from this concept, we introduce metasurfaces for near-field light shaping. Desired near-field intensity distributions can be created by engineering the distribution of individual scatterers on metallic surfaces and hence the interference of the individually launched surface plasmons. Using this ansatz, we demonstrate engineered-disorder metasurfaces which enable to direct, focus, and demultiplex incident light. We implement these structures by a peel-off process from molds, which results in ultra-smooth metallic surfaces, maximizing the plasmon propagation length. Far-field measurements based on a k-space spectroscopy setup allow us to image the local near-field and show excellent agreement with modelling and simulation. We envision that the creation of nearly arbitrary near-field distributions will enable nanoscale routing and sorting of light based on polarization, orbital angular momentum, and wavelength, as well as help realize novel coupling schemes to emitters and nanoscale systems.

O 82.4 Thu 11:15 H8

Strong polarization-tuned optical nonlinearity via femtosecond-laser plasmonic nanolithography in lithium niobate — •Han Zhu[1,2], Shengqiang Zhou[1], and Feng Chen[2] — [1]Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany — [2]Shandong University, Jinan 250100, China

Despite the advantages of lithium niobate (LN)-based photonic integration platforms in various applications, the inherently weak third-order nonlinear optical response of conventional materials limits the miniaturization and energy efficiency of nonlinear optical devices in compact optical systems. Localized surface plasmons (LSPs) provide a promising solution to this miniaturization challenge by confining and enhancing light fields at deep subwavelength scales. However, due to nanofabrication limitations, strongly coupled single-crystal LN-LSP structures have yet to be realized. Here, we demonstrate Au nanorod-LN hybrid plasmonic structures assembled via plasmonic nanolithography. By leveraging plasmon-mediated energy deposition and photon momentum transfer under femtosecond laser irradiation, the nanoparticles within the single-crystalline region are formed from implanted elements. With plasmons excited in distinct axial directions, the resulting nanorod-LN hybrid plasmonic material exhibits polarization-dependent nonlinearity, with the nonlinear absorption coefficient for long-axis polarized light augmented by five orders of magnitude compared to the pure LN. Utilizing this feature, we develop a Q-switched laser exhibiting pronounced polarization-dependent behavior.

O 82.5 Thu 11:30 H8

Nonlocal Substrate Influence on the Plasmon of a Supported Silver Nanoparticle — Kevin Oldenburg, Karl-Heinz Meiwes-Broer, and •Ingo Barke — ELMI-MV, Department *Life, Light & Matter*, and Institute of Physics, University of Rostock

The effect of a substrate on a particle plasmon (Localized Surface Plasmon Resonance, LSPR) is often considered to be of local nature, where the substrate primarily affects the plasmon at short distances [1]. Here we present spatially resolved plasmon excitation probabilities of a single 11 nm silver nanoparticle deposited from the gas phase onto a narrow rim of a carbon substrate ("cliffhanger"), thus providing a cross-sectional view. We employ electron energy loss spectroscopy (EELS) with a scanning transmission electron microscope (STEM) where we find the strongest substrate effect, i.e., the largest red shift, when the plasmon is excited farthest away. As will be discussed, this non-local substrate influence is a consequence of the simplicity and size of the system. These results are corroborated by simulations based on the boundary element method (BEM), which also help extract the full mode structure from the experimental data. Furthermore, we observe pronounced symmetry breaking, lifting the threefold degeneracy of the dominating dipole modes, potentially resolving long-standing discrepancies in the literature regarding plasmon energies of silver clusters in this size regime [2].

O 82.6 Thu 11:45 H8

Dynamic beam switching using individually adressable plasmonic gratings made from switchable metallic polymer in planar technology — •Jonas Herbig, Dominik Ludescher, Monika Ubl, Mario Hentschel, and Harald Giessen — 4th Physics Institute and Research Center SCoPE, Universität Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart, Germany

The ability to steer light in an optical system is vital for light detection and ranging (LiDAR) applications as required for autonomous driving and technology based on artificial intelligence (AI). One relevant drawback of conventional LiDAR platforms is their large size, making them unsuitable for integration into compact devices. Here, we demonstrate a compact and programmable electrode nanopattern utilizing the structuring of indium tin oxide (ITO) layer in conjunction with the conducting polymer poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS). This structure demonstrates the individ-

ual addressability of multiple subgratings, enabling switching between different superlattice periods with CMOS-compatible voltages, resulting in multiple diffraction angles of up to 26° at a wavelength of 2150 nm. This work lays the foundation for adaptive optics as well as single addressable pixels necessary for advanced display systems and other active devices, such as spatial amplitude and phase modulators exceeding 1000 l/mm.

O 82.7 Thu 12:00 H8

Disorder-driven localization of surface plasmon resonances in disordered assemblies of gold nanoparticles — •Kristina Weinel[1,2,3], Johannes Schultz[1], Mohammed Fayis Kalady[1], Daniel Wolf[1], Leonardo Agudo Jácome[3], and Axel Lubk[1,2] — [1]Leibniz Institute for Solid State and Materials Research (IFW) Dresden, Dresden, Germany — [2]Technical University Dresden (TUD) Dresden, Dresden, Germany — [3]Federal Institute of Materials Research and Testing (BAM), Berlin, Germany

The general wave phenomenon of Anderson localization, which is the absence of diffusion of waves in disordered systems, is studied for surface plasmon waves in two-dimensional disordered systems. To that end disordered assemblies of plasmonic gold nanoparticles (NPs) on an insulating silicon oxide substrate were synthesized by a newly developed synthesis method where an electron beam in a scanning electron microscope is used to heat a gold microparticle precursor until evaporation and deposition of the gold atoms on the substrate forming NPs of varying sizes. To reveal the surface plasmons and their localization behavior, electron energy loss spectroscopy in the transmission electron microscope is applied and compared with self-consistent dipole model simulations. Disorder-driven spatial and spectral localization of the hybridized localized surface plasmon modes was found experimentally and via simulation. Moreover, the localization exhibits a characteristic thickness dependency determining the localization length dependency on the plasmon energy.

O 82.8 Thu 12:15 H8

Nanophotonics of ultra-thin gold flakes — •Gayathri Haridas, Farid Aghashirinov, Julian Schwab, Bettina Frank, and Harald Giessen — 4-th Physics Institute, University of Stuttgart, Germany

In our work, we focus on fabricating ultrathin single-crystalline gold platelets using an electrochemical synthesis approach. This process involves the reduction of gold atoms from the electrode surface to form gold ions, which then nucleate as seeds and grow into well-defined crystalline platelets. By systematically adjusting and controlling the growth parameters, we aim to optimize the synthesis conditions to achieve reproducible and stable fabrication of platelets with precise control over their lateral size and thickness. The characterization of the synthesized platelets is carried out using spectroscopic techniques such as Scanning Electron Microscopy (SEM) and Atomic Force Microscopy (AFM), to understand the surface morphologies and height profiles of the crystals.

The primary objective is to reduce the thickness of platelets to the single-digit nanometer scale while maintaining their lateral sizes. At this regime, the gold platelets exhibit unique optical and electrical properties that are highly sensitive to their size. This arises from the quantization of electronic states. We are particularly interested in probing these quantum effects, which can give rise to further research in the field of quantum plasmonics and thereby establishing gold as a suitable platform for it.

O 83: 2D Materials: Electronic Structure and Exitations III (joint session O/HL/TT)

O 83.1 Thu 10:30 H11

Charge ordered phases in the hole-doped triangular Mott insulator 4*Hb*-TaS_2 — •Byeongin Lee[1], Junho Bang[1], Hyungryul Yang[1], Sunghun Kim[2], Dirk Wulferding[3], and Doohee Cho[1] — [1]Department of Physics, Yonsei University, Seoul 03722, Republic of Korea — [2]Department of Physics, Ajou University, Suwon 16499, Republic of Korea — [3]Center for Correlated Electron Systems, Institute for Basic Science, Seoul 08826, Republic of Korea

4*Hb*-TaS_2 has a unique layered structure, featuring a heterojunction between a 2D triangular Mott insulator and a charge density wave metal. Since a frustrated spin state in the correlated insulating layer is susceptible to charge ordering with carrier doping, it is required to investigate the charge distribution driven by interlayer charge transfer to understand its various phases. In this study, we utilize scanning tunneling microscopy and spectroscopy (STM/S) to examine the charge-ordered phases of 1*T*-TaS_2 layers within 4*Hb*-TaS_2, explicitly focusing on the non-half-filled regime. Our STS findings reveal an energy gap that exhibits an out-of-phase relation of the charge density. We attribute the emergence of the charge-ordered insulating phase in a doped triangular Mott insulator to the interplay between on-site and nonlocal Coulomb repulsion.

O 83.2 Thu 10:45 H11

Superlattice engineering in graphene and 1T-$NbSe_2$ heterostructures — •Keda Jin[1,2], Lennart Klebl[3], Junting Zhao[1,2], Tobias Wichmann[1,5], F. Stefan Tautz[1,5], Felix Lüpke[1], Dante Kennes[4], Jose Martinez-Castro[1,2], and Markus Ternes[1,2] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, 52425 Jülich, Germany — [2]Institut für Experimentalphysik II B, RWTH Aachen, 52074 Aachen, Germany — [3]I. Institute for Theoretical Physics, Universität Hamburg, 22607 Hamburg, Germany — [4]Institut für Theorie der statistischen Physik, RWTH Aachen, 52074 Aachen — [5]Institut für Experimentalphysik IV A, RWTH Aachen, 52074 Aachen, Germany

Superlattice engineering has become a major branch of condensed matter research, not at least due to the variety of exotic states observed twisted in van der Waals heterostructures. We here present a new method to periodically modulate graphene by stacking it on 1T/2H-$NbSe_2$. By tuning the twist angle, we realized two near-commensurate superlattices: $\sqrt{3}\times\sqrt{3}$ and 2×2 aligned with the charge density wave (CDW) of 1T-$NbSe_2$. Using scanning tunnelling microscopy, we visualized local stacking configurations for these two superlattices. We applied a newly developed symmetry analysis method to track rotational symmetry breaking as a function of bias. In the 2×2 superlattice, C_3 rotational symmetry was preserved. However, in the $\sqrt{3}\times\sqrt{3}$, a strong strip phase occurs. This symmetry breaking is explained by our tight-binding model. Our findings highlight a mechanism for superlattice-induced symmetry breaking that hints towards exotic states of matter.

O 83.3 Thu 11:00 H11

Influence of Edge Termination on the Electronic Structure of Single Layer MoS_2 on Graphene/Ir(111) — •Alice Bremerich[1], Marco Thaler[2], Thais Chagas[1], Borna Pielic[1], Laerte Patera[2], and Carsten Busse[1] — [1]Universität Siegen, Deutschland — [2]Universität Innsbruck, Österreich

MoS_2 is the prototypical semiconducting single-layer transition-metal dichalcogenide (TMDC). It exhibits a metallic edge state that induces partial charge accumulation at its edges, resulting in band bending effects. This 1D state acts as a barrier to electron transport across the edge and contributes significantly to quantum confinement effects in TMDC islands. In this study, we tune the edge state and the associated band bending by altering the edge termination of MoS_2/gr/Ir(111) and investigate the resulting changes in the electronic structure by Scanning Tunneling Microscopy and Spectroscopy (STM and STS) at 8 K.

Quasi-freestanding MoS_2 is grown on gr/Ir(111) by Molecular Beam Epitaxy (MBE). We prepare hexagonal islands that exhibit two geometrically different edge types (Mo- and S-type). We vary the chemical potential of sulfur and thereby modify the chemical environment of the boundaries. The partial charge at the perimeter depends on edge type as well as edge chemistry. In consequence, also the upward bending of both valence and conduction band shows distinct variations.

O 83.4 Thu 11:15 H11

magnetic-field-induced dimensionality transition of charge density waves in strained 2H-NbSe2 — •Ryo Ichikawa[1], Yukiko Takahashi[2], Eiichi Inami[3], and Toyo Kazu Yamada[1,4] — [1]Department of Material Science, Chiba University — [2]National Institute for Material Science, Tsukuba — [3]School of system Engineering, Kochi University of Technology — [4]Molecular Chirality Research center, Chiba University

Layered transition metal dichalcogenides (TMDs) exhibit various correlated phases, including charge density waves (CDW), superconductivity, and magnetic orders. Bulk 2H-NbSe2 (2H niobium diselenide) is one of the most extensively studied TMDs, showing a triangular (3Q) incommensurate CDW with a 3a period in real space (3 * 3, TCDW ~ 33 K). Electric and magnetic fields have been used to manipulate spatial or time inversion symmetry, while the CDW in 2H-NbSe2 remains robust even under large magnetic fields on the order of tens of Tesla. However, magnetic-field-sensitive CDWs have been reported in few-layer NbSe2, where a weak magnetic field of approximately 30 mT can switch the electronic phase within the thin film, resulting in a supercurrent diode effect. This study investigates the strained 2H-NbSe2 exhibiting the 2*2 CDW phase. We utilize low-temperature (4.3 K) scanning tunneling microscopy and spectroscopy (STM/STS) in ultrahigh vacuum (UHV). STS maps reveal the coherence of the 2*2 CDW patterns. However, applying an out-of-plane magnetic field induces a dramatic transformation akin to that observed in 1T-NbSe2, shifting the metallic 2D CDW pattern to a 1D CDW pattern.

O 83.5 Thu 11:30 H11

Ultrafast phonons dynamics of monolayer transition metal dichalcogenides — •yiming pan and fabio caruso — Kiel University, Germany

Valley degrees of freedom in transition-metal dichalcogenides influence thoroughly electron-phonon coupling and its nonequilibrium dynamics. Here we present a time-resolved ab-initio study of the ultrafast dynamics of chiral phonons following carrier excitation with circularly-polarized light. By investigating the valley depolarization dynamics of monolayer MoS_2 and WS_2, we find that a population imbalance of carriers distributed at K and K′ can lead to valley polarized phonons persisting beyond 10 ps, and characterized by a distinctive chirality [1]. Additionally, we find that strain can be exploited as a tool to control the phonon emission and the relaxation channels of hot carriers [2]. Finally, we briefly discuss available opportunities for experimental detection of these phenomena

[1] Y. Pan and F. Caruso, Nano Lett. 23, 7463 (2023)

O 83.6 Thu 11:45 H11

Probing Excitonic Properties and Structural Effects in WS_2-Graphene Heterostructures Using EELS and DFT-BSE Modeling — •Max Bergmann, Jürgen Belz, Oliver Massmeyer, Robin Günkel, Badrosadat Ojaghi Dogahe, Andreas Beyer, Stefan Wippermann, and Kerstin Volz — Department of Physics, Philipps-Universität Marburg, Germany

This study investigates the excitonic properties of WS_2 epitaxially grown on graphene by metal-organic chemical vapor deposition. We focus on understanding the effects of structural changes, such as variations in the number of WS_2 layers. Using monochromatic electron energy loss spectroscopy (EELS) in a scanning transmission electron microscope (STEM), we observe in the monolayer region of WS_2 an excitonic spectrum with excitonic peaks at 2.0 eV and 2.4 eV, as well as additional spectral features at higher energies. Measurements in the bilayer region show a small redshift of these features due to the additional layer. Complementary density functional theory and Bethe-Salpeter calculations show that this redshift in the K-valley excitons is due to both a change in quantum confinement and a change in the WS_2 lattice constant, with the latter being the dominant effect. Using STEM, this lattice distortion can be attributed to the heteroepitaxial alignment of the lower WS_2 layer to the graphene substrate, while the upper layer is relaxed. This study provides valuable insights into the relationship between atomic structure and optical properties in complex material systems, providing essential knowledge for the design and optimization of 2D heterostructures for advanced device applications.

O 83.7 Thu 12:00 H11

Optical excitations in 2H-MoS_2 bilayers under pressure — •Jan-Hauke Graalmann[1], Paul Steeger[2], Rudolf Bratschitsch[2], and Michael Rohlfing[1] — [1]University of Münster, Institute of Solid State Theory, Münster, Germany — [2]University of Münster, Institute of Physics and Center for Nanotechnology, Münster, Germany

Theoretical and experimental investigations have shown several changes in the optical spectrum of the 2H-MoS_2 bilayer under pressure [1].

By using density functional theory (DFT) and many-body perturbation theory in combination with linear elasticity, our computational investigations show an effective shift of the A exciton under pressure. It is strongly connected to the behavior of the direct band gap at the K point, which shifts in energy under pressure. The direction of this shift depends on the stress condition. While a hydrostatic pressure leads to a blueshift, a suppression of the in-plane contraction, as it appears in diamond anvil cell-experiments due to the interaction between the sample and the substrate, shows a redshift.

Moreover, we observe a similar behavior for the interlayer exciton, whereas the shift rate is smaller than that of the A exciton, which results in a decreasing A-IL splitting for an increasing pressure.

[1] P. Steeger, J. Graalmann et al., Nano Lett., 23, (2023)

O 83.8 Thu 12:15 H11

Visualizing and controlling charge states of metal nanoislands on a two dimensional semiconductor — •Junho Bang[1], Byeongin Lee[1], Jian-Feng Ge[2], and Doohee Cho[1] — [1]Department of Physics, Yonsei University, Seoul, Korea — [2]Department of Topological Quantum Chemistry, Max Planck Institute for Chemical Physics of Solids, München, Germany

Nanoscale objects show unique electronic behaviors when weakly coupled to electrodes. Coulomb blockade (CB) can occur in such systems, where the repulsive Coulomb interaction between electrons prevents additional electrons from entering the quantum dots, hindering their flow. Single electron tunneling occurs by these correlated electron transports, leading to the discrete charge states of objects in double barrier tunneling junctions. Despite enormous progress, challenges remain in precisely controlling the interplay between objects' charge states and tunneling dynamics under varying conditions. Here, we visualize the charge states and their spatial variation on the random array of the indium islands on two-dimensional semiconductor black phosphorus using scanning tunneling microscopy and spectroscopy. Our spatially resolved tunneling spectra reveal that the junction capacitance varies across the islands. Furthermore, we find that the CB features are visible outside the islands, which is attributed to the remote gating of the islands. Our work advances the manipulation of electron transport at the nanoscale, which will be helpful in the application of nanoscale object-based single-electron devices.

CO cryo-sorption on a FeNC catalyst as a spectroscopic probe of the active site density — •Benedikt P. Klein[1,3], Beomgyun Jeong[1], Hafiz Ghulam Abbas[2], Geunsu Bae[2], Adith R. Velmurugan[2], Chang Hyuck Choi[4], Geonhwa Kim[5], Dongwoo Kim[5], Ki-jeong Kim[5], Byeong Jun Cha[6], Young Dok Kim[6], Frederic Jaouen[7], Reinhard J. Maurer[3], and Stefan Ringe[2] — [1]Korea Basic Science Institute, Daejeon, ROK — [2]Korea University, Seoul, ROK — [3]University of Warwick, Coventry, UK — [4]POSTECH, Pohang, ROK — [5]PAL, Pohang, ROK — [6]Sungkyukwan University, Suwon, ROK — [7]University of Montpellier, France

To quantify the number of active sites in a catalyst is a crucial necessity for the evaluation of its performance. A possible quantification approach is the adsorption of a gas molecule to the catalytically active sites as a probe. If the adsorbed molecules can be reliably detected, their surface density can be determined by using spectroscopic techniques and the active site density of the catalyst can be obtained. For this approach it is necessary to identify the probe molecules according to their spectroscopic features, a task much helped by the computational simulation of spectra. In this the NAP-XPS and NAP-NEXAFS study, we present direct spectroscopic evidence for the adsorption of CO on an iron-nitrogen-carbon (FeNC) catalyst. The well defined spectroscopic features enable us to determine the active site density using by experimental data combined with state-of-the-art DFT based spectroscopy simulation.

O 84.2 Thu 11:00 H24

Nano-optical imaging of grating-coupled waveguide modes in 3R-MoS_2 — •Fabian Mooshammer[1], Xinyi Xu[2], Chiara Trovatello[2], P. James Schuck[2], and D. N. Basov[3] — [1]Regensburg Center for Ultrafast Nanoscopy (RUN), University of Regensburg, Regensburg, Germany — [2]Department of Mechanical Engineering, Columbia University, New York, USA — [3]Department of Physics, Columbia University, New York, USA

Waveguide modes in thin slabs of van der Waals crystals serve as reliable probes of the anisotropic dielectric response of the material and also hold great potential for the implementation of on-chip optical elements. Here, we show that near-field imaging can resolve the propagation patterns of waveguide modes, which encode the birefringence of transition metal dichalcogenides. We use a laser patterning procedure to write grating structures into 3R-MoS_2 crystals with grooves as sharp as 250 nm. Spatial maps of the scattered electric field in the vicinity of the gratings reveal a directional, polarization-splitting outcoupling of waveguide modes, which is in line with finite element simulations. Experiments over a range of near-infrared photon energies provide key parameters for waveguide second-harmonic generation. The latter is finally demonstrated by grating-coupling femtosecond pulses into the slabs. In the future, nano-optical imaging may be used to directly capture the frequency conversion process during the propagation of the modes. Our work demonstrates the feasibility of compact frequency converters and examines the tunings knobs that enable optimized coupling into layered waveguides.

Imaging Infrared Materials Excitations with Sum-Frequency Spectro-Microscopy — •Niclas S. Mueller[1], Alexander Fellows[1], Richarda Niemann[1,2], Andrew E. Naclerio[2], Ryan A. Kowalski[2], Ben John[1], Katayoun Gharagozloo-Hubmann[3], Soeren Wasserroth[1], Guanyu Lu[2,4], Joshua D. Caldwell[2], Piran R. Kidambi[2], Martin Wolf[1], Martin Thaemer[1], and Alexander Paarmann[1] — [1]Fritz-Haber-Institute of the Max-Planck-Society, Berlin, Germany — [2]Vanderbilt University, Nashville, TN, USA — [3]Freie Universitaet Berlin, Berlin, Germany — [4]Northwestern University, Evanston, IL, USA

Nonlinear optical microscopy and spectroscopy are powerful tools to characterize interfaces and lower-dimensional materials. Here, I show two examples how we use infrared + visible sum-frequency generation (SFG) to image mid-infrared

materials excitations with wide-field optical microscopy. The techniques provide combined spatial and spectral information, with sub-diffractional spatial resolution. 1. We visualize the propagation of infrared phonon polaritons in a metasurface of silicon carbide [1]. Through a combination of microscopy and spectroscopy, we observe the hybridization and strong coupling of propagating and localized polaritons, as well as the activation of edge states. 2. We visualize monolayers of hexagonal boron nitride, which are usually optically invisible. Resonant infrared excitation of phonons and heterodyne sum-frequency imaging enable us to image, both, the local topography and crystal orientation with unprecedented detail.

Towards Understanding Surface Restructuring: Automatic Process Exploration and Local Environment Analysis — •Patricia Poths, King Chun Lai, Francesco Cannizzaro, Christoph Scheurer, Sebastian Matera, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin

The formation of surface oxides on the Pd(100) surface is a prototypical example of catalyst surface restructuring under *operando* conditions. Despite extensive investigation of this process, its mechanism and corresponding time scales remain unknown. By combining a Machine-Learned Interatomic Potential with our newly-developed Automatic Process Explorer (APE) [1], we study the O-induced restructuring of the Pd(410) vicinal surface as an example for step-edge initiation of oxide formation. We identify ~3,000 unique elementary processes. Taking first steps towards a comprehensive mechanism, we analyze this rich library of processes utilizing a fuzzy classification methodology [2]. Many identified pathways involve non-intuitive complex collective motion of several atoms. These pathways can explain experimentally-observed restructuring, such as step bunching or microfaceting. Furthermore, the time scales of the majority of restructuring pathways are comparable to those of catalytic processes, implying significant coupling between surface restructuring and catalysis [3].

O 84.5 Thu 12:30 H24

band engineering via metal substitution in porphyrin-graphene hybrid systems — •feifei xiang[1], yanwei gu[2], amogh kinikar[1], nicolò bassi[1], andres ortega-guerrero[1], carlo a. pignedoli[1], giovanni bottari[3], tomás torres[3], klaus müllen[2], pascal ruffieux[1], and roman fasel[1] — [1]Empa, Swiss Federal Laboratories for Materials Science and Technology, 8600 Dübendorf, Switzerland — [2]Synthetic Chemistry, Max Planck Institute for Polymer Research, 55128 Mainz, Germany — [3]Departamento de Química Orgánica Universidad Autónoma de Madrid Madrid 28049, Spain

Graphene and its derivatives serve as a versatile platform for finely tuning physical properties across a wide range. Expanding the potential applications of graphene to optoelectronics and gas sensing has driven the development of new materials including hybrid molecular systems that integrate porphyrins with graphene. On-surface synthesis provides a viable approach to achieving such well-defined hybrid structures. Here, we present the synthesis and characterization of porphyrin-graphene hybrid systems (chemrxiv-2024-z9rgh), in which the porphyrin units feature varying metal substitutions. The strong electronic coupling between porphyrin and tailored graphene nanostructures enables the metal center to play a significant role in modulating the band structure through charge doping, and to generate new hybrid states arising from d-π interactions, which allows long range spin coupling between magnetic metal centers. Such robust hybrid molecular systems hold promise in applications in p-n heterojunctions and paves the way towards achieving coherent control of spin chains.

Quantifying the conductance of molecular structural variables using machine learning — •Hector Vazquez — Inst. of Physics, Czech Academy of Sciences

In single molecule electronics, where individual molecules are placed between two nanoscale electrodes, conductance depends critically on the geometry at the junction. Atomistic simulations using DFT-NEGF are ideally suited to address this, but their computational cost restricts their use to only few junction geometries. In experiments, however, molecular geometry is thought to change significantly since measurements are often carried out at room temperature.

Here we use an approximate method to calculate molecular conductance within DFT for thousands of geometries [1]. The method uses small Au-molecule-Au clusters and is thus computationally very efficient, yet reproduces DFT-NEGF conductance well. Combined with MD simulations of the junction, we compute for thousands of geometries the variation in conductance arising from thermally-induced conformational changes in the molecule.

We use machine-learning methods to identify which of the molecular structural parameters, all of which are changing continuously and simultaneously during the MD simulations, have a greater impact in conductance. This elucidates how molecular conformational changes contribute to the width of the conductance signal in single molecule junctions.

O 85.2 Thu 10:45 H25

Efficient implementation of charge-equilibration schemes for fourth-generation machine learning potentials — •Moritz R. Schäfer[1,2], Moritz Gubler[3], Stefan Goedecker[3], and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany — [3]Department of Physics, University of Basel, Switzerland

Fourth-generation high-dimensional neural network potentials (4G-HDNNPs) are a modern technique to compute energies and forces with close to ab initio accuracy for conducting extensive molecular dynamics simulations of complex systems. They are based on global information and include long-range charge transfer, electrostatics and atomic energies to describe the interactions in a system. A central component of 4G-HDNNPs is a charge equilibration (Q_{eq}) step, which due to its non-local nature dominates the computational costs. Here, we discuss efficient implementation strategies, and show their performance on selected benchmark systems.

O 85.3 Thu 11:00 H25

Real-time Bethe-Salpeter Equation for optical properties of molecules – Implementation and benchmark calculations — •Štěpán Marek, Maximilian Graml, and Jan Wilhelm — Institute of Theoretical Physics and Regensburg Center for Ultrafast Nanoscopy, University of Regensburg, Regensburg, Germany

We present an implementation of a real-time version of the Bethe-Salpeter equation (RT-BSE) in CP2K, offering new capabilities for investigating electron dynamics in molecules under laser excitation. The RT-BSE implementation is tested on Thiel's molecular benchmark set - a set of organic molecules of various types. We evaluate the accuracy and performance of the RT-BSE approach for the determination of absorption spectra of molecules, with respect to the Casida-BSE approach. We discuss the scaling of the method to show its potential for studying optical properties of large molecules and complex materials.

O 85.4 Thu 11:15 H25

Extension of FLAPW method FLEUR to phonon calculations of polar solids using DFPT — •Friedrich Hanrath[1,2], Thomas Bornhake[1,2], Gregor Michalicek[1], Daniel Wortmann[1], Gustav Bihlmayer[1], and Stefan Blügel[1,2] — [1]Peter Grünberg Institut, Forschungszentrum Jülich and JARA, Jülich, Germany — [2]Physics Department, RWTH Aachen University, Aachen, Germany

Phonons play a pivotal role in determining important properties of solids. In polar materials, phononic vibrations are altered by the interaction of macroscopic electric fields in the limit of long wavelengths. This gives rise to the characteristic splitting of longitudinal and transversal optical phonon frequencies. Density function perturbation theory (DFPT) is a state-of-the-art approach to calculate many essential physical properties of solids from first principles. By using an ionic displacement perturbation, it has previously been employed in order to calculate phonons in the framework of the full-potential linearized augmented plane-wave method FLEUR [1, 2]. — In this talk, this method is extended to a macroscopic homogeneous electric field perturbation allowing the calculation of static dielectric properties, Born effective charges and hence LO-TO-splitting. We present the current results for the static dielectric tensor for various semiconductors and insulators by comparing them with experimental results.

This work was supported by the CoE-MaX (EuroHPC JU, Grant No. 101093374) and DFG through CRC 1238 (Project C01).

Efficient treatment of long-range electrostatics in charge equilibration approaches — •Kamila Savvidi, Ludwig Ahrens-Iwers, and Robert Meissner — Hamburg University of Technology, Hamburg, Germany

We present a charge equilibration (QEq) method in the Large-scale Atomic/Molecular Massively Parallel Simulator (LAMMPS) based on real-space Gaussians of width η_i as charge densities. This implementation builds on the `ELECTRODE` package, which already supports Gaussian charge densities [1]. In addition, an efficient particle-particle particle-mesh k-space solver [2] is used, which significantly improves the computational performance compared to existing QEq implementations in LAMMPS. We validate our approach with the test cases of Ti/TiO_x and SiO_2 polymorphs. In the limit of very narrow Gaussians, we were able to show that our algorithm converges to EEM results for the case of Ti/TiO_x. By fitting the Coulomb energy of two isolated Gaussian charge distributions to the repulsion between two Slater-type orbitals, optimized widths for Si and O were obtained that led to results in good agreement to previous studies using STOs instead of Gaussians.

O 85.6 Thu 11:45 H25

Machine Learning for Polaronic Materials: TiO_2(110) at the nanoscale — •Firat Yalcin[1], Simon Trivisonne[1], Viktor Birschitzky[1], Carla Verdi[2], and Michele Reticcioli[1,3] — [1]University of Vienna, Austria — [2]University of Queensland, Australia — [3]CNR-SPIN L'Aquila, Italy

The combination of machine learning (ML) with density functional theory accelerates material simulations, expanding both spatial and temporal scales. However, current ML methods struggle to address polaron trapping. We present a novel machine learning force field (MLFF) approach that incorporates polaron trapping descriptors, enabling large-scale studies of polaronic materials. Using TiO_2(110) as a case study, we reveal how Nb dopants and oxygen vacancies affect polaron configurations and drive catalytic CO adsorption. Additionally, our method captures the dynamic evolution of polarons with unprecedented statistical robustness. This work advances fundamental understanding of defect-polaron interactions while offering a fully-automated and efficient computational suite for the study of polaronic materials.

O 85.7 Thu 12:00 H25

Uncertainty quantification for DFT calculations — •Teitur Hansen[1], Thomas Bligaard[2], and Karsten W. Jacobsen[1] — [1]DTU Physics, Kongens Lyngby, Denmark — [2]DTU Energy, Kongens Lyngby, Denmark

Density functional theory (DFT) is widely used for understanding material properties and chemical reactions. DFT simulations use approximations which result in errors when comparing to experiments. There are errors in different types of energies, lattice constants and other properties. Quantitative uncertainty estimates would be helpful for DFT simulations to highlight which results are trustworthy. Quantifying uncertainties not only improves trust in calculations but also identifies high-uncertainty predictions that can subsequently be revisited and reanalyzed.

We propose a method to model uncertainties using a probability distribution over exchange-correlation functionals. The probability distribution is trained on experimental values of molecular atomization energies, cohesive energies of solids, reactions energies, heat of formations, and lattice constants. The optimized probability distribution is then used to define an ensemble method which can be used to estimate the bias and variance on simulated materials properties. I will demonstrate that the method gives systematic improvements in error estimates over the Bayesian error estimation class of functionals (BEEF).

The proposed method is general enough to be applied to any simulation methodology where accurate reference benchmarks exist.

O 85.8 Thu 12:15 H25

Assessment of the Accuracy of Equation-of-motion Coupled- cluster band gaps in the Bulk Limit — •Evgeny Moerman[1], Alejandro Gallo[2], Andreas Irmler[2], Andreas Grüneis[2], and Matthias Scheffler[1] — [1]The NOMAD Laboratory at the FHI- MPG, Berlin — [2]Institute for Theoretical Physics, TU Wien, Vienna

As a highly regarded theoretical framework in molecular quantum chemistry, coupled-cluster (CC) theory is expected to yield reliable and systematically improvable results for both ground-state and ex cited state properties of materials. One major obstacle to obtaining converged CC results for periodic solids is the often slow convergence with respect to system size. We have investigated the finite-size convergence behaviour of band gaps in equation-of-motion CC (EOM-CC) theory and revealed a direct relation to the GW approximation [1]. Based on these findings, a GW-aided scheme to reliably estimate the size-converged EOM-CC band gap has been developed and tested [2], allowing to assess the true accuracy of the widely used EOM-CCSD method in the periodic case. We find that the accuracy of EOM-CCSD band gaps sensitively depends on the magnitude of orbital relaxation effects, suggesting that such low-order truncation methods as EOM- CCSD may not be sufficiently accurate even for simple materials and that higher orders of correlations seem to be necessary. - This work received support from the European Union's Horizon 2020 research and innovation program under Grant Agreement No.740233.

O 85.9 Thu 12:30 H25

Full periodic real-time TD-DFTB implementation for solids and low-dimensional materials — •Carlos R. Lien-Medrano[1], Franco P. Bonafé[2], Matías Berdakín[3], Cristián G. Sánchez[4], and Michael Sentef[1,2] — [1]University of Bremen, Bremen, Germany — [2]MPSD, Hamburg, Germany — [3]Universidad Nacional de Córdoba, Córdoba, Argentina — [4]Universidad Nacioanl de Cuyo, Mendoza, Argentina

The current real-time time-dependent density functional tight-binding (TD-DFTB) dynamics implementation in the DFTB+ package [1] employs the length gauge of the electric field. In this work, we introduce an implementation of the vector potential within the velocity gauge framework. This approach enables the extension of real-time dynamics simulations to periodic systems along arbitrary spatial directions, making it applicable to photo-induced dynamical processes in bulk, low-dimensional materials, and surfaces. To demonstrate its potential, we present proof-of-concept applications, including the inhomogeneous optical absorption around the K point in graphene, light absorption in bulk materials, and prospective applications in the field of valleytronics.

Low temperature STM/AFM detection of 2D electronic gas on reduced $SrTiO_3$ surface — •Akash Gupta, Marcin Kisiel, Remy Pawlak, and Ernst meyer — Department of Physics, University of Basel, Klingelbergstrasse 82, CH-4056 Basel, Switzerland

Perovskite such as $SrTiO_3$ ubiquitous to host various reconstruction with fine tuning of the annealing temperature. At 1050˚C, in oxygen poor conditions, a $\sqrt{5}\times\sqrt{5}$ surface reconstruction is formed with oxygen vacancies. These oxygen vacancies result in compactly confined electrons as two-dimensional electron gas (2DEG) system. The 2DEG is confirmed as filled surface states in Low Temperature (4 K, UHV) Scanning Tunneling Spectroscopy (STS). Additionally, Image Potential States (IPS) emerges at lower energies than vacuum level, revealing work function, as well. The charging of this 2DEG system can be induced with capacitively coupled tip of Atomic Force Microscope, and it results in giant dissipation peaks as signature of surface charging with change in the tip-sample voltage. Furthermore, quantum capacitance is calculated as function of the gate voltage. The evolution of dissipation peaks were observed with tip-sample distance. The Force-Distance curves confirm the 2DEG charging and is used to determine the tunneling rate of the charging within 2DEG system.

O 86.2 Thu 15:15 H2

Tunneling Spectroscopy of RuO_2(110): Electronic Structure, Correlation Effects and Substrate Interactions — •Philipp Kessler, Andreas Feuerpfeil, Hendrik Hohmann, Matteo Dürrnagel, Armando Consiglio, Jonas Erhardt, Michael Sing, Ralph Claessen, Ronny Thomale, and Simon Moser — Physikalisches Institut, Universität Würzburg, 97074 Würzburg, Germany

The (110) surface of RuO_2 hosts a flat band surface state (FBSS) close to the Fermi level that is prone to Fermi surface instabilities and can be readily observed in angle resolved photoemission. A local spectroscopic investigation of this FBSS to study such instabilities is, however, still outstanding. In this talk, we present the synthesis of high quality RuO_2(110) surfaces, enabling systematic scanning tunneling spectroscopy (STS) measurements across wide defect free domains. We observe hints of correlation effects, manifesting in signatures of a charge density wave and a zero-bias anomaly. Furthermore, we offer preliminary evidence suggesting that the electronic structure of RuO_2 depends on the oxide film thickness and immediate screening environment within the substrate. These findings illuminate the interplay between the Ru metal substrate and the RuO_2 oxide, advancing this topical material.

O 86.3 Thu 15:30 H2

Quasi-particle interference studies on ultra-thin films of Cu(111) — •Jungin Yeo — Chung-Ang University, Seoul 06974, Republic of Korea

Recently, ultra-thin crystalline Cu(111) film has been successfully grown on a sapphire substrate through the atomic sputtering epitaxy (ASE). In-depth studies were conducted to explore the crystal growth mechanism and the oxidation process. Ultra-thin film without grain boundary (GB) shows hidden intrinsic nature such as transport by hole carriers. Meanwhile, twin boundaries (TB) appear inevitably during the growth even such an atomically high-quality film. As two orientations adjacent to a TB satisfy the symmetry operation exactly, TBs are expected to show different electronic properties from GBs. The unique electronic properties resulting from the two-dimensional nature and the presence of TBs are currently under investigation. For our study, we utilized scanning tunneling microscopy (STM) to examine 20 nm thick ASE-grown Cu(111) films. The STM topography revealed an atomically flat surface with an indication of twin boundaries. We performed quasi-particle interference (QPI) measurements across TBs. The surface states of Cu(111) and quantum-confined states within the film thickness were successfully resolved. By analyzing the QPI data, we were able to reconstruct the electronic dispersion near the Fermi energy, both at the surface and within the bulk of 20 nm thick. The transmission probability across TBs will be discussed.

O 86.4 Thu 15:45 H2

Electronic structure of the correlated topological metals $CoTe_2$ and $NiTe_2$ — Abhijeet Shelke[1], Chien-Wen Chuang[2], Truc Ly Nguyen[1], Yo-Xun Chen[1], Masato Yoshimura[1], Nozomu Hiraoka[1], Satoru Hamamoto[3], Masaki Oura[3], Chia-Nung Kuo[4], Chin-Shan Lue[4], Atsushi Fujimori[5,1], and •Ashish Chainani[1] — [1]National Synchrotron Radiation Research Center, Hsinchu 300092, Taiwan — [2]Dept. of Physics, Tohoku University, Sendai 980-8578, Japan — [3]RIKEN SPring-8 Center, Hyogo 679-5148, Japan — [4]Dept. of Physics, NCKU, Tainan 70101, Taiwan — [5]Dept. of Physics, The University of Tokyo, Tokyo 113-0033, Japan

The transition-metal(TM) tellurides $CoTe_2$ and $NiTe_2$ are known to exhibit topological semi-metallic Dirac bands from ARPES studies. We carry out core level and valence band measurements using hard x-ray photoemission spectroscopy(HAXPES), x-ray absorption spectroscopy(XAS) and TM $2p-3d$ resonant photoemission spectroscopy(R-PES) to study electronic structure of $CoTe_2$ and $NiTe_2$. The R-PES spectra show clear evidence of TM LVV Auger two-hole correlation satellites. Using the Cini-Sawatzky method, we estimate an on-site Coulomb energy, U_{dd}~3 eV for Co in $CoTe_2$, and U_{dd}~4 eV for Ni in $NiTe_2$. Using these values in charge-transfer cluster model calculations, we simulate the TM $2p$ HAXPES core level and L-edge XAS spectra of $CoTe_2$ and $NiTe_2$. The electronic parameter analyses indicate a negative charge transfer energy Δ for both $CoTe_2$ and $NiTe_2$. The results indicate a p-type metal in terms of the Zaanen-Sawatzky-Allen phase diagram for $CoTe_2$ and $NiTe_2$.

O 86.5 Thu 16:00 H2

Visualizing topological ladder in $PtTe_2$ — •Mohammed Qahosh[1], Gustav Bihlmayer[2], Jakub Schusser[3], Muthu Masilamani[3], Friedrich Reinert[3], Claus M. Schneider[1], and Lukasz Plucinski[1] — [1]PGI-6 Forschungszentrum-Jülich — [2]PGI-1/IAS-1 Forschungszentrum-Jülich — [3]Experimentelle Physik VII and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg

We have examined the topological ladder [1] and band inversions in $PtTe_2$ using spin-polarized angle-resolved photoemission (spin-ARPES) with two-dimensional momentum imaging. Examining such spin images allows in-depth insight into the topological properties, not accessible by routine methods. We mapped extended momentum-space regions and visualized distinct topological ladder states, notably a surface Dirac cone at $E_B \sim 2.3$ eV, as well as states at $E_B \sim 1.0$ eV, $E_B \sim 1.6$ eV, and near the Fermi level. By comparison to *ab initio* calculations, we demonstrate a significant correlation between the measured and the initial state spin polarization. We discuss interatomic phase shifts [2] for orbitals mixed between Pt and Te sites as well as spin-orbit scattering that leads to additional spin polarization in spin-ARPES. [1] Nature Materials 17, 21 (2018). [2] Phys. Rev. Lett. 130, 146401 (2023).

O 86.6 Thu 16:15 H2

Origin of the Spin-Polarized Fermi Surface of a Tl Bilayer on Ag(111) — •Sven Schemmelmann[1], Yuichiro Toichi[2], Peter Krüger[3], Kazuyuki Sakamoto[2], and Markus Donath[1] — [1]Physikalisches Institut, Universität Münster, Germany — [2]Department of Applied Physics, Osaka University, Japan — [3]Institut für Festkörpertheorie, Universität Münster, Germany

ARPES measurements have shown that the Fermi surface of a Tl bilayer grown on Ag(111) exhibits two hexagonal-shaped states [1]. While the inner one is fully spin polarized, the outer one appears to be unpolarized. Spin-resolved inverse photoemission experiments of the unoccupied states reveal the origin of this peculiar behavior. We observe two downward dispersing states which are both spin split. The two spin branches of the one state are responsible for the two states observed forming the Fermi surface. Interestingly, the spin up branch coincides with the spin down branch of the other downward dispersing state. This is the reason why this state appears to be unpolarized.

[1] T. Kobayashi *et al.*, Nano Lett. **23**, 7675 (2023)

O 86.7 Thu 16:30 H2

Analyzing excitonic contributions to reflection anisotropy spectra — •Max Grossmann[1], Kai Daniel Hanke[2], Chris Yannic Bohlemann[2], Thomas Hannappel[2], Wolf Gero Schmidt[3], and Erich Runge[1] — [1]Theoretical Physics I, Institute of Physics, Technische Universität Ilmenau, 98693 Ilmenau, Germany — [2]Fundamentals of Energy Materials, Institute of Physics, Technische Universität Ilmenau, 98693 Ilmenau, Germany — [3]Lehrstuhl für Theoretische Materialphysik, Universität Paderborn, 33095 Paderborn, Germany

Reflection anisotropy spectroscopy (RAS) is a powerful optical tool for probing semiconductor surfaces. However, the interpretation of RA spectra is challenging due to the complex interplay of features caused by surface states and so-called surface-induced bulk anisotropy, as well as the significant influence of excitonic effects. Overcoming these challenges requires a close collaboration between experiment and theory. In this work, we combine high-quality low-temperature RAS measurements with state-of-the-art *ab initio* calculations in the framework of many-body perturbation theory to study the RAS of arsenic-terminated Si(100) surfaces. The excitonic contributions to the RAS are studied in detail through a thorough analysis of the results from a solution of the Bethe-Salpeter equation. Our approach aims to combine experimental observations with theoretical insights to decipher the complex effects that shape RAS spectra and to advance the understanding of the optical properties of semiconductor surfaces.

O 86.8 Thu 16:45 H2

Composition and band gap of aluminum alloyed beta-gallium oxide determined by XPS — •Lukas Schewe[1], Jana Rehm[2], Ming-Chao Kao[3], Vedran Vonk[3], Zbigniew Galazka[2], Saud Bin Anooz[2], Andreas Popp[2], and Jan Ingo Flege[1] — [1]Fachgebiet Angewandte Physik und Halbleiterspektroskopie, BTU Cottbus-Senftenberg — [2]Leibnitz-Institut für Kristallzüchtung, Berlin — [3]CXNS-Center for X-ray and Nano Science, DESY Hamburg

Beta-phase gallium oxide is a wide-gap semiconductor with a band gap of 4.85eV and promising prospects in high-power electronics. The electric breakdown field can be increased by alloying the oxide with aluminum, further enhancing its properties.

The present work discusses structural and electronic properties of β-$(Al_xGa_{1-x})_2O_3$ thin films and bulk crystals with Al content of up to 33 %. Their Al content was determined by X-ray photo-electron spectroscopy (XPS) and compared to the values estimated from X-ray diffraction (XRD) and inductively coupled plasma optical emission spectroscopy (ICP-OES). Additionally, the thin films have been investigated by XPS depth profiling, i.e., XPS combined by sequential Ar^+ sputtering, revealing lower aluminum content at the sample surface, which points to possible surface segregation of gallium during annealing. Furthermore, the band gap was determined by electron loss spectra from XPS and optical absorbance measurements and correlated to the Al content estimated for both thin films and bulk crystals.

O 86.9 Thu 17:00 H2

Higher-order van Hove singularities in Kagome metal RbV_3Sb_5 — •Gahee Lee — Department of Physics, Chung-Ang University, Seoul 06974, Republic of Korea

The divergence of the density of states (DOS) near the Fermi energy is crucial for enhancing electron correlations. Van Hove singularities (vHS) commonly cause this DOS divergence, with their properties determined by the dimensionality of electron dispersion. The atomic arrangement on the surface of layered materials can influence the effective dimensionality of electron dispersion, thereby shaping the characteristics of vHS. In V-based Kagome metals RbV_3Sb_5 (A = K, Rb, and Cs), the saddle-shaped dispersion results in two-dimensional vHS. Interestingly, the surface arrangement of atoms in a Kagome lattice can modify the effective dimensionality of electron dispersion, affecting the strength of electron correlations. In this study, we present a novel approach to enhancing electron correlation by arranging the surface Rb atoms. The resulting higher-order vHS significantly enhances the divergence of DOS and strengthens charge density waves in V-based Kagome metals.

O 86.10 Thu 17:15 H2

Single Hemisphere & Time-of-Flight Hybrid Photoelectron Momentum Microscopy — •Olena Tkach[1], Matthias Schmitt[2,3], Deepnarayan Biswas[2], Olena Fedchenko[1], Jieyi Liu[2], Hans-Joachim Elmers[1], Michael Sing[3], Ralph Claessen[3], Tien-Lin Lee[2], and Gerd Schönhense[1] — [1]JGU Mainz, Germany — [2]DIAMOND, Didcot, United Kingdom — [3]Universität Würzburg and Würzburg-Dresden Cluster of Excellence ct.qmat, Germany

The 2ns pulse period of the photon beams from most synchrotrons is too short for pure time-of-flight (ToF) photoelectron spectroscopy. With the use of a hemispherical analyzer (HSA) as a pre-filter, ToF momentum microscopy becomes possible at such high pulse rates. The first hemisphere & ToF hybrid MM

is operated at the soft X-ray branch (photon energies from 105 eV to 2 keV) of beamline I09 at DIAMOND. The HSA reduces the transmitted energy band to typically 0.5 eV, which is then dispersed by ToF recording. In the first experiments the total efficiency gain when switching from the standard 2D (k_x, k_y) to the 3D (k_x, k_y, E_{kin}) hybrid mode was about 25. It is determined by the number of resolved kinetic energies (here 12) and the transmission factor of the electron optics due to the higher pass energy (500 eV) of the HSA in hybrid mode. The α^2- term and the transit time spread due to different path lengths in the HSA are numerically corrected. The performance was validated by studying the well-known electronic structure of Au(111) and Cu(111), including circular dichroism (CDAD) measurements. The high efficiency was exploited in a series of measurements on the Kagome metal CsV_3Sb_5.

Nonlinear plasmonic near– and far fields in the context of Babinet's Principle — •Valentin Dichtl, Thorsten Schumacher, and Markus Lippitz — Experimental Physics III, University of Bayreuth

The third-order nonlinear material response of noble metals enables the formation of the third-harmonic near field around a plasmonic nanostructure [1]. The corresponding spatial emission pattern of the third-harmonic hot spots changes drastically when the fundamental wavelength is slightly tuned over a linear resonance of the nanorod.

However, third harmonic generation (THG) also leads to high temperatures in the structure and its surroundings. These temperatures are usually high enough to destroy more complex samples. Therefore, structures with the same emission properties but a higher ratio of THG to temperature are needed.

To overcome this, we are inspired by the Babinet principle. In this sense, a rod antenna can be replaced by a slit in a thin layer of gold. The surrounding gold should now dissipate heat more effectively than a single rod. This talk compares the (non-linear) emission properties of plasmonic nanostructures and their complementary counterparts, highlighting the applicability of Babinet's Principle.

Beyond-dipole, self-consistent light-matter coupling in plasmonic cavities from first principles — •Franco Bonafe[1], Carlos Bustamante[1], Heiko Appel[1], and Angel Rubio[1,2] — [1]MPI for Structure and Dynamics of Matter, Hamburg, Germany — [2]Center for Computational Quantum Physics (CCQ), The Flatiron Institute, New York, USA

The theoretical treatment of light-matter coupling of molecules in complex electromagnetic (EM) environments is key for making progress in the area of modified matter properties in cavities and strong coupling. While several semiclassical methods can treat the coupling of molecules with EM environments, no method has yet considered the combined effects of self-consistent radiative coupling of molecule and environement, and beyond-electric-dipole interactions to account for the effects of inhomogeneous EM fields. This multiscale problem is now possible to address using our full minimal coupling Maxwell-TDDFT framework [1], implemented in the Octopus package. In this talk, we show how the effects of self-consistent light-matter coupling for different systems. On the one hand, we report the spectral Lamb-like shifts of plasmonic dimers described from first principles when radiation-reaction is considered. Moreover, we discuss the effects of transverse and longitudinal field inhomogeneity in the spectral properties of molecules in plasmonic environments described by a Drude response, including retardation effects. Finally, outlooks on self-consistent coupling of electrons, phonons and structured light are discussed. [1] F.P. Bonafé, A. Rubio, H. Appel et al. arXiv:2409.08959v2 (2024)

O 87.3 Thu 15:30 H4

Polarisation-dependent Mie void resonances — •Serkan Arslan[1], Shaban B. Sulejman[2], Sebastian Klein[1], Jonathan Haehner[2], Dominik Ludescher[1], Tim Davis[1,2], Lukas Wesemann[2], Ann Roberts[2], Harald Giessen[1], and Mario Hentschel[1] — [1]Univesity of Stuttgart, 4th Physics Institute, Germany — [2]University of Melbourne, School of Physics & TMOS, Australia

Over the last decade, researchers in nanophotonics have extensively studied the properties and applications of high refractive index dielectric nanoresonators that support subwavelength Mie resonances. Recently, it was demonstrated that similar resonances also occur in wavelength- and subwavelength-sized holes in high refractive index dielectrics, now known as Mie voids. These Mie voids efficiently confine light within air and support resonances spanning from the IR to UV wavelengths, thereby providing a new building block and expanding the parameter space of dielectric nanophotonics.

Until now, only circular Mie voids have been investigated. Here, we present the first study of non-isotropic Mie voids, including elliptical and rectangular shapes. We numerically and experimentally investigate the polarisation dependence of the resonances and reflection spectra, paving the way for polarisation-dependent structural colors and optical security features. Specifically, we demonstrate polarisation-dependent color patterns and micrometer-sized color prints. Anisotropic Mie voids also allow for the design of Mie void metasurfaces based on a generalised geometric phase.

O 87.4 Thu 15:45 H4

Using strong coupling to control plasmonic catalysis — •Jakub Fojt, Paul Erhart, and Christian Schäfer — Department of Physics, Chalmers University of Technology, Gothenburg, Sweden

Plasmonic excitations decay within femtoseconds, leaving nonthermal (often referred to as "hot") charge carriers behind that can be injected into molecular structures to trigger chemical reactions that are otherwise out of reach – a process known as plasmonic catalysis. In this contribution, we demonstrate that strong coupling between resonator structures and plasmonic nanoparticles can be used to control the spectral overlap between the plasmonic excitation energy and the charge injection energy into nearby molecules. Our atomistic description couples real-time density-functional theory self-consistently to an electromagnetic resonator structure via the radiation-reaction potential. Control over the resonator provides then an additional knob for nonintrusively enhancing plasmonic catalysis, here more than 6-fold, and dynamically reacting to deterioration of the catalyst – a new facet of modern catalysis.

O 87.5 Thu 16:00 H4

Photoemission electron microscopy of Exciton-Polaritons in thin WSe_2 waveguides — •Tobias Eul[1], Victor DeManuel-Gonzalez[1], Miwan Sabir[1], Florian Diekmann[1], Kai Rossnagel[1,2,3], and Michael Bauer[1,2] — [1]Institute of Experimental and Applied Physics, Kiel University, 24098 Kiel, Germany — [2]Kiel Nano, Surface and Interface Science KiNSIS, Kiel University, 24118 Kiel, Germany — [3]Deutsches Elektronen-Synchrotron DESY, Ruprecht Haensel Lab, 22607 Hamburg, Germany

Exciton-polaritons emerging from the interaction of photons and excitons in the strong coupling regime are intriguing quasi-particles for the potential exchange of energy during light-matter interaction processes such as light harvesting. This coupling causes an energy anti-crossing in the photon dispersion centered around the exciton resonance, i.e. a Rabi-splitting between a lower and upper energetic branch. The size of this splitting correlates to the coupling strength between the exciton and the photonic modes. In this work, we investigate this coupling between excitons and photonic waveguide modes excited simultaneously in thin-film flakes of the transition-metal dichalcogenide WSe_2. Using a Photoemission electron microscope, we are able to extract the dispersion of the TE- and TM-modes propagating through these flakes as well as extract the energy splitting. Ultimately, our findings precipitate the investigation of the propagation of exciton-polaritons in the time-domain via time-resolved photoemission.

O 87.6 Thu 16:15 H4

Surface-mediated ultra-strong cavity coupling of two-dimensional itinerant electrons — Christian Eckhardt[1,2], Andrey Grankin[3], Dante Kennes[2,1], Michael Ruggenthaler[1], Angel Rubio[1], •Michael Sentef[4,1], Mohammad Hafezi[3], and Marios Michael[1] — [1]Max Planck Institute for the Structure and Dynamics of Matter, Hamburg — [2]Institut für Theorie der Statistischen Physik, RWTH Aachen University — [3]Joint Quantum Institute, Department of Physics, University of Maryland — [4]Institute for Theoretical Physics, University of Bremen

Engineering phases of matter in cavities requires effective light-matter coupling strengths that are on the same order of magnitude as the bare system energetics, coined the ultra-strong coupling regime. For models of itinerant electron systems, which do not have discrete energy levels, a clear definition of this regime is outstanding to date. Here we argue that a change of the electronic mass exceeding 10% of its bare value may serve as such a definition. We propose a quantitative computational scheme for obtaining the electronic mass in relation to its bare vacuum value and show that coupling to surface polariton modes can induce such mass changes. Our results have important implications for cavity design principles that enable the engineering of electronic properties with quantum light.

O 87.7 Thu 16:30 H4

Photoheating nanoscale Pd to temperatures exceeding attached Au nanoparticle antennas — Felix Stete[1], Shivani Kesarwani[2], Charlotte Ruhmlieb[2], Florian Schulz[2], Marc Herzog[1], Holger Lange[1,2], and •Matias Bargheer[1,3] — [1]Universität Potsdam — [2]Universität Hamburg — [3]Helmholtz-Zentrum Berlin

In the non-equilibrium following optical excitation, energy transfer processes at the nanoscale can exhibit extraordinary and surprising phenomena such as heat transport without heating and dominant phonon heat transport in the noble metal gold. Here we present transient absorption experiments on a systematic and well-characterized series of gold nanoparticles with a Pd satellite shell. Modeling the fluence dependence of the entire series of hybrid structures with a fixed set of thermophysical parameters shows that we can create hybrid nanophoto-catalysts that concentrate light energy into the catalytically active Pd. We can make a few Pd satellites efficiently collect nearly all photothermal energy deposited by plasmonically enhanced absorption in gold and heat up the Pd by 180 K while the gold core remains cold. Consequently, highly active catalytic sites emerge which can enhance light driven molecular transformations. The tailoring and modeling of such unexpected nanoscale energy transfer phenomena is backed up by ultrafast x-ray diffraction experiments that provide a material-specific direct measure of the crystal lattice response to energy in phonons and electrons of each material in heterostructures and nanocomposites.

O 87.8 Thu 16:45 H4

Investigation of light-matter coupling in tight binding models — •Jonas Reimann[1,2], Michael Ruggenthaler[1,2], and Angel Rubio[1,2,3] — [1]Max Planck Institute for the Structure and Dynamics of Matter, Luruper Chaussee 149, 22761 Hamburg, Germany — [2]Center for Free-Electron Laser Science, Luruper Chaussee 149, 22761 Hamburg, Germany — [3]Center for Computational Quantum Physics, The Flatiron Institute, New York, NY, USA

The theoretical and mathematical foundations for light-matter interactions in a continuum theory are well-established. With the Pauli-Fierz Hamiltonian as the basic building block there is a starting Hamiltonian with all the required properties to study systems containing both matter and light. This can for example be used in the arising field of cavity material engineering where the interplay of light and matter is utilized to design new material properties.

How to imprint these mathematical properties onto tight-binding models describing such materials is at the center of a long-ongoing discussion. A widely deployed approach in this context is the Peierls substitution, coupling light to the hopping elements of the matter Hamiltonian. In this contribution we investigate the reliability of the Peierls substitution in terms of fundamental light-mattter coupling properties within the context of cavity material engineering.

O 87.9 Thu 17:00 H4

Revealing the crystallization dynamics of phase-change materials in vicinity of metallic nanostructures with multiphysics simulations — •Luis Schüler[1,2], Lukas Conrads[2], Sebastian Meyer[2], Yingfan Chen[2], Lina Jäckering[2], Matthias Wuttig[2], Thomas Taubner[2], and Dmitry Chigrin[1,2] — [1]DWI - Leibniz Institute for Interactive Materials, Aachen — [2]I. Institute of Physics (IA), RWTH Aachen University, Aachen

Optical metasurfaces composed of metallic or dielectric scatterers (meta-atoms) promise a powerful way of tailoring light-matter interactions. Phase-change materials (PCMs) are prime candidates for non-volatile resonance tuning of metasurfaces based on a change in refractive index. Precise resonance control can be achieved by locally applying laser pulses to crystallize a PCM, modifying the dielectric surrounding of meta-atoms. However, the complex crystallization kinetics of PCMs in the vicinity of metallic meta-atoms have not been studied yet. Here, we investigate metallic dimer antennas on top of the PCM $Ge_3Sb_2Te_6$ and address these nanoantennas with laser pulses to crystallize the PCM below. Our study reveals inhomogeneous crystallization caused by the absorption and heat conduction of the metallic nanoantennas. A self-consistent multiphysics model, including electromagnetic, thermal, and phase-transition processes, is employed to simulate the crystallization and predict the resulting resonance shift of the antennas. This model enables the optimization of the laser parameters and the geometry of the meta-atoms to achieve an optimal resonance shift, thereby improving the efficiency of metasurfaces.

O 87.10 Thu 17:15 H4

How accurate is the pole expansion of the scattering matrix? — •Elias Fösleitner[1], Adrià Canós Valero[1], Egor Muljarov[2], and Thomas Weiss[1] — [1]Department of Theoretical Physics, University of Graz, Graz, Austria — [2]School of Physics and Astronomy, Cardiff University, Cardiff, United Kingdom

Optical metasurfaces are flat arrangements of nanostructures with different subwavelength sizes and orientations, which allow tailoring the light propagation in a layer of subwavelength thickness. Such metasurfaces are often described using their resonant states. These states, also known as quasi-normal modes, serve as the foundation for the pole expansion of the optical scattering matrix, providing a more efficient and insightful alternative to conventional full-wave simulations. Existing formulations of such an expansion have, however, limitations, particularly in terms of accuracy, efficiency, and convergence. The aim of this study is to compare different approaches for pole expansions and identify their advantages and limitations. Moreover, we discuss how the choice of basis functions of the scattering matrix influences its complex pole structure and the resulting pole expansion. Overall, these findings will allow for a faster prediction of optical properties by choosing the best suited resonant expansion and also provide additional insight that is necessary for many applications such as nanophotonic sensors.

O 88: 2D Materials: Stacking and Heterostructures (joint session O/HL)

Time: Thursday 15:00–17:45 Location: H6

O 88.1 Thu 15:00 H6

Systematic Study of Interlayer Interactions in Transition Metal Dichalcogenide Bilayers Using microARPES — •Thomas Nielsen[1], Chakradhar Sahoo[1], Alfred Jones[1], Zhihao Jiang[1], Kenji Watanabe[2], Takashi Taniguchi[2], Suman Chakraborty[4], Prasana Sahoo[4], Jill A. Miwa[1], Yong P. Chen[1,3], and Søren Ulstrup[1] — [1]Aarhus University, Denmark — [2]National Institute for Materials Science, Japan — [3]Department of Physics, Purdue University, USA — [4]Materials Science Centre, Indian Institute of Technology, India

Stacked transition metal dichalcogenide monolayers are emerging as a platform to study correlated phases such as Mott insulators or Wigner crystallization. Spatially resolved ARPES can potentially visualize the moiré bands and hybridization effects in the electronic structure underpinning these correlated phases. Observing these phenomena in ARPES in a reproducible way remains challenging, motivating systematic studies of interlayer interactions in twisted TMD bilayers. 20 different heterobilayers of WSe_2, WS_2, $MoSe_2$, and WS_2, as well as homobilayers of WSe_2 are fabricated with varying twist angles. Their electronic properties are measured using the microARPES branch at the ASTRID2 synchrotron at Aarhus University. Band alignments and hybridization effects are tracked as a function of material composition and twist angle. The used dry-transfer fabrication techniques do not yield the direct observation of flat bands from moiré effects in the valence band. Based on this work future avenues for reproducibly attaining moiré effects in photoemission from TMDs are discussed.

O 88.2 Thu 15:15 H6

Gate-Tunable miniband dispersion in twisted graphene superlattices near the magic angle measured with MicroARPES — •Alfred J. H. Jones[1], Zhihao Jiang[1], Dongkyu Lee[2], Youngji Park[2], Kimberly Hsieh[1], Paulina Majchrzak[1], Chakradhar Sahoo[1], Thomas S. Nielsen[1], Kenji Watanabe[3], Takashi Taniguchi[3], Philip Hofmann[1], Jill A. Miwa[1], Yong P. Chen[1,4], Jeil Jung[2], and Søren Ulstrup[1] — [1]Department of Physics and Astronomy, Aarhus University, Denmark — [2]Department of Physics, University of Seoul, Korea — [3]National Institute for Materials Science, Japan — [4]Department of Physics and Astronomy, Purdue University, USA

Twisted superlattices of mono- and bilayer-graphene are emerging as powerful tools to explore quantum many-body effects such as unconventional superconductivity and Mott insulating states. Access to the momentum-resolved electronic structure simultaneous to changing the carrier concentration and displacement field within a twisted superlattice device can directly provide key information on the miniband dispersion tunability that underpins the correlated phenomena.

Here, we present microARPES measurements from SGM4 at ASTRID2 on two-terminal "near-magic-angle" twisted bilayer (TBG) and double-bilayer graphene (TDBG) devices. Our findings for the two systems are strikingly different: On TBG, we find a filling factor-dependent bandwidth change of the flat moiré bands, whereas on TDBG the effect of tuning the doping and displacement field leads to non-monotonous bandwidth changes and tunable gap opening effects.

O 88.3 Thu 15:30 H6

Topological magnetic Moiré heterostructures — •Aymeric Saunot[1,3], Sebastien E. Hadjadj[2], Tonica Valla[1], Maxim Ilyn[3], and Ilya I. Klimovskikh[1] — [1]Donostia International Physics Center (DIPC), 20018 Donostia-San Sebastían, Basque Country, Spain. — [2]Materials Physics Center (MPC), Paseo Manuel de Lardizabal N5,b20018 Donostia, Spain. — [3]Departamento de Física de Materiales UPV/EHU, San Sebastían, Spain.

Over the last few years Moiré superlattices have become a hot topic in condensed matter, thanks to the experimental success of magic angle twisted graphene. Moiré superpotentials arise from either twist or atomic mismatch at the interface between van der Waals materials, leading to a rich physics of strongly correlated electrons. Intriguingly, creation of Moiré pattern on the surface of 3D topological insulator (TIs) is theoretically expected to lead to, among others, topological superconductivity, high Chern number systems and non-trivial magnetic textures.

Here, we present Moiré heterostructures made from 3D TIs and novel 2D magnetic insulators transition metal dihalides. We investigate the heterostructure's surface by means of STM, ARPES, XMCD, and LEED. Our results show that the Moiré periodicity and the symmetry of the potential, can be tuned based on the ratio between the lattice parameters of the heterostructure's layers. Band structure measurements excitedly show the main Dirac cone surrounded by several Dirac cone replicas creating new Dirac minicones at the crossing points, opening a whole new platform to study topological Moiré physics.

O 88.4 Thu 15:45 H6

SNOM of lateral TMDC heterojunctions — •Philipp Schwendke[1], Samuel Palato[1], and Julia Stähler[1,2] — [1]Humboldt-Universität zu Berlin — [2]Fritz-Haber-Institut der MPG

Two transition metal dichalcogenide monolayers, joined together laterally, form a one-dimensional heterojunction where charge transfer with associated space charge region and current rectification have been shown experimentally [1]. Furthermore, there are unique local electronic properties determining the excitonic response in the boundary region. Nanoscale spectroscopic methods are needed for the observation of such local optical properties. We use scanning near-field optical microscopy (SNOM) in combination with a continuous wave (cw) light source at 633 nm, as well as a pulsed laser tunable in a wide range from 250 nm to 1300 nm. We employ pseudo-heterodyne modulation for noise suppression and optical phase information, and quadrature-assisted discrete demodulation in order to use the tunable light source at kHz repetition rates. Resonant SNOM measurements show a quenching near the WS_2-MoS_2 boundary, which can be indicative of local energy shifts or electronic states specific to the boundary region. This is complementary to previous measurements which show quenching of photoluminescence [2], attributing it to exciton recombination. In addition, the agreement of results acquired with cw and pulsed light sources paves the way towards time-resolved near-field measurements.

O 88.5 Thu 16:00 H6

Charge density wave interactions in bilayer 1T-TaSe2 — •Robert Drost, Ziying Wang, Büşra Arslan, Adolfo Fumega, Jose Lado, and Peter Liljeroth — Aalto University, Department of Applied Physics

Van der Waals materials offer splendid opportunities for quantum material engineering through stacking and heterostructure formation. While well-proven for many essential two-dimensional materials, these techniques are less explored for correlated materials. The 1T phase of TaSe2 is a two-dimensional Mott insulator and and excellent model system for correlations in reduced dimensions. The correlation gap in 1T-TaSe2 is highly sensitive to the thickness of the material, suggesting that electron-electron interactions between the charge density waves play an important role in determining the electronic properties of few-layer TaSe2. We also observe and additional site dependence of the gap size, showing that the stacking order may be equally important. These effects hint at the possibility of using charge density wave stacking as a design element in new quantum materials.

O 88.6 Thu 16:15 H6

Giant Zeeman effect at a magnetic topological van der Waals interface — Tobias Wichmann[1,2], Keda Jin[1,3], Jose Martinez-Castro[1,3], Tom G. Saunderson[4,5], Honey Boban[6], Lukasz Plucinski[6], Yuriy Mokrousov[4,5], Markus Ternes[1,3], F. Stefan Tautz[1,2], and •Felix Lüpke[1,7] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich — [2]Institut für Experimentalphysik IV A, RWTH Aachen University — [3]Institut für Experimentalphysik II B, RWTH Aachen University — [4]Institute of Physics, Johannes Gutenberg University Mainz — [5]Peter Grünberg Institut (PGI-1) and Institute for Advanced Simulation (IAS), Forschungszentrum Jülich — [6]Peter Grünberg Institut (PGI-6), Forschungszentrum Jülich — [7]II. Physikalisches Institut, Universität zu Köln

We report giant Zeeman effects with Landé g-factors up to $g \approx 230$ at the interface of graphene and the van der Waals (vdW) ferromagnet Fe_3GeTe_2 (FGT). They arise from orbital moments generated by the non-trivial band topology of the FGT and cause a huge asymmetric level splitting when a magnetic field is applied. By exploiting the inelastic phonon gap of graphene, we can directly access the vdW interface to the FGT underneath by scanning tunnelling microscopy and spectroscopy. By analyzing the Faraday-like screening of the tunnelling tip by the graphene, we are able to quantify the electric field at the vdW interface.

O 88.7 Thu 16:30 H6

Nanoscale band-gap modulation and dual moiré superlattices in the weakly-coupled h-BN/graphite heterostructure — Fábio J. R. Costa[1,2], Luiz F. Zagonel[1], Tin S. Cheng[3], Jonathan Bradford[3], Christopher J. Mellor[3], Peter H. Beton[3], Sergei V. Novikov[3], Juliette Plo[4], Bernard Gil[4], Guillaume Cassabois[4,5], Klaus Kuhnke[2], Klaus Kern[2,6], and •Anna Rosławska[2] — [1]Unversity of Campinas, Brazil — [2]Max Planck Institute for Solid State Research, Stuttgart, Germany — [3]University of Nottingham, United Kingdom — [4]Laboratoire Charles Coulomb, Montpellier, France — [5]Institut Universitaire de France, Paris, France — [6]EPFL, Lausanne, Switzerland

Van der Waals materials, such as hexagonal boron nitride (h-BN), and their heterostructures are highly promising for novel nanophotonic and electronic devices. In such stacks, moiré patterns arise and modulate the electronic properties of the material at the scale of typical superstructure periods (approx. 10 nm), and as such are challenging to probe. Here, we investigate the moiré superlattices in the weakly coupled h-BN/graphite heterostructure at the atomic scale. Scanning tunneling microscopy (STM) imaging reveals extensive moiré unit cells on the surface, while spectroscopic measurements demonstrate significant modulation in the work function and band gap across the periodic supercell. Additionally, we identify a dual moiré superlattice in twisted bilayers of h-BN on graphite, providing an extra degree of freedom to tune the heterostructure's properties.

O 88.8 Thu 16:45 H6

Impact of point defects and grain boundaries on sulfur diffusion and memristive properties of MoS_2 single sheets — •Aaron Flötotto[1], Jules Oumard[1], Benjamin Spetzler[2], Martin Ziegler[2], Erich Runge[1], and Christian Dressler[1] — [1]Technische Universität Ilmenau, Germany — [2]Christian-Albrechts-Universität zu Kiel, Germany

The memristive properties of transition metal dichalcogenides, such as MoS_2, are currently the subject of intense research and have recently been traced back to the dynamics of sulfur vacancies [1, 2]. In this theoretical work, we employ molecular dynamics to determine the sulfur vacancy diffusion coefficients in the vicinity of various point defect structures and grain boundaries in single sheet MoS_2. To address the necessity of large cell sizes and long time scales, we utilize machine learning force fields, applying both Gaussian approximation potential and equivariant graph neural networks. We then compare the accuracy of these force fields and discuss the results in regard to the memristive properties of MoS_2. Our findings indicate a reduction in energy barriers for sulfur vacancy diffusion as the size of vacancy clusters increases and highlight the importance of certain interstitial sites in these vacancy clusters.

Machine-Learning the Electronic Structure of Twisted Bilayer Graphene — •Lenz Fiedler[1], Agnieszka Kuc[1], Florian Arnold[2], and Attila Cangi[1] — [1]Helmholtz-Zentrum Dresden Rossendorf, Dresden, Deutschland — [2]Technische Universität Dresden, Dresden, Deutschland

Twistronics, i.e., the study of twodimensional materials in which individual layers are twisted w.r.t.öne another, has the potential to significantly propel technological progress. Twisted bilayer materials, e.g., graphene, may exhibit a significant change in electronic structure and electrical properties based on twist angle. Their computational treatment with density functional theory (DFT) proves difficult, as small twist angles affect the periodicity of the cell and can only be simulated with large unit cells. In this talk, the recently introduced Materials Learning Algorithms (MALA) - a framework for accelerating DFT calculations based on machine learning - is applied to twisted bilayer graphene. Bilayer graphene serves as a proxy for the larger field of twistronics itself. It is shown how the electronic structure, including electronic density of states and electronic charge density, can be predicted from a small number of twist angles for a range of twisted bilayer graphene structures. Since the MALA framework uses the local density of states to encode the electronic structure on a numerical grid, predictions can be made on much larger length scales than with standard DFT calculations. This work demonstrates how machine learning can be used to computationally model twisted bilayer structures where standard first-principles methods are not viable.

O 88.10 Thu 17:15 H6

High-throughput *ab initio* screening of 2D heterostructures — •Anastasiia Nihei[1,2], Tom Barnowsky[1,2], Roman Kempt[1], and Rico Friedrich[1,2,3] — [1]TU Dresden — [2]Helmholtz-Zentrum Dresden-Rossendorf — [3]Duke University, Durham, USA

Heterostructure interfaces produced by stacking two-dimensional (2D) materials facilitate the development of advanced electronic functionalities down to the atomic level. The efficient autonomous creation and computational study of these systems is, however, a challenge due to the general incommensurability of the 2D monolayers. This often results in large unit cells with hundreds to thousands of atoms.

Here, we present an extensive *ab initio* screening of heterostructures made of 2D systems. The approach makes use of the AFLOW-Hetbuilder – a newly developed tool that automates the heterotructure generation based on coincidence lattice theory [1,2]. It is fully integrated into the AFLOW framework [3,4]. We study the binding energy of a large set of heterostructures and also analyse their structural, electronic, and magnetic properties [5]. The presented efficient workflow can enable the systematic data-driven design of 2D heterostructures.

Size-Dependent Diffusion of Radioactive Alcohols Through CNMs — •Neita Khayya, Andre Beyer, and Armin Gölzhäuser — Faculty of Physics, Bielefeld University, 33615 Bielefeld, Germany

Conventional membranes frequently struggle to achieve both, high permeance and high selectivity. On the other hand, two-dimensional membranes demonstrated remarkable progress. For example, nanometer-thin carbon nanomembranes (CNMs) from self-assembled monolayers of terphenylthiol molecules combine rapid water permeation with a rejection of ethanol in pressure-driven experiments as well as ultrahigh ionic exclusion in ion conductivity measurements. Although there has been great progress in understanding the distinctive characteristics of CNMs, more work is required to fully understand their transport characteristics, which requires complementary approaches. In this work, we employed the radio-active tracer diffusion method to study the size-depended concentration-driven permeation of different alcohols, namely [14C] CnH2n+1OH (n = 1*3) through thickness-varied CNMs from biphenylthiol (BPT), terphenylthiol (TPT) as well as quaterphenylthiol (QPT) molecules. Our findings align with vaporous alcohol pressure-driven permeation measurements regarding the size exclusion through CNMs. Interestingly, our results indicate an increased permeation rate in the liquid phase, which can be rationalized by hydrogen bonds created inside the membrane between the water molecules and diffused alcohols.

O 89: Metal and Semiconductor Substrates: Structure, Epitaxy and Growth

From Unit Cells to Diffraction Patterns: `celltools`, a Python Toolkit for Structural Modeling — •Sebastian Hammer[1] and Bradley J. Siwick[2] — [1]Experimental Physics VI, University of Würzburg, 97074 Würzburg — [2]Departments of Physics and Chemistry, McGill University, Montreal H3A 0B8, Canada

The coupling of lattice and electronic system crucially determines the properties of modern materials. This interaction is at the heart of many emergent phenomena, such as charge-density wave formation, polaron dynamics, and transient metal-insulator transitions, which have peaked the interest of researchers.

While electronic properties can often be reliably described by quantum chemical methods, capturing structural changes is computationally more demanding. Hence, diffraction experiments are the usual method of choice to investigate structural distortions. However, extracting atomic positions from diffraction data is tedious and not straight forward.

In this contribution, I introduce the python package `celltools`, a versatile tool for constructing and manipulating unit cells as well as simulating their diffraction patterns. Using the case study of excimer formation in the prototypical molecular semiconductor zinc-phthalocyanine investigated with ultra-fast electron diffraction [1], I demonstrate how this tool enables the extraction of momentary atomic position from time-resolved diffraction datasets.

Automation of data acquisition and measurement evaluation in LEED $I(V)$ — •Florian Dörr[1], Michael Schmid[1], Lutz Hammer[2], Ulrike Diebold[1], and Michele Riva[1] — [1]Institute of Applied Physics, TU Wien, Austria — [2]Solid State Physics, FAU Erlangen, Germany

We designed a system capable of acquiring and evaluating quantitative low-energy electron diffraction [LEED $I(V)$] data, the Vienna Package for Erlangen LEED (ViPErLEED). The system contains three parts: One part performs data acquisition and is discussed in this contribution. The other two parts focus on the extraction of LEED-$I(V)$ curves from image series [1] and simulation of $I(V)$ spectra for quantitative structure optimization [2].

The data acquisition package consists of open-source hardware for controlling the LEED electronics and software for calibration and the actual measurements. Compared with previous solutions, the package contains functions that improve data quality, such as low-noise measurement of the beam current I_0, automatic calibration of the beam energy, and analysis of the response time of the LEED controller. On the image acquisition side, the software corrects for deficiencies of the camera, such as hot or dead pixels. We will discuss issues that affect the accuracy and duration of LEED-$I(V)$ measurements; this is especially important for sensitive samples that easily degrade.

X-ray reflectivity of μm-samples — •Steffen Tober[1], Wieland Corts[1,2], Steven Leake[3], Toka Matar[1,2], Lisa Randolph[1], Breno Saraiva[4,5], Vedran Vonk[4], Andreas Stierle[4,5], and Hans-Georg Steinrück[1,2] — [1]Forschungszentrum Jülich, Institute for Sustainable Hydrogen Economy (INW), Jülich — [2]RWTH Aachen, Institute of Physical Chemistry, Aachen — [3]ESRF, Grenoble — [4]Deutsches Elektronen-Synchrotron (DESY), Centre for X-Ray and Nanoscience (CXNS), Hamburg — [5]University of Hamburg, Physics Department, Hamburg

X-ray reflectivity (XRR) non-destructively probes electron density profiles of surfaces and interfaces with sub-nm resolution. Large beam footprints in grazing-incidence geometries commonly limit XRR to mm-sized, flat samples because the beam spillover for smaller samples significantly reduces the signal to noise ratio. To probe samples such as individual particles in electrodes or catalysts, a significant reduction of the footprint is needed. As demonstrated for crystal truncation rods [1], the nm-sized X-ray beams of modern synchrotron sources can be used for XRR on μm-sized samples with reduced footprint. We present first proof-of-principle studies comparing XRR of mm- and μm-sized thin-film samples measured with 80 and 400 nm X-ray beams at ESRF ID01 and the necessary optimisation of alignement- and scan procedures [2]. Our results show the general feasibility of nm-beam XRR to be adapted for future *in situ/operando* studies.

How a quartz crystal microbalance reacts to a thermal load — Martina Fellinger[1], Eduardo Pitthan[2], Christian Cupak[1], Friedrich Aumayr[1], Daniel Primetzhofer[2], and •Michael Schmid[1] — [1]Institute of Applied Physics, TU Wien, Austria — [2]Department of Physics and Astronomy, Uppsala University, Sweden

The most common technique for measuring deposition rates in vacuum is the quartz crystal microbalance (QCM). QCMs are also employed for the determination of sputter yields; further applications are in chemistry and biology. In all these applications, the response of the resonance frequency f to temperature is important. Apart from the crystal's sensitivity to a homogeneous temperature [the $f(T)$ curve], the influence of the thermal stress on the frequency has to be taken into account. In contrast to standard AT-cut crystals, SC-cut (stress-compensated) crystals are insensitive to radial stress. Therefore, SC-cut crystals are used for high-precision measurements or if the power dissipated on the crystal is high (e.g., for sputter yield measurements). Nevertheless, stress effects must be taken into account if the heat source is not exactly centered. The static $f(T)$ response and the effects of local heating, including stress effects, lead to a superposition of a fast response (within $\lesssim$ 1 s) and a slow frequency change over several minutes; the latter being related to the thermal resistance between the crystal and the crystal holder. Examples of finite-element simulations for a localized heat source will be shown and compared to experimental data of SC-cut crystals irradiated by MeV ions with up to 70 mW power, causing a temperature increase by up to 100 K.

Bilayer Formation of Tl on Ag(111): Spatial and Electronic Structural Insights — •Sarah Laufer[1], Sven Schemmelmann[1], Yuichiro Toichi[2], Kazuyuki Sakamoto[2], and Markus Donath[1] — [1]Physikalisches Institut, Universität Münster, Germany — [2]Department of Applied Physics, Osaka University, Japan

Ultrathin thallium films on Ag(111) have become a model system for studying the spatial and electronic properties of atomic-layer systems [1-3]. In this study, we focus on investigating the formation of bilayer Tl on Ag(111), leveraging Auger electron spectroscopy, low energy electron diffraction (LEED), and inverse photoemission (IPE) to investigate both spatial and electronic structure. LEED studies indicate that the Tl layers are rotated with respect to the substrate, with the angle of rotation depending on the Tl coverage and deposition temperature. Furthermore, IPE measurements reveal distinct unoccupied electronic states for both the monolayer and the bilayer. With increasing deposition time, the intensity of the monolayer-related state is reduced, while the intensity of the bilayer-related state increases. These results provide insight into the bilayer growth mechanism of Tl on Ag(111) and offer experimental criteria for differentiating between mono- and bilayer.

O 89.6 Thu 16:15 H8

Capping of terbium silicide nanostructures on Si(111) — •Markus Bachler[1], Milan Kubicki[1], Hüseyin Çelik[2], Sören Selve[3], Martin Franz[1], Michael Lehmann[2], and Mario Dähne[1] — [1]Institut für Festkörperphysik, Technische Universität Berlin, 10623, Germany — [2]Institut für Optik und Atomare Physik, Technische Universität Berlin, 10623, Germany — [3]Zentraleinrichtung Elektronenmikroskopie (ZELMI), Technische Universität Berlin, 10623, Germany

Rare earth silicide films on Si surfaces are of great interest because of their appealing properties, such as extremely low Schottky barrier heights on *n*-type Si, abrupt interfaces, and the formation of two- and three-dimensional films or one-dimensional nanowires. However, a protective layer is required for further utilisation of these properties, and capping by Si has the further advantage of no lattice mismatch to the substrate and the opportunity to form three-dimensionally stacked nanostructures. For this purpose, rare earth silicides on Si(111) with their very low to no lattice mismatch to Si are very promising for epitaxial capping.

Here we studied capping of thin Tb silicide layers on the Si(111) surface with Si by using scanning tunneling microscopy, cross-sectional high-resolution transmission electron microscopy as well as cross-sectional scanning transmission electron microscopy with energy dispersive X-ray analysis. We observed that overgrowth of the Tb silicide layers with amorphous and crystalline Si leads to intact double layers, demonstrating the stability of the Tb silicide layer upon capping.

O 89.7 Thu 16:30 H8

Exploring surface properties of hexagonal Si and Ge — •Martin Keller[1], Abderrezak Belabbes[1,2], Jürgen Furthmüller[1], Friedhelm Bechstedt[1], and Silvana Botti[1,3] — [1]Friedrich-Schiller-Universität Jena, Germany — [2]Sultan Qaboos University, Muscat, Oman — [3]Ruhr Universität Bochum, Germany

We present ab initio calculations, using density functional theory in a slab geometry, that explore structural and electronic properties of the surfaces of hexagonal silicon and germanium, which are novel materials for active optoelectronic applications. We study the relaxed 1 × 1 a, m, c and r-plane facets, who's surface energies allow the creation of Wulff constructions of Si and Ge nanocrystals and wires. Our focus lies on understanding surface stability and its implications on material and device design, as well as the effects of the relaxation on the electronic properties. The comparison with experimental findings offers practical insights for substrate selection for thin film growth and the construction of heterostructures.

O 89.8 Thu 16:45 H8

Strong electron doping of single-layer MoS_2 on an oxidized contact — •Marco Bianchi[1,2], Charlotte Sanders[3], Davide Curcio[4], Daniel Lizzit[5], Paolo Lacovig[1], Ezequiel Tosi[6], Jill Miwa[2], Silvano Lizzit[1], and Philip Hofmann[2] — [1]Elettra Sincrotrone Trieste S.C.p.A., Trieste, IT — [2]Dep. of Physics and Astronomy, iNANO, Aarhus University, DK. — [3]Artemis Program, UK Central Laser Facility, Harwell, STFC, UK — [4]IOM, Consiglio Nazionale della Ricerca, Trieste, IT — [5]DPIA - University of Udine, IT — [6]Instituto de Ciencia de Materiales de Madrid (ICMM - CSIC), ES

One of the major obstacles for the use of two-dimensional semiconductors in devices continues to be the high contact resistance to metallic conductors and the associated losses. Promising results have recently been obtained by using group V semimetals as contact materials. The obtained low contact resistance was explained partly by the a degenerate doping of the two-dimensional semiconductor. Here we study the band alignment and structure of such a system, a single-layer of MoS_2 on Au(111) with an intercalated layer of Bi. We investigate the electronic structure and growth by angle-resolved photoemission spectroscopy, X-ray photoemission spectroscopy, low energy electron diffraction and scanning tunneling microscopy. Our results show no evidence for an occupation of the MoS_2 conduction band when the material is brought into close contact with Bi. Surprisingly, however, a subsequent oxidation of the intercalated Bi gives rise to an extremely strong electron doping of the conduction band with a carrier density on the order of 10^{13} cm^{-2}.

O 89.9 Thu 17:00 H8

Growth of two-dimensional Ta-S structures from TaS_3 nuclei to TaS islands — •Catherine Grover[1], Alice Bremerich[1], Kai Mehlich[1], Abdus Samad[2], Udo Schwingenschlögl[2], Carsten Busse[1], and Thais Chagas[1] — [1]Department Physik, Universität Siegen, D-57072 Siegen, Germany — [2]Physical Science and Engineering Division, King Abdullah University of Science and Technology, 23955-6900 Thuwal, Saudi Arabia

Transition metal dichalcogenides (TMDCs) are emerging as promising 2D materials, known for their unique physical and electronic properties. Despite the rapid growth of research in this field, the exact mechanisms governing their growth remain largely speculative, especially when compared to more well-understood systems, such as metal-on-metal growth.

In this study, we employ Scanning Tunneling Microscopy (STM) to investigate the growth process of ultrathin tantalum sulfide (Ta-S) phases. We observe the evolution from embedded TaS_3 nuclei to Ta_3S_6 islands, and ultimately to TaS islands. These findings provide new insights into the growth dynamics of Ta-S phases, revealing the underlying processes.

Furthermore, these structural observations are supported by Density Functional Theory (DFT) calculations, which compare the energies of various structures, offering additional validation of the experimental results.

O 89.10 Thu 17:15 H8

Ab initio surface phase diagram of $(Al_xGa_yIn_{1-x-y})_2O_3$ — •Qaem Hassanzada[1], Yuanyuan Zhou[1,2], and Matthias Scheffler[1] — [1]The Fritz Haber institute, Berlin, Germany — [2]The Leibniz-Institut für Kristallzüchtung, Berlin, Germany

Group III sesquioxides with ultra-wide bandgaps are the most promising candidates for high-power electronics. Numerous efforts have been made to grow group-III sesquioxides, however, the fundamental understanding of growth process is still shallow. The prerequisite to understand growth process is detailed information about the surface geometry and stoichiometry under growth conditions. This can be provided in surface phase diagrams. In this study, we explore the surface phase diagram of Group III sesquioxides, $(Al_xGa_yIn_{1-x-y})_2O_3$, for the entire compositional range, using ab initio atomistic thermodynamics [1, 2] and the sure-independence screening and sparsifying operator (SISSO) [3] machine learning methods. We predict the most probable phases under the corresponding growth conditions. For instance, in the Ga-rich region, we predict the formation of a Ga monolayer, which may be related to the experimental hypothesis of Ga adlayer formation at a lower O/Ga ratio [4] reminiscent of the phenomena in GaN.

O 89.11 Thu 17:30 H8

Ultrathin NiO(100) films on Ag(100): Pitfalls in understanding growth using intensity-voltage low-energy electron diffraction — •Jan Lachnitt[1], Shuvankar Das[2], Krishnakumar S. R. Menon[2], and Jan Ingo Flege[1] — [1]Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology Cottbus-Senftenberg, Germany — [2]Surface Physics & Material Science Division, Saha Institute of Nuclear Physics, Kolkata, India

Ultrathin NiO films have prospective applications in heterogeneous catalysis, microelectronics, and spintronics and are thus an object of active research. In model systems, the Ag(100) surface is frequently used as support for these films, as its cubic lattice parameter is only 2.2% smaller than that of NiO, enabling pseudomorphic growth for very small thicknesses. Interestingly, the early-stage growth of NiO films on Ag(100) turns out to be complex compared to other simple oxide systems, such as MgO/Ag(100). We have grown pseudomorphic NiO(100) films of well-defined average thickness in steps of 0.5 monolayer (ML), up to 3 MLs, and studied them with intensity-voltage low-energy electron diffraction (IV-LEED). We have also employed density-functional theory (DFT) calculations to gain additional insights. Our IV-LEED results indicate a deviation from layer-by-layer growth, expected to take place from 2 MLs onwards [1], and the detailed analysis of the oxide-metal system has turned out to be tricky. We discuss the pitfalls and limitations of common IV-LEED procedures and compare the results with our DFT calculations and existing literature.

Relativistic Orbital Effects in Hyperfine Splittings on Surfaces — •Katharina Lorena Franzke, Wolf Gero Schmidt, and Uwe Gerstmann — University of Paderborn Warburger Str. 1 33098 Paderborn

The recent combination of electron spin resonance and scanning tunneling spectroscopy (ESR-STM) provide a new platform to access single spins of atoms and molecules on surfaces [1, 2]. Characteristic hyperfine (hf) splittings due to the interaction between the electronic spin and the magnetic moments of the nuclei can be measured and compared with theoretical predictions from density functional theory (DFT). In comparison with defects in bulk material, however, the calculated data deviates considerably from the experimental values. Limited accuracy of the xc functionals or the direct influence of the electric field of the STM-tip have been discussed as possible reasons.

Large parts of the observed discrepancies however stem from a relativistic effect, the suppression of orbital quenching at surfaces. We developed a fully relativistic method that allows the calculation of this orbital contribution for complex structures [3]. For Pb ions as well as PbPc molecules on the MgO/Ag(111) substrate, this orbital part leads to additional hf splittings in the GHz range and is thereby required to achieve overall accuracy in predicting the hf interactions of single spins in 2D nanostructures.

Electric Control of Molecular Spins on a Surface — •Paul Greule[1], Wantong Huang[1], Máté Stark[1], Kwan Ho Au-Yeung[1], Christoph Sürgers[1], Wolfgang Wernsdorfer[1], Christoph Wolf[2], and Philip Willke[1] — [1]Physikalisches Institut (PHI), Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]Center for Quantum Nanoscience, Institute for Basic Science (IBS), Seoul 03760, Korea

Single electronic spins hosted by atoms or molecules are candidates for future quantum technologies. To utilize them as functional building blocks in quantum information processing it is necessary to gain local control of their quantum properties. Lately, electron spin resonance combined with scanning tunnelling microscopy (ESR-STM) was demonstrated as a versatile method to access atoms and molecules on a surface [1]. For single Ti atoms it was shown that the Zeeman energy of electron spins can be tuned via the applied bias voltage in the tunnelling junction [2] constituting an atomic-scale electric field control. In our work, we present a voltage-dependent shift of the ESR frequency for two different molecular spin systems, Iron-phthalocyanine (FePc) and FePc-Fe ferrimagnet complexes. Intriguingly, we observe a strong non-linearity in the shift connected to the molecular orbital of FePc. We rationalize this theoretically by many-body interactions with the exchange bias field of the tip. Moreover, we show how the bias voltage control can be used to detune Rabi oscillations in pulsed ESR experiments. [1] Y. Chen et al., Adv. Mater. 2022, 2107534 [2] P. Kot et al., Nat Commun 14, 6612 (2023)

O 90.3 Thu 15:30 H11

Coherent control of a single Er electron spin on surface — Dasom Choi[1,2], Yaowu Liu[1,3,4], Stefano Reale[1,3], Jeongmin Oh[1,2], We-hyo Seo[1,3], Andreas Heinrich[1,2], Soo-hyun Phark[1,3], and •Fabio Donati[1,2] — [1]Center for Quantum Nanoscience, Institute for Basic Science, Korea — [2]Physics Department, Ewha Womans University, Korea — [3]Ewha Womans University, Seoul, Korea — [4]Department of Energy, Politecnico di Milano, Milano, Italy

Electron spins on surface provide an atomic scale qubit platform for quantum information science using scanning tunneling microscopy (STM) [Phark et al. ACS Nano 17, 14144 (2023), Wang et al. Science 382, 87 (2023)]. A bottleneck of this new platform lies in the decoherence stemming from the strong interaction with the environments. Lanthanide atoms, with their highly localized 4f electrons, offer a potential solution to this issue and make them as strong candidates of single atomic spin qubits on surfaces with a high quality factor $Q = 2\Omega T_2$ (Ω = Rabi rate, T_2 = coherence time). In this talk, we present a recent advance in the qubit quality factor, achieved using erbium (Er) atoms on a MgO surface [Reale et al. Phys. Rev. B 107, 045427 (2023)]. We performed a coherent control of the Er atoms using pulsed electron spin resonance (ESR), sensed by a nearby Ti spin [Reale et al. Nat. Commun. 15, 5289 (2024)]. Notably, a single Er spin showed a fivefold improvement in the qubit quality factor compared to the prototypical Ti spin on the same substrate [Yang et al. Science 366, 509-512 (2019)]. This result represents a step towards implementing quantum processes into atomic spin qubits on surfaces.

O 90.4 Thu 15:45 H11

Spin interactions at the periphery between atomic and condensed-matter physics — •Dmitriy Borodin, Andrés Pinar Solé, Merve Ercelik, and Andreas J. Heinrich — IBS Center for Quantum Nanoscience, Seoul, South Korea

Exchange interactions are essential for the formation of chemical bonds between atoms and dictate the electronic structure of molecules. In a condensed-matter system, a manifold of exchange mechanisms coexists, ultimately defining the local magnetic structure and phase stability. In this work, we use low-temperature scanning probe microscopy to investigate the exchange mechanisms and interaction energies between atoms on surfaces and magnetic tips. By controlling the atom-tip separations on a picometer scale, we can continuously tune the interaction energies and observe changes in the local magnetic structure of the tip. Furthermore, we explore the impact of the elemental composition of magnetic tips on their exchange interactions with surface-bound atoms and identify experimental strategies to adjust the sign and strength of these interactions.

O 90.5 Thu 16:00 H11

Switching Dynamics in Fe Spin Chains: Quantum vs. Classical Behavior — •Henrik Lichtl[1], Lukas Veldman[1], Johannes Schust[1], Nicolaj Betz[1,2], Laëtitia Farinacci[1,3], Susanne Baumann[1], and Sebastian Loth[1,2] — [1]University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany — [2]Center for Integrated Quantum Science and Technology (IQST), University of Stuttgart, Stuttgart, Germany — [3]Carl-Zeiss-Stiftung Center for Quantum Photonics Jena - Stuttgart - Ulm, Germany

That quantum spins transition to classical magnets at a certain size is well-known, but the behavior of magnets at this transition point has remained elusive. Here we develop a method to measure high speed magnetization curves in a scanning tunneling microscope (STM) that reach magnetic field sweep rates up to kT/s. This allows us to measure the magnetization reversal of antiferromagnetic few-atom spin chains, constructed of Fe atoms on a Cu2N surface. By resolving the statistics of the quantum jumps between the antiferromagnetic ground states, we can clearly distinguish between classical and quantum regimes of magnetic switching. Quantum mechanical behavior quenches rapidly with increasing size such that chains of more than five atoms in length can behave as classical magnets. The ability to modulate spin systems at high speed brings techniques that were previously reserved for bulk measurements to the atomic scale and provides deep insights into the coupling mechanisms between quantum spins and their environment.

O 90.6 Thu 16:15 H11

Many-body effects in impurity spectroscopy using ESR-STM — •Christoph Wolf[1,2], Xue Zhang[3], Jose Reina-Galvez[1,2], Jan Martinek[4], and Nicolas Lorente[5,6] — [1]Center for Quan tum Nanoscience, Institute for Basic Science (IBS), Seoul, Korea — [2]Ewha Womans University, Seoul, Korea — [3]Spin-X Institute, China University of Technology, Guangzhou, China — [4]Institute of Molecular Physics, Polish Academy of Science, Poland — [5]Centro de Fisica de Materiales, CFM/MPC (CSIC-UPV/EHU), Spain — [6]6Donostia International Physics Center (DIPC), Spain

Recent advances in understanding how harmonic electric fields drive coherent spin transitions in the ESR-STM have lead to a re-evaluation of experimentally observed phenomena in the ESR-STM spectra of atomic and molecular spin adsorbed on ultrathin insulating layers. In this talk, I will show the most up to date development of our transport approach, which is based on a single-orbital Anderson impurity model attached to magnetic leads. I will focus on two aspects: first, the DC bias control of the resonance frequency of the ESR transition, which can be interpreted as an exchange bias field. This allows the full physical characterization of the adsorbate spin and the junction parameters in ESR-STM. All simulations are qualitatively and quantitatively evaluated against experimental data of individual titanium atoms and Iron(II)phthalocyanine molecules which are prototypical spin-1/2 qubits. Second, I will discuss the optimization of quantum-coherent control in the low-current regime, which shows a distinct optimum for the quantum-bit figure of merit ΩT2.

O 90.7 Thu 16:30 H11

Driving nuclear spin transitions on a single atom using STM — •Cristina Mier Gonzalez, Hester Vennema, Evert Stolte, Jinwon Lee, and Sander Otte — Delft University of Technology, 2628 CJ Delft, The Netherlands

Nuclear spins are highly isolated from its electronic environment compared to electron spins. This degree of isolation makes nuclear spins a promising platform for quantum technologies [1]. The development of ESR-STM has made possible the indirect measurement of nuclear spins on single atoms through the hyperfine interaction [2]. More recently, single-shot read-out on Ti isotopes has shown a nuclear lifetime of about 5 seconds [3].

In this work we aim to controllably address nuclear spin transitions using ESR-STM. We propose a double resonance measurement scheme to controllably drive

the nuclear spin of a ^{47}Ti isotope (I = 5/2). Our study paves the way for coherent manipulation of single nuclear spins using STM.

O 90.8 Thu 16:45 H11

Single-shot readout of an individual nuclear spin using a scanning tunnelling microscope — •Evert Stolte[1], Jinwon Lee[1], Hester Vennema[1], Rik Broekhoven[1], Esther Teng[1], Allard Katan[1], Lukas Veldman[2], Philip Willke[3], and Sander Otte[1] — [1]Department of Quantum Nanoscience, TU Delft — [2]Institute for Functional Matter and Quantum Technologies, University of Stuttgart — [3]Physikalisches Institut, Karlsruhe Institute of Technology

Nuclear spins owe their long-lived magnetic states to their excellent isolation from the environment. At the same time, a limited degree of interaction with their surroundings is necessary for reading and writing the spin state. Therefore, detailed knowledge of and control over the atomic environment of a nuclear spin is key to optimizing conditions for quantum information applications. Scanning tunnelling microscopy (STM), combined with electron spin resonance (ESR), provides atomic-scale information of individual nuclear spins via the hyperfine interaction. However, STM has thus far only sparingly been used to investigate nuclear spins in the time domain. As such, no nuclear spin lifetimes have yet been reported. Here, we demonstrate single-shot readout of an individual ^{49}Ti nuclear spin with an STM. Employing a pulsed measurement scheme, we find its lifetime to be in the order of seconds. Furthermore, we shed light on the pumping and relaxation mechanisms of the nuclear spin by investigating its response to both ESR driving and tunnelling current. These findings give an atomic-scale insight into the nature of nuclear spin relaxation and are relevant for the development of atomically assembled qubit platforms.

O 90.9 Thu 17:00 H11

Spin Excitations of High-Spin Fe(II) in Metal-Organic Chains on Metal and Superconductor — •Jung-Ching Liu[1,2], Chao Li[2], Outhmane Chahib[2], Xing Wang[3], Simon Rothenbühler[4], Robert Häner[4], Silvio Decurtins[4], Ulrich Aschauer[5], Shi-Xia Liu[4], Ernst Meyer[2], and Rémy Pawlak[2] — [1]Department of Physics, Technical University of Munich, James-Franck-Str.1, 85748 Garching, Germany — [2]Department of Physics, University of Basel, Klingelbergstrasse 82, 4056 Basel, Switzerland — [3]Paul Scherrer Institut, Forschungsstrasse 111, 5232 Villigen PSI, Switzerland — [4]Department of Chemistry and Biochemistry, University of Bern, Freiestrasse 3, 3012 Bern, Switzerland — [5]Department of Chemistry and Physics of Materials, University of Salzburg, Jakob-Haringer-Strasse 2A, 5020 Salzburg, Austria

Magnetic anisotropy induced by the substrate plays an important role in many-body interactions in metal-organic frameworks at surfaces. Investigated by STM at 1K, we present the study of magnetic signature at Fe atoms with high spin-state (S=2) using PTO as ligands. On Ag(111), we found long-range Fe-Fe coupling in addition to low-energy spin-flip excitations. Despite of the identical chain structure, such long-range superexchange through PTO is not observed on tunneling spectra on Pb(111) superconductor. We ascribe this distinct spin-spin coupling behavior to the depletion of electronic states around the Fermi level on Pb(111) as compare to Ag(111). We believe our study provides a route for fundamental studies in spin-spin and spin-substrate interactions with different lattice structures.

O 90.10 Thu 17:15 H11

Control of the Landau-Zener Gap in Atomic Structures — •Piotr Kot[1,2], Yaowu Lei[1,2], Valeria Sheina[1,2], We-hyo Seo[1,2], Andreas Heinrich[1,2], and Soo-hyon Phark[1,2] — [1]Center for Quantum Nanoscience, Institute for Basic Science, Seoul, South Korea — [2]Department of Physics, Ewha Womans University, Seoul, South Korea

Avoided crossings in quantum systems have been shown to be a useful tool for the study of qubits and the actualization of faster qubit operations. This is done by taking advantage of Landau-Zener transitions, allowing one to measure quantum interferometric effects. However, implementing these techniques in on surface atoms has not yet been demonstrated experimentally, and is a crucial next step for studying this new class of spin qubits. Here we present preliminary steps towards studying quantum interferometric effects in Ti dimers using electron spin resonance scanning tunnelling microscopy. Firstly, we have fine-tuned the Landau-Zener gap in our dimers by studying the dipole and exchange interaction between the atoms. We have found that only several dimers have the correct gap magnitude for our experimental conditions. Secondly, we have found that by using three atom structures we are able to position the avoided crossing within our range of interest. Experiments in the near future will include measuring Landau-Zener transitions, Stueckelberg oscillations and quantum interferometry maps.

O 91: Focus Session Chemical Imaging for the Elucidation of Molecular Structure I (joint session O/BP)

Unravelling the multiscale molecular heterogeneity at interfaces is one of the main challenges in modern biophysics and surface science due to the major role specific structural properties play in determining their macroscopic function and behavior. In the last few decades, several specialized chemical imaging techniques have been developed that can reveal many of these crucial structural details, representing an enormous advance in our elucidative capabilities. Clear examples of this range from super-resolution and 3D tomography to tag-free characterization down to the single-molecule level. This focus session will explore the vast range of methods and possibilities for characterizing the different structural aspects in heterogeneous molecular systems and specifically highlight the potential complementarity of the different techniques through multi-modal approaches. Overall, by bringing together different communities, this session aims to foster scientific exchanges that could spark the next major developments in chemical imaging.

Organized by Martin Thämer (FHI Berlin), Alexander Fellows (FHI Berlin), and Kerstin Blank (University Linz)

Time: Thursday 15:00–17:30 Location: H24

Invited Talk O 91.1 Thu 15:00 H24

Infrared Nanoscopy and Tomography of Intracellular Structures — Joachim Heberle[1], Katerina Kanevche[1], •Emmanuel Pfitzner[1], David Burr[2], Janina Drauschke[2], Andreas Elsaesser[2], and Jacek Kozuch[1] — [1]Freie Universität Berlin, Department of Physics, Experimental Molecular Biophysics, — [2]Experimental Biophysics and Space Sciences, Arnimallee 14, 14195, Berlin, Germany

Although techniques such as fluorescence-based super-resolution imaging or confocal microscopy simultaneously gather morphological and chemical data, these techniques often rely on localized and chemically specific markers. To eliminate this flaw, we have developed a method of examining cellular cross-sections using the imaging power of scattering-type scanning near-field optical microscopy (sSNOM) and Fourier-transform infrared spectroscopy at a spatial resolution far beyond the diffraction limit (nanoFTIR). Herewith, nanoscale surface and volumetric chemical imaging are performed using the intrinsic contrast generated by the characteristic absorption of mid-infrared radiation by the covalent bonds. We employ infrared nanoscopy to study the subcellular structures of eukaryotic (C. reinhardtii) and prokaryotic (E. coli) species, revealing chemically distinct regions within each cell. Serial 100 nm-thick cellular cross-sections were compiled into a tomogram, yielding a three-dimensional infrared image of subcellular structure distribution at 20 nm spatial resolution. The presented methodology can image biological samples with less interference due to the low energy of infrared radiation and the absence of labeling.

Invited Talk O 91.2 Thu 15:30 H24

Coherent Raman Imaging — •Michael Schmitt[1] and Juergen Popp[1,2] — [1]Institute of Physical Chemistry and Abbe Center of Photonics, Friedrich-Schiller-University Jena, Helmholtzweg 4, 07743 Jena, Germany — [2]Leibniz Institute of Photonic Technology, Member of Leibniz Health Technologies, Albert-Einstein-Straße 9, 07745 Jena, Germany

Raman-based technologies have profoundly impacted life sciences and biomedical research. Despite their unmatched molecular specificity, traditional Raman spectroscopy suffers from limited sensitivity, making it less suitable for rapid imaging. This limitation is addressed by coherent Raman scattering (CRS) microscopy, primarily through coherent anti-Stokes Raman scattering (CARS) and

stimulated Raman scattering (SRS). This talk examines the potential of CARS and SRS imaging for biological and biomedical analysis, offering detailed insights into the molecular composition of biomedical specimens, such as cells or tissue. The presentation will focus on the applications of these techniques in molecular and functional diagnostics in the fields of medicine and life sciences. Furthermore, recent developments in translating CRS into compact, clinically viable systems, such as handheld probes, will be presented, focusing on intraoperative tumour diagnostics for early detection and improved improved therapeutic outcomes.

Invited Talk O 91.3 Thu 16:00 H24

Sum Frequency Generation Microscopy of Electrochemical Interfaces — •Steven Baldelli — University of Houston, Houston, Texas

Sum frequency generation spectroscopy (SFG) is a valuable technique to study the molecular properties of surfaces. As a second-order technique, it is uniquely sensitive to the average organization of molecules at the surface. However, as most surfaces are spatially heterogeneous, it isn't easy to interpret the spectrum as a single domain. The development of SFG into microscopy has allowed a more detailed and accurate analysis of the spatio-spectro-temporal evolution of surface chemistry. The SFG microscope development will be presented, and compressive sensing and the application toward electrocatalysis will be used.

O 91.4 Thu 16:30 H24

Elucidating the Composition, Order, and 3D Molecular Orientation of Thin Films with Phase-Resolved Sum-Frequency Generation Microscopy — •Alexander Fellows, Ben John, Martin Wolf, and Martin Thämer — Fritz-Haber-Institute, Berlin, Germany

The vast majority of molecular interfaces have highly heterogeneous structures, ranging across all length-scales. These manifest as variations in density, composition, and molecular packing structure, all of which are critical in controlling the macroscopic properties and functional behaviour of the films. While various chemical imaging techniques can access many of these important structural details, characterising their relative order and specific packing arrangements represents a formidable challenge.

Here, we present a chemical imaging approach based on phase-resolved sum-frequency generation (SFG) microscopy. By probing molecular vibrations, this technique achieves molecular recognition and thus is sensitive to the local composition and density. Furthermore, through its symmetry selection rules, output SFG signals are dependent on absolute molecular orientations. This hence allows it to distinguish different molecular conformations and characterise the amount of orientational order in the system. Finally, with an azimuthal-scanning approach, the in-plane and out-of-plane signal contributions can be separated, allowing the 3D molecular orientations to be elucidated. By applying SFG imaging to model lipid monolayers, we gain an unprecedented overview of their hierarchical packing structures.

O 91.5 Thu 16:45 H24

Low temperature multimode atomic force microscopy using an active MEMS cantilever — Michael G. Ruppert[1], Miguel Wiche[2], André Schirmeisen[2], and •Daniel Ebeling[2] — [1]University of Technology Sydney, Australia — [2]Justus Liebig University Giessen, Germany

Low-temperature atomic force microscopy (AFM) is one of the most powerful tools in surface science. With the chemical bond imaging technique, i.e., by using CO functionalized AFM tips, it became possible to visualize the chemical structure of individual organic molecules, which is essential for studying on-surface reactions and molecular manipulation processes. Routinely, such measurements are performed with qPlus sensors. Here, we present a proof of concept for an active microelectromechanical systems (MEMS) microcantilever with integrated piezoelectric sensing and demonstrate its capability to obtain scanning tunneling microscopy as well as high-resolution non-contact atomic force microscopy images on an atomically flat Au(111) surface. Equipped with a focused ion beam deposited tungsten tip, the active MEMS cantilever is able to obtain high contrast scanning tunneling and frequency shift images at the fundamental and a higher eigenmode of the cantilever. This is interesting for the application of multifrequency AFM operation modes that could enhance the capabilities of the bond imaging technique.

O 91.6 Thu 17:00 H24

Instrumentation for high-resolution biomolecule imaging enabled by electrospray ion beam deposition (ES-IBD) — •Lukas Eriksson[1], Tim Esser[1,2], and Stephan Rauschenbach[1] — [1]University of Oxford, Oxford, UK — [2]Thermo Fisher Scientific, Eindhoven, Netherlands

Direct imaging of (bio-)molecules with cryogenic electron microscopy (cryo-EM) or scanning probe microscopy (SPM) is a powerful approach for elucidating molecular structure. However, sample preparation can be a major challenge: either very time- and resource-intensive or incompatible with the vacuum environment required by the imaging method.

Here, we explore preparative mass spectrometry as an alternative workflow towards structural elucidation of biomolecules. A novel, custom-built deposition stage extending a commercial mass spectrometer (Thermo Fisher Scientific Orbitrap UHMR) allows for the mass-filtered, soft-landed deposition of a wide mass range of target molecules (m = 100 to 10^6 Da) onto various surfaces, including cryo-EM grids and metal crystals for SPM. Successful deposition and subsequent imaging requires extensive control over conditions such as pressure, temperature, ion trajectories, sample surfaces, and sample transfer to obtain clean, chemically pure samples of the desired species in the right (i.e. native) configuration. The sample holder also enables controlled growth of ice layers for embedding deposited molecules, allowing high-resolution reconstructions of proteins from cryo-EM.

O 91.7 Thu 17:15 H24

LFM study of copper oxide — •Sophia Schweiss, Alfred J. Weymouth, and Franz J. Giessibl — Universität Regensburg, Regensburg, Deutschland

Small-amplitude FM-AFM is a method to study surfaces and adsorbates with atomic resolution. At low temperature, the tip apex can be prepared so that it ends in a single O-atom, making the tip inert and enhancing imaging [1, 2]. With a laterally oscillating tip, i.e. lateral force microscopy (LFM), the conservative (frequency shift, Δf) and non-conservative (dissipated energy, E_{diss}) components of the tip-sample interaction can also be independently measured. Here too, inert tip apices are commonly used. One measurement of E_{diss} relies on the cocking and snapping of the tip over a single chemical bond, for which the current state of the art utilizes CO-terminated tips. In this work, a CO-terminated tip [1] is used to investigate the (2×1)O reconstruction of Cu(110) with LFM. Simulations are performed to guide interpretation. In this larger ongoing study, these LFM measurements will be repeated for a CuOx tip [2] to evaluate it as a tool for measuring E_{diss}.

Electronic and Optical properties of K-Sb and Na-Sb binary crystals from ab initio many-body theory — •Richard Schier and Caterina Cocchi — Carl von Ossietzky Universität Oldenburg, Institut für Physik

Alkali-based photocathode materials have come into the limelight as novel semiconducting materials for electron sources. However, challenges in sample purity and polycrystallinity hinder the direct experimental determination of their intrinsic properties. First-principles methods can effectively complement experiments in predicting favorable structures and gaining insight into their electronic and optical properties. In this work, we investigate K-Sb and Na-Sb binary crystals emerged as stable phases from high-throughput screening [1]. Using many-body perturbation theory on top of density functional theory, we find that all considered materials have optical gaps in the near-infrared region between 0.7 - 1.2 eV. The character of the excitations and electron-hole correlations therein are highly dependent on the composition and crystal structure of the compound. Excitonic effects appear more pronounced in the K-Sb crystals, where binding energies are of the order of 100 - 200 meV and the oscillator strength is sizably redistributed to lower-energy peaks. These characteristics indicate that K-Sb crystals are favorable candidates for efficient electron sources. [1] R. Schier, D. Guo, H.-D. Saßnick, and C. Cocchi, Adv. Theory Simulations (2024), https://doi.org/10.1002/adts.202400680.

O 92.2 Thu 15:15 H25

Automated Wannier functions inspired by topological quantum chemistry — •Stepan S. Tsirkin — Centro de Física de Materiales, San Sebastián, Spain

Despite Wannier functions (WFs) becoming a popular and powerful technique for studying diverse electronic properties of materials, the construction of high-quality WFs remains a non-trivial task, often requiring manual intervention and expertise, which obstructs high-throughput calculations using WF-based methods.

I present an approach for selecting initial projections for Wannier functions based on the symmetry indicators of DFT bandsstructure. The initial projections

are searched among the possible orbitals at the Wyckoff positions of the crystal, referred to as Elementary Band Representations in the terminology of Topological Quantum Chemistry [Nature 547, 298 (2017)]. Thus, the projections are by construction compatible with the symmetry of the bands, making them suitable for the construction of symmetry-adapted WFs (SAWFs) [Sakuma, PRB 87, 235109 (2013)]. This approach has been implemented in the codes WannierBerri (WB) [NPJ Comput. Mater. 7, 33 (2021)] and IrRep [CPC 272, 108226 (2022)]. Additionally, WannierBerri now implements the construction of SAWFs without several limitations found in the corresponding implementation in Wannier90. In particular, WB can handle spin-orbit coupling, a frozen window, and is compatible with multiple DFT codes (VASP, Quantum Espresso, Abinit, etc.).

This method does not require manual inspection on bands, which makes it suitable for high-throughput calculations.

O 92.3 Thu 15:30 H25

Learning conductance of aromatic and antiaromatic molecular junctions — •Mohammad Ali Mohammadi Keshtan and Hector Vazquez — Inst. of Physics, Czech Academy of Sciences

Single-molecule junction conductance depends on molecular conformation. The standard computational method to study the conductance of a molecular junction is DFT-NEGF. However, DFT-NEGF is computationally expensive, so finding a fast and accurate method to compute the conductance of a large numbers of structures is vital.

Here, we use machine learning (ML) methods, including kernel ridge regression and Gaussian process regression, to overcome these limitations. To train the regression models, we first generate thousands of junction geometries using classical molecular dynamics at room temperature. For each geometry we then compute conductance using a computationally efficient approximation which considers a Au-molecule-Au complex [1], and build SOAP and Coulomb matrix descriptors.

We study a pair of aromatic/antiaromatic porphyrin-like molecules [2], whose large size further hampers the use of DFT-NEGF. We explore the performance of the different ML models, compare the results with DFT-NEGF, and discuss the relative importance of the different descriptors. Our work demonstrates how ML models can be efficiently trained and used to compute single molecule junction conductance.

O 92.4 Thu 15:45 H25

Electronic excitations in nanostructures from the Bethe-Salpeter equation — •Maximilian Graml, Štěpán Marek, and Jan Wilhelm — Institute of Theoretical Physics and Regensburg Center for Ultrafast Nanoscopy (RUN), University of Regensburg, Regensburg, Germany

Electronic structure calculations are a well-established tool for the identification of candidate materials for technological applications, e.g., in photocatalysis, photovoltaics and energy storage. For the quantitative description of optical properties, many-body perturbation theory within the GW approximation and the Bethe-Salpeter equation (BSE) on top of GW is regarded as the state-of-the-art method.

In this contribution, we present the implementation of the BSE within the open-source package CP2K, enabling the accurate calculation of electronic excitations in molecules and nanostructures. To validate our approach, we benchmark the excitation energies against those obtained with the FHI-aims package.

We further apply our BSE implementation to study electronic excitations in graphene nanostructures, where we investigate the optical absorption spectra and the spatial extent of excited states as a function of nanostructure size. We observe that both properties converge on the scale of 5 nm nanostructure size, guiding experiments towards the rational design of nanostructures in graphene-based optical devices.

O 92.5 Thu 16:00 H25

Electronic Coupling on Surfaces from First-Principles: Chemisorped Systems — •Simiam Ghan and Jens Nørskov — Technical University of Denmark DTU

We use density-functional theory to calculate the electronic coupling matrix elements between adsorbates and surfaces, applying a recently developed diabatization method[1] to fully chemisorped systems. The scheme is demonstrated by calculating ultrafast electron transfer lifetimes within a Fermi golden rule framework, which compares favorably to core-hole-clock measurements for systems including Black Phosphorous, S/Ru(0001) and CO/Ru(0001). We thereby demonstrate the suitability of diabatization schemes for the description of coupling in chemisorped systems, enabling an advantageous interpretation of the electron transfer process. We discuss prospects for the use of first-principles coupling matrix elements to describe other surface phenomena, such as chemisorption and heterogenous catalysis, e.g. within Newns-Anderson models.

O 92.6 Thu 16:15 H25

Enhancing structure relaxation with machine-learned interatomic potentials — Sudarshan Vijay[1,2], Martijn Marsman[1], Georg Kresse[1,3], and •Martin Schlipf[1] — [1]VASP Software GmbH, Berggasse 21, 1090 Vienna, Austria — [2]Department of Chemical Engineering, Indian Institute of Technology Bombay, Powai, Mumbai, Maharashtra 400076 India — [3]Faculty of Physics and Center for Computational Materials Science, University of Vienna, Kolingasse 14-16, A-1090 Vienna, Austria

Machine learning interatomic potentials (MLIPs) offer a cost-effective way to predict ground-state properties of materials compared to density functional theory (DFT) calculations. MLIPs are often used to replace DFT due to their ability to access large length and longer time scales. In this study, we explore whether MLIPs can also enhance DFT by preconditioning commonly used optimization algorithms for structure relaxation. We demonstrate that applying this preconditioner to methods such as conjugate gradient (CG) and Broyden-Fletcher-Goldfarb-Shanno (BFGS) results in faster convergence but at the expense of stability. For this particular tasks, state-of-the-art MLIPs are not accurate enough to replace DFT; prerelaxing the structures with MLIPs tends to perform worse compared to starting the relaxation directly within DFT. Our analysis of the convergence behavior for both standard and preconditioned methods suggests that advancements in line-search techniques could enhance the effectiveness of this preconditioning approach for structure relaxation.

O 92.7 Thu 16:30 H25

Constrained Density Functional Theory with Numeric Atomic Orbitals — •Tavinder Singh[1,2] and Harald Oberhofer[1,2] — [1]University of Bayreuth — [2]Bavarian Center for Battery Technology

Even in perfectly crystalline materials, simulation of some phenomena, such as the occurence and transport of polarons, rests on the simulation method's ability to describe localized charge carriers. This is generally hampered by both, the need to break a system's symmetry to accommodate such a localized state, and the infamous electron delocalization error of most semi-local density functionals. In this respect, constrained density functional theory (CDFT) has proven to be a viable tool addressing both. Constraining charges to pre-selected localized states naturally breaks the symmetry and mitigates DFT errors. In our contribution, we describe our implementation of CDFT in the FHI-aims package based on Numeric Atomic Orbital (NAOs) projectors. As a prototype, we consider polaron localization in the zero-strain anode material, $Li_4Ti_5O_{12}$ (LTO), and compared the computed relative energies and barriers with the literature as benchmark. Our results provide valuable insights into the applicability and accuracy of CDFT for studying localized electronic states in complex materials.

O 92.8 Thu 16:45 H25

Efficient Phonon Dispersions of 2D Films by Extension of DFPT in FLAPW Method *FLEUR* to Film Geometry. — •Thomas Bornhake[1,2], Alexander Neukirchen[1,2], Gregor Michalicek[1], Daniel Wortmann[1], Gustav Bihlmayer[1], and Stefan Blügel[1,2] — [1]Peter Grünberg Institut, Forschungszentrum Jülich and JARA, Jülich, Germany — [2]Physics Department, RWTH Aachen University, Aachen, Germany

Phonons are crucial in 2D materials, governing a range of physical properties and phenomena, *e.g.* from dynamical stability to spin-flip scattering. Thus, an efficient method for calculating phonons under arbitrary excitations is inevitable. Typically, phonons of film systems are calculated from *ab initio* using supercells that separate the film from periodic images by computationally costly empty space. Recently, we have succeeded in calculating the phonon dispersion using the state of the art density functional perturbation theory (DFPT) in the all-electron full-potential linearized augmented planewave (FLAPW) method *FLEUR* [1,2]. In this talk we present our extension to a truly 2D treatment of films embedded in semi-infinite vacuum [3]. We discuss some details of the implementation and compare results with respect to accuracy and efficiency to the repeated slab approaches.

This work was supported by CoE-MaX (EuroHPC JU, Grant No. 101093374) and DFG through CRC 1238 (Project C01).

O 92.9 Thu 17:00 H25

Excitations in oxides: from bits to qubits — •Vijaya Begum-Hudde[1], Yi-Ting Lee[1], Barbara Jones[2], and Andre Schleife[1] — [1]University of Illinois, Urbana-Champaign, USA. — [2]IBM

Defects in materials are ubiquitous and may adversely affect their functional properties. Often the defects are confined to a small space, and defect embedding allows us to define an active space comprising of these defect states and to incorporate screening effects of the host material, enabling access to electronic properties with a high-level theory.

In this talk I will focus on the structural and electronic properties of near-surface vacancies in α-Al_2O_3 (0001) to investigate the influence of defects and hydration on the initiation and propagation of corrosion in this material. Utilizing first-

principles calculations and quantum-defect embedding theory calculations, this study will analyse defect states and their ground- and excited-state properties. An active space is defined consisting of strongly localized states of the surface O vacany, and the remainder is treated as the environment. Next, an effective Hamiltonian is used for the active space that also includes the environment's effective screening and is solved via full configuration interaction (FCI). Simulations are performed on a quantum computer with a Unitary coupled-cluster ansatz for the determination of ground- and excited-state properties. Error mitigation techniques will be demonstrated, reducing error due to the hardware noise and showing very good concordance with the FCI results within chemical accuracy.

We acknowledge funding by the IBM-Illinois Discovery Accelerator Institute.

O 92.10 Thu 17:15 H25

Electronic band structure at finite temperature: A unifying approach that incorporates electron-electron and electron-vibration interactions — •Min-Ye Zhang[1,2], Xinguo Ren[2], and Matthias Scheffler[1] — [1]The NOMAD Laboratory at the FHI of the Max-Planck-Gesellschaft — [2]Institute of Physics, Chinese Academy of Sciences, China

An accurate first-principles description of electronic band structure at finite temperature requires accounting for self-energy contributions from both electron-electron (e-e) and electron-vibration (e-vib) interactions. In the widely used electron-phonon coupling (EPC) model[1], the two types of interactions are considered separately, and the model fails for strongly anharmonic materials. In this work, we integrate the two types of interactions beyond the EPC model by extending the statistically anharmonic, higher-order vibronic coupling approach[2] with the many-body *GW* method. This is achieved by combining *ab initio* molecular dynamics and periodic G^0W^0 method in an all-electron framework employing numeric atom-centered orbitals[3]. We demonstrate the robustness and efficiency of our G^0W^0 implementation, particularly through a proper treatment of long-range dielectric responses. As a proof of concept, we present the temperature-dependent electronic band structure of Si, incorporating both e-e and e-vib interactions.

Electronic and optical properties of computationally predicted Na-K-Sb crystals — •Chung Xu, Richard Schier, and Caterina Cocchi — University of Oldenburg

Due to their favorable electronic and optical properties, sodium-potassium-antimonides are an emerging class of crystals used as photocathodes in particle accelerators. Using first-principles methods based on density-functional theory and many-body perturbation theory, we investigate the electronic and optical properties of cubic NaK_2Sb and hexagonal Na_2KSb, two computationally predicted polymorphs of established photocathode materials that can emerge as metastable phases in polycrystalline samples. Our results indicate that both systems are indirect band-gap semiconductors with fundamental gaps on the order of 0.7 and 0.8 eV, respectively. Their direct gaps are very close to these values and Their optical spectra are characterized by weakly bound excitons in the near-infrared region which represent favorable characteristics for efficient photoemission. Our study suggests that the presence of cubic NaK_2Sb and hexagonal Na_2KSb in photocathode samples is not detrimental for their application as photocathodes [1].

Thermal dependence of conductance in short pi-conjugated single-molecule junctions — •Václav Kubíček and Hector Vazquez — Inst. of Physics, Czech Academy of Sciences

Conductance measurements at room temperature in single-molecule junctions are affected by the internal dynamics of the molecule, since many different internal conformations are averaged. Further temperature changes lead to different conformational sampling and may alter conductance values, opening the possibility of thermally active molecular devices.

For example, it was measured that raising the temperature from 300 K to 330 K results in a change in conductance for oligophenylenes [1]. In our work, we calculate the temperature dependence of conductance for several short pi-conjugated molecular wires. By combining classical statistical model with DFT simulations, we explore their accessible geometries and compute the resulting changes in conductance.

Our results show that by engineering chain composition, conductance increases or decreases are achievable with increasing temperature. Our results demonstrate the importance and potential applicability of thermally induced conformational changes in conductance.

Comparison of non-equilibrium Green function and wave packet methods for studying the CISS effect — •Thibaut Lacroix, Clemens Vittmann, Jaemin Lim, Susana F. Huelga, and Martin B. Plenio — Intitut für Theoretische Physik, Universität Ulm, Ulm, Deutschland

Non-equilibrium Green function (NEGF) technique has been widely employed to simulate quantum transport at the molecular scale. It is one of the main methods used to study transport properties of chiral molecules which are central to the investigation of chirality induced spin selectivity (CISS). Equivalent to the solution of a scattering problem, this approach leads to an energy resolved description of transport properties that can be used to obtained spin-dependent currents.

Alternatively, the description of electronic transport can be performed at the level of the Schrödinger equation. In that case, one considers an initial wave packet in the position basis – which therefore corresponds to a superposition of energy eigenstates – and computes its dynamics under the total Hamiltonian of the molecule and the leads. One benefit of this approach is to readily give access to the transient dynamics of the electron inside of the molecule, thus opening the possibility to study the internal mechanisms underlying CISS. We demonstrate that NEGF results can be recovered from wave packet evolution and that tailored wave packets enable to access directly specific transport properties of interest. These results show that while they rely on different formalisms wave packet evolution and NEGF do give the same information about the response of the system.

A quantum sandwich world and how we can explore it with soft x-rays — •Kai Rossnagel — Kiel University, Kiel, Germany — DESY, Hamburg, Germany

Without materials, there is nothing. Without quantum materials, there is nothing interesting.

Quantum materials express our desire to find and explain new states of matter and new physical phenomena induced by the quantum mechanical interactions of electrons. Paradigmatic examples are quantum material sandwiches made by stacking and twisting single layers of layered materials, which currently represent one of the richest and most tunable discovery and engineering platforms in all of condensed matter physics.

To see and understand how these and other quantum materials work, we need spectroscopic tools that can provide direct snapshots of electron behavior in energy-momentum space. The most powerful toolbox for this is soft x-ray spectroscopy. And the single most powerful tool is angle-resolved photoelectron spectroscopy (ARPES), which has recently been transformed into a true *in operando* technique using both nanofocused and ultrashort-pulsed soft x-ray beams to directly probe nonequilibrium electronic function in materials and devices on relevant nanometer length and femtosecond time scales, respectively.

Here, we give an overview of recent innovations in quantum material sandwiches, focusing on transition-metal dichalcogenides, and in nanoscopic and femtostroboscopic imaging of their electronic structures.

O 96: Plasmonics and Nanooptics: Light-Matter Interaction, Spectroscopy II

Time: Friday 10:30–13:00 Location: H4

O 96.1 Fri 10:30 H4

Enhancing light-matter interaction through inverse design of optical devices. — •Carlos Bustamante[1], Mark Svendsen[2], Franco Bonafé[1], Burak Gurlek[1], Maxim Sukharev[3], Abraham Nitzan[4], and Angel Rubio[1] — [1]MPSD, Hamburg, Germany — [2]Niels Bohr Institute, University of Copenhagen, Denmark — [3]Department of Physics, Arizona State University, USA — [4]Department of Chemistry, University of Pennsylvania, USA

Light-matter interaction plays a crucial role in processes such as spontaneous emission, energy transfer and polaritonic formation. This interaction is sensitive to alterations in the electromagnetic environment which can be caused by the presence of optical materials. In classical optics, changes in the topology of optical materials can lead to the fabrication of optical devices tailored towards specific characteristics, using inverse design methodologies like density-based topology optimization (TO). This work presents the application of optical devices, derived from TO, that can be used to modify light-matter interaction among molecules. To achieve this, we have implemented a TO algorithm that can solve Maxwell equations in the frequency domain on a 2D grid. These tailored devices enhance locally one component of the transverse electric field obtained from classical emitters. In subsequent semiclassical simulations, Maxwell equations were classically propagated with the emitters replaced by pentacene molecules using the quantum mechanical simulation software DFTB+. The results highlight the significant potential of optical devices produced by TO to influence the above-mentioned processes.

O 96.2 Fri 10:45 H4

Squeezing few-cycle light pulses in space and time in the gap of a nanoplasmonic resonator — •Tom Jehle, Sam S. Nochowitz, Juanmei Duan, and Christoph Lienau — Universität Oldenburg, D-26129, Germany

The spatial confinement of light to (sub-)nanometer spot sizes in the gap of a nanoparticle-on-mirror resonator or in the gap of a tunnelling junction has led to dramatic advances in nanosensing [1] and tip-enhanced Raman Spectroscopy [2]. So far, the time dynamics of the fields emitted from such nanocavities have achieved little attention and only recently the time structure of a Terahertz field scattered from the junction of an STM tip could be recorded [3]. Here, we introduce a broadband interferometric scattering-type SNOM technique [4] to reconstruct amplitude and phase of light scattered from a sharp gold taper acting as a near-field probe. Direct Fourier transform gives the time structure of the electric field. We distinguish the near-field scattered from the apex and that emitted by spatially well separated scattering mode of the taper. The apex field decays within 13 fs, a decay time mainly given by the radiative damping of the apex mode. Upon approaching the tip to a gold surface, we observe a 3.5-fold reduction in the decay time to less than 4 fs: coupling to the image dipole drastically increases the radiative damping in the tip-surface junction. Our results pave the way towards linear and nonlinear ultrafast oscilloscopy with nm/fs resolution. [1] R. J. Chikkardy et al., Nature 535, 127 (2016); [2] R. O 96.3 Fri 11:00 H4

Full-wave simulations of core-shell nanoparticle investigation by tapping mode near-field optical microscopy — •Dario Siebenkotten, Dinghe Dai, Richard Ciesielski, Arne Hoehl, and Bernd Kästner — Physikalisch-Technische Bundesanstalt, Abbestr. 2-12 10587 Berlin

Core-shell nanoparticles are important in applications such as optoelectronics, biosensing, and medicine, where their unique optical and geometric properties play a critical role in functionality. Quantifying the properties of both, the core and the shell, is crucial to understand the nanoparticle's ultimate functionality. However, optical investigation of their properties, while widely employed, is generally diffraction-limited and thus unsuitable for the investigation of individual nanoparticles, as they only provide averaged ensemble information. Scattering-type scanning near-field optical microscopy (s-SNOM) promises access to a single nanoparticle's size and optical properties through the use of an atomic force microscopy tip as an optical antenna, which confines the sampling fields to nanoscale dimensions. To explore the single nanoparticle s-SNOM response, we model different core-shell nanoparticles using Finite Element Modelling, revealing complex resonance-antiresonance behaviour in dependence of their geometrical and optical properties. We further explore the origin of the emergent antiresonance through the use of Fourier-demodulation of the probe tapping [1], closely mimicking the experiment. [1] Mooshammer et al., ACS Photonics 7, 344-351 (2020)

O 96.4 Fri 11:15 H4

Near-field microscopy of complex polaritonic excitations — •Farid Aghashirinov[1], Bettina Frank[1], Harald Giessen[1], Andrea Manchini[2], Lin Nan[2], Giacomo Venturi[2], Nicola Melchioni[2], and Antonio Ambrosio[2] — [1]4-th Physics Institute, University of Stuttgart, Stuttgart, Germany — [2]Vectorial Nano-Imaging, Istituto Italiano di Tecnologia, Milano, Italy

We investigate directional near-infrared (NIR) plasmon polaritons (PPs) in mechanically exfoliated bulk molybdenum oxide dichloride (MoOCl2) flakes on a glass substrate with gold disk launchers positioned on top of the flakes, through experimental and theoretical methods [1]. MoOCl2, a natural van der Waals crystal, exhibits low-loss, in-plane hyperbolic PPs across the visible and NIR ranges, and displays a unique anisotropic optical response based on the polarization of the incident light. When light polarization aligns with the flake's shortest axis, MoOCl2 behaves optically metallic, while aligning with the longest axis reveals a dielectric behaviour. To experimentally study the hyperbolic PPs in MoOCl2, we use a near-field excitation and detection approach. Gold disks serve as excitation sources, scattering incident light to couple it with the material's polaritonic modes, while a reflection scattering-type scanning near-field optical microscope (s-SNOM) enables subwavelength imaging. For tunable wavelength illumination, we use a broadband laser from Stuttgart Instruments (SI), which, when combined with s-SNOM, allows us to investigate these modes across a wide wavelength range, capturing detailed insights into their behavior and propagation. [1] G. Venturi et al., Nat Commun 15, 9727 (2024)

O 96.5 Fri 11:30 H4

Discovery of phonon-polaritonic skyrmions: Transition from bubble- to Néel-type — •Florian Mangold[1], Enrico Baù[2], Lin Nan[2], Julian Schwab[1], Thorsten Gölz[2], Andrea Mancini[2], Bettina Frank[1], Andreas Tittl[2], and Harald Giessen[1] — [1]4th Physics Institute, Research Center SCoPE, and IQST, University of Stuttgart, Germany — [2]Chair in Hybrid Nanosystems, Nano-Institute Munich, Ludwig-Maximilians Universität München, Germany

Optical skyrmions constitute an emerging and rapidly developing field in the domain of solid-state physics and photonics, allowing for control over topological light textures through light-matter interactions. However, until now their practical applications have been severely limited by inherent restrictions of materials with high optical losses and a lack of tunability between different topological properties. We leverage the steep dispersion of silicon carbide thin films to image surface phonon polariton skyrmion lattices via near-field microscopy and experimentally demonstrate topological tuning between Bubble- and Néel-type skyrmions, a unique advantage that polar dielectrics offer over most existing approaches. The ability to control and manipulate these skyrmion lattices through

small changes (<10%) in excitation wavelength allows for tailoring the size of individual skyrmions by a factor of 4. Tuning topological properties has been a long-standing goal in the field of optics. Our results expand the tunability of skyrmions in evanescent waves and are a starting point to investigate other topological features in phononic systems such as merons, skyrmion bags and other complex structured light fields.

O 96.6 Fri 11:45 H4

Tracking Non-Equilibrium Electron Distributions to Propel Chemical Dynamics at Surfaces — •Henry T. Snowden[1], Reinhard J. Maurer[1], Markus Uehlein[2], and Baerbel Rethfeld[2] — [1]University of Warwick, Coventry, UK — [2]RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany

A mechanistic understanding of ultrafast light-matter interactions with surfaces and nanoparticles is invaluable for the study of ultrafast dynamics at surfaces. Immediately after a laser pulse, non-equilibrium electrons are generated in metals which rapidly relax to a thermal distribution that follows the two-temperature model. Here, we study the longevity of electronic non-equilibrium which depends on the electronic structure and other materials properties. We simulate the temporal evolution of non-equilibrium electron distributions with the Athermal Electron Model (AthEM), which explicitly considers electronic nonequilibrium, a laser term and electron scattering in the relaxation time approximation. Equipped with this approach, we investigate how athermal electron-hole pair distributions differ in various materials configurations such as intermetallic interphases, and nanoparticles. We will use this information to discuss the requirements to create long-lived non-equilibrium distributions from which high-energy charge carriers can be harvested.

O 96.7 Fri 12:00 H4

Collective Behavior of SiC Phonon Polariton Resonators — •Richarda Niemann[1,2], Sören Wasserroth[1], Guanyu Lu[2], Christopher R. Gubbin[3], Martin Wolf[1], Simone de Liberato[3], Joshua D. Caldwell[2], and Alexander Paarmann[1] — [1]Fritz Haber Institute, Berlin, Germany — [2]Vanderbilt University, Nashville, TN, USA — [3]University of Southampton, Southampton, UK

Structuring polar materials with microresonators enables light confinement to sub-wavelength scales and the emergence of localized phonon polaritons (PhPs). Previous studies on PhP single resonators and 2D resonator arrays investigated the coupling behavior of resonators with their surrounding [1,2]. Here, we bridge the gap between a single resonator and a 2D array by studying subdiffractional SiC microresonators on a SiC substrate in 1D arrays with sumfrequency generation (SFG) spectro-microscopy [3,4]. The high spatial resolution on the order of the lateral size of the microresonators allows us an in-depth analysis of the build-up of collective modes in 1D arrays with sizes from one to several resonators. We observe different optical responses for in-phase and out-of-phase excitation showing the importance of phase relationships for coupling between the resonators. By investigating arrays with different periods, we gain information about the coupling mechanisms.

High-Throughput Phonon Polariton Materials Discovery from First Principles — •Elena Gelzinyte[1], Giulia Carini[1], Niclas S. Mueller[1], Martin Wolf[1], Karsten Reuter[1], Johannes T. Margraf[2], Alexander Paarmann[1], and Christian Carbogno[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]University of Bayreuth

Phonon Polaritons (PhPs), quasi-particles that arise from strong coupling between infrared photons and optical lattice vibrations, are promising in nanophotonic applications for highly directional and confined light propagation with low optical loss [1]. However, little is still known about the trends in material space that drive the emergence and characteristics of PhPs. To describe these trends, we compute the permittivity function [2] as the basis for describing PhP dispersion. We employ Kubo's linear-response theory, where the harmonic and anharmonic phonon properties as well as Born effective charges are used to model the involved couplings. This approach is validated on materials with well-characterised PhP behaviour, such as h-BN, MoO_3 and β-Ga_2O_3, and then applied to 5,000 materials from the JARVIS database [3]. By analysing the trends emerging from these data, we identify qualitative metrics that capture the material's ability to support PhPs. Finally, we highlight some examples and outliers of this high-throughput screening process.

Electron Relaxation in Noble Metals: Microscopic Theory of Orientational Relaxation, Thermalization and Cooling — •Jonas Grumm and Andreas Knorr — Institut für Theoretische Physik, Nichtlineare Optik und Quantenelektronik, Technische Universität Berlin, Berlin, Germany

The excitation of electrons in noble metals by light fields with high intensities results in non-equilibrium electron occupations. The relaxation back to thermodynamic equilibrium, proceeding on scales from a few femtoseconds to several picoseconds, depends strongly on these excitation conditions: Typically, during the first tens of femtoseconds after the excitation, momentum polarization induced by the distinct polarization direction of the light field dominates the electron gas.

To address the relaxation dynamics of this momentum polarized state, we solve a kinetic momentum-resolved Boltzmann equation with focus on electron-phonon interaction and introduce orientational relaxation as first temporal step in a sequence of relaxation processes followed by thermalization and cooling. Applying a self-consistent treatment of Maxwell's equations and material dynamics we are able to present results for the optical and thermal properties of plasmonic nanostructures after linear and non-linear optical excitations. Thereby, Pauli-blocking non-linearities in the electron-phonon interaction modify the relaxation dynamics for strong excitations and effect the optical response of the electron gas.

O 96.10 Fri 12:45 H4

Sum-Frequency Generation Spectro-Microscopy in Barium Titante — •Dorothee Mader[1], David Pesquera[2], Saptam Ganguly[2], Richarda Niemann[1,3], Martin Wolf[1], Sebastian F. Maehrlein[1], Jose Santiso[2], and Alexander Paarmann[1] — [1]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [2]Catalan Institute of Nanoscience and Nanotechnology, Barcelona, Spain — [3]Vanderbilt University, Nashville, USA

Ferroelectric Barum Titanate (BTO) can be switched by excitation of phonons in the infrared (IR), enabeling the applications in future optical technologies.[1] Here, we investigate the resonance behavior of BTO in the IR by employing infrared-visible (IR-VIS) sum-frequency generation (SFG) spectro-microscopy using the free-electron laser of the Fritz Haber Institute.[2,3] As a second-order nonlinear technique, this method is sensitive to the material's symmetry. Additionally, as it is employed resonantly, it can reveal vibrations, local structure and bonding of the material. We demonstrate resonant ferroelectric imaging using SFG spectro-microscopy for bulk BTO and 500 nm thin BTO membranes.

O 97: Organic Molecules on Inorganic Substrates: Electronic, Optical and Other Properties II

Time: Friday 10:30–12:30 Location: H6

O 97.1 Fri 10:30 H6

Nanostructuring of organic radicals on hybrid interfaces — •Arkaprava Das, Ewa Malgorzata Nowik-Boltyk, Tobias Junghoefer, and Maria Benedetta Casu — Institute of Physical and Theoretical Chemistry, University of Tübingen, 72076 Tübingen, Germany

Organic radicals are potential candidates for groundbreaking applications like energy storage, quantum computing, and spintronics. In order to investigate the nature of the adsorption of the radical derivative molecules on hybrid surfaces based on polycrystalline Au and native SiO_2, we investigate their electronic structure and morphology. The electronic structure at the interface is investigated by using X-ray photoelectron spectroscopy (XPS) and the morphology is studied with scanning electron microscopy. The substrate-dependent interface interactions have resulted in different nanostructures crucial for device fabrication whereas changes in line shape of core level spectra confer direct evidence of changed electronic properties.

O 97.2 Fri 10:45 H6

Beyond the Koopmans' theorem: Energy-level alignment of PTCDA on BlueP-Au-network on Au(111) — •Maximilian Schaal[1], Felix Otto[1], Marco Gruenewald[1], Roman Forker[1], Keisuke Fukutani[2], Satoshi Kera[2], and Torsten Fritz[1] — [1]Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany — [2]Institute for Molecular Science, Myodaiji, Okazaki 444-8585, Japan

Koopmans' theorem is often used to relate the observed spectroscopic features in UP spectra to the orbital energies of molecules calculated by Hartree-Fock calculations. However, this theorem neglects the self-energy (charging energy),

which can be as large as 1 eV for molecules in the gas phase [1]. Therefore, the ground state energy levels of the frontier orbitals are not sufficient to describe the energy-level alignment and the initial and final states must be considered [2].
In this study, we present a framework to investigate the energy-level alignment of a monolayer of PTCDA decoupled from the Au(111) surface by a BlueP-Au-network [3]. We have determined the electronic transport and the optical gap using differential reflectance and (low-energy inverse) photoelectron spectroscopy. From these values, we determined the exciton binding energy and the charging energy. Finally, we compared the energy levels of the adsorbed monolayer with measured and calculated quantities of molecules in the gas phase.

O 97.3 Fri 11:00 H6

Disentangling the components of a multireference excited state in an isolated chromophore — Rodrigo Ferreira[1,2], Tomáš Neuman[1], Amandeep Sagwal[1], Jiří Doležal[2], Petr Kahan[1], and •Martin Švec[1,2] — [1]Institute of Physics, Czech Academy of Sciences — [2]Institute of Organic Chemistry and Biochemistry, Czech Academy of Sciences

Excited states of open-shell chromophores are commonly multireference in their nature. Distinguishing the components of these superposition states in a single chromophore by experimental means is a challenging task as it would essentially require capturing their orbital occupancies in the excited state. We demonstrate this can be achieved by atomically precise mapping of photon-induced tunneling current under a varying electric field, on a model case of a PTCDA anionic excited state coupled to a plasmonic nanocavity. To simulate the cascade of energy conversions and charge transfer events occurring within the molecule, a set of rate equations is derived from a many-body state scheme using an input from TD-DFT. The resulting bias-dependent tunneling current maps reach a very good agreement with the experimental data, corroborating the validity of the theoretical understanding.

O 97.4 Fri 11:15 H6

Second harmonic spectroscopy of Fe-porphyrin/Cu(001) interfaces — •Newsha Vesalimahmoud, Mahendra Kabbinahithlu, Ping Zhou, Uwe Bovensiepen, and Andrea Eschenlohr — University of Duisburg-Essen, Faculty of Physics and CENIDE, Lotharstr. 1, 47057 Duisburg, Germany

When a molecule interacts with a metal surface, metal-molecule interaction induces a rearrangement of their electronic densities, shifting the molecular orbitals relative to the metal's Fermi level. This study focuses on the FeOEP/Cu(001) interface, using interface-sensitive SHG spectroscopy. We analyze polarization- and wavelength-dependent SHG for varying molecular adsorbate thicknesses on Cu(001) using a fundamental beam in the 500-600 nm range. Polarization-dependent measurements show a higher SHG yield for p-P polarization than s-P SHG, as the intrinsic value of $\left|\chi^{(2)}_{zzz}\right|$ is much larger than $\left|\chi^{(2)}_{zxx}\right|$. As the number of monolayers increases, P-polarized SHG intensity decreases due to reduced nonlinear susceptibility from less polarizable free electrons, while S-polarized SHG shifts from 4-fold to 2-fold symmetry. The SHG spectra show an intensity peak at 2.17 eV due to a one ω resonance in Cu(001). After adsorption of 2, 5, and 8 monolayers (ML) of FeOEP on Cu(001), the spectral dependence remains similar to the Cu(001) surface, except for an enhancement at 2.21 eV for 5ML and 8ML. This enhancement is attributed to the energetic position of the lowest unoccupied molecular orbital (LUMO) at the FeOEP/Cu(001) interface.

O 97.5 Fri 11:30 H6

Probing the Roles of the Substrate Material, Spin Scattering, Temperature and Cooperative Effects in CISS — •Paul V. Möllers[1], Adrian J. Urban[2,3], Bianca C. Baciu[4], Rafael Rodriguez[5], Albert Guijarro[4], Jeanne Crassous[5], Steven De Feyter[3], Hiroshi M. Yamamoto[2], and Helmut Zacharias[1] — [1]Center for Soft Nanoscience (SoN), University of Münster, Busso-Peus-Str. 10, 48149 Münster, Germany — [2]Institute for Molecular Science, Research Center of Integrative Molecular Systems, Division of Functional Molecular Systems, 38 Nishigonaka, Myodaiji Okazaki, Aichi prefecture, 444-8585 Japan — [3]Division of Molecular Imaging and Photonics, Department of Chemistry, KU Leuven, Celestijnenlaan 200 F, 3001 Leuven, Belgium — [4]Departamento de Química Orgánica, Instituto Universitario de Síntesis Orgánica, Unidad asociada al CSIC, Universidad de Alicante, E-03080, Alicante, Spain — [5]University of Rennes, CNRS, Institut des Sciences Chimiques de Rennes (ISCR), UMR 6226, Rennes, France

Monolayers of heptahelicene ([7]H) and helical tetrapyrrole (TPBT) complexes were adsorbed onto different single-crystalline metal substrates, and the spin polarization of photoelectrons emitted from these surfaces was measured. The substrate material, the temperature and the surface coverage were systematically varied to investigate the roles of the substrate spin–orbit coupling, molecular vibrations, and intermolecular interactions in the generation of the spin polarization. Furthermore, thiolized (chemisorbed) [7]H and all-carbon (physisorbed) [7]H layers were compared.

O 97.6 Fri 11:45 H6

Electrons don't wear bowties: The mechanism of Fermi-level pinning and charge for mixed donor-acceptor layers — •Richard Berger1 and Oliver T. Hofmann — TU Graz, Institute of Solid State Physics

Controlling the work function of metal substrates is critical when optimizing the performance of organic electronic devices. A particular powerful method to obtain such control is by employing a monolayer of strong electron donors or electron acceptors, i.e. so-called Fermi-level pinned systems which form charge-transfer-induced dipoles with the underlying substrate However, while the major advantage of this Fermi-level pinned systems is that the effective work function of the interface is (essentially) independent of the underlying substrate, there are only limited ways to fine-tune it. A more flexible way could be to employ a mixture of electron donors and acceptors. However, for such complex systems the underlying charge-transfer mechanism is less clear. In this work, we elucidate this mechanism using machine-learning augmented density functional theory calculations to predict both the atomistic and the electronic structure of the interface using a mixture of F4TCNQ and paraquat as an example. Counterintuitively, we find that the nominally weaker donor overpowers the stronger acceptor, resulting in a dependence of the work function that is effectively determined by the nominal coverage of the donor. At the same time, we find that multiple geometries are energetically very similar, but result in different work function, affecting the reproducibility of different experimental realizations.

O 97.7 Fri 12:00 H6

Magnetic Coupling in Triangulene Dimers: Impact of Number and Dihedral Angles of para-Biphenyl Linkers — •Marco Lozano[1], Elena Perez-Elvira[2], Qiang Huang[3], Ji Ma[3], Aurelio Gallardo[2], Ana Barragan[2], Alba Garcia-Frutos[2], Koen Lauwaet[2], Jose Gallego[4], Pavel Jelinek[1], David Ecija[2], Diego Soler-Polo[1], and Jose Urgel[2] — [1]Institute of Physics of the Czech Academy of Science, CZ-16253 Praha, Czech Republic — [2]IMDEA Nanoscience, C/ Faraday 9, Campus de Cantoblanco, 28049 Madrid, Spain — [3]Center for Advancing Electronics Dresden (cfaed) & Faculty of Chemistry and Food Chemistry, Technische Universität Dresden, 01069 Dresden, Germany — [4]Instituto de Ciencia de Materiales de Madrid (ICMM), CSIC, Cantoblanco, 28049 Madrid, Spain

Triangulene and its homologues are promising building blocks for high-spin low-dimensional networks with long-range magnetic order. Despite the recent progress in the synthesis and characterization of coupled triangulenes, key parameters such as the number or the dihedral angles of organic linking units remain scarce, making further studies crucial for an essential understanding of their implications. Here, we investigate the synthesis of two triangulene dimers linked by two or one para-biphenyl units on a metal surface in an UHV environment. First-principles calculations and model Hamiltonians reveal how the spin excitation and radicalism depend on the rotation of the para-biphenyl units.

O 97.8 Fri 12:15 H6

Insights into Nonlinear CD-ee Dependence in Tryptophan Thin Films — •Charitini Panagiotopoulou, Changseop Jeong, Ueli Heiz, and Aras Kartouzian — Chair of Physical Chemistry, School of Natural Sciences & Catalysis Research Center, Technische Universität München, Lichtenbergstr. 4, 85748 Garching, Germany

Chiral analysis is essential, especially for enantio-separation and -enrichment, with Circular Dichroism (CD) spectroscopy being a fast and straightforward method for studying enantiomeric excess (ee) and its dependence on circular dichroism (CD-ee dependence). While most systems show linear CD-ee dependence, studies reporting non-linear CD-ee behaviour are relatively rare and, thus, more attractive for research. Building on our earliest findings of negative nonlinear CD-ee dependence in polycrystalline BINOL thin films (Liang et al. 2023), we extend this study to a different system: the well-known amino acid responsible for synthesizing important proteins in humans, Tryptophan. We prove our hypothesis that the non-linear CD-ee dependence is not limited to BINOL films and can be applied to biomolecules, and we outline this non-linear dependence with different methods, such as CD spectroscopy, SHG-CD spectroscopy and FTIR study. This behaviour is linked to the structural characteristics of Tryptophan when a series of different enantiomeric excesses are deposited onto thin films via molecular evaporation. This approach paves the way for extensive exploration in the field of biomolecular chirality.

O 98: Metal and Semiconductor Substrates: Adsorption and Reactions of Small Molecules

Time: Friday 10:30–12:30 Location: H8

O 98.1 Fri 10:30 H8

Bonding properties of a CO molecule with metallic adatoms — •Fabian Stilp, Marco Weiss, Maximilian Krüger, and Franz J. Giessibl — Department of Physics, University of Regensburg

CO terminated AFM tips are often used to investigate molecules on surfaces as they are a powerful tool to make the internal structure of such molecules visible. Their chemical inertness results in high resolution of the single atoms and bonds in such molecule via Pauli repulsion. However, it was shown by Huber et al. [1] that CO terminated tips can form weak bonds to some species of adatoms on a Cu (111) sample such as Fe and Cu as evident by an attractive center within a repulsive ring in constant height AFM measurement. In contrast, Si adatoms only interact via van der Waals attraction and Pauli repulsion.

Can one predict the strength of the bond between the CO molecule and an arbitrary atom just from its electron configuration? To set the rules for this prediction we expand our collection of AFM measurements on various adatoms by adding Ni and Ag.

Ni has a partially filled d-shell and thus forms a chemical bond of similar strength as Fe. Surprisingly, Ag with its similar electron configuration as Cu, immediately goes to Pauli repulsion while Cu first forms a weak bond.

O 98.2 Fri 10:45 H8

Adsorption sites of merocyanines on the Ag(100) surface determined by NIXSW — •Anna Juliana Kny[1], Anja Haags[2], Sergey Subach[2], and Moritz Sokolowski[1] — [1]Clausius Institut für Physikalische und Theoretische Chemie, Universität Bonn, Germany — [2]Forschungszentrum Jülich, Germany

The growth of thin organic layers is strongly influenced by the interactions between the molecule and the substrate surface. We report about the adsorption sites of a series of merocyanine (MC) molecules on the Ag(100) surface. MCs are prochiral donor-acceptor molecules which are in focus for applications due to high transition dipole moments. [1] Remarkably, SPA-LEED data reveal commensurate structures for all of our investigated MCs, although the size of the unit cells depends on the length of the alkyl side chains.[2] In order to answer the question of what is behind the commensurate growth of these complex molecules, we performed an XPS and an NIXSW investigation. We find a strong binding of the two sulfur heteroatoms, located in the thiophene and the thiazole rings, to the Ag surface. This can be seen in charge transfer and an adsorption of the S-atoms close to on-top sites. This is found for all investigated structures. Furthermore, compatible with the symmetry of the unit cell, the results reveal that the four molecules per unit cell sit on two different adsorption sites.

We acknowledge experimental support from D.A. Duncan (DLS). Supported by the DFG through the research training group 2591 and the Diamond Light Source, UK.

O 98.3 Fri 11:00 H8

Electron-Induced Dehydrogenation of Acetylene and Ethylene on Si(100) — Rafik Addou, Damian Allis, Ryan Groome, Si Yue Guo, Aru Hill, Hadiya Ma, Cameron Mackie, •Oliver MacLean, Marc Savoie, Marco Taucer, Alexander Therien, Finley van Barr, and Ryan Yamachika — CBN Nanotechnologies Inc.

Low-Temperature Scanning Tunneling Microscopy (STM) is a powerful tool for manipulating individual atoms and molecules on surfaces. The Si(100) surface is a technologically relevant substrate; however, its high reactivity and structural complexity has led to limited examples of molecular manipulation. Here, we demonstrate the electron-induced dehydrogenation of two simple hydrocarbons on Si(100) at 4 K. Excitation by tunneling electrons at or above +3.2 V led to rotation, migration, or desorption of acetylene, consistent with previous observations on ethylene. At similar biases, dehydrogenation to C2 was also observed, which bound in on-dimer, inter-dimer, and inter-row configurations, as supported by STM simulations. At +4.2 V and above, excitation induced rotation of C2 between configurations, but conversion back to the starting adsorbates was never observed. Tunneling-electron excitation of ethylene yielded the same C2 products. Dehydrogenation of acetylene by field emission was also observed, with an effect ranging from a single to thousands of molecules, depending on the parameters chosen. This exploration of electron-induced dehydrogenation and rotation points to new possibilities in molecular manipulation on semiconductors.

O 98.4 Fri 11:15 H8

Selectivity on and off: adsorption of allyl ethers on Si(001) — •Sophie Göbel[1], Timo Glaser[1], Alexa Adamkiewicz[2], Jannick Peters[1], Julian Heep[1], Ulrich Höfer[2], and Michael Dürr[1] — [1]Institut für Angewandte Physik and Zentrum für Materialforschung, Justus-Liebig-Universität Giessen, Germany — [2]Fachbereich Physik, Philipps-Universität Marburg, Germany

Adsorption of organic molecules with more than one functional group on solid surfaces is of importance in the field of molecular electronics as they can be the starting point for multilayer systems [1]. To obtain well-organized monolayers of such bifunctional molecules, the understanding of their adsorption behavior, in particular in terms of their selectivity, is mandatory.

For allyl methyl ether (AME) and allyl ethyl ether (AEE), which combine an ether group with a C=C double bond, we show by means of XPS and STM that the adsorption of these molecules on Si(001) proceeds selectively via ether cleavage up to room temperature. The results are surprising as both functional groups involved show in general high reactivity on Si(001) and the ether group is less reactive when the isolated functional groups are compared. In contrast to AME and AEE, no such selectivity was observed for methoxy butene, where both functional groups are separated by an additional CH_2 unit. The results are discussed in terms of the interplay of electronic and geometric structure and its influence on the adsorption process.

[1] T. Glaser, et al., Chem. Mater. 36, 561 (2024).

O 98.5 Fri 11:30 H8

The Effect of Doping in Inelastic H Atom Scattering from Silicon — •Malte Opfermann, Sophia Tödter, Kerstin Krüger, and Oliver Bünermann — Institut für physikalische Chemie, Georg-August-Universität Göttingen, 37077 Göttingen, Germany

Recent inelastic H atom scattering experiments from the semiconducting Ge(111)c(2x8) have shown a bimodal energy loss distribution. One of the components was narrow with a small energy loss. The other component has shown a broad and large energy loss with an onset equal to the surface band gap.[1] While the low energy loss channel is explained by an adiabatic molecular dynamics simulation, the high energy loss component is not described theoretically yet.

To gain a better understanding of the underlying mechanism, we extended our studies to the Si(100)2x1 surface which is semiconducting as well. Despite its electronic structure being similar to the Ge(111)c(2x8) surface, it shows a different H atom energy-loss distribution. The first component is much broader and the second component does not show a clear onset at the surface band gap, both indicators of electronic effects. To further investigate, we carried out scattering experiments from samples with various doping levels.

O 98.6 Fri 11:45 H8

Adsorption and bowl inversion of sumenene adsorbed on Au(111): a density functional theory — •Ikutaro Hamada[1], Ranmaru Kuno[1], Kota Iwata[2], Yoshiaki Sugimoto[2], and Hidehiro Sakurai[3] — [1]Department of Precision Engineering, Graduate School of Engineering, Osaka University, Suita, Osaka 565-0871, Japan — [2]Department of Advanced Materials Science, The University of Tokyo, Kashiwa, Chiba 277-8561, Japan — [3]Division of Applied Chemistry, Graduate School of Engineering, Osaka University, Suita, Osaka 565-0871, Japan

Sumanene, a bowl-shaped π-conjugated compound, has been shown to form an ordered overlayer on noble metal surfaces. It has also been shown to exhibit conformation change, namely, bowl inversion, depending on its environment [1,2]. Experimentally, we have found that on Au(111), sumanene forms an ordered overlayer that differs from the previously reported structure for Au(111), but resembles the one observed on Ag(111). Moreover, we have demonstrated that bowl inversion can be induced using an atomic force microscopy tip. In this work, we employ van der Waals density functional to investigate the geometric and electronic structure of sumanene on Au(111). We also investigate the detailed mechanism of the bowl inversion of sumanene within the overlayer on the surface.

O 98.7 Fri 12:00 H8

Enhancing the electronic-coupling and conductivity of monolayer film of ferrocenyl molecules by Pd and Cu doping — •Sunny M P Gautam, Himani Malik, Vikash Meghwal, Sruthi Manoharan, Vinithra Gurunarayanan, Ramesh Ramapanicker, and Thiruvancheril G Gopakumar — Department of Chemistry, Indian Institute of Technology Kanpur, India

Enhancing the conductivity and tuning the electronic structure of molecular films is crucial for their application in electronics. In this study, we explore the impact of metal doping (Pd and Cu) on the electronic structure and conductivity of two custom-designed ferrocenyl molecules, 3-ferrocenyl propanoic acid (FcC3) and 5-ferrocenyl pentadienoic acid (FcC5), on a graphite surface. Although the microscopic arrangement of the molecules within the film remains largely unchanged after doping, the incorporation of Pd and Cu at the 4-coordinated carboxyl dimer site of FcC3/FcC5 leads to a significant increase in conductivity. Electronic structure calculations of the FcC3/FcC5 dimers with metal show a substantial reduction in the HOMO-LUMO gap compared to

their hydrogen-bonded counterparts, indicating stronger intermolecular electronic coupling through the Pd and Cu atoms, which lowers the barrier for electron/hole transport.

O 98.8 Fri 12:15 H8

Ge(CH2I)4 on Si(100) - Matching the Molecule to the Surface — •Brandon Blue, Rafik Addou, Damian G. Allis, Eduardo Barrera-Ramirez, Jeremy Barton, Adam Bottomley, Nina Culum, Michael Drew, Tyler Enright, Alan Godfrey, Ryan Groome, Aru Hill, Taleana Huff, Robert J. Kirby, Samuel Lilak, Cameron J. Mackie, Oliver MacLean, Terry McCallum, Mathieu Morin, Matthew Moses, Jonathan Myall, Ryan Plumadore, Adam Powell, Henry Rodriguez, Marc Savoie, Benjamin Scheffel, Marco Taucer, Denis Alexander Therien, Dusan Vobornik, and Janice Wong — CBN Nanotechnologies Inc.

We present an on-surface, multi-technique analysis of a synthetic, custom molecule for Si(100): tetrakis(iodomethyl)germane - Ge(CH2I)4, or TIMe-Ge. TIMe-Ge consists of four iodomethyl (CH2I) legs bound to a Ge atom core in a tetrahedral geometry. TIMe-Ge was selected based on its expected reactivity and surface behavior with Si(100)-2x1 as part of a set of design criteria which we'll present and discuss. The suitability of TIMe-Ge with respect to these criteria were supported by simulations and literature precedent. TIMe-Ge was found to covalently bond with Si(100)-2x1 in a limited number of configurations via C-I dissociative addition by STM, DFT, and XPS. The fourth CH2I is oriented away from the surface and towards the SPM for interaction, including controlled generation of C-centered radicals via bias pulses and UV photochemistry. We anticipate that TIMe-Ge and its congeners will aid in the development of molecular nanotechnologies and the study of requisite intermediates.

O 99: Ultrafast Electron Dynamics IV

Time: Friday 10:30–13:00 Location: H11

O 99.1 Fri 10:30 H11

Large-amplitude coherent phonon dynamics in a van der Waals ferroelectric — •Jan Gerrit Horstmann[1], Quintin Meier[2], Thomas Lottermoser[1], and Manfred Fiebig[1] — [1]Dept. of Materials, ETH Zurich, Switzerland — [2]Institut Néel, CNRS UPR2940, Grenoble, France

We explore the all-optical control of coherent phonon dynamics in the van der Waals ferroelectric WTe_2. Double-pulse optical excitation is harnessed to enhance the amplitude of the prominent interlayer shear mode beyond the limit of single-pulse excitation, with the resulting structural dynamics monitored via time-resolved second harmonic generation. A strong correlation between shear phonon amplitude and damping suggests higher-order coupling to lower-lying modes. At largest initial phonon amplitudes, Fourier transforms of the delay-dependent SHG traces reveal a frequency contribution at twice the shear-mode frequency. We discuss second-harmonic phonon generation and ultrafast phononic modulation of the nonlinear susceptibility as potential underlying mechanisms. Coherent vibrational control over relaxation pathways and electronic properties of ferroic van der Waals materials could enable novel types of devices for energy-efficient electronics.

O 99.2 Fri 10:45 H11

Giant acceleration of polaron transport by ultrafast laser-induced coherent phonon — •Huimin Wang[1,2], Xinbao Liu[1,2], Shiqi Hu[1,2], Daqiang Chen[1,2], Qing Chen[1,2], Cui Zhang[1,3], Mengxue Guan[1,2], and Sheng Meng[1,2,3] — [1]Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China. — [2]School of Physical Sciences, University of Chinese Academy of Sciences, Beijing 100190, China. — [3]Songshan Lake Materials Laboratory, Dongguan, Guangdong 523808, China

Polaron formation is ubiquitous in polarized materials, but severely hampers carrier transport for which effective controlling methods are urgently needed. Here, we show that laser-controlled coherent phonon excitation enables orders of magnitude enhancement of carrier mobility via accelerating polaron transport in a prototypical material, lithium peroxide (Li2O2). The selective excitation of specific phonon modes, whose vibrational pattern directly overlap with the polaronic lattice deformation, can remarkably reduce the energy barrier for polaron hopping. The strong nonadiabatic couplings between the electronic and ionic subsystem play a key role in triggering the migration of polarons, via promoting phonon-phonon scattering within sub-picoseconds. These results extend our understanding of polaron transport dynamics to the non-equilibrium regime and allow for optoelectronic devices with ultrahigh on-off ratio and ultrafast responsibility, competitive with those of state-of-the-art devices fabricated based on free electron transport. H.M.Wang et al. Sci.Adv.9,eadg3833(2023).

O 99.3 Fri 11:00 H11

Ultrafast charge density wave, Van Hove singularity and flat-band dynamics in the Kagome metal CsV_3Sb_5 — •Mohamed Amine Wahada[1], Chris Nicholson[1], Andrea Capa Salinas[2], Brenden R. Ortiz[2], Lawson Lloyd[3], Tommaso Pincelli[3], Tulio de Castro[1], Martin Wolf[1], Ralph Ernstorfer[3], Stephen D. Wilson[2], and Laurenz Rettig[1] — [1]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Faradayweg 4-6, 14195 Berlin, Germany — [2]Materials Department and California Nanosystems Institute, University of California Santa Barbara, Santa Barbara, California 93106, USA — [3]Institut für Optik und Atomare Physik, Technische Universität Berlin, 10623 Berlin, Germany

The Kagome metal family AV3Sb5 (A=K, Rb, Cs) features an unconventional superconducting phase, coexisting with a parent charge density wave (CDW) phase. The origin of the CDW is still under debate. Moreover, this family exhibits a number of Van Hove Singularities (VHS) and a flat-band (FB) below the Fermi level, offering a unique platform for high electronic correlation. In order to gain insight into these properties, we study the ultrafast dynamics in CsV3Sb by using time and angle-resolved photoemission spectroscopy (trARPES). We discuss the ultrafast melting of CDW order, concomitant with a shift and a broadening for both the FB and the VHS, all being modulated by coherent phonon modes.

O 99.4 Fri 11:15 H11

Ultrafast Nonequilibrium Dynamics of Room Temperature Charge Density Wave Fluctuations in 1T-$TiSe_2$ — •Hibiki Orio[1], Samuel Beaulieu[2], Sarath Sasi[2], Akib Jabed[2], Muthu P.T. Masilamani[1], Maximilian Ünzelmann[1], Jan Minar[3], Friedrich Reinert[1], Kai Rossnagel[4], Sotirios Fragkos[2], and Jakub Schusser[1,3] — [1]Universität Würzburg, Experimentelle Physik VII and Würzburg-Dresden Cluster of Excellence, Würzburg, Germany — [2]Université de Bordeaux - CNRS - CEA, CELIA, Talence, France — [3]New Technologies-Research Center, University of West Bohemia, Pilsen, Czech Republic — [4]Institute of Experimental and Applied Physics, Kiel University, Kiel, Germany

$TiSe_2$ exhibits a 2×2×2 charge density wave (CDW) phase below 200 K, driven by the interplay between electron-hole and electron-lattice interactions. Nanoscale CDW domains, referred to as CDW fluctuations, persist even above the transition temperature. This exotic phase provides an intriguing platform for exploring the robustness of electron-hole interactions and electron-phonon coupling at elevated temperatures. Using time- and polarization-resolved XUV momentum microscopy, we investigate CDW fluctuations in $TiSe_2$ and their ultrafast light-induced dynamics. Our band structure mapping reveals that the backfolded Se 4p band associated with the CDW phase remains detectable even at room temperature. Furthermore, we demonstrate the ultrafast melting of these CDW fluctuations on an electronic timescale, followed by rapid recovery modulated by coherent amplitude phonon modes.

O 99.5 Fri 11:30 H11

Coherent phonons and quasiparticle renormalization in semimetals from first principles — •Christoph Emeis, Stephan Jauernik, Sunil Dahiya, Yiming Pan, Carl E. Jensen, Petra Hein, Michael Bauer, and Fabio Caruso — Kiel University, Germany

Coherent phonons offer a powerful means to manipulate structural and electronic properties of materials on ultrafast timescales, making them a key tool for exploring light-induced phase transitions and non-equilibrium dynamical phenomena.

We present an *ab initio* theory for the displacive excitation of coherent phonons in semimetals. We formulate a computational workflow for modelling light-induced structural changes and the resulting transient band-structure renormalization following excitation with a femtosecond laser. This framework is based on first-principles simulations of ultrafast electron and coherent phonon dynamics in the presence of electron-phonon interactions. We validate our approach through a combined theoretical and experimental study of coherent phonons in the semimetal antimony. The robust agreement between photoemission experiments and simulations corroborates our approach and paves the way for new opportunities to control structural and electronic degrees of freedom in semimetals via coherent phonon excitation.

C. Emeis *et al.* arXiv:2407.17118

O 99.6 Fri 11:45 H11

Ultrafast energy flow among electrons and phonons in a Pb/Si nanoscale heterosystem — •Christian Brand[1], Mohammad Tajik[1], Tobias Witte[1], Laurenz Rettig[2], Birk Finke[1], Björn Sothmann[1,3], Uwe Bovensiepen[1,3], and Michael Horn-von Hoegen[1,3] — [1]Department of Physics, University of Duisburg-Essen, Germany — [2]Department of Physical Chemistry, Fritz Haber Institute, Germany — [3]Center for Nanointegration Duisburg-Essen, Germany

In condensed matter, microscopic excitations interact on ultrafast time scales. The combination of suitable time domain experiments allows the analysis of processes such as the energy transfer from electrons to the nuclei subsequent to femtosecond laser pulse excitation. In this study, we used time-resolved photoelectron spectroscopy and ultrafast electron diffraction to probe the spatially confined dynamics of electrons and phonons in ultrathin epitaxial Pb films on Si(111). While the electrons lose their excess energy within 400 fs, the lattice vibrational displacements gradually increase over 3-8 ps. Within the time gap, the energy is transiently stored in high-frequency phonon modes as simulated in a three-temperature model. Their temperature is experimentally accessible by the transient electron temperature after equilibration with such hot phonons. The excitation of low-frequency phonons and the subsequent thermalization and equilibration of the lattice are facilitated by anharmonic phonon-phonon coupling within the Pb film.

O 99.7 Fri 12:00 H11

Resolving ultrafast atomic motion in WTe_2 — •Hanqian Lu[1,2], Victoria C. A. Taylor[2], Hyein Jung[1,2], Jannik Malter[1,2], Ralph Ernstorfer[1,2], and Yoav W. Windsor[1,2] — [1]Technische Universität Berlin, 10623 Berlin, Germany — [2]Fritz Haber Institute of the Max Planck Society, 14195 Berlin, Germany

WTe_2 is a layered transition metal dichalcogenide with a distorted layered structure leading to distinct material properties. Here we study its lattice dynamics following ultrafast photoexcitation, using femtosecond electron diffraction (FED). We observe a strong coherent lattice response as well as growth of incoherent atomic vibrations, which we qualitatively describe as previously done. With the goal of describing such motions microscopically, we develop a quantitative model that extracts both the coherent and the incoherent atomic motions of each W and Te atom in the unit cell.

O 99.8 Fri 12:15 H11

Structural dynamics of the silicon (111)-(7×7) surface upon optical excitation studied by ultrafast reflection high-energy electron diffraction — •Jonas Darius Fortmann[1], Birk Finke[1], Christian Brand[1], and Michael Horn-von Hoegen[1,2] — [1]Faculty of Physics, University of Duisburg-Essen, 47057 Duisburg, Germany — [2]Center for Nanointegration (CENIDE), University of Duisburg-Essen, 47057 Duisburg

We present first results on the ultrafast structural dynamics of the Si(111)-(7×7) surface subsequent to an optical excitation. The surface is excited by an 800 nm fs-laser pulse at various fluences. The structural dynamics is followed through ultrafast reflection high-energy electron diffraction (URHEED) at a sample temperature of 80 K by means of the Debye-Waller effect. The surface has been excited for incident fluences > 1.6 mJ/cm^2 at a drop of RHEED intensity by only 0.8%. For the highest fluence of 5.4 mJ/cm^2 the intensity drop was 2% which is equivalent to a rise of surface temperature by 7 K. The fluence dependence is explained by linear absorption through the metallic surface state of the 7×7 reconstruction. For higher fluences we observe an additional three photon absorption due to bulk excitation in order to overcome the direct bandgap. The recovery to the groundstate occur via several processes at different time constants. The system has not fully recovered the groundstate after 200 μs, which indicates the population of a long-lived electronic state.

O 99.9 Fri 12:30 H11

Ultrafast imaging ellipsometry or interferometry - Which one is more suitable to measure the dielectric function of laser-excited materials? — •Markus Olbrich, Theo Pflug, Andy Engel, and Alexander Horn — Laserinstitut Hochschule Mittweida, Hochschule Mittweida, Technikumplatz 17, 09648 Mittweida, Germany

Changes of the dielectric function of materials due to excitation by ultrafast laser radiation are crucial for understanding fundamental processes such as absorption of electromagnetic radiation or the relaxation of the excited electrons resulting in changes in the density of state of the material. The transient dielectric function can either be measured by ultrafast ellipsometry or interferometry. This study evaluates the advantages and disadvantages of each method exemplarily for an excited thin gold film induced by ultrafast laser radiation ($\lambda = 800$ nm, $\tau_H = 40$ fs) at fluences below and above the ablation threshold. The focus of the presentation is on characterizing the methodology including the experimental effort, the obtained signal-to-noise ratio, the data evaluation particularly in the limits of the applied optical model, as well as the physical interpretation of the measured data.

O 99.10 Fri 12:45 H11

Anisotropic electronic response in hexagonal boron nitride to laser excitations from real-time time-dependent density functional theory — •Cheng Wang, Markus E. Gruner, and Rossitza Pentcheva — Department of Physics, University of Duisburg-Essen

Hexagonal boron nitride (h-BN) has a graphite-derived structure where nitrogen (N) and boron (B) atoms occupy alternating sites. In the framework of real-time time-dependent density functional theory (RT-TDDFT), as implemented in the Elk code, we systematically study the response of bulk and single layer h-BN to laser pulses with in- and out-of-plane polarization, different photon energies, duration and fluences. Our analysis focuses on transient charge redistribution and changes in occupation numbers, revealing a marked dependence on both polarization and frequency in bulk and monolayer h-BN. For a photon energy of 4.8 eV, slightly above the DFT band gap, we find a notable charge transfer from N to B p_z-orbitals in both bulk and monolayer for in-plane polarization. At 9.5 eV, excitations occur primarily between occupied and unoccupied N p_x-orbitals with a small charge transfer to B. In the monolayer, these excitations are suppressed for out-of-plane polarization. Finally, we compare our findings for monolayer h-BN with analogous calculations for graphene.

We gratefully acknowledge the funding provided by the DFG through CRC 1242, project C02. We acknowledge computation time at the MagnitUDE and AmplitUDE HPC systems at the University of Duisburg-Essen.

O 100: Focus Session Chemical Imaging for the Elucidation of Molecular Structure II (joint session O/BP)

Unravelling the multiscale molecular heterogeneity at interfaces is one of the main challenges in modern biophysics and surface science due to the major role specific structural properties play in determining their macroscopic function and behavior. In the last few decades, several specialized chemical imaging techniques have been developed that can reveal many of these crucial structural details, representing an enormous advance in our elucidative capabilities. Clear examples of this range from super-resolution and 3D tomography to tag-free characterization down to the single-molecule level. This focus session will explore the vast range of methods and possibilities for characterizing the different structural aspects in heterogeneous molecular systems and specifically highlight the potential complementarity of the different techniques through multi-modal approaches. Overall, by bringing together different communities, this session aims to foster scientific exchanges that could spark the next major developments in chemical imaging.

Organized by Martin Thämer (FHI Berlin), Alexander Fellows (FHI Berlin), and Kerstin Blank (University Linz)

Time: Friday 10:30–12:45 Location: H24

Invited Talk O 100.1 Fri 10:30 H24

Multidimensional Super-resolution Imaging: Wasting Light to Learn New Things — •Steven Lee — University of Cambridge

The talk will outline two single-molecule fluorescence approaches that can be used to determine orthogonal metrics about a single emitter.

The first half introduces "POLCAM," a simplified single-molecule orientation localization microscopy (SMOLM) method based on polarised detection using a polarisation camera. POLCAM's fast algorithm operates over 1000 times faster than the current state-of-the-art, allowing near-instant determination of molecular anisotropy. To aid adoption, open-source image analysis software and visualization tools were developed. POLCAM's potential was demonstrated in studying alpha-synuclein fibrils and the actin cytoskeleton of mammalian cells. (Nature Methods 2024). The second approach focuses on "Single-Molecule Light Field Microscopy" (SMLFM), encoding 3D positions into 2D images for volumetric super-resolution microscopy. SMLFM shows an order-of-magnitude speed improvement over other 3D PSFs, resolving overlapping emitters through parallax. Experimental results reveal high accuracy and sensitivity in point detection, enabling whole-cell imaging of single membrane proteins in live primary B cells and high-density volumetric imaging in dense cytosolic tubulin datasets. (Nature Comms 2024)

Invited Talk O 100.2 Fri 11:00 H24

MALDI mass spectrometry imaging: application examples ranging from food analysis to pharmaceutical research — •Andreas Römpp — Bioanalytical Sciences and Food Analysis, University of Bayreuth, Bayreuth, Germany

Mass spectrometry imaging is an analytical technique that provides spatially-resolved molecular information for a wide range of compound classes. In contrast to many histological methods, it does not require labeling. The capabilities and limitations of MS imaging will be discussed on the basis of several application areas with a focus on food analysis and pharmaceutical research. In our study 'MALDI mass spectrometry imaging: from constituents in fresh food to ingredients, contaminants and additives in processed food' (https://doi.org/10.1016/j.foodchem.2022.132529) we analyzed a range of plant-based and meat-based food. The analysis of natamycin in cheese and acrylamide in gingerbread constitute the first mass spectrometry imaging measurements of a food additive and a food contaminant, respectively. MS imaging is the only method that can analyze the distribution of drug compounds in animal models or human tissue (without labeling). This is exemplified on the detection of anti-tuberculosis drugs in mouse model tissue including our most recent study on the clinical stage antibiotic BTZ-043 which has just been accepted for publication in Nature Communications (https://doi.org/10.1038/s41467-025-56146-9).

O 100.3 Fri 11:30 H24

On-Surface Synthesis and Characterization of a Nitrogen-Containing Heterocycle — •Marco Thaler[1], Ricardo Ruvalcaba Briones[2], Matthias Zeilerbauer[1], Shadi Fatayer[2], and Laerte Patera[1] — [1]University of Innsbruck, Austria — [2]King Abdullah University of Science and Technology, Thuwal, Saudi Arabia

Nitrogen-containing heterocycles are fundamental building blocks in nature, forming the core of essential biomolecules and pharmaceuticals. This study demonstrates the on-surface formation of an N-heterocyclic organic compound via thermal activation of a tailored precursor. High-resolution non-contact atomic force microscopy (nc-AFM) provides bond-level resolution of the synthesized structures. Complementary scanning tunneling spectroscopy visualizes changes in the electronic structure resulting from the formation of the heterocycle. Density functional theory calculations (DFT) reveal the most probable reaction mechanism, highlighting the critical role of hydrogen release as the driving force of the reaction. These findings emphasize the versatility of on-surface synthesis as a powerful tool for creating complex organic compounds.

O 100.4 Fri 11:45 H24

Elasticity Mapping of Nonahelicene with Submolecular Resolution by NC-AFM — •Max Halbauer[1], Takashi Kumagai[2], Martin Wolf[1], and Akitoshi Shiotari[1] — [1]Fritz-Haber-Institute, Faradayweg 4-6, 14195 Berlin, Germany — [2]Institute for Molecular Science, 38 NishigoNaka, Myo-daiji, Okazaki 444-8585, Japan

Controlled modification of atomic configurations of molecules and materials is an exciting goal for non-contact atomic force microscopy (NC-AFM). Certain changes like shifts of the electronic energy gaps may be expected, but are not well explored and not established on the molecular scale. Here we report quantitative measurement of atomic-scale deformation in single molecules with NC-AFM. Individual molecules of nonahelicene ([9]H) and coronene (Cor) were studied on a Ag(110) surface under ultrahigh vacuum and cryogenic conditions by the measurement of frequency-shift distance curves for this. The molecular responses can be replicated with an empirical Lennard-Jones model, but for [9]H an elastic contribution is required to account for its elastic nature. Furthermore, a 3D-force mapping technique, termed molecular deformation mapping (MDM), allows to study the lateral position dependence of the elastic response. The MDM of [9]H reveals a spatially strongly anisotropic behaviour for the elasticity, interaction forces, elongation and binding energy of the tip to the molecule. The result is rationalized in terms of an aromaticity model.

O 100.5 Fri 12:00 H24

Detection and control of quantum proton ordering in hydrogen bonds at the atomic scale — •Yiqi Zhang — Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China

Directly probing the spatial arrangements and quantum nature of protons in hydrogen-bonded (H-bonded) materials and biosystems is the key to understand their macroscopic properties and functions. Here, exploiting bond-resolved atomic force spectroscopy (BR-AFS) combined with path-integral molecular dynamics method, we demonstrate for the first time that BR-AFS measurements along the apparent H-bond between proton donor and acceptor atoms allows the identification of both classical H-bonds with inherent directionality and non-classical H-bonds with quantum proton delocalization in self-assembled imidazole derivatives on surfaces. Unlike the conventional unidirectional H-bonding in linear chains, chiral cyclic hexamers exhibit unique quantum proton ordering in their ground states, which contain a mix of classical and non-classical H-bonds, breaking rotational symmetry. Furthermore, we show the capability to switch the quantum-proton-ordering state on and off by altering the adsorption registry coupled with a collective transfer of six protons within the cyclic H-bonds. These findings open new pathways for detecting and controlling complex proton orders and for engineering proton-based quantum states with atomic-level precision.

O 100.6 Fri 12:15 H24

Imaging of the conformations of individual β-cyclodextrins with non-contact AFM — Marko Grabarics[1], •Benjamin Mallada[1,2,3], Shayan Edalatmanesh[2,3], Stephan Rauschenbach[1], Pavel Jelinek[2,3], and Bruno de la Torre[2] — [1]Kavli Institute for Nanoscience Discovery, University of Oxford, UK — [2]CATRIN, Palacký University Olomouc, CZ — [3]Institute of Physics, Czech Academy of Sciences, CZ

Glycans, biopolymers essential to biology and materials science, are highly complex due to their structural diversity, conformational flexibility, and numerous possible isomers. Conventional methods often struggle to resolve these structures with atomic precision, especially under solvent-free conditions. We employ nc-AFM under UHV to determine the atomic structure of β-cyclodextrin (β-CD), a cyclic glucose molecule.

Our results reveal the adsorption geometries, hydroxy group positions, and stabilizing hydrogen bonds on a Au(111) surface. The primary face forms a closed hydrogen-bond network, while the secondary face exhibits pairwise interactions between OH groups of the same glucose monomer. DFT calculations validate these findings, enabling precise structural assignment and capturing subtle conformational differences.

This work highlights nc-AFM's capability to overcome the limitations of conventional sequencing techniques and represents the first application of nc-AFM to glycans. Future integration with ion deposition techniques could extend its utility to more complex glycans.

O 100.7 Fri 12:30 H24

Domain size effects in the spectra of micro-heterogeneous samples — •Thomas Mayerhöfer[1,2] and Jürgen Popp[1,2] — [1]Leibniz Institute of Photonic Technology (IPHT), Albert-Einstein-Str. 9, 07745 Jena, Germany — [2]Institute of Physical Chemistry and Abbe Center of Photonics, Friedrich Schiller University, Helmholtzweg 4, 07743 Jena, Germany

Samples are often not composed of a single pure compound but are instead mixtures of different substances. Under the Bouguer-Beer-Lambert approximation, the absorbance spectra of such mixtures can be simply derived by summing the spectra of the individual components, with each spectrum weighted by the molar fraction of the corresponding compound.

In the context of wave optics, the resolving power of light at a given wavelength becomes crucial. If a microscope using light at this wavelength can distinguish structural details within the sample, the sample is classified as micro-heterogeneous. In this case, spatial averaging occurs at the intensity level, involving reflectance and transmittance rather than absorbance.

The shift from micro-heterogeneity to macro-heterogeneity is gradual and cannot be described by an analytical formula due to the wave nature of light. This has significant implications for spectrum interpretation, as it can lead to substantial variations in peak shapes, positions, and intensities, e.g., during mitosis.

O 101: Topology and Symmetry-protected Materials (joint session O/TT)

Time: Friday 10:30–12:15 Location: H25

O 101.1 Fri 10:30 H25

Topological material in the III–V family: heteroepitaxial InBi on InAs — •L. Nicolaï[1], J. Minár[1], M.C. Richter[2,3], O. Heckmann[2,3], J.-M. Mariot[4], U. Djukic[2], J. Adell[5], M. Leandersson[5], J. Sadowski[6], J. Braun[7], H. Ebert[7], J.D. Denlinger[8], I. Vobornik[9], J. Fujii[9], P. Šutta[1], G.R. Bell[10], M. Gmitra[11,12], and K. Hricovini[2,3] — [1]Univiversity of West Bohemia — [2]CY Cergy-Paris Université — [3]Université Paris-Saclay — [4]Sorbonne Université — [5]Lund University — [6]Polish Academy of Sciences — [7]LMU München — [8]ALS — [9]Istituto Officina dei Materiali, CNR — [10]University of Warwick — [11]Pavol Jozef Šafárik University in Košice — [12]Slovak Academy of Sciences

InBi(001) is formed epitaxially on InAs(111)-A by depositing Bi on to an In-rich surface. ARPES measurements reveal topological electronic surface states, close to the $\overline{M}$ high symmetry point. InBi surprisingly shows coexistence of Bi and In surface terminations. For the Bi termination, the study gives a consistent physi-

cal picture of the topological surface electronic structure of InBi(001) terminated by a Bi bilayer rather than a surface formed by splitting to a Bi monolayer termination. Theoretical calculations based on relativistic DFT and the one-step model of photoemission clarify the relationship between the InBi(001) surface termination and the topological surface states, supporting a predominant role of the Bi bilayer termination. Furthermore, a tight-binding model based on this Bi bilayer termination with only Bi–Bi hopping terms gives a deeper insight into the spin texture[1]. [1] Nicolaï *et al.* Phys. Rev. Research 6.4 (2024): 043116.

O 101.2 Fri 10:45 H25

Hidden spin-texture in an inversion-symmetric Dirac crystal — Kenta Hagiwara[1,2], Peter C. Schmitz[1], Philipp Rüssmann[1], Xin Liang Tan[1,2], Ying-Jiun Chen[3], Kui-Hon Ou Yang[4], Raman Sankar[5], Chien Jing[4], Yi-Hsin Shen[4], Mahmoud Zeer[1], Dongwook Go[6], Iulia Cojocariu[1], Daniel Baranowski[1], Vitaliy Feyer[1], Minn-Tsong Lin[1,6], Stefan Blügel[1], Claus M. Schneider[1,2], Yuriy Mokrousov[1,5], and •Christian Tusche[1,2] — [1]Peter Grünberg Institut, Forschungszentrum Jülich, — [2]Faculty of Physics, University of Duisburg-Essen — [3]Ernst Ruska-Centre, Forschungszentrum Jülich — [4]Department of Physics, National Taiwan University, Taipei, Taiwan — [5]Academia Sinica, Taipei, Taiwan — [6]Johannes-Gutenberg University Mainz

A hidden spin polarization refers to a local spin polarization caused by apparent symmetry breaking and offers new perspectives for spintronics applications. Transition metal dichalcogenides can host various topological phases depending on the symmetry of their crystal structure. Here, by means of spin-resolving momentum microscopy, we reveal the spin texture of both topologically and symmetrically distinct surface and bulk Dirac cones in the inversion symmetric Dirac semimetal $NiTe_2$. We discovered a "hidden" spin polarization the bulk Dirac cone, localized at the different Te layers of the inversion symmetric bulk unit cell, such that the overlap of the two states results in a topologically trivial Dirac cone enforced by the global crystal symmetry. This work establishes a link between topology, spin-texture, and symmetry, enabling control by external perturbations.

O 101.3 Fri 11:00 H25

Edge spectroscopy of the quantum spin Hall insulator indenene — •Jonas Erhardt[1,2], Mattia Ianetti[3], Gianni Profeta[3], Domenico Di Sante[4], Giorgio Sangiovanni[2,5], Simon Moser[1,2], and Ralph Claessen[1,2] — [1]Physikalisches Institut, Universität Würzburg — [2]Würzburg-Dresden Cluster of Excellence ct.qmat — [3]Department of Physical and Chemical Sciences, University of L'Aquila — [4]Department of Physics and Astronomy, University of Bologna — [5]Institut für Theoretische Physik und Astrophysik, Universität Würzburg

The non-trivial topology of the quantum spin Hall insulator indenene was recently demonstrated through bulk probes that reveal its topological band ordering [1,2]. According to the bulk-boundary correspondence, this ensures the existence of robust metallic states confined to the edge of this triangular indium monolayer. In this study, we employ scanning tunneling spectroscopy to investigate all three edge types of indenene for this correspondence. Our results demonstrate metallic edge density of states with suppressed backscattering near the bulk band gap, providing strong evidence for the existence of topologically protected edge states in indenene.

O 101.4 Fri 11:15 H25

Bismuthene at the Graphene/SiC Interface: A Protected Quantum Spin Hall Insulator — •Niclas Tilgner[1], Susanne Wolff[1], Serguei Soubatch[2], Andres D. P. Unigarro[1], Sibylle Gemming[1], F. Stefan Tautz[2], Christian Kumpf[2], Thomas Seyller[1], Fabian Göhler[1], and Philip Schädlich[1] — [1]Institute of Physics, Chemnitz University of Technology, Germany — [2]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, Germany

Quantum spin Hall insulators (QSHIs) hold the potential to revolutionize next-generation technologies. Kane and Mele identified 2D honeycomb structures of heavy atoms with strong spin-orbit coupling as promising candidates for these materials. To realize this potential, however, the QSHI must be shielded from environmental influences. Previous research has demonstrated the intercalation of 2D Bi layers beneath graphene on SiC, resulting in the formation of two distinct phases. Among those, the β-phase exhibits a $(\sqrt{3}\times\sqrt{3})R30^\circ$ periodicity relative to the substrate. We identify the Bi adsorption site using x-ray standing wave imaging, a method which deterimes the element specific, 3D atomic distribution with respect to the bulk unit cell. After subsequent hydrogen intercalation, the Bi position changes significantly from hollow to top site adsorption. Further measurements with angle-resolved photoelectron spectroscopy reveal the band structure of the QSHI bismuthene with a pronounced Rashba splitting and slight p-type doping. We propose that the initial β-phase has to be considered as an electronically inactive layer of bismuthene, whose electronic structure can be established by subsequent hydrogen intercalation.

O 101.5 Fri 11:30 H25

Probing the Electronic Structure at the Boundary of Topological Insulators in the Bi2Se3 Family by Combined STM and AFM — •Christoph S. Setescak[1], Irene Aguilera[2], Adrian Weindl[1], Matthias Kronseder[1], Andrea Donarini[1], and Franz J. Giessibl[1] — [1]University of Regensburg, Regensburg, Germany — [2]University of Amsterdam and European Theoretical Spectroscopy Facility (ETSF), Amsterdam, The Netherlands

We develop a numerical scheme for the calculation of tunneling current I and differential conductance dI/dV of metal and CO terminated STM tips on the topological insulators Bi2Se3, Bi2Te2Se and Bi2Te3 and find excellent agreement with experiment. The calculation is an application of Chen's derivative rule, whereby the Bloch functions are obtained from Wannier interpolated tightbinding Hamiltonians and maximally localized Wannier functions from first-principle DFT+GW calculations. We observe signatures of the topological boundary modes, their hybridization with bulk bands, Van Hove singularities of the bulk bands and characterize the orbital character of these electronic modes using the high spatial resolution of STM and AFM. Bare DFT calculations are insufficient to explain the experimental data, which are instead accurately reproduced by many-body corrected GW calculations.

O 101.6 Fri 11:45 H25

Revealing higher-order topological bulk-boundary correspondence in Bi crystals with spin-helical hinge state loop and proximity superconductivity — •Dongming Zhao[1], Yang Zhong[1], Tian Yuan[1], Haitao Wang[1], Tianxing Jiang[1], Yang Qi[1], Hongjun Xiang[1,2,3], Xingao Gong[1,2,3], Donglai Feng[2,3,4], and Tong Zhang[1,2,3,4] — [1]Fudan University, Shanghai, China — [2]Collaborative Innovation Center for Advanced Microstructures, Nanjing, China — [3]Shanghai Research Center for Quantum Sciences, Shanghai, China — [4]Hefei National Laboratory, Hefei, China

Topological materials are typically characterized by gapless boundary states, known as bulk-boundary correspondence. Recently, this concept has been generalized in higher-order topological insulators (HOTIs). E.g., a 2nd-order 3D TI hosts 1D topological hinge states winding around the crystal. A complete verification of HOTI will require probing all crystal boundaries. Here we studied a promising candidate of 2nd-order TI, Bi, in the form of mesoscopic crystals grown on superconducting V3Si. Using low-temperature STM, we directly observed dispersive 1D states on various hinges. Upon introducing magnetic scatterers, new scattering channels emerged selectively on certain hinges, revealing their spin-helical nature. Combining first-principle calculation and global symmetry analysis, we find these hinge states topological and formed a closed loop encircling the crystal. This provides direct evidence on the HOTI in Bi. Moreover, proximity superconductivity is observed in the topological hinge states serving as a promising platform for realizing topological superconductivity.

O 101.7 Fri 12:00 H25

Simultaneous Atomic-Scale Imaging and Electronic Characterization of Wet-Chemically Prepared Bi_2Se_3 Nanoplatelets — •Auke Vlasblom, Victor Wesselingh, Jara Vliem, Daniel Vanmaekelbergh, and Ingmar Swart — Utrecht University, Utrecht, The Netherlands

Colloidal semiconductor nanoparticles are of great interest for various optoelectronic applications, such as integration in displays, solar cells and electronics. For applications, the surface of nanoparticles is of critical importance. However, until now, no technique exists to simultaneously investigate the atomic structure (e.g. the presence of defects) and the electronic properties of a nanoparticle, foremost limited by the presence of ligands that prevent direct access to the surface with a local probe. Here, we present a new and widely applicable procedure that allows investigation of the surface of a nanoparticle with a local probe. Using this method, nanoparticles are transferred to an atomically clean substrate under ultra-high vacuum conditions. We demonstrate the procedure for topological two-dimensional Bi_2Se_3 nanoplatelets deposited on Au(111). We reveal the atomic and electronic structure of the surface of colloidally synthesised Bi_2Se_3 nanoplatelets with scanning tunneling microscopy and spectroscopy measurements. In this talk, I will highlight the various types of defects that occur at the (sub-)surface of Bi_2Se_3 nanoplatelets and I will show their influence on the electronic structure.

Quantum sensing with atomic-scale spatial resolution — •Andreas Heinrich — IBS Center for Quantum Nanoscience, Seoul, Korea

There is a strong international research effort in the area of quantum nanoscience, where the concepts of quantum coherence, superposition and entanglement of quantum states are exploited in solid state and molecular systems. One of the very prominent applications in this realm is Quantum Sensing, where a quantum system is used to measure some external fields with high energy and high spatial resolution. In this talk we will focus on quantum-coherent experiments in Scanning Tunneling Microscopy (STM). STM enables the study of surfaces with atomic-scale spatial resolution and offers the ability to study individual atoms and molecules on surfaces. To make a movable quantum sensor with atomic-scale spatial resolution, we attached a single molecule of PTCDA to the spin-polarized apex of an STM tip. In contrast to all other known molecules, its coupling to the tip is so weak that this molecule performs as an excellent electron spin resonance (ESR) sensor on a bare metallic surface. We show how this sensor can be used to measure atomic-scale magnetic and electric fields emanating from single atoms on a surface and compare its performance to the well-established NV center in diamond.

Invited Talk SOE 1.1 Mon 15:00 H45

Interplay between multiscaling and rough volatility — •Tiziana Di Matteo — King's College London, London, UK

The multiscaling behaviour of financial time-series is one of the acknowledged stylized facts in the literature [1]. Its source in financial markets has been long debated [2,3]. In this talk I will discuss the origin of multiscaling in financial time-series, investigate how to best quantify it [4] and I will introduce a new methodology that provides a robust estimation and tests the multi- scaling property in a statistically significant way [5]. I will show results on the application of the Generalized Hurst exponent tool to different financial time-series, and I will show the powerfulness of such tool to detect changes in markets' behaviours, to differentiate markets accordingly to their degree of development, to asses risk and to provide a new tool for forecasting [6]. I will also show results to assess the interplay between price multiscaling and volatility roughness, defined as the (low) Hurst exponent of the volatility process [7] and finally I will discuss some new results on the origin of the multiscaling in rough volatility models [8]. SOE 1.2 Mon 15:30 H45

The Mechanism and Impact of Ultra Extreme Fast Events on Stock Markets — •Luca Henrichs, Anton J. Heckens, and Thomas Guhr — Universität Duisburg-Essen, Lotharstr. 1, 47048 Duisburg

Recent years have seen much discussion about the mechanism of Ultra Extreme Fast Events (UEEs), which are rapid and strong price changes. In particular, the influence of algorithmic trading or high-frequency traders (HFTs) was studied [1] [2]. HFTs are computer programs that can react faster to UEEs than humans. However, the rapid trading of HFTs would make it extremely difficult to intervene to stabilize a market. Hence, a deeper understanding of UEEs is called for.

In our study, we compare various characteristics of UEEs for the years 2007, 2008, 2014 and 2021. In comparison to the study [1], we show that various statistical properties of UEEs are robust over the years. The recovery rate after a UEE is of particular interest here and indicates that certain underlying mechanisms changed only very little. In contrast to [1], which says that human traders with large market orders generate UEEs, we concluded that liquidity plays a major role in the emergence of UEEs, independent of HFTs and human traders.

A New Traders' Game? — Cedric Schuhmann, •Anton J. Heckens, and Thomas Guhr — Universität Duisburg-Essen, Lotharstr. 1, 47048 Duisburg

Traders on financial markets generate non–Markovian dynamics through their competition with each other. This competition can be interpreted as a game between different types of traders. We study the non–stationarity of this game and show that it has changed significantly since the global crisis of 2008.

To reveal the market mechanism, we analyze self–response functions for individual stocks as well as cross–response functions for pairs of different stocks. While the non–Markovian dynamics in the former is liquidity–driven it is only expectation–driven in the latter which might be interpreted as emergence of correlations. Averages greatly improve the statistics, we work out averaged response functions for different years. We thus considerably extend the analysis of Ref. [1,2] in which only the crisis year 2008 was studied.

SOE 2: Award Session: Young Scientist Award for Socio- and Econophysics (YSA)

Time: Monday 16:15–17:30 Location: H45

Presentation of the Award to the Awardee

Prize Talk SOE 2.1 Mon 16:30 H45

Higher-order network science — •Federico Battiston — Department of Network & Data Science, Central European University, Vienna, Austria

The complexity of many biological, social and technological systems stems from the richness of the interactions among their units. Over the past decades, a variety of complex systems has been successfully described as networks whose interacting pairs of nodes are connected by links. Yet, from human communications to ecological systems, interactions can often occur in groups of three or more nodes and cannot be described simply in terms of dyads. Until recently little attention has been devoted to the higher-order architecture of real complex systems. However, a mounting body of evidence is showing that taking the higher-order structure of these systems into account can enhance our modeling capacities and help us understand and predict their emergent dynamical behavior. Here I will present an overview of network science beyond pairwise interactions. I will discuss the higher-order organization of real-world complex systems, and characterize new emergent phenomena in dynamical processes beyond pairwise interactions, with a focus on social systems.

After the Award Session, there will be an informal get-together with beer and pretzels at the Poster Session

SOE 3: Poster

Time: Monday 17:30–19:30 Location: P4

SOE 3.1 Mon 17:30 P4

Causal Hierarchy in the Financial Market Network - Uncovered by the Helmholtz-Hodge-Kodaira Decomposition — •Tobias Wand[1,2,3], Oliver Kamps[1], and Hiroshi Iyetomi[3,4] — [1]CeNoS Münster — [2]Institut für Theoretische Physik, Universität Münster — [3]Faculty for Data Science, Rissho University, Kumagaya, Japan — [4]Canon Institute for Global Studies, Tokyo, Japan

Granger causality can uncover the cause-and-effect relationships in financial networks. However, such networks can be convoluted and difficult to interpret, but the Helmholtz-Hodge-Kodaira decomposition can split them into rotational and gradient components which reveal the hierarchy of the Granger causality flow. Using Kenneth French's business sector return time series, it is revealed that during the COVID crisis, precious metals and pharmaceutical products were causal drivers of the financial network. Moreover, the estimated Granger causality network shows a high connectivity during the crisis, which means that the research presented here can be especially useful for understanding crises in the market better by revealing the dominant drivers of crisis dynamics.

This contribution is based on the publication Wand et al., Entropy 2024, 26(10), 858 and was supported by the JSPS Summer Program.

SOE 3.2 Mon 17:30 P4

A Game-Theoretic Approach to Misinformation on Social Media — •Grace Galanthay and Eckehard Olbrich — Max Planck Institute for Mathematics in the Sciences, Leipzig, Germany

Misinformation and disinformation are considered a significant problem with the rise of social media. While much research concentrates on the spread of information, our work focuses on the strategic actions of individual actors. Using a game-theoretic signaling framework, we study interactions where a sender communicates a noisy signal about the state of the world to a receiver, whose response determines payoffs for both actors. Existing "cheap talk" models explore strategic communication between two actors with misaligned preferences. We extend this framework to multiple senders and adapt the theoretical model to social media, where the traditional roles of sender and receiver merge. Our extension to a multi-actor signaling game in social media contexts represents a distinct approach to modeling the spread and strategic use of mis- and disinformation on digital platforms.

SOE 3.3 Mon 17:30 P4

Unraveling 20th-century political regime dynamics using the physics of diffusion — •Paula Pirker-Díaz[1], Sönke Beier[1], Matthew Wilson[2], and Karoline Wiesner[1] — [1]Institute of Physics and Astronomy, University of Potsdam, Potsdam, Germany — [2]Department of Political Science, University of South Carolina, Columbia, USA

Uncertainty remains regarding why some countries democratize while others do not, and why some remain democratic while others backslide into autocracy. Also the nature and changes of intermediate regimes is particularly unclear. By applying the Diffusion Map, a spectral dimensionality-reduction technique, on V-Dem political data (1900-2021), we identify a low-dimensional manifold describing electoral regimes. Using the diffusion equation from statistical physics, we measure the time scale on which countries change their degree of electoral quality, freedom of association, and freedom of expression depending on their position on the manifold. Democracies show sub-diffusive dynamics, while collapsing autocracies exhibit super-diffusive dynamics. Intermediate regimes display distinct and more unstable diffusion behaviors, linked to a higher risk of civil conflict. This research bridges statistical physics and political science, offering a quantitative framework for understanding regime transformation and risk-of-conflict assessment. [arXiv:2411.11484]

SOE 3.4 Mon 17:30 P4

Analysis of (Mis)information Spread across Telegram Communities — Roman Ventzke[1,2], Anastasia Golovin[1,2], Sebastian Mohr[1,2], Andreas Schneider[1,2], and •Viola Priesemann[1,2] — [1]Max-Planck-Institut für Dynamik und Selbstorganisation, Göttingen — [2]Georg-August-Universität Göttingen

Statistically, do lies spread better than the truth? To effectively combat the proliferation of misinformation in online social media, it is important to understand how content spreads in social networks. We investigate the dynamics of (mis)information diffusion on the Telegram messaging platform to understand if (and how) the spread of both true information and misinformation differs.

As a basis for this study, we employ a novel large dataset of messages from Telegram group chats and channels. This dataset comprises more than 2.3 billion messages from more than 150,000 different chats and focuses on COVID-19-related content since the start of the pandemic.

Tracking information propagation, we show that information spread can be modeled by a Random Field Ising Model. Our results show that on Telegram misinformation spreads further than reliable information and is linked to "super spreaders". We also investigate whether factors like emotional engagement can drive misinformation spread.

SOE 3.5 Mon 17:30 P4

Interplay between algorithms, cognition and social interactions — •Beniamin Sereda and Janusz Hołyst — Faculty of Physics, Warsaw University of Technology, Koszykowa 75, PL-00-662 Warsaw, Poland

Modern societies are increasingly facing the issue of opinion polarisation, amplified by recommendation systems and their role in forming information cocoons. To understand how the evolution of user preferences and the topology of social networks influence opinion dynamics, the integrative agent-based model DAISY was developed. This model assumes three distinct levels of interactions: algorithmic, social, and cognitive. Algorithmic interactions are governed by recommendation algorithms, the social level reflects user preferences regarding whom to contact in the context of recommended items, and the cognitive level describes how individuals process information.The dynamics of preferences are driven by the algorithmic level, while opinion dynamics occur on the social and cognitive levels. Co-evolutional perspective on dynamics allows observation of how changes in network topology, triggered by recommendation systems, shape opinion evolution. Simulations show that increased personalisation accelerates the formation of informational cocoons, though in a non-linear and complex manner. Analysing social network evolution also revealed a deeper understanding of the irreversibility of processes within the system.

SOE 3.6 Mon 17:30 P4

Phase transition in maximally robust networks — •Thilo Gross[1,2,3] and Laura Barth[1,2,3] — [1]Helmholtz Institute for Functional Marine Biodiversity (HIFMB), Oldenburg — [2]Alfred-Wegener Institute (AWI), Helmholtz Center for Polar and Marine Research, Bremerhaven — [3]Carl-von-Ossietzky Universität Oldenburg

Here is a puzzle: You are building a network, but you know already that a certain proportion of nodes will fail, which will remove them and their links from your network. You don't know which nodes will fail, but you want your network to retain a connected component of functioning nodes that is as large as possible, after the failures have occured. Given a certain number of nodes and links, how do you connect the nodes? What kind of structure do you build?

Here we study a closely related though slightly simpler question: Instead of a fixed number of nodes and links, we consider an infinite network with a given mean degree. And, instead of allowing control over each individual link, we assume that the network is constructed as a configuration model. Hence the challenge becomes to pick the network's degree distribution such that after a certain proportion of nodes has failed the expectation value for the size of the giant component is still as large as possible.

We show this question can be solved using an analytical calculation, which reveals an infinite sequence of phase transitions between different configuration model structures.

SOE 3.7 Mon 17:30 P4

Game-theoretic model of group work contributions, neurodiverse versus neurotypical — •Lilliana Etheridge and Jens Christian Claussen — University of Birmingham, Edgbaston, UK

Evolution of cooperation and contribution to public goods have been long standing themes in game theory. Group work in the educational context, as well as teams in industry often have formalized workflows where individuals can decide to contribute different amounts. For this context, we formulate a game-theoretic model and analyze it via agent-based simulations, both for neurotypical and neurodiverse contributors, modeled by differing decision behaviour.

SOE 3.8 Mon 17:30 P4

Weakly coupled FitzHugh-Nagumo oscillators and the influence of noise — •Max Contreras[1,2] and Philipp Hövel[2] — [1]Technische Universität Berlin, Germany — [2]Saarland University, Saarbrücken, Germany

We investigate neural oscillators modeled by FitzHugh-Nagumo systems that are weakly and diffusively coupled on a one-dimensional ring with finite coupling range. Operated in the oscillatory regime, we observe a simultaneous presence of robust collective oscillations and neuronal avalanches. The mechanism behind these avalanches is based on an inhibitory effect of interactions, which may quench the otherwise spiking of units due to an interplay with the maximal canard. The result are subthreshold oscillations close to an unstable fixed point. Furthermore, we explore the response of the networked system to noise, and find that for weak coupling, the network-mediated inhibition is weakened and that for intermediate coupling strength, noise can promote synchronized spiking.

SOE 3.9 Mon 17:30 P4

Characterizing similarities and differences in people's views based on open-ended expressions with LLMs and network science — •Ezequiel Lopez-Lopez and Stefan Herzog — Max Planck Institute for Human Development, Berlin

Citizens have diverse views on critical issues like pandemic management and climate change. Current methods to gather these views are limited: polls and surveys lack nuance, while qualitative approaches do not scale. We developed a computational framework that combines Large Language Models with network science to rapidly analyze citizens' evolving views without oversimplifying them. This novel approach extracts concepts from unstructured text and represents them in networks, offering deeper insights and faster analysis than traditional qualitative methods. We applied this framework to UK citizens' ideas on five UN Sustainable Development Goal-related policy problems. Our results demonstrate the framework's ability to capture nuanced differences across political, demographic, and cognitive variables. This approach has the potential to significantly enhance evidence-based policymaking and citizen engagement in complex societal issues.

SOE 3.10 Mon 17:30 P4

Multisensory processing in superior colliculus and primary sensory cortex — •Daniel Gerber[1], Peter Severin Graff[1,2], Björn Kampa[2], and Simon Musall[1,2,3] — [1]Institute of Biological Information Processing (IBI-3), Forschungszentrum Jülich, Jülich, Germany — [2]Department of Systems Neurophysiology, Institute for Zoology, RWTH Aachen University, Aachen, Germany — [3]Institute of Experimental Epileptology and Cognition Research, University of Bonn Medical Center, Bonn, Germany

The superior colliculus (SC) plays a crucial role in integrating multisensory stimuli and is associated with various cognitive functions, such as decision-making. It receives inputs from different sensory modalities, either directly from sensory

organs or from primary sensory regions in the cortex. However, the distinctions between multisensory integration in the SC and the cortex remain unclear. To study the physiological underpinning of multisensory integration in these areas, awake mice were exposed to visual, tactile, and multisensory stimuli, while neural activity was recorded in primary visual cortex (V1), primary somatosensory cortex (S1) and the SC simultaneously using high-density Neuropixels electrodes. To investigate the influence of the cortical projection to the SC, in some trials V1 and/or S1 were optogenetically inhibited. A generalized linear model is used to analyse the spiking activity. We present that SC is modulated by cortical input but does not strongly rely on it. We also present the change in neural activity over the course of repeated stimulus.

SOE 4: Urban systems, Scaling, and Social Systems

Time: Tuesday 9:30–12:00 Location: H45

Invited Talk SOE 4.1 Tue 9:30 H45

Urban scaling and conflicting goals — •Diego Rybski — Institute of Ecological Urban and Regional Development (IOER) — Complexity Science Hub (CSH)

Urban scaling, the power-law correlations between an urban indicator and city population, represents the most famous theme of contemporary urban science. The vast majority of publications on the topic empirically quantify the scaling properties for given indicators and countries. Other work is dedicated to mathematically explaining the non-linear scaling based on few but plausible assumptions. In this contribution, two approaches to urban scaling are discussed in the context of conflicting goals. First, we compare cities in terms of emitted carbon emissions vs. heat island intensity. We derive a theoretical solution, but we find that empirical parameters do not allow for any optimal size. Instead, the fundamental allometry between area and population should represent an optimum. Thus, second, we propose a simple model that leads to an optimum in the form of the fundamental allometry. Although many cities are challenged, it makes sense that some sort of optimization takes place, which should also be reflected in observed scaling.

SOE 4.2 Tue 10:00 H45

Dynamics of Cities — Airton Deepman[1], •Renan Lucas Fagundes[2], Eugenio Megias[3], Roman Pasechnik[4], Fabiano Lemes Ribeiro[5], and Constantino Tsallis[6,7,8] — [1]USP, Sao Paulo, Brazil — [2]IOER, Dresden, Germany — [3]UGR, Granada, Spain — [4]Lund University, Lund, Sweden — [5]UFLA, Lavras, Brazil — [6]CBPF, Rio de Janeiro, Brazil — [7]SFI, Santa Fe, USA — [8]CSHV, Vienna, Austria

In recent years, the challenge has been to understand urban phenomena and their impact on the lives of people in cities in order to achieve the sustainable development goals. One of the most intriguing urban phenomena to emerge since the 1940s is fundamental allometry, which elucidates the manner in which urban areas evolve in tandem with their population size. However, most of the models in the literature investigate urban phenomena while employing the static properties of cities. In this study, we demonstrate that the combination of nonextensive statistics with fractal geometry provides a powerful tool for investigating the dynamic evolution of cities. We conducted a case study on Brazilian cities. Our findings indicate that cities evolve near the critical point of percolation, which facilitates connectivity and efficiency in space occupation. Additionally, we observed a correlation between the fractal dimension and the allometric exponent, which is associated with fundamental geometric and diffusion aspects. This research has implications for the design of infrastructure in urban areas and the promotion of economic growth. Early version of the respective manuscript: https://doi.org/10.48550/arXiv.2407.12681

SOE 4.3 Tue 10:15 H45

Scale-dependent Power Law Properties in Social Activities — •Kenta Yamada[1], Jiwei Jiang[2], Hideki Takayasu[2], and Misako Takayasu[2] — [1]Univ. of the Ryukyus, Okinawa, Japan — [2]Science Tokyo, Tokyo, Japan

This presentation explores the power-law characteristics of hashtag usage on Weibo, a Chinese social media platform. The study investigates the heavy-tailed distribution of daily hashtag frequencies and proposes a generalized random multiplicative model to understand the formation of these distributions[1].

Data containing approximately 20 million Weibo posts from July to August 2021 were analyzed. The analysis confirmed that hashtag frequency distributions follow a fat-tailed pattern, consistent with previous research[2]. A key finding was that the growth rate of hashtag usage depends on its frequency.

To model this, a generalized random multiplicative process incorporating size dependency was introduced. Simulations demonstrated that increasing granularity in dividing the hashtag frequency range improved the model's accuracy in replicating real distributions. The power-law exponents estimated through theoretical methods aligned closely with observed data.

SOE 4.4 Tue 10:30 H45

Dynamical Power Laws in a Multiplicative Growth Model with Resets — •Alexander Jochim and Stefan Bornholdt — Institute for Theoretical Physics, University of Bremen

The observation that wealth distributions follow power laws – dating back to Pareto's 1897 work – has long intrigued physicists, offering a glimpse of universal principles in complex systems. Models based on multiplicative growth with resets are well-known for generating these heavy-tailed distributions, where the power-law exponent depends on the underlying parameters. Yet, such models often treat societal influences as static, ignoring the dynamic feedback between wealth and social behavior.

In this work, we introduce a minimal model where multiplicative growth with resets produces a wealth distribution that evolves dynamically through coupling to social mechanisms. This adaptive feedback leads to time-dependent power-law exponents, reflecting the interplay between wealth inequality and shifting societal behaviors. Our approach captures emergent phenomena in a non-equilibrium toy model for how collective social behaviors influence – and are influenced by – the statistical properties of wealth.

By framing wealth distributions as part of a coupled dynamical system, this work connects statistical physics with the study of adaptive social systems, offering fresh perspectives on the evolving patterns of inequality.

Statistical mechanics of a voter model with an evolving number of opinion states — Jeehye Choi[1], Byungjoon Min[1,2], and •Tobias Galla[3] — [1]Department of Physics, Chungbuk National University, Cheongju, Chungbuk, Korea — [2]Department of Medicine, University of Florida, Gainesville FL, USA — [3]Institute for Cross-Disciplinary Physics and Complex Systems IFISC, Palma de Mallorca, Spain

The voter model (VM) describes population of interacting individuals. At each step a randomly chosen individual copies the state ("the opinion") of a neighbour.

Here, we introduce and study a VM in which new opinion states can be introduced spontaneously. Opinions can also go extinct via the voter dynamics. This leads to stationary states with a variable number of opinions in the population or network.

We use statistical physics methods to characterise these stationary states, drawing parallels to the evolution of "mating types" in biological populations. Mating types are forms of the sperm-egg system. Unlike for true sexes, there can be more than two mating types (some fungi have thousands). We transfer methods from number theory, previously used to characterise the evolution of mating types [1], to compute how many opinions will ultimately be present in a VM with a dynamic number of states.

SOE 4.6 Tue 11:15 H45

The noisy voter model with complete and partial aging — •Raul Toral — Institute for Cross-Disciplinary Physics and Complex Systems IFISC (CSIC-UIB), Campus UIB, 07122 Palma de Mallorca, Spain

Many agent-based models of social interaction use the Markovian assumption, namely that the transition rates from one to another state depend only on the current state of the system and not on its previous history. This, being obviously wrong in many situations, it is widely used because of its mathematical simplicity. In this work, I will consider the effect that a particular non-Markovian effect, known in the literature as "aging" or "inertia" has on the paradigmatic noisy voter model. This is a widely used model in social and economics situations to describe transitions to consensus or synchronized behavior. While the standard version of the model displays a discontinuous change of behavior from unsynchronized to consensus as a function of a parameter which depends on the free-will, or tendency to act independently on the neighbors, this transition is size-dependent and disappears in the thermodynamic limit. I will show that a genuine -second order- phase transition can appear as a consequence of aging,

modeled as a reluctance to change state as a function of the length of time that has been spent in the current state. We investigate the situation where aging acts on both socially influenced and random opinion changes (complete aging), and compare it with previous results where aging acts only on pairwise interactions (partial aging).

SOE 4.7 Tue 11:30 H45

Emergence of polarization in an opinion dynamics framework with bimodal random external field — •Jan Korbel[1], Remah Dahdoul[1], Rudolf Hanel[1,2], and Stefan Thurner[1,2,3] — [1]Complexity Science Hub Vienna, Austria — [2]Medical University of Vienna, Austria — [3]Santa Fe Institute, NM, US

We present the opinion dynamics model with an external field, where the individual opinions are coupled as in a standard Ising spin-spin interaction. Furthermore, we consider that the spins are coupled with the random field. Contrary to the common random-field Ising model, the random field is considered to be binary, either +h or -h. The interpretation of this model is that the particles represent the individuals influenced both by their neighborhood as well as external sources, e.g., election campaigns. With increasing field coupling, we observe that the transition from the ferromagnetic to paramagnetic phase becomes the first order. Furthermore, it can be shown that for a high enough field, the system becomes polarized, i.e., the external field is dominating in comparison with the spin-spin interactions. Finally, we show that for low enough temperatures, the system always gets polarized above the threshold external field, no matter whether the magnitude of the positive field is much larger or smaller than the magnitude of the negative field.

SOE 4.8 Tue 11:45 H45

Phase Transitions in Socially Balanced Systems: Why More Interactions Drive Polarization — •Markus Hofer[1,2], Jan Korbel[1,2], Rudolf Hanel[1,2], and Stefan Thurner[1,2,3] — [1]Medical University of Vienna, Center for Medical Data Science, Institute of the Science of Complex Systems, Spitalgasse 23, 1090, Vienna, Austria — [2]Complexity Science Hub Vienna, Metternichgasse 8, 1030, Vienna, Austria — [3]Santa Fe Institute, 1399 Hyde Park Rd, Santa Fe, NM 87501, USA

Survey data show massive evidence that the average number of close social connections has increased over the past two decades. At the same time opinions in societies are becoming increasingly divided. To understand if these phenomena are related, we use a multidimensional spin model [1] that has been experimentally shown [2] to be realistic both in terms of homophily and social balance. Within the model individuals interact dyadically yet realistic triad statistics as expected from social balance theory emerges naturally. We find a phase transition where at a critical connectivity of the underlying social network a rapid transition from practically no to strong polarization occurs. By understanding how increased social connectivity necessarily leads to polarization we discuss strategies to mitigate polarization in highly connected societies.

SOE 5: Agent-Based Modeling

Time: Tuesday 12:15–13:00 Location: H45

SOE 5.1 Tue 12:15 H45

Co-evolving networks for opinion and social dynamics in agent-based models — •Soeren Nagel[2], Quang Nuh Vu[1], and Nataša Djurdjevac Conrad[1] — [1]Zuse Institue Berlin — [2]Department of Mathematics and Computer Science, Institute of Computer Science, Freie Universität Berlin

The coevolution of public opinions and social interactions is a fundamental aspect of social systems, yet existing models often fail to include this feedback loop. While many studies explore how opinions influence social ties, The reversed influence is however often overlooked. To bridge this gap, we introduce a novel stochastic agent-based model (ABM) that integrates opinion dynamics and social mobility within a shared "social space."

The feedback loop between opinion and social dynamics generates emergent phenomena such as consensus and echo chambers, whose dynamics we analyze through a network-based order parameter. The model exhibits critical transitions for both noise intensity and relative size of opinion and social network.

Our findings demonstrate the potential of coevolutionary models to capture the transient dynamics of social clustering and opinion polarization.

Applying the model to empirical data from the General Social Survey, we investigate opinion distributions on politically charged issues, and demonstrate, that the model is capable of capturing real-world dynamics.

SOE 5.2 Tue 12:30 H45

An Agent-Based Model to Investigate Geder Bias in Peer Review — •Sophie Lake and Jens Christian Claussen — University of Birmingham, Edgbaston, UK

Fairness in the refereeing process is a challenging goal but essential to ensure the quality of the scientific publication landscape. Selfishness, various biases, friendship networks as well as time efficiency influence the behaviour of researchers when making decisions on refereeing manuscripts. A longstanding challenge is the under-representation of women in many scientific disciplines and therefore in editorial boards and referee pools. We build on a model by Thurner and Hanel (2011, EPJB 84:707) that introduced different referee strategies. Here we extend the model by gender-specific strategies, and use agent-based simulations to analyze the impact of evaluation bias, homophilic editors and friendship networks.

SOE 5.3 Tue 12:45 H45

Do weekends matter in agent-based models for epidemiology? — •Aleksandr Bryzgalov — Institut für Medizinische Epidemiologie, Biometrie und Informatik (IMEBI) Medizinische Fakultät der Martin-Luther-Universität Halle-Wittenberg, Deutschland

German Epidemic Micro-Simulation System (GEMS) is an agent-based framework that was recently developed to study and analyse the consequences of the COVID-19 pandemic.

Using GEMS we focused on a study of weekend impact on developing the infection spread throughout the population. We compared the dynamics in two cases: considering only regular days (people have constant contact rates) and considering workdays-weekends(contact rates are specific for workdays and weekends). The total number of contacts was the same in both cases. We used the transmission parameters related to the Omicron (B.1.1.529) pathogen. In our simulations, we varied the distribution of workplace sizes, but the household structure was fixed.

The results show the dependence of total attack rate of workplace size distribution: smaller workplaces in combination with workdays-weekend periodicity produce more infections than the same with only regular days. On the opposite, bigger workplaces in combination with workdays-weekend periodicity produce fewer infections than the same with only regular days.

Analyzing Political Regime Stability Through the Diffusion Equation: Insights from V-Dem Data (1900-2021) — •Karoline Wiesner — University of Potsdam, Potsdam, Germany

Democratic stagnation and autocratic resurgence have marked the 21st century, raising questions about the stability of democracies and their implications for peace and prosperity. Utilizing the diffusion equation from statistical physics we provide firm evidence that democracy is the most stable regime type across the 20th and 21st centuries on average, surpassing the average life time of electoral autocracies. The latter also exhibit heightened susceptibility to sudden collapse. We explore these dynamics using the Diffusion Map dimensionality-reduction technique applied to V-Dem data (1900-2021). In this context, we will discuss some less explored mathematical aspects of the diffusion-map method, including its probabilistic interpretation and sensitivity to parameters and to the structure of the data. These recent results will be of interest, not least, to those wanting to apply the method to socio-economic data.

Knowing armed conflict type hurts prediction — •Niraj Kushwaha[1], Edward D. Lee[1], and Woi Sok Oh[2] — [1]Complexity Science Hub, Austria — [2]Princeton University, USA

Moving beyond heuristic classifications of armed conflicts such as local, civil, interstate wars etc. to systematic categorization is useful but challenging. Using information-theoretic techniques we generate chains of related conflict events from the high-resolution Armed Conflict & Location Event Dataset and integrate them with other datasets spanning climate, geography, infrastructure, economics, raw demographics, and composite demographics. Using an unsupervised clustering algorithm based on multinomial mixture, we discover that three conflict archetypes exist; "major unrest," "local conflict," and "sporadic & spillover events." Major unrest predominantly occurs in densely populated areas with good infrastructure and flat, riparian geography. Local conflicts arise in mid-populated regions with diverse socio-economic and geographical features. Sporadic and spillover conflicts are small, occurring in sparsely populated areas with poor infrastructure and economic conditions. The three types stratify into a hierarchy of factors, revealing a quantitative taxonomy that highlights population, infrastructure, and economics as the most discriminative variables. Surprisingly, we find that knowing the type negatively impacts predictability of conflict intensity such as fatalities, conflict duration, and other measures of size. Hence, we develop an empirical and bottom-up approach that identifies conflict types but also cautions us about the limited utility of public data sets for conflict prediction.

SOE 6.3 Tue 14:45 H45

On the coincidence of weather extremes and geopolitical conflicts: Risk analysis in regional food markets — •Nkongho Ayuketang Arreyndip — Economic analysis of Climate Impacts and Policy Division, Euro-Mediterranean Center on Climate Change(CMCC), Via della Libertà, 12- 30175 Venice (VE), Italy.

Under increasing geopolitical tensions between important breadbaskets and climate extremes, the co-existence of weather and geopolitical extreme events can lead to devastating agricultural production losses. These losses can affect the entire food supply chain and lead to food shortages and price increases in regional markets. This work models these events' impacts taking the Russian-Ukrainian war and the extreme heat waves of Summer 2022 as a case study. Four(4) war scenarios are considered such as the invasion phase, the peak of the war, Ukraine's resistance, sanctions against Russia, and refugee crises in Europe. Using data from the US Department of Agriculture (USDA), Statista, WITS, and Acclimate production value losses. Results show that the agricultural sectors of southern European countries such as France, Italy, and Spain were most affected by the extreme events, although the direct impact of refugees was lower compared to their northern counterparts. Strict sanctions against Russia coupled with Ukraine's resistance will benefit EU food markets, but at the same time the agricultural sectors of smaller nations and weaker economies, particularly those of Russia's allies, will be highly vulnerable. We suggest that their impact on weak economies should not be overlooked when developing and adopting conflict resolution measures.

SOE 7: Focus Session: Self-Regulating and Learning Systems: from Neural to Social Networks

Living systems have a remarkable ability to self-stabilize. How do such systems, made up of small, active units, achieve meaningful goals without global control? This focus session will explore recent advances in self-regulating networks, demonstrating how these systems transition between states, adapt to perturbations and learn to navigate new environments.

Organized by Anastasia Golovin, Johannes Zierenberg, and Viola Priesemann

Time: Wednesday 9:30–12:45 Location: H45

Invited Talk SOE 7.1 Wed 9:30 H45

When networks can think: The meaning of self-regulation in the presence of humans — •Alina Herderich — IDea_Lab, University of Graz, Austria

Feedback, global states, adaptation - given their many parallels modeling societies as self-regulating physical systems is tempting. How do the dynamics of a system change in which each of the agents has attitudes, desires, intellect? This talk explores communalities and differences between self-regulation in psychology and physics. First, I will define and illustrate the meaning of self-regulation in psychology. Second, I will explain how regulation can differ when humans regulate themselves versus others. Third, I will showcase challenges that arise when modeling groups of humans as self-regulating systems. For example, how do humans monitor the state of their group? What are the quantities that are regulated in groups of humans? And how do we differentiate between desired and undesired states especially if the targets are not morally neutral? Finally, I will close the talk with highlighting what psychology can learn from physics and vice versa in the context of self-regulating systems.

SOE 7.2 Wed 10:00 H45

Societal self-regulation induces complex infection dynamics and chaos — Joel Wagner[1,2], •Simon Bauer[1], Sebastian Contreras[1,2], Luk Fleddermann[1,2], Ulrich Parlitz[1,2], and Viola Priesemann[1,2] — [1]Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — [2]Institute for the Dynamics of Complex Systems, University of Göttingen, Göttingen, Germany

Classically, endemic infectious diseases are expected to display relatively stable, predictable infection dynamics, like recurrent seasonal waves. However, if the human population reacts to high infection numbers by mitigating the spread of the disease, this delayed behavioural feedback loop can generate infection waves itself, driven by periodic mitigation and subsequent relaxation. We show that such behavioural reactions, together with a seasonal effect of comparable impact, can cause complex and unpredictable infection dynamics, including Arnold tongues, co-existing attractors, and chaos [1]. Importantly, these arise in epidemiologically relevant parameter regions where the costs associated to infections and mitigation are jointly minimised. By comparing our model to data, we find signs that COVID-19 was mitigated in a way that favoured complex infection dynamics.Our results challenge the intuition that endemic disease dynamics necessarily implies predictability and seasonal waves, and show the emergence of complex infection dynamics when humans optimise their reaction to increasing infection numbers.

SOE 7.3 Wed 10:15 H45

Dynamical theory for adaptive biological systems — •Tuan Pham[1] and Kunihiko Kaneko[2] — [1]Institute of Physics, University of Amsterdam, Science Park 904, Amsterdam, The Netherlands — [2]Niels Bohr Institute, University of Copenhagen, Blegdamsvej 17, Copenhagen, 2100-DK, Denmark

Biological, social and neural networks are adaptive - their connections slowly change in response to the state of their constituting elements–the nodes, such as genes, individuals or neurons so as to make the collective states functionally robust under environmental stochasticity. To explain this kind of robust behavior, we develop an exact analytical theory for non-equilibrium phase transitions in multi-timescale and multi-agent dynamical systems, where there exists a correspondence between global adaptation and local learning. As an illustration of our general theory, we apply it to biological evolution, where phenotypes are shaped by gene-expression fast dynamics that are subjected to an external noise while genotypes are encoded by the configurations of a network of gene regulations. This network slowly evolves under natural selection with a mutation rate, depending on how adapted the shaped phenotypes are. Here we show how, high reciprocity of network interactions results in a trade-off between genotype and phenotype that, in turn, gives rise to a robust phase within an intermediate level of external noise. SOE 7.4 Wed 10:30 H45

Response functions in residual networks as a measure for signal propagation — •Kirsten Fischer[1,2], David Dahmen[1], and Moritz Helias[1,3] — [1]Institute for Advanced Simulation (IAS-6), Jülich Research Centre, Jülich, Germany — [2]RWTH Aachen University, Aachen, Germany — [3]Department of Physics, Faculty 1, RWTH Aachen University, Aachen, Germany

Residual networks (ResNets) demonstrate superior trainability and performance compared to feed-forward networks, particularly at greater depths, due to the introduction of skip connections that enhance signal propagation to deeper layers. Prior studies have shown that incorporating a scaling parameter into the residual branch can further improve generalization performance. However, the underlying mechanisms behind these effects and their robustness across network hyperparameters remain unclear.

For feed-forward networks, finite-size theories have proven valuable in understanding signal propagation and optimizing hyperparameters. Extending this approach to ResNets, we develop a finite-size field theory to systematically analyze signal propagation and its dependence on the residual branch's scaling parameter. Through this framework, we derive analytical expressions for the re-

sponse function, which measures the network's sensitivity to varying inputs. We obtain a formula for the optimal scaling parameter, revealing that it depends minimally on other hyperparameters, such as weight variance, thereby explaining its universality across hyperparameter configurations.

SOE 7.5 Wed 10:45 H45

Feature learning in deep neural networks close to criticality — Kirsten Fischer[1,2], •Javed Lindner[1,3,4], David Dahmen[1], Zohar Ringel[5], Michael Krämer[4], and Moritz Helias[1,3] — [1]Institute for Advanced Simulation (IAS-6), Computational and Systems Neuroscience, Jülich Research Centre, Jülich, Germany — [2]RWTH Aachen University, Aachen, Germany — [3]Department of Physics, RWTH Aachen University, Aachen, Germany — [4]Institute for Theoretical Particle Physics and Cosmology, RWTH Aachen University, Aachen, Germany — [5]The Racah Institute of Physics, The Hebrew University of Jerusalem, Jerusalem, Israel

Neural networks excel due to their ability to learn features, yet its theoretical understanding continues to be a field of ongoing research. We develop a finite-width theory for deep non-linear networks, showing that their Bayesian prior is a superposition of Gaussian processes with kernel variances inversely proportional to the network width. In the proportional limit where both network width and training samples scale as $N, P \to \infty$ with P/N fixed, we derive forward-backward equations for the maximum a posteriori kernels, demonstrating how layer representations align with targets across network layers. A field-theoretic approach links finite-width corrections of the network kernels to fluctuations of the prior, bridging classical edge-of-chaos theory with feature learning and revealing key interactions between criticality, response, and network scales.

Topical Talk SOE 7.6 Wed 11:15 H45

Self-organization in neural systems — •Philipp Hövel — Saarland University, Saarbrücken, Germany

Key feature of networked neural systems is the emergence of self-organized, collective dynamics giving rise to various forms of synchronization: The network is more that the sum of its parts. The nodes equiped with a neural model exhibit rich dynamical scenarious depending on the topology and type of coupling, which might also involve transmission delays due to finite signal propagation speed. In my talk, I will review a number of studies on coupled neural systems, where the considered examples include empirical, artificial, and adaptive networks. I will finish with recent results on network-induced inhibition giving rise to avalanches of neural activity interspersed by with long periods of quiescence.

SOE 7.7 Wed 11:45 H45

Critical drift in a neuro-inspired network — •Thilo Gross — Helmholtz Institute for Functional Marine Biodiversity (HIFMB) Im Technologiepark 5, 26129 Oldenburg, Germany — Alfred-Wegener Institute (AWI), Helmholtz Center for Polar and Marine Research, Bremerhaven, Germany — Carl-von-Ossietzky University, Oldenburg, Germany

It has been postulated that the brain operates in a self-organized critical state that brings multiple benefits, such as optimal sensitivity to input. Thus far, self-organized criticality has typically been depicted as a one-dimensional process, where one parameter is tuned to a critical value. However, the number of adjustable parameters in the brain is vast, and hence critical states can be expected to occupy a high-dimensional manifold inside a high-dimensional parameter space. Here, we show that adaptation rules inspired by homeostatic plasticity drive a neuro-inspired network to drift on a critical manifold, where the system is poised between inactivity and persistent activity. During the drift, global network parameters continue to change while the system remains at criticality.

SOE 7.8 Wed 12:00 H45

Transient Recurrent Dynamics Shapes Representations in Mice — •Lars Schutzeichel[1,2,3], Jan Bauer[1,4], Peter Bouss[1,2], Simon Musall[3], David Dahmen[1], and Moritz Helias[1,2] — [1]Institute for Advanced Simulation (IAS-6), Jülich Research Centre, Germany — [2]Department of Physics, Faculty 1, RWTH Aachen University, Germany — [3]Institute of Biological Information Processing (IBI-3), Jülich Research Centre, Germany — [4]The Edmond and Lily Safra Center for Brain Sciences, The Hebrew University of Jerusalem, Israel

Different stimuli evoke transient neural responses, but how is stimulus information represented and reshaped by local recurrent circuits? We address this question using Neuropixels recordings from awake mice and recurrent network models, inferring stimulus classes (e.g., visual or tactile) from activity. A two-replica mean-field theory reduces complex network dynamics to three key quantities: the mean population activity (R) and overlaps ($Q^{=}$, $Q^{\neq}$), reflecting response variability within and across stimulus classes. The theory predicts the time evolution of R, $Q^{=}$, and $Q^{\neq}$. Validated in experiments, it reveals how inhibitory balancing governs the dynamics of R, while chaotic dynamics shape overlaps, providing insights into the mechanisms underlying transient stimulus separation. The analysis of mutual information of an optimally trained population activity readout reveals that sparse coding (small R) allows the optimal information representation of multiple stimuli.

SOE 7.9 Wed 12:15 H45

Employing normalizing flows to examine neural manifold characteristics and curvatures — •Peter Bouss[1,2], Sandra Nestler[3], Kirsten Fischer[1,2], Claudia Merger[4], Alexandre René[2,5], and Moritz Helias[1,2] — [1]IAS-6, Forschungszentrum Jülich, Germany — [2]RWTH Aachen University, Germany — [3]Technion, Haifa, Israel — [4]SISSA, Trieste, Italy — [5]University of Ottawa, Canada

Despite the vast number of active neurons, neuronal population activity supposedly lies on low-dimensional manifolds (Gallego et al., 2017). To learn the statistics of neural activity, we use Normalizing Flows (NFs) (Dinh et al., 2014). These neural networks are trained to estimate the probability distribution by learning an invertible map to a latent distribution.

We adjust NF's training objectives to distinguish between relevant and noise dimensions, by using a nested dropout procedure in the latent space (Bekasov & Murray, 2020). An approximation of the network for each mixture component as a quadratic mapping enables us to calculate the Riemannian curvature tensors of the neural manifold. We focus mainly on the directions in the tangent space, in which the sectional curvature shows local extrema.

Finally, we apply the method to electrophysiological recordings of the visual cortex in macaques (Chen et al., 2022). We show that manifolds deviate significantly from being flat. Analyzing the curvature of the manifolds yields insights into the regimes where neuron groups interact in a non-linear manner.

SOE 7.10 Wed 12:30 H45

Neural self-organization of muscle-driven robots via force-mediated networks — •Claudius Gros[1] and Bulcsu Sandor[2] — [1]Institute for Theoretical Physics, Goethe University Frankfurt — [2]Department of Physics, Babes-Bolyai University, Cluj-Napoca, Romania

We present self-organizing control principles for simulated robots actuated by synthetic muscles. Muscles correspond to linear motors exerting force only when contracting, but not when expanding, with joints being actuated by pairs of antagonistic muscles. Individually, muscles are connected to a controller composed of a single neuron with a dynamical threshold that generates target positions for the respective muscle. A stable limit cycle is generated when the embodied feedback loop is closed, giving rise to regular locomotive patterns. In the absence of direct couplings between neurons, we show that the network generated by force-mediated intra- and inter-leg couplings between muscles suffice to generate stable gaits.

SOE 8: Networks, From Topology to Dynamics (joint session SOE/BP/DY)

Time: Wednesday 15:00–17:30 Location: H45

SOE 8.1 Wed 15:00 H45

Self-organized transport in noisy dynamic networks — •Frederic Folz[1], Joshua Rainer Ganz[1], Kurt Mehlhorn[2], and Giovanna Morigi[1] — [1]Theoretische Physik, Universität des Saarlandes, 66123 Saarbrücken, Germany — [2]Algorithms and Complexity Group, Max-Planck-Institut für Informatik, Saarland Informatics Campus, 66123 Saarbrücken, Germany

We present a numerical study of multicommodity transport in a noisy, nonlinear network. The nonlinearity determines the dynamics of the edge capacities, which can be amplified or suppressed depending on the local current flowing across an edge. We consider network self-organization for three different nonlinear functions: For all three we identify parameter regimes where noise leads to self-organization into more robust topologies, that are not found by the sole noiseless dynamics. Moreover, the interplay between noise and specific functional behavior of the nonlinearity gives rise to different features, such as (i) continuous or discontinuous responses to the demand strength and (ii) either single or multistable solutions. Our study shows the crucial role of the activation function on noise-assisted phenomena.

SOE 8.2 Wed 15:15 H45

Critical properties of Heider balance on multiplex networks — •Krishnadas Mohandas, Krzysztof Suchecki, and Janusz Hołyst — Faculty of Physics, Warsaw University of Technology, Koszykowa 75, PL-00-662 Warsaw, Poland

Heider's structural balance theory has proven invaluable in comprehending the dynamics of social groups characterized by both friendly and hostile relationships. Extending this understanding to multiplex networks, we investigate Heider balance dynamics in systems where agents exhibit correlated relations across multiple layers. In our model, intralayer interactions adhere to Heider dynamics, while interlayer correlations are governed by Ising interactions, using heat bath dynamics for link signs. This framework reveals a multifaceted equilibrium landscape, with distinct phases coexisting across layers. Starting from a paradise state with positive links in all layers, increasing temperature induces a discontinuous transition to disorder, similar to single-layer scenarios but with a higher critical temperature, as verified through extended mean-field analysis and agent-based simulations.

We extend this analysis to Erdös-Rényi random graphs in noisy environments. We predict a first-order transition with a critical temperature scaling as p^2 for monolayers and follow a more complex behavior for bilayers. To replicate dynamics observed in complete graphs, intralayer Heider interaction strengths must scale as p^{-2}, while interlayer interaction strengths scale as p^{-1} in random graphs. Numerical simulations confirm these analytical predictions for dense graphs.

SOE 8.3 Wed 15:30 H45

Functional Motifs in Food Webs and Networks — •Melanie Habermann[1,2,3], Ashkaan Fahimipour[4], Justin Yeakel[5,6], and Thilo Gross[1,2,3] — [1]Helmholtz Institute for Functional Marine Biodiversity (HIFMB), Oldenburg, GER — [2]Alfred-Wegener Institute (AWI), Helmholtz Center for Polar and Marine Research, Bremerhaven, GER — [3]Carl-von-Ossietzky University, Institute for Chemistry and Biology of the Marine Environment (ICBM), Oldenburg, GER — [4]Florida Atlantic University, Boca Raton, FL, USA — [5]University of California Merced, Merced, CA, USA — [6]The Santa Fe Institute, Santa Fe, NM, USA

It is interesting to ask when the presence of a small subgraph in a complex network is sufficient to impose constraints on system dynamics that are independent of the broader network structure. We refer to these subgraphs as functional motifs. A classic example can be found in ecology with the competitive exclusion motif in food webs, where two species compete for the same resource without regulation. The presence of this motif precludes any stable equilibrium for the entire system. However, examples of other motifs with similarly definitive implications for system stability are rare. But our usual notion of asymptotic stability is just one among many different concepts of stability. Another one, reactivity, captures a system's immediate response to small perturbations. In this talk, we explain why functional stability motifs are rare and show that every subgraph is a functional reactivity motif. This highlights reactivity as a promising concept for exploring a vast range of networked phenomena.

SOE 8.4 Wed 15:45 H45

Infecting Apex Predators Could Lead to Their Extinction — •Fakhteh Ghanbarnejad[1] and Hooman Saveh[2] — [1]SRH University of Applied Sciences, Leipzig, Germany — [2]Sharif University of Technology, Tehran, Iran

Food webs have been extensively studied from both ecological and mathematical aspects. However, most of the models studied in this area do not capture the effects of infectious diseases simultaneously. Recently, the idea of including an infectious disease in a food web model has been investigated. We study and simulate a small food chain consisting of only prey, predators, and apex predators governed by the generalized Lotka-Volterra equations and we implement the Susceptible-Infected-Recovered (SIR) model on only one of the species at a time in the food chain. To study the effects of an infectious disease on the food chain, we introduce a new parameter that increases predation rate by a factor of w and decreases hunting rate by a factor of $1/w$ for infected species. When the infectious disease is in our predators we observe that predators do not extinct under any set of parameters, however, an oscillation in its population size occurs under some circumstances which we do not observe in ordinary SIR or the generalized Lotka-Volterra equations alone. When an infectious disease is present in apex predators, oscillations in the population size do not happen; but if the set of parameters is in a specific range the apex predators may extinct. Furthermore, the chance of survival of the community, known as community persistence, increases for the predators and decreases for the apex predators.

Behavioral Heterogeneity in Disease Spread: Contrasting Effects of Prevention Strategies and Social Mixing — •Fabio Sartori[1,2] and Michael Maes[1] — [1]Chair of Sociology and Computational Social Science, Karlsruhe Institute of Technology, Karlsruhe — [2]Max Planck Institute for Dynamics and Self Organisation, Göttingen, Germany

Despite mounting evidence of behavioral heterogeneity in response to disease threats, the majority of epidemiological models assume uniform behavior across populations for mathematical tractability. We analyze three distinct mechanisms of behavioral response to disease threat: susceptibility reduction (e.g., mask-wearing), active testing, and vaccination propensity. Through extensive numerical analysis, we demonstrate that the impact of behavioral heterogeneity strongly depends on the specific mechanism involved. While heterogeneous susceptibility-reducing behaviors generally decrease disease spread, heterogeneity in testing rates and vaccination propensity typically amplifies epidemic severity. Furthermore, we show that non-homogeneous mixing patterns, particularly when correlated with behavioral traits, exacerbate disease spread across all three mechanisms. These findings reveal fundamental principles about the interplay between behavioral heterogeneity and epidemic dynamics, challenging the conventional homogeneous assumption and providing important implications for public health interventions and policy design.

SOE 8.6 Wed 16:30 H45

Modelling retweet cascades using multivariate Hawkes processes on sparse networks — Alexander Kreiss[1] and •Eckehard Olbrich[2] — [1]Leipzig University, Germany — [2]Max Planck Institute for Mathematics in the Sciences, Leipzig, Germany

We apply a model that considers vertices in a network who are able to cast events, e.g. users of the online social media platform Twitter. Furthermore, there is a directed edge from vertex A to vertex B if A takes note of the events cast by B and changes its own behavior accordingly. More precisely, the model assumes that the activity of B increases the activity of A and likewise its other neighbors. This is called peer effects. However, there might also be other information, which also influences the activity of the vertices, e.g. the time of the day for social media posts. This is called global effects. We use a Hawkes model that incorporates, both, peer and global effects. This allows for the estimation of the network, that is, the influence structure while controlling for network effects or the estimation of the global effects while controlling for peer effects. The estimation is based on a LASSO strategy, which respects sparsity in the network. We apply this model to retweets on Twitter in order to reconstruct potential retweet cascades and identify accounts that are influential in sharing information.

SOE 8.7 Wed 16:45 H45

Influence, Incidence, Imitators and Individualists: Comparing social influence models of protective behavior in an epidemic — •Andreas Reitenbach — Karlsruhe Institute of Technology, Karlsruhe, Germany

To manage a pandemic, it is critical that citizens voluntarily engage in protective behavior (e.g. masking or vaccinating). Voluntary behavior is subject to complex dynamics of social influence, however. While various models couple social influence dynamics with disease spreading, assumptions about how individuals influence each other differ markedly. Models assuming herding implement that agents imitate their peers. On the contrary, rational agents (individualists) engage in protective behavior when their peers are not and vice versa, potentially free-riding on others' contributions to herd immunity.

Here, I study whether and why these competing behavior models translate into different disease dynamics. Following a recent call to abstract from psychological mechanisms underlying social influence, I translate the behavior theories into influence-response functions.

I find that individualists self-coordinate on a moderate level of protection and experience long-lasting but flat incidence curves. Herding, in contrast can result in rapid cycling through waves of high incidence and strong collective efforts to mitigate. Whether herders or individualists navigate an epidemic better can depend on the population's hospital capacity and disease parameters.

SOE 8.8 Wed 17:00 H45

Formalism and Physical Principles of Human Mobility and Routine — •Marlli Zambrano[1], Ashish Thampi[2], Alejandra Rincon[2], Andrzej Jarynowski[1], Steven Schulz[2], and Vitaly Belik[1] — [1]FU Berlin, Germany — [2]Machine Learning Unit, NET CHECK GmbH, Berlin, Germany

The physical principles underlying human mobility have been extensively studied in recent years, enabled by the availability of large-scale mobile phone data. While significant progress has been made in understanding general mobility patterns, capturing the dynamics of individual trajectories, specifically how mobility varies from person to person and day to day, remains challenging due to the need for highly detailed and persistent data. This study addresses this challenge by examining sequences of individual daily mobility motifs, as defined by Schneider et al., from a stochastic process perspective. The analysis uses a persistent mobile phone user panel in Berlin, with high-frequency GPS data collected over four years. Twenty motifs were identified, covering 96% of all observations. The extent of inter- and intra individual variability is explored, focusing on how motifs change within individuals over time and differ between individuals in various contexts (e.g., weekends, seasons). Additionally, sequences of motifs are modeled as a stochastic process, and properties such as transition probabilities are analyzed. These findings provide deeper insights into the variability and structure of human mobility, contributing to a better understanding of individual mobility dynamics.

SOE 8.9 Wed 17:15 H45

The world air transportation network: import risk of diseases, pandemic potentials and passenger routes — •Pascal Klamser[1,2], Adrian Zachariae[1,2], Benjamin Maier[3], Olga Baranov[4], and Dirk Brockmann[1,2] — [1]Technische Universität Dresden, Dresden, Germany — [2]Robert Koch-Institute, Berlin, Germany — [3]University of Copenhagen, Copenhagen, Denmark — [4]LMU München, München, Germany

Disease propagation between countries strongly depends on their effective distance, a measure derived from the world air transportation network. It reduces the complex spreading patterns of a pandemic to a wave-like propagation from the outbreak country, establishing a linear relationship to the arrival time of the unmitigated spread of a disease. However, in the early stages of an outbreak, what concerns decision-makers in countries is understanding the relative risk of active cases arriving in their country*essentially, the likelihood that an active case boarding an airplane at the outbreak location will reach them. While there are data-fitted models available to estimate these risks, accurate mechanistic, parameter-free models are still lacking.

We (i) introduce the "import risk" model, which defines import probabilities using the effective-distance framework, (ii) show its application to estimate the pandemic potential of emerging variants of COVID-19 and (iii) show that the effective distance shortest path tree, on which the "import risk" model is based on, is an extremely accurate representation of true passenger routes.

SOE 9: Members' Assembly

Time: Wednesday 18:00–19:30 Location: H45

All members of the Physics of Socio-economic Systems Division are invited to participate.

SOE 10: Focus Session: Large Language Models, Social Dynamics, and Assessment of Complex Systems

Recent Large Language Models (LLMs) learn the statistics of human communication, and hence they present a promising way of simulating societal interactions and opinion formation. Moreover, their flexible architecture makes them versatile to also learn the statistics of other complex systems. - We will discuss how to make best use of these advancements to model social interactions and dynamics across different scales and settings, how to use them to assess sentiments, narratives and opinions, and also how one can use LLMs to also understand other complex systems. Our aim is to offer an evaluative perspective on both the potential and challenges that are intrinsic to this rapidly evolving research area.

Organized by Vincent Brockers, Johannes Zierenberg, and Viola Priesemann

Time: Thursday 15:00–18:15 Location: H45

Invited Talk SOE 10.1 Thu 15:00 H45

Emergent Behaviors in LLMs-Populated Societies — •Giordano De Marzo[1,2,3], Claudio Castellano[4,2], Luciano Pietronero[2], and David Garcia[1,3] — [1]Konstanz University — [2]CREF Enrico Fermi Research Center — [3]CSH Vienna — [4]CNR-ISC Institute for Complex Systems

Applications of Large Language Models (LLMs) increasingly involve collaborative tasks where multiple agents interact, forming "LLM societies." In this context, we explore whether large groups of LLMs exhibit emergent group behaviors similar to those in human societies. First, by simulating social network formation, we observe that LLMs spontaneously form scale-free networks. Agents connect through linear preferential attachment, mirroring the Barabasi-Albert model and real-world social networks. Second, we investigate the ability of LLMs to reach consensus on arbitrary norms without external preferences, thereby self-regulating their behavior. In human societies, consensus without institutions is limited by cognitive capacities. Similarly, we find that LLMs can reach consensus, with the opinion dynamics described by a majority force coefficient that determines the likelihood of consensus. This majority force strengthens with higher language understanding but decreases with larger group sizes, resulting in a critical group size beyond which consensus becomes unattainable. For more advanced LLMs, this critical size grows exponentially with language capabilities, exceeding the typical size of informal human groups.

SOE 10.2 Thu 15:30 H45

A Framework for Multi-Step Discussions of LLM-Based Agents — •Vincent Brockers[1,2], David Ehrlich[2,3], and Viola Priesemann[1,2] — [1]Max Planck Institute for Dynamics and Self-Organization — [2]University of Göttingen — [3]Göttingen Campus Institute for Dynamics of Biological Networks

Recent studies have demonstrated the utility of Large Language Models (LLMs) across various settings and domains, particularly in their ability to approximate human behavior for simulating and studying societal phenomena. A critical component of this capability is their proficiency in generating realistic dialogues. We are interested in the collective dynamics that arise from their dialogues, in particular in the context of understanding collective opinion dynamics.

We developed a framework for simulating multi-step discussions among LLM-based agents, which is crucial for these studies. We conduct an in-depth analysis of the components of such simulations, highlighting the challenges and specifically investigating potential biases.

We find that these opinion dynamics are primarily influenced by model-inherent topic biases, which exhibit attractors in the opinion space. Additionally, the framing of opinion evaluation plays a crucial role in analyzing these dynamics. Our findings offer valuable insights for future research aimed at optimizing the design of LLM agent-based simulations and enhancing our modeling capabilities of complex systems, such as human networks.

SOE 10.3 Thu 15:45 H45

Collective Turing Tests on LLMs — •Azza Bouleimen[1,2], Giordano de Marzo[3], Taehee Kim[3], Silvia Giordano[2], and David Garcia[3] — [1]University of Zurich, Zurich, Switzerland — [2]SUPSI, Lugano, Switzerland — [3]University of Konstanz, Konstanz, Germany

In this project, we investigate whether social media conversations generated by independent LLMs are indistinguishable from those of humans, i.e., whether LLMs used to generate social media content can pass the Turing test. Formally, we conduct an experiment in which we prepare a series of English Reddit submissions to which we attach two conversations. One of the conversations is an authentic human conversation ,while the other is generated artificially using an LLM. We generate conversations using GPT-4o and llama 3 70B. We vary the temperatures of the models used and the length of the conversations. We recruit participants from Prolific. These subjects are asked to select the conversation they believe is generated by AI. Our preliminary results suggest that, overall, participants are fooled by LLM 40% of the time. Llama 3 70B conversations appear to fool users more often than GPT-4o ones. Through this study, we investigate to what extent and with which configurations LLM could be best used to simulate user conversations on social media. To the best of our knowledge, this is the first attempt to evaluate the performance of LLMs in mimicking a social media conversation between a group of individuals.

SOE 10.4 Thu 16:00 H45

Dialogue React: Enhancing Conversation Synthesis for Social Science Simulations — •Ruggero Marino Lazzaroni — RWTH Aachen

Recent advancements in Large Language Models (LLMs) have spurred significant progress in conversation synthesis and social dynamics modeling. However, existing approaches often fall short in generating human-like dialogues suitable for complex social science simulations and opinion formation studies. This research introduces DialogueReact, a novel framework that builds upon previous work in conversation synthesis by incorporating react prompting, dialogue acts and agentic behaviour across different scales. By leveraging LLMs' ability to learn communication statistics, DialogueReact generates qualitatively better conversations compared to previous state-of-the-art methods. Our findings demonstrate the potential of DialogueReact to improve social science research by providing an extra tool for simulating complex social interactions and understanding collective behavior in social systems.

SOE 10.5 Thu 16:15 H45

Computational modeling of LLM powered personalized recommendations — •Alessandro Bellina[1,2,4], Giordano De Marzo[1,3,4], David Garcia[3], and Vittorio Loreto[1,2,4] — [1]Centro Ricerche Enrico Fermi, Piazza del Viminale, 1, I-00184 Rome, Italy — [2]Sony Computer Science Laboratories Rome, Joint Initiative CREF-SONY, Piazza del Viminale, 1, 00184, Rome, Italy — [3]University of Konstanz, Universitaetstrasse 10, 78457 Konstanz, Germany — [4]Dipartimento di Fisica Università La Sapienza, P.le A. Moro, 2, I-00185 Rome, Italy

Large language models (LLMs) are transforming recommendation systems by tailoring content to user preferences, but they also risk reinforcing filter bubbles and driving polarization. This study investigates the dual impact of LLM-based recommendations, analyzing their inherent biases and exploring how prompt engineering can mitigate these effects. By combining synthetic simulations with real-world Twitter data, we assess how LLMs influence user behavior and the extent to which recommendations amplify or reduce polarization. Preliminary results suggest that prompt engineering enables greater control over recommendations, fostering diversity and creativity. This research provides insights into the risks and opportunities of LLM-powered systems, offering a framework for designing more inclusive and balanced recommendation algorithms.

SOE 10.6 Thu 16:30 H45

Statistical Modelling of Physics Classroom Interactions — •Niklas Stausberg, Karina Avila, Steffen Steinert, Jochen Kuhn, and Stefan Küchemann — Lehrstuhl für Didaktik der Physik, Ludwig-Maximilians-Universität München, Geschwister-Scholl-Platz 1, 80539 München

Teacher-student and student-student dialogues are one of the central means to mediate learning in classroom settings, as they foster active participation, promote cognitive engagement, scaffold conceptual understanding, and enhance metacognitive skills. However, strategies for effective classroom dialogues have primarily been studied at an organizational level, and the nuanced mechanisms through which real-time teacher-student and student-student interactions influence individual learning outcomes within the classroom remain largely unexplored.

New advances in analysis of verbal interactions now offer opportunities to perform granular analyses of classroom dialogues. Using a combination of response times and speed, voice emotion recognition, and self-regulation state detection enables clustering of patterns in students' cognitive, emotional, and self-regulatory states and map them to specific types of teacher and student responses to gain insights into the dynamics of effective classroom interactions. In this talk, we discuss how statistical modeling of classroom interactions, e.g. via percolation theory, can be used to provide additional perspectives in the understanding of social learning processes.

SOE 10.7 Thu 17:00 H45

Disentangling individual vs. collective contributions to polarization in political voting — Gavin Rees and •Edward Lee — Complexity Science Hub, Vienna, Austria

Politics around the world exhibit increasing polarization, most visibly demonstrated by rigid voting configurations in legislatures. This impacts their ability to seek effective compromise and pass impactful legislation. The crux of polarization is the emergence of a unidimensional ideological axis that primarily determines voting. Yet, legislative bills often negotiate multiple issues, whose effects may add up or compete for any individual vote. We develop a model inspired from statistical physics that accounts for voters with multi-dimensional preferences that can be linearly combined to generate coalitions. This allows us to capture higher-order correlations beyond those captured in direct spin-spin interaction models. As a result, the model is dramatically simpler, fits the data better, and is more interpretable than canonical maximum entropy or utility-based models from political science for large voting bodies. We study roll-call voting in US Congress, and we find coexistence of non-polarized with polarized modes. We show how increased partisan polarization is the contribution of two terms: increased party-line voting by the individual plus depletion of votes that would elicit complex, bipartisan response. Both decrease over time, but the latter falls much faster. Thus, we propose a more principled way of tracking the emergence of polarization at the level of the voter and the collective issues the many vote on.

SOE 10.8 Thu 17:15 H45

Understanding Information Spread in Social Networks through the Lense of Self-Organized Criticality: A Study on Telegram — •Roman Ventzke[1,2], Anastasia Golovin[1,2], Sebastian Bernd Mohr[1,2], Andreas Schneider[1,2], and Viola Priesemann[1,2] — [1]Max-Planck-Institut für Dynamik und Selbstorganisation, Göttingen — [2]Georg-August-Universität Göttingen

To effectively address the proliferation of misinformation in social media, one fundamentally needs to understand how information spreads in online social networks. We investigate the dynamics of information spread using a large dataset from the messenger platform Telegram, showing that information spread in the networks happens in bursty avalanches with scale-free statistics that resembles critical behavior of physical systems.

We find that the critcal exponents of the system can be well described by a mean-field Random Field Ising Model (RFIM), alluding to an important role of complex contagion and peer-pressure effects in the propagation of information. By coarse-graining dynamics in the topic space we show additional evidence that the process indeed belongs to the RFIM class. We demonstrate through simulations that the spreading process on the network can be well-described by mean-field models and discuss how self-regulation of the network gives rise to criticality.

SOE 10.9 Thu 17:30 H45

Dynamics of information spread: the phase space of topics on Telegram — •Anastasia Golovin[1,2], Simon Bauer[1], Sebastian Mohr[1], and Viola Priesemann[1,2] — [1]Max Planck for Dynamics and Self-Organisation, Göttingen, Germany — [2]Institute for the Dynamics of Complex Systems, University of Göttingen, Germany

The information that is spread on digital platforms shapes public discourse and influences decision-making. In this talk, we explore the dynamics of topics discussed on Telegram, a privacy-oriented messenger that became a hub for misinformation spread during the COVID-19 pandemic. Using transformer-based topic modeling techniques, we map each Telegram channel onto a trajectory in a high-dimensional phase space of topics. Treating these trajectories as a stochastic dynamical system, we identify topic areas that act as attractors, pulling trajectories from their neighborhood, and others that emerge only transiently in response to global events. This approach bridges computational social science and dynamical systems theory, offering a novel perspective on understanding discourse dynamics in communication networks.

SOE 10.10 Thu 17:45 H45

Computational approaches to analyzing political narratives — •Armin Pournaki[1,2,3] and Tom Willaert[4] — [1]Max Planck Institute for Mathematics in the Sciences, Leipzig, Germany — [2]Laboratoire Lattice, École Normale Supérieure - PSL - CNRS, Paris, France — [3]médialab, Sciences Po, Paris, France — [4]Brussels School of Governance, Vrije Universiteit Brussel, Brussels, Belgium

Narratives are key interpretative devices by which humans make sense of political reality. As the significance of narratives for understanding current societal issues such as polarization and misinformation becomes increasingly evident, there is a growing demand for methods that support their empirical analysis. To this end, we propose a graph-based formalism and machine-guided method for extracting, representing, and analyzing selected narrative signals from digital textual corpora, based on Abstract Meaning Representation (AMR) [1]. The formalism and method introduced here specifically cater to the study of political narratives that figure in digital trace data. We demonstrate the method on corpora gathered from archived political speeches and social media posts. [1] https://arxiv.org/abs/2411.00702

SOE 10.11 Thu 18:00 H45

Optimizing pandemic mitigation in the presence of seasonality, emerging variants and vaccination — •Laura Müller[1,2], Fabio Sartori[1,3], Jonas Dehning[1,2], Maximilian F. Eggl[4], and Viola Priesemann[1,2] — [1]Max-Planck-Institute for Dynamics and Self-Organization, Göttingen, Germany — [2]Institute for the Dynamics of Complex Systems, University of Göttingen, Göttingen, Germany — [3]Karlsruhe Institute of Technology, Karlsruhe, Germany — [4]Institute of Neuroscience, CSIC-UMH, Alicante, Spain

Mitigation efforts are often necessary to control the spread of infectious diseases during pandemics and epidemics. However, these measures come with societal and economic costs. We present a general optimization framework based on control theory to balance the trade-off between mitigation costs and infection rates, aiming to identify the optimal time-dependent mitigation strategies across a range of scenarios: constant reproduction number, seasonal changes, emerging variants, vaccination rollout, and delayed mitigation onset. Our results show that timely reactions and proactive, preventative measures are crucial in pandemic management to save both lives and costs.

Low Temperature Physics Division
Fachverband Tiefe Temperaturen (TT)

Stefan Kehrein

Program Overview

(Lecture Halls H31, H32, H33, H36 and Poster P3 and P4)

Plenary Talks Chaired by the Low Temperature Physics Division

PLV VI	Wed	14:00–14:45	H1	**Topological spin-textures – from domain walls to Hopfions: Current innovations and future challenges** — •Stefan Blügel
PLV XI	Fri	8:30– 9:15	H1	**Exploring correlated phases and topology in van der Waals platforms** — •Roser Valenti

Symposia Coorganized by the Low Temperature Physics Division

Invited Talks of the joint SKM Dissertationspreis 2025 (SYSD)

See SYSD for the full program of the symposium.

SYSD 1.1	Mon	9:30–10:00	H2	**Nanoscale Chemical Analysis of Ferroic Materials and Phenomena** — •Kasper Aas Hunnestad
SYSD 1.2	Mon	10:00–10:30	H2	**Advanced Excitation Schemes for Semiconductor Quantum Dots** — •Yusuf Karli
SYSD 1.3	Mon	10:30–11:00	H2	**Aspects and Probes of Strongly Correlated Electrons in Two-Dimensional Semiconductors** — •Clemens Kuhlenkamp
SYSD 1.4	Mon	11:00–11:30	H2	**Mean back relaxation and mechanical fingerprints: simplifying the study of active intracellular mechanics** — •Till Münker
SYSD 1.5	Mon	11:30–12:00	H2	**Coherent Dynamics of Atomic Spins on a Surface** — •Lukas Veldman

Invited Talks of the joint Symposium Spins in Molecular Systems: Strategies and Effects of Hyperpolarization (SYMS)

See SYMS for the full program of the symposium.

SYMS 1.1	Wed	15:00–15:30	H1	**Exploring the Non-Perturbative Magnetic Resonance Drive Regime with spin selection rules in a π-Conjugated Polymer** — •Christoph Boehme
SYMS 1.2	Wed	15:30–16:00	H1	**The puzzle of spin and charge transport in the chirality induced spin selectivity effect** — •Bart van Wees
SYMS 1.3	Wed	16:00–16:30	H1	**Nano- and Microscale NMR spectroscopy with spin qubits in diamond** — •Nabeel Aslam
SYMS 1.4	Wed	16:45–17:15	H1	**Spin effects in adsorbed organometallic complexes** — •Richard Berndt
SYMS 1.5	Wed	17:15–17:45	H1	**Quantum Computing with Molecules** — •Mario Ruben

Invited Talks of the joint Symposium Nonequilibrium Collective Behavior in Open Classical and Quantum Systems (SYQS)

See SYQS for the full program of the symposium.

SYQS 1.1	Thu	15:00–15:30	H1	**Active quantum flocks** — •Markus Heyl
SYQS 1.2	Thu	15:30–16:00	H1	**Robust dynamics and function in stochastic topological systems** — •Evelyn Tang
SYQS 1.3	Thu	16:00–16:30	H1	**Nonequilibrium Dynamics of Disorder-Driven Ultracold Fermi Gases** — •Artur Widera
SYQS 1.4	Thu	16:45–17:15	H1	**Topological classification of driven-dissipative nonlinear systems** — •Oded Zilberberg
SYQS 1.5	Thu	17:15–17:45	H1	**Learning dynamical behaviors in physical systems** — •Vincenzo Vitelli

Invited Talks of the joint Symposium Electronic Structure Theory for Quantum Technology: From Complex Magnetism to Topological Superconductors and Spintronics (SYES)

See SYES for the full program of the symposium.

SYES 1.1	Fri	9:30–10:00	H1	**Ab-initio Design of superconductors** — •Lilia Boeri
SYES 1.2	Fri	10:00–10:30	H1	**Topological superconductivity from first principles** — •László Szunyogh
SYES 1.3	Fri	10:30–11:00	H1	**First-principles study and mesoscopic modeling of two-dimensional spin and orbital fluctuations in FeSe** — •Myrta Grüning
SYES 1.4	Fri	11:15–11:45	H1	**Non-collinear magnetism in 2D materials from first principles: Multiferroic order and magnetoelectric effects.** — •Thomas Olsen
SYES 1.5	Fri	11:45–12:15	H1	**Spin-phonon and magnon-phonon interactions from first principles** — •Marco Bernardi

Invited Talks in Focus Sessions

Invited Talks of the Focus Session "Magnetic Phenomena from Phonon Chirality and Angular Momentum" (joint session MA/TT)

TT 1.1	Mon	9:30–10:00	H20	**Driving Coherent Phonon-Phonon Angular Momentum Transfer via Lattice Anharmonicity** — •Sebastian Maehrlein
TT 1.2	Mon	10:00–10:30	H20	**Chiral phonons, phono-magnetism, and spin-rotation coupling** — •Matthias Geilhufe
TT 1.3	Mon	10:30–11:00	H20	**Geometry of temporal chiral structures and photoinduced chirality-spin coupling** — •Olga Smirnova
TT 1.4	Mon	11:15–11:45	H20	**Phonon thermal Hall effect** — •Kamran Behnia
TT 1.5	Mon	11:45–12:15	H20	**Giant effective magnetic moment of chiral phonons** — •Swati Chaudhary

Invited Talks of the Focus Session "Many-Body Phenomena in Nanomagnets: Kondo, Spinons, Spinarons and Beyond" (joint session O/TT)

TT 6.1	Mon	15:00–15:30	H24	**Kondo and Yu-Shiba-Rusinov resonances: transport and coupling** — •Laëtitia Farinacci
TT 6.2	Mon	15:30–16:00	H24	**Electron delocalization in a 2D Mott insulator** — •Amadeo L. Vazquez de Parga
TT 6.3	Mon	16:00–16:30	H24	**Kondo or no Kondo, that is the question** — •Alexander Weismann
TT 6.4	Mon	16:30–17:00	H24	**Evidence for spinarons in Co atoms on noble metal (111) surfaces** — •Artem Odobesko
TT 6.5	Mon	17:00–17:30	H24	**Spinarons: A new view on emerging spin-driven many-body phenomena in nanostructures** — •Samir Lounis

Invited Talks of the Focus Session "Strongly Correlated Quantum States in Moire Heterostructures" (joint session TT/HL/MA)

TT 18.1	Tue	9:30–10:00	H36	**The Thermoelectric Effect and Its Natural Heavy Fermion Explanation in Twisted Bilayer and Trilayer Graphene** — •Bogdan Andrei Bernevig
TT 18.2	Tue	10:00–10:30	H36	**Angle-Tuned Chiral Phase Transition in Twisted Bilayer Graphene** — •Laura Classen
TT 18.3	Tue	10:30–11:00	H36	**Quantum Optics of Semiconductor Moire Materials** — •Atac Imamoglu
TT 18.4	Tue	11:15–11:45	H36	**Probing the Band Structures of Multilayer Graphene Using the Quantum Twisting Microscope** — •Martin Lee
TT 18.5	Tue	11:45–12:15	H36	**Gate-Tunable Bose-Fermi Mixture in a Strongly Correlated Moiré Bilayer Electron System** — •Nathan Wilson

Invited Talks of the Focus Session "Nonlinear Spectroscopy of Collective Excitations in Quantum Magnets" (joint session TT/MA)

TT 27.1	Wed	9:30–10:00	H36	**Detecting Anyons Using Nonlinear Pump-Probe Spectroscopy** — •Max McGinley
TT 27.2	Wed	10:00–10:30	H36	**Two-Dimensional Nonlinear Dynamic Response of Frustrated Magnets** — •Wolfram Brenig
TT 27.3	Wed	10:30–11:00	H36	**Imaging Magnetization Dynamics and Collective Spin Excitations in Compensated Magnets on Ultrafast Timescales** — •Benjamin Stadtmüller
TT 27.4	Wed	11:15–11:45	H36	**Revealing Dynamics of Hidden Sectors with Nonlinear Spectroscopy** — •Yoshito Watanabe
TT 27.5	Wed	11:45–12:15	H36	**Theory of Nonlinear Spectroscopy of Quantum Magnets** — •Stefan Birnkammer

Invited Talks of the Focus Session "Ising Superconductivity in Monolayer Transition Metal Dichalcogenides" (joint session TT/HL/MA)

TT 44.1	Thu	9:30–10:00	H36	**Evidence of Unconventional Superconductivity in Monolayer and Bulk van der Waals Material TaS_2** — •Somesh Chandra Ganguli
TT 44.2	Thu	10:00–10:30	H36	**Signatures of Unconventional Superconductivity in Transition Metal Dichalcogenides** — •Miguel Ugeda
TT 44.3	Thu	10:30–11:00	H36	**Friedel Oscillations and Chiral Superconductivity in Monolayer $NbSe_2$** — •Magdalena Marganska
TT 44.4	Thu	11:15–11:45	H36	**Unconventional Pairing in Ising Superconductors** — •Andreas Kreisel
TT 44.5	Thu	11:45–12:15	H36	**High-Field Study of Ising Superconductivity in TMDs** — •Oleksandr Zheliuk

Individual Invited Talks

TT 15.1	Tue	9:30–10:00	H31	**Solving Many-Body Problems on Quantum Computers** — •Benedikt Fauseweh
TT 24.1	Wed	9:30–10:00	H31	**Possible Origin of High-Field Reentrant Superconductivity in UTe_2** — •Toni Helm
TT 24.7	Wed	11:30–12:00	H31	**Unconventional Superconductivity in Epitaxial $KTaO_3$-Based Heterostructures** — •Denis Maryenko
TT 31.1	Wed	15:00–15:30	H31	**Quantum Skyrmion Hall Effect** — •Ashley Cook
TT 33.8	Wed	17:00–17:30	H33	**Emergent Dynamical Gauge Fields in Generic Kitaev Spin Liquids: From Monolayer to Multilayers** — •Aprem Joy
TT 48.1	Thu	15:00–15:30	H32	**Optical Conductivity as a Probe for Chiral Majorana Edge Modes** — •Lina Johnsen Kamra

All Sessions

TT 1.1–1.8	Mon	9:30–13:00	H20	**Focus Session: Magnetic Phenomena from Phonon Chirality and Angular Momentum I (joint session MA/TT)**
TT 2.1–2.11	Mon	9:30–12:30	H31	**Nonequilibrium Quantum Systems (joint session TT/DY)**
TT 3.1–3.12	Mon	9:30–12:45	H32	**Correlated Magnetism – General**
TT 4.1–4.13	Mon	9:30–13:00	H33	**Topological Insulators**

TT 1: Focus Session: Magnetic Phenomena from Phonon Chirality and Angular Momentum I (joint session MA/TT)

The magnetic moment of the electron lies at the heart of magnetism and spintronics. However, recent research has unveiled the angular momentum and magnetic moment of chiral phonons as fundamental quantities in their own right. These chiral phonons give rise to a plethora of novel lattice phenomena analogous to electronic effects, such as the phonon Hall and phonon Zeeman effects. Moreover, they play a critical role in angular momentum transfer on ultrafast timescales, as seen in the Einstein-de Haas effect. Chiral phonons can also generate effective magnetic fields reaching the tesla scale, inducing magnetization in antiferromagnetic, paramagnetic, and even nonmagnetic materials - a phenomenon reminiscent of the Barnett effect. These advancements showcase phonon chirality and angular momentum as powerful emerging tools for generating and controlling magnetism. This focus session aims to highlight the latest breakthroughs in chiral-phonon magnetism and foster connections between the rapidly evolving field of chiral phononics and the broader magnetism research community.

Coordinators: Dominik M.Juraschek, Eindhoven University of Technology, d.m.juraschek@tue.nl; Martina Basini, ETH Zürich, m.basini@ethz.ch

Time: Monday 9:30–13:00 Location: H20

Invited Talk TT 1.1 Mon 9:30 H20

Driving Coherent Phonon-Phonon Angular Momentum Transfer via Lattice Anharmonicity — •Sebastian Maehrlein — Fritz Haber Institute of the Max Planck Society — Helmholtz Zentrum Dresden Rossendorf — TU Dresden

The discrete rotational symmetry of crystal structures leads to the conservation of quantized angular momentum in solids. Whereas the exchange of energy and linear momentum between lattice vibrations (phonons) via anharmonic coupling is a cornerstone of solid-state physics, conservation and transfer of angular momentum within the lattice remained a postulate, yet. Recently, phonon angular momentum, often in the form of chiral phonons, was linked to gigantic magnetic fields, dynamical ferroelectricity, ultrafast demagnetization, or magnetic switching. However, the fundamental process of phonon to phonon angular momentum transfer required for demagnetization and other spin-related relaxation phenomena remained elusive.

Here we drive coherent phonon-phonon angular momentum transfer by establishing helical nonlinear phononics. Thereby, we directly observe phonon helicity-switching dictated by (pseudo) angular momentum conservation and the discrete rotational symmetry of the lattice. Ab-initio modeling in conjunction with classical equations of motion confirm the experimentally observed anharmonic phonon-phonon coupling as the dominating lattice angular momentum transfer channel. Our results thus open the field of helical or chiral nonlinear phononics, turning lattice angular momentum into the long missing tuning knob for ultrafast material control.

Invited Talk TT 1.2 Mon 10:00 H20

Chiral phonons, phono-magnetism, and spin-rotation coupling — •Matthias Geilhufe — Department of Physics, Chalmers University of Technology, 412 96 Göteborg, Sweden

High-intensity THz lasers enable the coherent excitation of individual phonon modes. The ultrafast control of emergent magnetism through phonons and phonon angular momentum opens new avenues for tuning functional materials. Recent experiments suggest a substantial magnetization in various materials [1,2], presenting a challenge for theoretical modeling. I will provide an introduction to magnetization induced by phonon angular momentum via the phonon inverse Faraday effect [3]. Additionally, I will discuss a coupling mechanism based on inertial effects, which facilitates the interaction between rotational degrees of freedom and electron spin [4].

Invited Talk TT 1.3 Mon 10:30 H20

Geometry of temporal chiral structures and photoinduced chirality-spin coupling — •Olga Smirnova[1,2,3], Philip Flores[1], Aycke Roos[1], David Ayuso[4], Piero Decleva[5], Stefanos Carlstroem[1], Serguei Patchkovskii[1], and Andres Ordonez[4] — [1]Max-Born Institute, Berlin — [2]Technische Universität Berin — [3]Technion - Israeli Institute of Technology, Haifa, Israel — [4]Imperial College London, UK — [5]CNR IOM and Dipartimento di Scienze Chimiche e Farmaceutiche, Universita degli Studi di Trieste, Italy

In non-relativistic physics the concepts of geometry and topology are usually applied to characterize spatial structures, or structures in momentum space. We introduce the concept of temporal geometry [1], which encompasses geometric and topological properties of temporal shapes, e.g. trajectories traced by a tip of a time-dependent vector on sub-cycle time scale, and apply it to light-driven ultrafast electron currents in chiral molecules. The geometric concepts: curvature and connection emerge as ubiquitous features of photoexcited chiral electron dynamics. To demonstrate the link between the geometric fields and spin, we extend the concept of curvature to spin-resolved photoionization, and show that it is responsible for enantio-sensitive locking of the cation orientation to the photoelectron spin. This translates into chirality induced spin selectivity in photoionization of oriented chiral molecules both in one photon and two-photon processes.

Invited Talk TT 1.4 Mon 11:15 H20

Phonon thermal Hall effect — •Kamran Behnia — Ecole Supérieure de Physique et de Chimie Industrielles, Paris, France

In insulating solids and liquids, heat is carried by phonons. The phonon scattering time is close to the so-called Planckian time near the melting temperature. It increases with cooling, as phonon-phonon Umklapp scattering events rarefy. A rigorous determination of thermal conductivity of insulators from first principles has been a major accomplishment of the quantum theory of solids. In contrast, our understanding of momentum and energy exchange between phonons at low temperatures is imperfect. In this context, the experimental detection of phonon thermal Hall effect in a growing number of insulators is a challenge to the condensed matter theory. The list now includes elmental insulators, such as black phosphorus, silicon and germanium, in which the spin degree of freedom is irrelevant and the atomic bonds are covalent. We will examine how magnetic field can influence anharmonicity.

Invited Talk TT 1.5 Mon 11:45 H20

Giant effective magnetic moment of chiral phonons — •Swati Chaudhary[1,3], Dominik Juraschek[2], Martin Rodriguez-Vega[3], and Gregory A Fiete[4] — [1]The Institute for Solid State Physics, The University of Tokyo, Japan — [2]Eindhoven University of Technology, Eindhoven, Netherlands — [3]The University of Texas at Austin, Austin, USA — [4]Northeastern University, Boston, USA

Chiral phonons carry angular momentum and lead to magnetic responses in applied magnetic fields or when resonantly driven with ultrashort laser pulses. On the basis of purely circular ionic motion, these phonons are expected to carry a magnetic moment of the order of a few nuclear magnetons. However, some recent experiments have demonstrated a phonon magnetic moment of the order of a few Bohr magnetons. This kind of giant magnetic response points towards the electronic contribution to the magnetic moment of phonons. Many diverse mechanisms have been discovered for this enhanced magnetic response of chiral phonons. The orbital-lattice coupling is one such mechanism where low-energy electronic excitations on a magnetic ion hybridize with phonons and endow a large magnetic moment to phonons. In this talk, I'll present a microscopic model for the effective magnetic moments of chiral phonons based on this mechanism.

We apply our model to two types of materials: rare-earth halide paramagnets and transition-metal oxide magnets. In both cases, we find that chiral phonons can carry giant effective magnetic moments of the order of a Bohr magneton, orders of magnitude larger than previous predictions.

TT 1.6 Mon 12:15 H20

Extrinsic Phonon Thermal Hall Effect — •Dimos Chatzichrysafis[1], Robin Richard Neumann[1,2], and Alexander Mook[1] — [1]Johannes Gutenberg-Universität, Mainz, Germany — [2]Martin-Luther-Universität Halle-Wittenberg, Germany

The thermal Hall effect is a developing tool to investigate charge-neutral excitations, exposing the quantum many-body ground state of correlated materials. Since a sense of chirality for the energy carriers is necessary for the generation of a thermal Hall effect, it is natural to expect that quasiparticles of magnetic excitations are responsible for the Hall transport. This conventional wisdom has been recently challenged in experiments [1] which revealed a universal character of the thermal Hall effect independent on the magnetic texture and the lattice structure, even in systems where magnetism is completely absent. This finding asks for the re-investigation of the role of phonons in the thermal Hall effect.

Here, we develop a theory for a phononic thermal Hall effect where the source of chirality is given by the presence of the molecular Berry phase. As a toy model we study a non-magnetic system on a Bravais square lattice. We go beyond the intrinsic mechanism [2] usually studied in literature and consider the contribution of different possible extrinsic sources of phonon Hall transport. Our results demonstrate that phonon thermal Hall effects can be native to very generic systems.

TT 1.7 Mon 12:30 H20

Signatures of chiral phonons in $MnPS_3$ — •Banhi Chatterjee and Peter Kratzer — Faculty of Physics, University of Duisburg-Essen, Lotharstr. 1, 47057, Duisburg, Germany

Chiral phonons can exist in two-dimensional transition metal dichalcogenide (TMDC) monolayers without inversion symmetry. They can be observed in the non-equilibrium state triggered by optical excitations using circularly polarized light. In existing literature a detailed theoretical calculation of the circular phonons production rate has already been done for the TMDC MoS_2. We investigate the antiferromagnetic semiconductor $MnPS_3$ with a similar hexagonal crystal structure and band-structure like MoS_2 but a larger unit cell as a novel candidate material that may allow for excitation of circular phonons. In $MnPS_3$, although the total magnetic moment is zero in the ground state, exciting the system using circularly polarized light induces a net magnetic moment. The damping of the magnons observed experimentally points to the transfer of orbital angular moment to combined phonon-magnon excitations. Using DFT+U and density functional perturbation theory (DFPT) we obtain in-plane chiral phonon modes at the valley-points of a monolayer $MnPS_3$ and for these modes the S atoms make circular motions. We further study the electron-phonon coupling between these chiral phonon modes and the excited electronic states carrying orbital angular momentum, particularly the dominant d-electrons, in order to theoretically investigate the experimentally observed damping of magnons.

TT 1.8 Mon 12:45 H20

Elliptically polarized coherent phonons in a degenerate mode — Arne Ungeheuer, Mashood T. Mir, Ahmed Hassanien, Lukas Nöding, Thomas Baumert, and •Arne Senftleben — Institut für Physik, Universität Kassel

Controlled excitation of phonons in crystalline solids is an emerging way to alter the property of a material to create phenomena such as transient magnetic polarization [1,2]. Here, we want to focus on controlling the polarization properties of coherent optical phonons that can be launched by ultrashort laser pulses. we demonstrate the excitation of elliptically polarized coherent optical phonons of the E_{2g} shearing mode in graphite. This is achieved by exciting the superposition of two orthogonally polarized phonon modes using a tailored pair of time-delayed optical pulses with tilted polarization. The elliptically polarized coherent phonons are detected by ultrafast electron diffraction [3], where we determine the amount of ellipticity and the sense of rotation.

TT 2: Nonequilibrium Quantum Systems (joint session TT/DY)

Time: Monday 9:30–12:30 Location: H31

TT 2.1 Mon 9:30 H31

Solving the nonequilibrium Dyson equation with quantics tensor trains — •Ken Inayoshi[1], Maksymilian Środa[2], Anna Kauch[3], Philipp Werner[2], and Hiroshi Shinaoka[1] — [1]Department of Physics, Saitama University, Saitama, Japan — [2]Department of Physics, University of Fribourg, Fribourg, Switzerland — [3]Institute of Solid State Physics, TU Wien, Vienna, Austria

The nonequilibrium Green's function (NEGF) method is a powerful tool to investigate dynamical phenomena in quantum many-body systems. However, the time-translational symmetry breaking of Green's functions (GFs) makes the simulation of long-time dynamics computationally and memory-intensive. To overcome these, various memory compression techniques have been proposed for the NEGF method [1,2]. Among these, quantics tensor trains (QTT) have been attracting a focus for its ability to exponentially compress the data size of GFs [3]. While a prototype NEGF method with QTT has been developed [4], its benchmarks were limited to the short-time dynamics due to technical challenges such as the slow convergence of self-consistent calculations. We propose an improved implementation to reach the longer time regions, using a variational method for solving the Dyson equation and a causality-based divide-and-conquer algorithm [5,6]. In this contribution, we benchmark our method in relevant test cases [6].

TT 2.2 Mon 9:45 H31

Fractionalized prethermalization in the one-dimensional Hubbard model — •Anton Romen[1,2], Johannes Knolle[1,2,3], and Michael Knap[1,2] — [1]Technical University of Munich, Garching, Germany — [2]Munich Center for Quantum Science and Technology, München, Germany — [3]Blackett Laboratory, Imperial College London, London, United Kingdom

Prethermalization phenomena in driven systems are generally understood via a local effective Floquet Hamiltonian. It turns out that this picture is insufficient for systems with fractionalized excitations. A first example is a driven Kitaev spin liquid which realizes a quasistationary state with vastly different temperatures of the matter and flux sectors, a phenomenon dubbed fractionalized prethermalization. In our work we argue that similar heating dynamics also occur in driven 1D tJ-models. In the weak doping limit of this model, the electron fractionalizes into quasiparticles carrying charge and spin. We show that the nonequilibrium heating dynamics of this model feature a quasistationary state characterized by a low spin and high charge temperature. We argue that the lifetime of this quasistationary state is determined by two competing processes depending on the specific drive chosen: A Fermi Golden Rule that describes the lifetime of the quasiparticles and the exponential lifetime of a Floquet prethermal plateau. Using a time dependent variant of the Schrieffer-Wolff transformation we systematically analyze the different classes of drives emerging from the respective Hubbard model. Lastly, we discuss potential ways towards an experimental realization in cold atom experiments.

TT 2.3 Mon 10:00 H31

Computing the lifetime of spin-orbital excitations in TiOCl using Lanczos techniques — •Paul Fadler[1,2], Philipp Hansmann[1], Kai Phillip Schmidt[1], Angela Montanaro[1,3], Filippo Glerean[4], Enrico Maria Rigoni[1,3], Daniele Fausti[1,3], and Martin Eckstein[2] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg — [2]Universität Hamburg — [3]University of Trieste — [4]Harvard University, Cambridge

TiOCl is a spin-Peierls compound with optically active d-d-transitions at 0.7 eV and 1.5 eV. A pump-push-probe spectroscopy experiment on this system revealed a nonlinear signal asymmetric with respect to the order in which these transitions are pumped. This asymmetry could arise from differing lifetimes of the excitations due to multi-magnon and orbital-fission decay processes. To test this hypothesis we derive a spin-orbital Hamiltonian from ab-initio calculation. Within this description the pumped excitations are orbitons, i.e., hybrid spin-orbital quasiparticles, that can be understood as orbital excitations surrounded by a magnon cloud. We evaluate their lifetimes using Fermi's golden rule for all spin-orbital decay channels, which we compute on a large cluster using Lanczos techniques. Comparing the theoretical prediction to the asymmetry and absolute decay times of the nonlinear signal in the experiment we conclude, that multi-magnon and orbital-fission decay processes could be the dominant decay channels for the 0.7 eV excitation. On the other hand for the 1.5 eV excitation other types of processes such as phonon-assisted decays or non-linearities in the double-pump scheme have to be taken into account.

TT 2.4 Mon 10:15 H31

Comprehensive analysis of electronic relaxation in one dimension Kondo lattice model — •Arturo Perez Romero, Mica Schwarm, and Fabian Heidrich-Meisner — Institut for Theoretical Physics, Georg-August-Universität Göttingen, D-37077 Göttingen, Germany

Recent advancements in laser technology have made it possible to create non-equilibrium conditions on timescales that outpace energy exchange across a wide range of degrees of freedom. The above represents a challenge not only for condensed matter experimental physicist, but also for theoretical physicist who are motivated to describe a great variety of far-from-equilibrium systems. In this paper, we study the real-time dynamics of two paradigmatic models: the Kondo lattice model (KLM) and Kondo-Heisenberg model (KHM) in one dimension. We analyze the role of exchange couplings for the relaxation of a single charge carrier via the time-dependent Lanczos method. We conduct a comprehensive study of the time evolution by evaluating the z-spin component of the conduction electron, the local spin-spin correlation between localized and conduction electron, the spin-spin correlation between localized spins, and the electronic momentum distribution momentum. The study includes a comparison with statistical mechanics predictions for steady state and a research of the effect of diagonal disorder.

This work was funded by the Deutsche Forschungsgemeinschaft (DPG, German Research Foundation) via CRC 1073

TT 2.5 Mon 10:30 H31

An attempt to extend the adiabatic theorem — •Sarah Damerow[1,2] and Stefan Kehrein[1] — [1]Institut für Theoretische Physik, Universität Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen — [2]I. Institut für Theoretische Physik, Universität Hamburg, Notkestraße 9-11, 22607 Hamburg

A conjectured extension of the adiabatic theorem to quantum quenches, i.e., maximally non-adiabatic changes, is presented.The proposed extension is framed as follows: "as long as quenched states within the same magnetic phase are concerned, the overlap between the initial and final ground states is the largest possible." This conjecture is investigated analytically and is tested numerically using Exact Diagonalisation in two models: the Transverse Field Ising Model (TFIM) and the Axial Next Nearest Neighbour Ising Model (ANNNI).

TT 2.6 Mon 10:45 H31

Towards Floquet-GW: interacting electrons in time-periodic potentials — •Ayan Pal[1,2], Erik G. C. P. Van Loon[1,2], and Ferdi Aryasetiawan[1] — [1]Division of Mathematical Physics, Department of Physics, Lund University, Professorsgatan 1, 223 63, Lund, Sweden — [2]NanoLund, Lund University, Professorsgatan 1B, 223 63, Lund, Sweden

The Floquet theory of time-periodic systems provides a middle ground between equilibrium and completely non-equilibrium physics. Here, we study interacting electrons in time-periodic potentials using the combination of Floquet theory and many-body methods such as RPA and GW. We apply these techniques to the electron gas and to lattice models and study the electronic and dielectric properties, for example the appearance of side bands in the spectral functions. These methods have the potential to describe the impact of periodic laser pulses on the plasmonic and optical properties of (moderately) correlated materials.

15 min. break

TT 2.7 Mon 11:15 H31

Universal quench dynamics in Yukawa-Sachdev-Ye-Kitaev models — •Haixin Qiu and Stefan Kehrein — Institute for Theoretical Physics, Georg-August-Universität Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

Understanding the non-equilibrium properties of non-Fermi liquids without quasiparticles is essential for exploring the dynamics of strongly correlated systems. Here we investigate the quantum quench of a non-Fermi liquid model, the Yukawa-Sachdev-Ye-Kitaev model with interactions involving one boson and q fermions and its lattice extensions. We compute various in and out of equilibrium quantities for general q within the large-N dynamical mean field scheme by integrating the Kadanoff-Baym equations. We find transient oscillations and relaxation dynamics are insensitive to the quench amplitudes deep inside the non-Fermi liquid phase. Notably, the relaxation dynamics involve two distinct transient temperatures and relaxation rates for bosonic and fermionic degrees of freedom, both of which show non-Fermi liquid or universal behaviors. Signatures of prethermalization are also found when quenching near the Fermi liquid phase.

This work is supported by Deutsche Forschungsgemeinschaft (DFG) SFB 1073 (217133147) and FOR 5522 (499180199).

TT 2.8 Mon 11:30 H31

Long-range induced synchronization of Higgs oscillations in topological superconductors — Andreas Alexander Buchheit[1], Benedikt Fauseweh[2,3], and •Torsten Kessler[4] — [1]Saarland University, Department of Mathematics and Computer Science, Germany — [2]TU Dortmund University, Department of Physics, Germany — [3]German Aerospace Center (DLR), Cologne, Germany — [4]Eindhoven University of Technology, Department of Mechanical Engineering, Netherlands

We investigate the impact of long-range electron-electron interactions on the non-equilibrium dynamics of unconventional superconductors. Using recently developed mathematical tools for the efficient treatment of longe-range interactions on lattices, we simulate the time evolution of a triplet superconductor with arbitrary power law interaction. Owing to the long-range interaction, a chiral phase with d+p symmetry emerges. We find that the long-range interaction stabilizes the Higgs oscillation in this phase. While the d-wave's initial mode decays rapidly, it begins to mirror the stable Higgs oscillation of the p-wave condensate part. Eventually, the two parts oscillate with a joint frequency. We demonstrate that this behavior can also be observed in the optical conductivity resulting from an external probe pulse.

TT 2.9 Mon 11:45 H31

Tuning of slow dynamics in quantum East Hamiltonians motivated by Graph theory — •Heiko Georg Menzler[1], Mari Carmen Bañuls[2,3], and Fabian Heidrich-Meisner[1] — [1]Institut für Theoretische Physik, Georg-August-Universität Göttingen, D-37077 Göttingen, Germany — [2]Max-Planck-Institut für Quantenoptik, D-85748 Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), Schelling Strasse 4, D-80799 München

In-between fully ergodic/localized quantum system there exist many systems with atypical relaxation behaviors. One of these systems is the quantum East (QE) model. The classical East model is a central, exemplary model for glassy dynamics and kinetic constraints. Also its quantum counterpart features slow dynamics without conservation laws or disorder. However, the presence of slow dynamics has not yet been fully understood from a quantum perspective. Introducing an interpretation of constrained dynamics based on graph theory, we theoretically demonstrate control over the slow dynamics of QE models. As a general hypothesis, we propose that strong hierarchies between nodes on the Fock space graph are related to the presence of slow dynamics. To quantify hierarchical structures, we develop a measure of centrality for generic Hamiltonian matrices, reminiscent of established centrality measures from graph theory. Based on these ideas, we show how we can introduce detuning to alter the hierarchical structure in the QE model and acutely change the resulting constrained dynamics, evidenced by eigenstate structure in the detuned QE models.

TT 2.10 Mon 12:00 H31

Optical signatures of dynamical excitonic condensates — •Alexander Osterkorn[1], Yuta Murakami[2], Tatsuya Kaneko[3], Zhiyuan Sun[4], Andrew J. Millis[5,6], and Denis Golež[1,7] — [1]Jožef Stefan Institute, Ljubljana, Slovenia — [2]RIKEN, Wako, Japan — [3]Osaka University, Toyonaka, Japan — [4]Tsinghua University, Beijing, P.R. China — [5]Columbia University, New York, USA — [6]Flatiron Institute, New York, USA — [7]University of Ljubljana, Ljubljana, Slovenia

Excitons, or bound electron-hole pairs, can condense into an excitonic insulator state, similarly to Cooper pairs in superconductors. A non-equilibrium carrier concentration, such as the one transiently induced by photo-doping or sustained by a tuneable bias voltage in bilayers, can create a dynamical excitonic insulator state, yet proving phase coherence in such setups remains challenging. We examine the condensate phase behavior theoretically and show that optical spectroscopy can distinguish between phase-trapped and phase-delocalized dynamical regimes. In the weak-bias regime, trapped phase dynamics result in an in-gap absorption peak nearly independent of bias voltage, while at higher biases its frequency increases approximately linearly. In the large bias regime, the response current grows strongly under the application of a weak electric probe leading to negative weight in the optical response, which we analyze relative to predictions from a minimal model for the phase. This work opens new avenues for experimentally probing coherence in excitonic condensates and the detection of their dynamical regimes.

TT 2.11 Mon 12:15 H31

Visualizing dynamics of charges and strings in (2+1)D lattice gauge theories — Tyler A. Cochran[1,2], •Bernhard Jobst[3,4], Eliott Rosenberg[1], Yuri D. Lensky[1], Adam Gammon-Smith[5], Michael Knap[3,4], Frank Pollmann[3,4], and Pedram Roushan[1] — [1]Google Research, CA, USA — [2]Princeton University, NJ, USA — [3]Technical University of Munich, 85748 Garching, Germany — [4]MCQST, 80799 München, Germany — [5]University of Nottingham, NG7 2RD, UK

Lattice gauge theories (LGTs) can be employed to understand a wide range of phenomena. Studying their dynamical properties can be challenging as it requires solving many-body problems that are generally beyond perturbative limits. We investigate the dynamics of local excitations in a $\mathbb{Z}_2$ LGT using a two-dimensional lattice of superconducting qubits. We first construct a simple variational circuit which prepares low-energy states that have a large overlap with the ground state; then we create particles with local gates and simulate their quan-

tum dynamics via a discretized time evolution. As the effective magnetic field is increased, our measurements show signatures of transitioning from deconfined to confined dynamics. For confined excitations, the magnetic field induces a tension in the string connecting them. Our method allows us to experimentally image string dynamics in a (2+1)D LGT from which we uncover two distinct regimes inside the confining phase: for weak confinement the string fluctuates strongly in the transverse direction, while for strong confinement transverse fluctuations are effectively frozen.

TT 3: Correlated Magnetism – General

Time: Monday 9:30–12:45 Location: H32

TT 3.1 Mon 9:30 H32

The zoo of states in the 2D Hubbard model — •Robin Scholle[1], Pietro Bonetti[1,2], Demetrio Vilardi[1], and Walter Metzner[1] — [1]Max Planck Institute for Solid State Research, Stuttgart, Germany — [2]Harvard University, Cambridge, USA

We use real-space Hartree-Fock theory to construct a magnetic phase diagram of the two-dimensional Hubbard model as a function of temperature and doping. We are able to detect various spin- and charge order patterns including Néel, stripe and spiral order without biasing the system towards one of them. For an intermediate interaction strength we predominatly find Néel order close to half-filling, stripe order for low temperatures or large doping, and an intermediate region of spiral order.

I will give a short summary of the method followed by a presentation of our current results and an outlook for possible further applications.

TT 3.2 Mon 9:45 H32

Hidden quantum correlations in the ground states of quasiclassical spin systems — •Levente Rózsa[1,2], Dennis Wuhrer[3], Sebastián A. Díaz[3], Ulrich Nowak[3], and Wolfgang Belzig[3] — [1]HUN-REN Wigner Research Centre for Physics, Budapest, Hungary — [2]Budapest University of Technology and Economics, Budapest, Hungary — [3]University of Konstanz, Konstanz, Germany

Entanglement is a unique property of quantum systems, which is widely studied in strongly correlated materials and in quantum information theory. Here, we investigate the entanglement between magnons, the quanta of spin waves, around a classical spin-spiral ground state stabilized by frustrated exchange interactions [1]. We find that the entanglement between pairs of sites completely vanishes in certain parameter regimes, where quantum correlations can only be observed in multi-site clusters. We analyze the magnitude and the spatial dependence of the entanglement in the vicinity of classical phase transitions, and discuss the role of the symmetries of the ground state.

[1] L. Rózsa et al., arXiv:2411.08394.

TT 3.3 Mon 10:00 H32

Measurement of magnetic anisotropy in CsV_3Sb_5 using torque magnetometry — •Tobi Gaggl[1], Toshiki Kiyosue[2], Ryo Misawa[3], Tomoya Asaba[2], Max Hirschberger[3], and Yuji Matsuda[2] — [1]Technical University of Munich, Germany — [2]Kyoto University, Japan — [3]The University of Tokyo, Japan

Materials with a kagome lattice have emerged as a fertile ground for exploring nontrivial electronic states arising from the interplay between band topology and magnetic frustration. The kagome metals AV_3Sb_5 (A=K, Cs or Rb), which exhibit charge density wave ordering (CDW), may host such exotic states. It is believed that the CDW in kagome metals is of unconventional nature, thus advanced techniques for precise measurements are required for characterization.

This study investigates the CDW phase transition in CsV_3Sb_5 using a piezoresistive cantilever rotating in a magnetic field as an angular-dependent torquemeter. This method enables precise measurements of magnetization in single crystals and a powerful setup sensitive to changes in rotational symmetry. The results show a distinct two-fold out-of-plane magnetic anisotropy, which is due to the two-dimensional nature of the kagome lattice and consistent with previous calculations. The progression of the measured temperature-dependent magnetic anisotropy shows a clear kink at 94 K, confirming previously published results for the onset of CDW. My current work focuses on the development of novel kagome materials that could exhibit CDWs.

TT 3.4 Mon 10:15 H32

Detection of skyrmion lattices by dilatometric measurements — •Mathias Doerr[1], Justus Grumbach[1], Sergey Granovsky[1], Martin Rotter[1], and Max Hirschberger[2,3] — [1]Technische Universität Dresden, Institut für Festkörper- und Materialphysik, 01062 Dresden, Germany — [2]Department of Applied Physics and Quantum-Phase Electronics Center, University of Tokyo, Tokyo 113-8656, Japan — [3]RIKEN Center for Emergent Matter Science (CEMS), Wako, Saitama 351-0198, Japan

Magnetic skyrmion lattices (SkL) with a characteristic structure size smaller than 3 nm in metallic $Gd_3Ru_4Al_{12}$ with a planar breathing kagome lattice, already demonstrated by X-ray diffraction and topological Hall effect studies [1], open up new possibilities for the effective transmission of information. The interplay between helically determined skyrmion patterns and underlying crystallographic structures offers the possibility to clearly determine the stability region of skyrmions by dilatometric measurements. We report high-precision measurements of magnetostriction and thermal expansion on $Gd_3Ru_4Al_{12}$ and construct the magnetic phase diagram. Additional MonteCarlo simulations with *McPhase* confirm an asymmetric magnetic triple-$\boldsymbol{q}$ structure without symmetry breaking at the ordering temperature. The relationship between crystallographic distortion and formation of the SkL is also discussed.

TT 3.5 Mon 10:30 H32

Electronic structure of the noncentrosymmtric tetragonal antiferromagnet $EuPtSi_3$ — •Katharina Müller[1], André Deyerling[1], Andreas Bauer[1,2], Wolfgang Simeth[1,3], Christian Franz[1,4], Christian Pfleiderer[1,2,5,6], and Marc A. Wilde[1,2] — [1]Physik Department, TUM School of Natural Sciences, TUM, Germany — [2]Zentrum für Quantum Engineering (ZQE), TUM, Germany — [3]Los Alamos National Laboratory, Los Alamos, NM, USA — [4]Jülich Centre for Neutron Science (JCNS) at MLZ, Forschungszentrum Jülich GmbH, Germany — [5]Munich Center for Quantum Science and Technology (MCQST), TUM, Germany — [6]Heinz Maier-Leibnitz Zentrum (MLZ), TUM, Germany

The localized Eu^{2+} moments of the rare-earth compound $EuPtSi_3$ were reported to show magnetic ordering below the Néel temperature T_N = 17 K [1]. With a magnetic field applied in the magnetically hard basal plane, four different types of noncollinear antiferromagnetic order emerge, one of which is commensurate with the lattice [2]. This coplanar canted magnetic structure breaks the crystal symmetry such that Berry curvature contributions are allowed and electronic transport phenomena may be affected. We study this link between the magnetic and the electronic structure with ab initio calculations, in particular highlighting the effect of changing the canting angle from the antiferromagnetic towards the spin-polarized state.

TT 3.6 Mon 10:45 H32

Thermal Hall transport driven by spin fluctuations — •Ignacio Salgado-Linares[1,2], Alexander Mook[3], and Johannes Knolle[1,2] — [1]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 München, Germany — [3]Johannes Gutenberg University Mainz, Institute of Physics, Staudingerweg 7, Mainz 55128, Germany

In recent years, the thermal Hall effect has emerged as a powerful tool for probing topological phenomena of magnetic systems. At low temperatures, the thermal Hall transport of long-range ordered magnets can be described in the framework of linear spin-wave theory (LSWT). However, how to treat regimes with increased thermal fluctuations or non-linearities beyond LSWT is an outstanding question. Therefore, within this project, we developed a numerical technique to extract the thermal Hall transport properties, which intrinsically includes nonlinear effects. In particular, we use semi-classical spin dynamics simulations to compute thermal currents due to chiral spin fluctuations in a square lattice model with Heisenberg interaction and DMI. The results are expected to shed new light on the topological thermal transport in systems where topology does not arise from static spin textures, but from spin fluctuations.

TT 3.7 Mon 11:00 H32

Pressure tuning of ferromagnetism in the Kagome metal CrNiAs — •Bin Shen[1], Franziska Breitner[1], Victoria A. Ginga[2], Philipp Gegenwart[1], and Alexander A. Tsirlin[2] — [1]EP VI, EKM, University of Augsburg, Germany — [2]Felix Bloch Institute, University of Leipzig, Germany

Ferromagnetic Kagome metals attract considerable interest as quantum materials with nontrivial topological electronic states. Here, we present our extensive study on single crystals of CrNiAs, crystallizing in a hexagonal structure with space group of $P\bar{6}2m$, featuring a distored kagome lattice of magnetic Cr. CrNiAs undergoes a ferromagnetic phase transition at T_C = 135 K, where the *c*-axis is the easy axis. At T^* = 90 K another phase transition is found, likely driven by magnetism, associated with a shrinkage of the *c*-axis while the *ab*-plane expands. Anomalous Hall effect is observed in the magnetically ordered state of CrNiAs. We also report the pressure tuning of ferromagnetism.

TT 3.8 Mon 11:30 H32

Electronic transport measurements in Kagome metal $Yb_{0.5}Co_3Ge_3$ — •Zhiyuan Cheng[1], Heng Wu[2], Yaojia Wang[2], Peter van Veldhuizen[1], Federica Galli[1], Mazhar Ali[2], Julia Chan[3], and Semonti Bhattacharyya[1] — [1]Leiden University, Leiden, the Netherlands — [2]Delft University of Technology, Delft, the Netherlands — [3]Baylor University, Waco, United States

Kagome lattice has a unique geometry that gives rise to interesting band structures. As a result, Kagome lattices exhibit various properties, such as superconductivity, topological surface states, and complex magnetism. However, it is still yet to be well understood how these quantum properties intertwine with each other. Electrical doping, strain, and pressure can be utilized as powerful tools to modulate and investigate the rich physics of such complex systems.

In this project, we investigate a Kagome metal $Yb_{0.5}Co_3Ge_3$ that is known to exhibit charge density wave and complex magnetism. Susceptibility measurements performed in this material demonstrate the presence of Yb^{3+} moments with anti-ferromagnetic interactions and an onset of a week magnetic transition below 25 K. Yet, this complex magnetism is not completely understood.

We carried out magnetotransport measurements on $Yb_{0.5}Co_3Ge_3$ to study the interplay of its quantum properties at both ambient pressure (0 GPa) and high pressure (up to 2.0 GPa). Our ambient-pressure measurement shows that this complex magnetism gives rise to Kondo effect. High-pressure measurements reveal a clear signature of an enhancement of the Kondo effect with respect to the pressure.

TT 3.9 Mon 11:45 H32

Altermagnetism from interaction-driven itinerant magnetism — Samuele Giuli[1], •Carlos Mejuto-Zaera[1,2], and Massimo Capone[1,3] — [1]International School for Advanced Studies (SISSA), Trieste, Italy — [2]Current: Laboratoire de Physique Théorique (LPT), Toulouse, France — [3]CNR-IOM Democritos, Trieste, Italy

Altermagnetism is a phase of collinear spin-ordering presenting anisotropic magnetic properties, leading to great interest in its potential application for spintronic and thermoelectric devices. Realizing this promise will likely hinge on the design of tunable altermagnetic platforms, in which the magnetic and electric responses can be reliably controlled. A viable path towards this goal concerns leveraging electron interactions for the stabilization of altermagnetism, a strategy which is developing increasing traction in the field. In this work, we propose a mechanism driven by the interplay between a local Hubbard repulsion and the presence of a van Hove singularity in a two-band model. Here, the itinerant magnetism caused by the van Hove singularity colludes with the exchange mechanism driven by the Hubbard repulsion to generate an altermagnetic state in a sizeable portion of the phase diagram. Importantly, this correlated altermagnetic phase exhibits a tuneable spin-current, whose sign can be changed by tuning the interaction strength and/or particle doping. We study the role of strong electronic correlations in the stabilization of this phase by leveraging on the ghost rotationally invariant slave boson embedding. Further, we comment on the stability of the phase, and potential material realizations.

TT 3.10 Mon 12:00 H32

Investigation of the magnetoelastic coupling in $CaMn_2P_2$ and $SrMn_2P_2$ — •Sven Graus, Ashiwini Balodhi, N. S. Sangeetha, Teslin R. Thomas, Maximilian van de Loo, Andreas Kreyssig, and Anna E. Böhmer — Experimentalphysik IV, Ruhr-Universität Bochum, 44801 Bochum, Germany

Mn-based 122-compounds exhibit complex magnetic ordering in the antiferromagnetic state. In contrast to other related materials $CaMn_2P_2$ shows a strong first-order and $SrMn_2P_2$ a weak first-order antiferromagnetic phase transition [1]. Since the antiferromagnetic ordering breaks the three-fold symmetry of the lattice, one expects lattice distortions, which we investigated by high-resolution thermal expansion measurements. Thermal-expansion data of $CaMn_2P_2$ show a significant decrease of the sample length upon entering the antiferromagnetic state. Applying different uniaxial pressures along the [1 1 0] and [1 -1 0] directions alters the transition in qualitatively distinct ways. Increasing uniaxial pressure shifts the transition temperature upwards which shows magnetoelastic coupling and is consistent with the interpretation of an orthorhombic lattice distortion in the antiferromagnetic phase. In $SrMn_2P_2$, an anomaly in the thermal expansion is clearly resolvable upon entering the antiferromagnetic state. From 300 K to 6 K the linear thermal expansion coefficient α continuously decreases, reaching negative values below ~100 K.

TT 3.11 Mon 12:15 H32

Synthesis of $CsMn_2P_2$ and study of its low temperature physical properties — •Matthias Kroll, N. S. Sangeetha, Sven Graus, Maik Golombiewski, Andreas Kreyssig, and Anna E. Böhmer — Experimentalphysik IV, Ruhr-Universität Bochum, 44801 Bochum, Germany

The growth of $CsMn_2P_2$ single crystals is challenging due to the high vapor pressure of cesium and phosphorus and the high melting point of manganese. We optimized the growth conditions for the reproducible synthesis of $CsMn_2P_2$ single crystals by systematically studying various growth techniques. The quantity and quality of the phase of interest in the resulting samples was characterized by x-ray powder diffraction, electron microscopy and energy-dispersive x-ray analysis. We perform thermal-expansion and magnetic field-dependent resistivity measurements at low temperatures to analyze the nature of the three phase transitions at 64, 17 and 11 K that cannot be explained conclusively so far [1,2]. At 17 K, a dramatic change of the electrical-transport behavior as well as a large thermal-expansion anomaly are observed.

We acknowledge support by the Deutsche Forschungsgemeinschaft (DFG) under CRC/TRR 288 (Project A02).

TT 3.12 Mon 12:30 H32

Strain-tuning of magnetic properties of $Ca_{1-x}Sr_xCo_{2-y}As_2$ and elastoresistance measurements in different symmetry channels — •Teslin Rose Thomas, Michael Paul, N. S. Sangeetha, Sven Graus, Max Brückner, Andreas Kreyssig, and Anna E. Böhmer — Experimentalphysik IV, Ruhr-Universität Bochum, 44801 Bochum, Germany

The $Ca_{1-x}Sr_xCo_{2-y}As_2$ system belongs to the well-studied $ThCr_2Si_2$ structural family where Sr substitution induces a crossover from a collapsed tetragonal (cT) phase to an uncollapsed tetragonal (ucT) phase, along with different magnetic anisotropies [1,2].

In this study, we investigate how the cT-ucT crossover and the associated magnetic orders respond to in-plane symmetric and asymmetric strain in different configurations. We show that large in-plane symmetric strain can effectively tune the magnetic properties of the system. We also find a significant response of the resistance to in-plane symmetric strain with a temperature dependence that varies dramatically based on the doping level. The resistance response to symmetric strain dominates the response to asymmetric strain.

We acknowledge support from the Deutsche Forschungsgemeinschaft (DFG) under CRC/TRR 288 (Project A02).

TT 4: Topological Insulators

Time: Monday 9:30–13:00 Location: H33

TT 4.1 Mon 9:30 H33

Magnetotransport measurements on magnetic topological insulator nanostructures fabricated with shadow wall epitaxy — •Jan Karthein[1,2], Gion Toehgiono[1,2], Max Vassen-Carl[1,2], Taizo Kawano[3], Sosuke Otsubo[3], Makoto Kohda[3], Peter Schüffelgen[1,2], Detlev Grützmacher[1,2], and Thomas Schäpers[1,2] — [1]Peter Grünberg Institut (PGI-9), Forschungszentrum Jülich, 52425 Jülich, Germany — [2]JARA-Fundamentals of Future Information Technology, Jülich-Aachen Research Alliance, Forschungszentrum Jülich and RWTH Aachen University, 52425 Jülich, Germany — [3]Department of Materials Science, Graduate School of Engineering, Tohoku University, 6-6-02 Aramaki-Aza Aoba, Aoba-ku, 980-8579 Sendai, Japan

We present a novel way to fabricate magnetic topological insulator nanostructures based on digital alloying and shadow wall epitaxy. The combination of these two techniques allows the preparation of structures in the micrometer and nanometer range without the need for lithography and etching steps on the material under investigation. The magnetotransport properties of micro and nano Hall bars fabricated in this way are investigated at cryogenic temperatures and in high magnetic fields. Different sizes of Hall bars are measured and their magnetic properties are studied. An anomalous Hall effect is observed, indicating the successful preparation of Hall bars based on magnetic topological insulator thin films. The Curie temperature of Hall bars with different widths is extracted and found to be systematically dependent on the dimensions.

TT 4.2 Mon 9:45 H33

Thermopower and resistivity of the topological insulator Bi_2Te_3 in the amorphous and crystalline phase — •Ena Osmic[1,2], Jose Barzola Quiquia[3], Stephan Winnerl[4], Winfried Böhlmann[5], Peter Häussler[3], and Joachim Wosnitza[1,2] — [1]Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, Dresden, Germany — [2]Institut für Festkörper- und Materialphysik, TU Dresden, Germany — [3]Division of Thin Film Physics, TU Chemnitz, Germany — [4]Institut für Ionenstrahlphysik und Materialforschung, HZDR, Dresden, Germany — [5]Felix-Bloch Institute for Solid-state Physics, Universität Leipzig, Germany

We investigated the temperature dependence of the thermopower $S(T)$ and resistance $R(T)$ in thin films of the topological insulator Bi_2Te_3, prepared *in situ* by sequential flash-evaporation at 4 K. In the amorphous phase, $S(T)$ is negative and significantly larger than in other amorphous materials, while in the crystalline phase, it remains negative and shows a linear temperature dependence. The resistivity $\rho(T)$ transitions from semiconducting behavior in the amorphous state to linear metallic behavior upon crystallization. For $T > 15$ K, the linear $\rho(T)$ reflects metallic surface states typical of topological insulators, while for $T < 10$ K, the conductivity shows a logarithmic temperature dependence dominated by electron-electron interactions. Raman spectroscopy confirms crystallization in the trigonal *R*3*m* space group, and energy-dispersive X-ray spectroscopy indicates high compositional homogeneity with no magnetic impurities.

TT 4.3 Mon 10:00 H33

Phonon thermal Hall effect in weakly compensated topological insulators — •Rohit Sharma[1], Yongjian Wang[1], Yoichi Ando[1], Achim Rosch[2], and Thomas Lorenz[1] — [1]II. Physikalisches Institut, Universität zu Köln, Zülpicher Str. 77, 50937 Köln, Germany — [2]Institute for Theoretical Physics, University of Cologne, 50937 Cologne, Germany

The phonon thermal Hall effect has recently been observed in various classes of insulating materials, yet its origin remains unresolved [1-3]. In a series of well-compensated $Bi_{2-x}Sb_xTe_{3-y}Se_y$ samples, the thermal Hall conductivity $\kappa_{xy}(B)$ exhibits a linear and negative field dependence, with a thermal Hall ratio κ_{xy}/κ_{xx} on the order of 10^{-3}, consistent with observations in other insulating materials. Conversely, weakly compensated samples of $TlBi_{0.15}Sb_{0.85}Te_2$ exhibit a nonlinear dependence of $\kappa_{xy}(B)$, with κ_{xy}/κ_{xx} exceeding 2% across an extended temperature range. The electronic contribution to thermal transport, $\kappa_{xy}^{\mathrm{el}} = \sigma_{xy}L_0T$, was calculated using the Wiedemann-Franz law and compared to the measured κ_{xy}. Remarkably, the measured κ_{xy} is significantly larger than $\kappa_{xy}^{\mathrm{el}}$ throughout the temperature range investigated. Possible mechanisms driving the nonlinear $\kappa_{xy}(B)$ and the large thermal Hall ratio in $TlBi_{0.15}Sb_{0.85}Te_2$ will be discussed.

TT 4.4 Mon 10:15 H33

Scattering theory of chiral edge modes in topological magnon insulators — •Stefan Birnkammer[1,2], Michael Knap[1,2], Johannes Knolle[1,2], Alexander Mook[3], and Alvise Bastianello[1,2] — [1]Technical University Munich, Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), München, Germany — [3]Johannes Gutenberg Universtät, Mainz, Germany

Topological magnon insulators exhibit robust edge modes with chiral properties similar to quantum Hall edge states. However, due to their strong localization at the edges, interactions between these chiral edge magnons can be significant, as we show in a model of coupled magnon-conserving spin chains in an electric field gradient. The chiral edge modes remain edge-localized and do not scatter into the bulk, and we characterize their scattering phase: for strongly-localized edge modes we observe significant deviation from the bare scattering phase. This renormalization of edge scattering can be attributed to bound bulk modes resonating with the chiral edge magnons, in the spirit of Feshbach resonances in atomic physics. We argue a real-time measurement protocol using spin-polarized scanning tunneling spectroscopy to study their scattering dynamics. Our result show that interaction among magnons can be encoded in an effective edge model of reduced dimensionality, where the interactions with the bulk renormalize the effective couplings. This work paves the way to develop a many-body effective theory for chiral edge magnons.

TT 4.5 Mon 10:30 H33

Multiplicative Chern insulators — •Archi Banerjee[1,2] and Ashley M. Cook[1,2] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Max Planck Institute for the Chemical Physics of Solids, Dresden, Germany

Extending on the previous work on multiplicative topological phases, here we study bulk-boundary correspondence and response signatures of multiplicative Chern insulators (MCIs). Constructing the MCI Bloch Hamiltonian as a symmetry-protected tensor product of two topologically non-trivial parent Chern insulators (CIs), we study 2D MCIs and introduce 3D MCIs, constructed by requiring the two 2D parent Hamiltonians share only one momentum component, rather than both as in the case of the 2D MCI. We study the robustness of bulk-boundary correspondence against bulk perturbations breaking the tensor product structure of the child Hamiltonian, and find the bulk-boundary correspondence remains gapless and evolves to that of a topological skyrmion phase in cases considered here. We also study the response of the 2D MCI to time reversal symmetric flux insertion through two spatially-separated locations in the lattice. We observe a 4π periodic Aharonov-Bohm (AB) effect in which unpaired Majorana zero-modes and associated spin angular momentum are transferred between these two locations. We interpret the AB effect from the perspective of the effective field theories of the quantum skyrmion Hall effect as corresponding to a generalised $\nu = 1/2$ FQHE.

TT 4.6 Mon 10:45 H33

Probing the tomographic regime by nonlinear thermoelectric and magneto-transport in topological Fermi liquids — •Habib Rostami[1] and Johannes Hofmann[2] — [1]Department of Physics, University of Bath, United Kingdom — [2]Department of Physics, Gothenburg University, Sweden

In 2D Fermi liquids, odd-parity Fermi surface deformations [PRL. 123, 116601 (2019)] exhibit anomalously slow relaxation rates, suppressed as $\tau_{\mathrm{AN}}^{-1} \sim T^4$ with temperature T, deviating from the standard Fermi-liquid scaling, $\tau_{\mathrm{FL}}^{-1} \sim T^2$. This near ballistic (tomographic) regime currently lack a precise experimental probes. We link light-induced nonlinear thermoelectric currents to prolonged relaxation times, τ_{AN} [Phys. Rev. Research 6, L042042 (2024)]. These currents, arising in topological Fermi liquids, depend on novel heat capacities, including the Berry curvature capacity $C_\Omega = \partial_T\langle\Omega^2\rangle$ and velocity-curvature capacity $C_{\mathrm{v}} = \partial_T\langle v\Omega\rangle$. Quantified in Bi_2Te_3, these effects predict non-monotonic thermoelectric responses, providing features for experimental testing. In another study [arXiv:2411.08102v1], we show that weak magnetic fields suppress tomographic transport signatures by breaking time-reversal symmetry, a prerequisite for the odd-parity collisional relaxation effect. This suppression, occurring at much lower fields than those needed to disrupt hydrodynamic transport, suggests a practical experimental method to extract the odd-parity mean free path.

TT 4.7 Mon 11:00 H33

Finite size topology in magnetic topological insulators — •Joe Winter[1,2], Michał Pacholski[1], and Ashley Cook[1] — [1]MPI PKS, Dresden, Germany — [2]University of St Andrews, St Andrews, Scotland

The antiferromagnetic topological insulator phase is a foundational realization of three-dimensional topological phases of matter with magnetic order. It is furthermore an example of an axion insulator and condensed matter platform for realizing exotic axion dynamics of high-energy physics. At systems sizes where the sample size is comparable with the correlation length of the topological surface states, it is expected for these states to hybridise. We however show the strength of this hybridisation is oscillatory with respect to system parameters and resonances occur where the surface states can reform. We then confirm the defining response signature of the underlying 3D AFM TI phase persists in this geometry, at these resonances. We then open boundary conditions in a second direction to confirm the additional bulk-boundary correspondence of the finite-size topological phases spectral flow, finding q(3-2)D topologically-protected, gapless edge modes. The co-existence of the q(3-2)D topologically non-trivial edge states with a topological response associated with the 3D bulk topological invariant, the magnetoelectric polarizability, confirms finite-size AFM topological phases occur. This further demonstrates that finite-size topology is a generic feature of topological phases and very relevant experimentally.

Genuine topological Anderson insulator from impurity induced chirality reversal — •Avedis Neehus, Frank Pollmann, and Johannes Knolle — Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany

We investigate a model of Dirac fermions with topological mass impurities which open a global topological gap even in the dilute limit. Surprisingly, we find that the chirality of this mass term, i.e., the sign of the Chern number, can be reversed by tuning the magnitude of the single-impurity scattering. Consequently, the disorder induces a phase disconnected from the clean topological phase, i.e., a genuine topological Anderson insulator. In seeming contradiction to the expectation that mass disorder is an irrelevant perturbation to the Dirac semimetal, the tri-critical point separating these two Chern insulating phases and a thermal metal phase is located at zero impurity density and connected to the appearance of a zero energy bound state in the continuum corresponding to a divergent topological mass impurity. Our conclusions based on the T-matrix expansion are substantiated by large scale Chebyshev-Polynomial-Green-Function numerics. We discuss possible experimental platforms.

TT 4.9 Mon 11:45 H33

Topological phases of arbitrary numbers of coupled Su-Schrieffer-Heeger wires — •Anas Abdelwahab — Leibniz Univesität Hannover, Institut für Theoretische Physik, Hannover

The phase diagrams of arbitrary number N_w of Su-Schrieffer-Heeger (SSH) wires have been identified, with respect to the dimerization and the single particle wire-wire coupling, where the latter is either perpendicular or diagonal between adjacent wires. Even number of perpendicularly coupled wires exhibit either gapless or trivial topological phases. Odd number of perpendicularly coupled wires can exhibit gapless, trivial or nontrivial topological phases with winding number $w = 1$. The diagonally coupled wires reveal topological phases with winding numbers in the range $0 \leq w \leq N_w$. The critical lines in their phase diagrams can reveal topological critical phases [1]. Each band of the diagonally coupled wires becomes a comletely flat band at specific lines in the phase diagram. The presence of W states [2] at the edges of coupled SSH wires with open boundary conditions will be dicussed.

Local and energy-resolved topological invariants for Floquet systems — •Arnob Kumar Ghosh, Rodrigo Arouca, and Annica M. Black-Schaffer — Department of Physics and Astronomy, Uppsala University, Box 516, 75120 Uppsala, Sweden

Periodically driven systems offer a perfect breeding ground for out-of-equilibrium engineering of topological boundary states at zero energy (0-mode), as well as finite energy (π-mode), with the latter having no static analog. The Floquet operator and the effective Floquet Hamiltonian, which encapsulate the stroboscopic features of the driven system, capture both spectral and localization properties of the 0- and π-modes but sometimes fail to provide complete topological characterization, especially when 0- and π-modes coexist. In this work [1], we utilize the spectral localizer, a powerful local probe that can provide numerically efficient, spatially local, and energy-resolved topological characterization. In particular, we apply the spectral localizer to the effective Floquet Hamiltonian for driven one- and two-dimensional topological systems with no or limited symmetries and are able to assign topological invariants, or local markers, that characterize the 0- and the π-boundary modes individually and unambiguously. Due to the spatial resolution, we also demonstrate that the extracted topological invariants are suitable for studying driven disordered systems and can even capture disorder-induced phase transitions.

TT 4.11 Mon 12:15 H33

Characterizing exceptional topology through tropical geometry — •Ayan Banerjee[1], Rimika Jaiswal[2], Madhusudan Manjunath[3], and Awadhesh Narayan[4] — [1]Max Planck Institute for the Science of Light, Erlangen — [2]University of California Santa Barbara, USA — [3]Indian Institute of Technology Bombay, India — [4]Indian Institute of Science, Bangalore

Non-Hermitian Hamiltonians describing open quantum systems have been widely explored in platforms ranging from photonics to electric circuits [1]. A defining feature of non-Hermitian systems is exceptional points (EPs), where both eigenvalues and eigenvectors coalesce. The study of EPs has become an exciting frontier at the crossroads of optics, photonics, acoustics, and quantum physics. Tropical geometry is an emerging field of mathematics at the interface between algebraic geometry and polyhedral geometry, with diverse applications to science [2]. Here, we introduce Newton's polygon method and adopt the notion of a geometrical object known as amoeba in developing a unified tropical geometric framework to characterize different facets of non-Hermitian systems [3]. We introduce a framework linking tropical geometry to non-Hermitian physics, enabling the study of EPs, skin effects, and disorder properties.

Operator approach to quantum geometry and semi-classical dynamics — •Chen Xu[1,2], Andreas Haller[1], Suraj Hegde[3], Tobias Meng[2], and Thomas Schmidt[1] — [1]Department of Physics and Materials Science, University of Luxembourg, Luxembourg — [2]TU Dresden, Department of Physics — [3]IISER-Thiruvananthapuram, India

We develop an operator-based approach for computing the quantum geometric contributions to the equations of motion of the position and momentum operators in an multiband system, without resorting to semiclassical wave-packet approximations. We identify contributions such as the Berry curvature and the quantum metric tensor induced anomalous velocity as fundamentally effective multiband effects. We show using this approach that in general higher-order operator-valued geometric quantities emerge in studying the dynamics in the presence of inhomogeneous external fields. We also demonstrate how to derive the dynamics from a generic coupling between Bloch momentum and an inhomogeneous external field, thus generalizing previous studies.

TT 4.13 Mon 12:45 H33

Exciton condensation driven by bound states of Green's function zeros — •Ivan Pasqua, Andrea Blason, and Michele Fabrizio — International School for Advanced Studies (SISSA), Via Bonomea 265, I-34136 Trieste, Italy

The spectral properties of electronic systems are encoded in the single-particle Green's function, with theoretical efforts traditionally focusing on the position and nature of its poles. Only recently, Green's function zeros have been recognized as important hallmarks of non-symmetry breaking strongly correlated insulators and, possibly, of fractionalized excitations. The analysis of the zeros offers a new perspective on the increasingly studied topic of excitonic insulators (EI), typically understood as the condensation of bound states between the valence and conduction bands of poles of the Green's function. Indeed this picture appears paradoxical in Mott insulators (MI), where the large gap between the Hubbard bands seemingly precludes the formation of such bound states. Yet, a continuous transition from a MI and an EI is observed in the Bernevig-Hughes-Zhang model using the dynamical cluster approximation. We find that a non-topological EI intrudes between the QSH and MI regimes. Our analysis suggests that excitons in the MI, which soften at the transition to the EI, could be bound states between valence and conduction bands of Green's function zeros. Our work proposes a novel mechanism for exciton condensation and highlights the role of Green's function zeros in diagnosing the properties of correlated phase of matter.

TT 5: Superconductivity: Properties and Electronic Structure I

TT 5.1 Mon 9:30 H36

Superconducting properties of $[(SnSe)_{1+\delta}]_m[NbSe_2]$ superlattices with varying $NbSe_2$ interlayer spacing — •Linus P. Grote[1], Wieland G. Stoffel[1], Tom Herter-Lehmann[1], Willi Vallant[1], Alina Dietrich[1], Olivio Chiatti[1], Danielle Hamann[2], David C. Johnson[2], and Saskia F. Fischer[1,3] — [1]Novel Materials Group, Humboldt-Universität zu Berlin, 10099 Berlin, Germany — [2]Department of Chemistry and Materials Science Institute, University of Oregon, Eugene OR 97403, USA — [3]Center for the Science of Materials Berlin, 12489 Berlin, Germany

In layered superconductors understanding and controlling the coupling of superconducting layers is crucial due to its strong impact on their properties [1]. We examine the properties of $[(SnSe)_{1+\delta}]_m[NbSe_2]$ superlattices, which allow for nearly arbitrary stacking sequences due to the growth technique [2]. Given this degree of freedom we study how coupling mechanisms enable the occurance of superconductivity. Temperature-dependent resistance measurements revealed superconductivity for $NbSe_2$ interlayer distances of 2.4 nm or smaller. This behaviour is explained by the interplay of grain boundaries, cross-plane tunneling and systematical variation of the $NbSe_2$ interlayer distances. Additionally, magnetoresistance hysteresis measurements were conducted to investigate the charge carrier states and microscopic superconducting structures. The results provide new insights into the coupling mechanisms of 2D superconductors.

TT 5.2 Mon 9:45 H36

Atomic-scale mapping of superconductivity in the incoherent CDW mosaic phase of a transition metal dichalcogenide — •Sandra Sajan[1], Haojie Guo[1], Tarushi Agarwal[2], Irián S. Ramírez[1], Chandan Patra[2], Maia G. Vergniory[1], Fernando de Juan[1], Ravi P. Singh[2], and Miguel M. Ugeda[1] — [1]Donostia International Physics Center, Paseo Manuel de Lardizábal 4, 20018 San Sebastián, Spain — [2]Department of Physics, Indian Institute of Science Education and Research Bhopal, Bhopal 462066, India

The emergence of superconductivity in the 1T phase of TaS_2 is preceded by the intriguing loss of long-range order in the charge density wave (CDW). Such decoherence, attainable by different methods, results in the formation of nm-sized coherent CDW domains bound by a two-dimensional network of domain walls (DW)-mosaic phase, which has been proposed as the spatial origin of the superconductivity. We report the atomic-scale characterization of the supercon-

ducting state of 1T-TaSSe, a model 1T compound exhibiting the CDW mosaic phase. We use high-resolution scanning tunneling spectroscopy and Andreev spectroscopy to probe the microscopic nature of the superconducting state in connection with the electronic structure of the DW network. Spatially resolved conductance maps at the Fermi level reveal a uniform landscape, independent of domain structure, indicating no link to superconductivity. This is confirmed at 340mK within the superconducting dome, where the gap's subtle inhomogeneity remains unconnected to DWs providing new insights into the fundamental interplay between SC and CDW in these relevant strongly correlated systems.

TT 5.3 Mon 10:00 H36

Ab-initio investigation of transition metal – superconductor interfaces — •Adamantia Kosma[1], Stefan Blügel[1], and Philipp Rüssmann[1,2] — [1]Peter Grünberg Institut, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — [2]Institute for Theoretical Physics and Astrophysics, University of Würzburg, 97074 Würzburg, Germany

The realisation of Majorana-based topologically protected qubits requires a careful design and optimization of material interfaces for superconductor (SC)/topological insulator (TI) heterostructures. To this end, we perform ab-initio simulations to investigate the superconducting properties at the interface of transition metal overlayers (M = Os, Ir, Pt, Au) deposited on a Nb(110) film. Our density functional theory calculations are based on the full-potential Korringa-Kohn-Rostoker (KKR) Green function method and its Kohn-Sham Bogoliubov-de Gennes (KS-BdG) extension [1,2]. In our study we explore the possibility to control the work function mismatch through the overlayer, and we uncover the proximity induced superconductivity. Our findings show that some of these structures might be promising material candidates for interfacing a TI with a superconductor without unwanted band bending effects at SC/M/TI interfaces.

We thank the ML4Q (EXC 2004/1 – 390534769) for funding.

TT 5.4 Mon 10:15 H36

Local limit disorder characteristics of superconducting radio frequency cavities I. Frequency shift — •Matúš Hladký, Anastasiya Lebedeva, Marcel Polák, and František Herman — Comenius University in Bratislava

Negative resonant frequency shift abnormalities in the vicinity of the critical temperature have been observed in recent experiments on Superconducting Radio Frequency cavities.

We present a simple, straightforward approach using the Dynes superconductor theory [1] and discuss its results. In the ideal dirty limit, we analytically elaborate on the width and depth of the resulting dip. Studying the sign of the slope of the resonant frequency shift at crit. temperature in the moderately clean regime reveals the role of the pair-breaking and pair-conserving disorder. Next, we compare and also fit our results with the recent experimental data from the N-doped Nb sample presented in Ref. [2]. Our analysis remarkably complies with the experimental findings, especially concerning the dip width. We offer straightforward, homogeneous-disorder-based interpretation within the moderately clean regime.

Local limit disorder characteristics of superconducting radio frequency cavities II. Quality factor — Anastasiya Lebedeva, Matúš Hladký, Marcel Polák, and •František Herman — Comenius University in Bratislava

Nowadays superconducting radio frequency (SRF) cavities represent fundamental tools used for (Standard Model) particle acceleration, (beyond Standard Model) particle probing, and long-lifetime photon preservation. We study their Quality factor properties mainly at low temperatures within the Dynes superconductor model [1]. We scrutinize and use the local limit response to the external electromagnetic field. Assuming the same regime at low temperatures, we address details of the high-quality plateaus. This work presents (and studies the limits of) the simple effective description of the complex problem corresponding to the electromagnetic response in the superconductors combining homogeneous conventional pairing and two different kinds of disorder scattering.

This work has been supported by the Slovak Research and Development Agency under the Contract no. APVV-23-0515, by the European Union's Horizon 2020 research and innovation program under the Marie Skłodowska-Curie Grant Agreement No. 945478.

TT 5.6 Mon 10:45 H36

THz response of ultra thin NbN films grown by atomic layer deposition — •Frederik Bolle[1], Yayi Lin[1], Heidemarie Schmidt[2], Martin Dressel[1], and Marc Scheffler[1] — [1]1. Physikalisches Institut, Universität Stuttgart — [2]Leibniz IPHT, Jena

Most elementary excitations and collective modes of superconductors lie in the THz frequency range, making THz spectroscopy an ideal tool to directly measure the superconducting energy gap and superfluid density. By combining the spectral ranges from continuous, coherent backward wave oscillators and time-domain methods we can investigate a broad frequency range from 1.6 cm^{-1} (0.2 meV) up to 100 cm^{-1} (12.4 meV). We characterize the superconducting state of grown NbN films in particular concerning the behavior of its energy scales as the film becomes increasingly two dimensional approaching the superconductor insulator transition (SIT). We investigate films with thickness ranging from 4.5 nm and 20 nm and find a continuous suppression of the superconducting energy gap and superfluid density with reduced film thickness. These results enable a quantitative device design for various applications of NbN thin films such as high kinetic inductance circuitry.

TT 5.7 Mon 11:00 H36

Superfluid stiffness in strongly disordered NbN superconducting films — •Alexander Weitel Weitzel[1], Lea Pfaffinger[1], Matthias Stosiek[2], Animesh Panda[3], Ferdinand Evers[3], and Christoph Strunk[1] — [1]Inst. of Exp. a. Appl. Phys., University of Regensburg, D-93040 Regensburg, Germany — [2]TUM Sch. of Nat. Sci., Dep. of Phys. PH-I, D-85748 Garching bei München — [3]Inst. of Theoretical Phys., University of Regensburg, D-93040 Regensburg, Germany

In BCS-superconductors, the spectral gap, E_g, the pairing amplitude, Δ, and the mean-field critical temperature T_{c0} are essentially identical. At strong disorder, close to the superconductor-insulator transition (SIT), this is no longer the case. Moreover, in BCS-theory the superfluid stiffness, J_s, is determined by Δ and normal state resistance R_N. Also this relation typically no longer holds close to SIT. Recently, we have experimentally determined $J_s(T)$ in ultra-thin NbN films by measuring kinetic inductance and found a sharp Berezinski-Kosterlitz-Thouless (BKT) transition. Our latest experimental data cover $J_s(T)$ over a wide range of disorder strength, up to normal state resistance $\sim h/e^2$. We find a sharp BKT-transition right up to the SIT and independently measure the characteristic scales E_g, J_s, T_{c0} and T_{BKT} over two orders of magnitude in R_N. We present complementary numerical calculations of the superfluid stiffness, obtained from the Boguliubov-de Gennes (BdG) theory of disordered samples in a very broad range of disorder strengths. A detailed comparison of our measurements with the computational results will be presented.

TT 5.8 Mon 11:30 H36

Molecular hydrogen in the N-doped LuH_3 system as a possible path to superconductivity — •Cesare Tresca[1], Pietro Forcella[2], Andrea Angeletti[3], Luigi Ranalli[3], Cesare Franchini[3,4], Michele Reticcioli[3], and Gianni Profeta[1,2] — [1]CNR-SPIN L'Aquila, Italy — [2]University of L'Aquila, L'Aquila, Italy — [3]University of Vienna, Vienna, Austria — [4]University of Bologna, Bologna, Italy

The discovery of ambient superconductivity would mark an epochal breakthrough long-awaited for over a century, potentially ushering in unprecedented scientific and technological advancements. The recent findings on high-temperature superconducting phases in various hydrides under high pressure have ignited optimism, suggesting that the realization of near-ambient superconductivity might be on the horizon. However, the preparation of hydride samples tends to promote the emergence of various metastable phases, marked by a low level of experimental reproducibility. Identifying these phases through theoretical and computational methods poses a considerable challenge, often resulting in contentious outcomes. In this contribution, we consider N-doped LuH_3 as a prototypical complex hydride: By means of machine-learning-accelerated force-field molecular dynamics, we have identified the formation of H_2 molecules stabilized at ambient pressure by nitrogen impurities. Importantly, we demonstrate that this molecular phase plays a pivotal role in the emergence of a dynamically stable, low-temperature, experimental-ambient-pressure superconductivity.

TT 5.9 Mon 11:45 H36

Challenges in identifying nematic superconductivity of CsV_3Sb_5 kagome metal via transport measurements — •Yu-Chi Yao[1,2], Fei Sun[1], José Guimarães[1,2], and Haijing Zhang[1] — [1]Max Planck Institute for Chemical Physics of Solids, 01187, Dresden, Germany — [2]School of Physics and Astronomy, University of St Andrews, St Andrews, KY16 9SS, UK

Nematicity refers to the spontaneous symmetry breaking beyond the crystal-imposed anisotropy in the electron wavefunction. On the other hand, understanding the interplay between nematicity and superconductivity could be crucial for determining the underlying pairing mechanism in various correlated systems, such as cuprates [1] and iron-based [2] unconventional superconductors.

In this study, we focus on the recently discovered kagome metal CsV_3Sb_5, which is famous for its multiple competing or coexisting orders [3,4]. By using CsV_3Sb_5 as the prototypical system, we address the challenges of identifying nematic superconductivity in transport measurements and systematically disentangle the extrinsic factors, such as imperfections in field alignment, from intrinsic nematic supercondcuting behavior.

Unique electronic transport characteristics in superconducting MgB_2 films — •Clemens Schmid[1], Markus Gruber[1], Corentin Pfaff[2], Theo Courtois[2], Anton Pokusinskyi[3], Alexander Kasatkin[4], Karine Dumesnil[2], Stephane Mangin[2], Thomas Hauet[2], and Oleksandr Dobrovolskiy[3] — [1]Faculty of Physics and Vienna Doctoral School in Physics, University of Vienna, Austria — [2]Institute Jean Lamour, Université de Lorraine-CNRS, Nancy, France — [3]Cryogenic Quantum Electronics, EMG and LENA, Technische Universität Braunschweig, Germany — [4]G.V. Kurdyumov Institute for Metal Physics, NAS Ukraine, Kyiv, Ukraine

Maximizing the velocity of Abrikosov vortices in superconductors and characterizing the associated energy relaxation times is essential for possible applications like single photon detectors. Here, we investigate the current-voltage curves of MgB_2, a material whose thin film structures remain superconducting at temperatures up to 30 K. Furthermore, capabilities of a single photon response have been observed previously in MgB_2 films. Our experiments reveal peculiar shapes of the current-voltage curves, showing multiple steps in their transitions to the normal state. While the microscopic mechanisms underlying these steps are a topic of current debates, one explanation could imply the occurrence of composite and fractional vortices associated with the two-band nature of the superconductivity in MgB_2, a property which is in-line with the presence of two slopes in the temperature-magnetic-field phase diagram. We compare our findings across multiple layered structures and for varying thicknesses of the MgB_2.

TT 5.11 Mon 12:15 H36

Single-crystal growth and superconducting properties of $Sr_xBi_2Se_3$ — •Max Brückner[1], Jule Kirschke[1], Fatih Cetin[1], Sven Graus[1], Maik Golombiewski[1], Fotios Maragkos[2,3], Varvara Foteinou[2], Shibabrata Nandi[4,5], Haneen Abushammala[1], Andreas Kreyssig[1], and Anna E. Böhmer[1] — [1]Experimentalphysik IV, Ruhr-Universität Bochum, 44801 Bochum — [2]Central Unit for Ion Beams and Radionuclides, Ruhr-Universität Bochum, 44801 Bochum — [3]Department of Physics, National Technical University of Athens, 15780 Athens, Greece — [4]Forschungszentrum Jülich GmbH, Jülich Centre for Neutron Science and Peter Grünberg Institut, JARA-FIT, 52425 Jülich — [5]Experimentalphysik IVc, JARA-FIT, RWTH Aachen, 52074 Aachen

Bi_2Se_3 is a topological insulator in which Sr-intercalation induces superconductivity with an unexpected two-fold anisotropy of H_{c2} in the basal plane. We examine how its properties relate to different single-crystal growth conditions, including self-flux growth of free-standing single crystals from a Bi-rich melt. The Sr-content was determined by proton-induced x-ray emission spectroscopy in our as-grown crystals with a resolution of up to 30 ppm. Transport measurements in magnetic fields showed superconductivity with $T_c \sim 2$-3 K at surprisingly low Sr-content. In addition, we identified $SrBi_2Se_4$ as a secondary phase in our growth. Its superconducting properties were found to be similar to the ones of $Sr_xBi_2Se_3$.

This work is supported by the ERC grant Distort-to-Grasp (No. 101040811).

TT 5.12 Mon 12:30 H36

Tuning superconducting properties in 3D nanoarchitectures — •Elina Zhakina[1], Luke Turnbull[1], Weijie Xu[1], Markus König[1], Paul Simon[1], Wilder Carrillo-Cabrera[1], Amalio Fernandez-Pacheco[2], Dieter Suess[3], Claas Abert[3], Vladimir M. Fomin[4], Uri Vool[1], and Claire Donnelly[1] — [1]Max-Planck-Institut für Chemische Physik fester Stoffe, Nöthnitzer Str. 40, 01187, Dresden, Germany — [2]Institute of Applied Physics, TU Wien, Wiedner Hauptstr. 8-10/134,1040 Vienna, Austria — [3]University of Vienna, Vienna, Austria — [4]Leibniz IFW Dresden, Dresden, Germany

Introducing 3D nanoconfinement into the superconducting system can open a path for local geometrical control and the possibility of going beyond intrinsic properties. However, the fabrication of such intricate nanoarchitectures remains challenging.

In this context, we present an extended approach to creating superconducting 3D nanoarchitectures through focused electron-beam-induced deposition of tungsten. This method allows the realisation of 3D superconducting nanostructures with arbitrary geometries within a wide range of critical temperatures, providing local geometrical control of critical fields and, for example, the realisation of reconfigurable weak links. With transport measurements, we demonstrate the motion of superconducting vortices within these 3D superconducting nanostructures. Therefore, three-dimensional superconducting nanostructures offer new horizons for experimental investigations of the dynamics of vortices, anisotropy and possible applications of curvilinear 3D nanoarchitectures.

TT 5.13 Mon 12:45 H36

Vortex mass observed in far-infrared circular dichroism of high-T_c superconductors — •Roman Tesař[1], Michal Šindler[1], Pavel Lipavský[2], Jan Koláček[1], Christelle Kadlec[1], Wen-Yen Tzeng[3], Chih-Wei Luo[4], and Jiunn-Yuan Lin[4] — [1]Institute of Physics, Czech Academy of Sciences, Prague, Czech Republic — [2]Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic — [3]National Formosa University, Yunlin, Taiwan — [4]National Yang Ming Chiao Tung University, Hsinchu, Taiwan

The effective mass of the Abrikosov vortex (fluxon) in type-II superconductors remains an open and still not fully solved problem. Only a few experimental techniques are currently known to examine the fluxon mass, while numerous theoretical models have been developed that predict inconsistent values scattered over several orders of magnitude. We present an experimental method to determine fluxon mass based on the interaction with circularly polarized FIR/THz laser radiation. A rotating electric field induces the motion of fluxons along cyclotron trajectories, which leads to magnetic circular dichroism at terahertz frequencies. The modified Kopnin-Vinokur theory with experimentally established parameters provides a sufficient framework for estimating fluxon mass at low temperatures. We demonstrate the proposed method on thin films of $YBa_2Cu_3O_{7-\delta}$ with different doping levels. We also briefly mention other applications of the experimental technique used, such as probing cyclotron resonance in semiconductors and magnon modes in magnetic materials.

TT 6: Focus Session Many-Body Phenomena in Nanomagnets: Kondo, Spinons, Spinarons and Beyond (joint session O/TT)

The electron spin, a fundamental quantum mechanical property, plays a crucial role in determining the electronic and magnetic properties as well as the dynamics of matter. Its role becomes even more important at surfaces, 2D materials and nanomagnets as the low-dimensionality increases electron correlation. A fundamental understanding of spin excitations is significant for both fundamental science and modern applications. For decades, the interpretation of experimental signatures of spin excitations were focused on the Kondo effect paradigm, with Co atoms on the (111) surface of noble metals as the prototypical example. However, recent first-principles predictions and spin-polarized scanning tunnelling spectroscopy in high magnetic fields have demonstrated the existence of many-body states, called spinarons. These states arise from the binding of electronic states to spin excitations in the presence of spin-orbit coupling. Such findings, along with other studies, challenge the Kondo interpretation. Furthermore, related non-trivial many-body states may emerge in thin-film geometries, as shown by photoemission spectroscopy and first-principles manybody investigations or in quantum spin liquids. These examples testify that many-body phenomena are not only critically important for the fundamental understanding of spin excitations, they also impact a wide range of material characteristics, including electronic, magnetic, thermodynamic, and transport properties. This focus session will provide a forum to discuss intriguing many-body states driven by spin excitations, and serve as a forum to discuss the current knowledge on their origins, unique properties, and implications.

Kondo and Yu-Shiba-Rusinov resonances: transport and coupling — •Laëtitia Farinacci[1,2,3], Gelavizh Ahmadi[3], Gaël Reecht[3], Benjamin W. Heinrich[3], Contanstin Czekelius[3], Felix von Oppen[3], and Katharina J. Franke[3] — [1]University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany — [2]Carl-Zeiss-Stiftung Center for Quantum Photonics Jena-Stuttgart-Ulm, Germany — [3]Fachbereich Physik, Freie Universität Berlin, Germany

The exchange coupling between a magnetic impurity and a superconducting substrate leads to the formation of magnetic bound states, known as Yu-Shiba-Rusinov (YSR) states, inside the superconducting gap, as well as a Kondo resonance outside the gap. Studying these two many-body phenomena in parallel provides valuable insights into their characteristic properties.

We observed striking correlations between the asymmetries of the YSR state and the Kondo effect induced by FeTPyP molecules on Pb(111) in a scanning tunneling microscope (STM) [1]. We show that both asymmetries originate from interfering tunneling paths via a spin-carrying orbital and the highest occupied molecular orbital.

Additionally, we studied the formation of YSR bands in a self-assembled kagome lattice of magnetic molecules on Pb(111) and track YSR hybridization from kagome precursors to larger islands [2]. This work will motivate further studies to resolve possible spin-liquid or Kondo-lattice-type behavior.

Electron delocalization in a 2D Mott insulator — •Amadeo L. Vazquez de Parga[1,2,4,5], Cosme G. Ayani[1,2], Michele Pisarra[3], Iván M. Ibarburu[1], Clara Rebanal[1], Manuela Garnica[2,4], Fabián Calleja[2], and Fernando Martín[1,2] — [1]Universidad Autónoma de Madrid, Madrid, Spain — [2]IMDEA Nanociencia, Madrid, Spain — [3]Universitá della Calabria, Rende, Italy — [4]Instituto Nicolás Cabrera, Madrid, Spain — [5]Condensed Matter Physics Center (IFIMAC), Madrid, Spain

We follow by means of low temperature Scanning Tunneling Microscopy and Spectroscopy, the buildup of a 2D Kondo lattice in a system composed by a 2D Mott insulator, a single 1T-TaS2 layer, stacked on the surface of a metallic crystal, 2H-TaS2. When the sample temperature is lower than 27K, the magnetic moments present in the Mott insulator experience the Kondo screening by the conduction electrons of the metal, leading to the appearance of a Kondo resonance at the Fermi level. Below 11 K, a gap opens within the Kondo resonance, which is the signature of the formation of a coherent quantum state that extends all over the sample, i.e., a Kondo lattice [1]. Quasi particles interference maps reveal the emergence of a Fermi contour in the 2D Mott insulator when the temperature drops below 11K, indicating the delocalization of the highly correlated Mott electrons [2]. The observed modifications in the LDOS are well explained by state-of-the-art Density Functional Theory calculations.

Invited Talk TT 6.3 Mon 16:00 H24

Kondo or no Kondo, that is the question — •Alexander Weismann, Neda Noei, Niklas Ide, and Richard Berndt — Institut für experimentelle und angewandte Physik, Christian-Albrechts-Universität zu Kiel, Kiel, Germany

The spin properties of individual atoms and molecules can produce distinctive spectral features in tunneling spectra near zero bias. Among these features, Kondo resonances and inelastic spin-flip excitations are often challenging to distinguish, despite their markedly different spectral line shapes. A Kondo resonance indicates a non-magnetic ground state, where the atomic spin is screened by conduction band electrons. In contrast, spin-flip excitations observed in zero-field tunneling spectra require magnetic anisotropy, which arises from spin-orbit coupling (SOC), to play a significant role. In this study, we demonstrate that the well-known Co/Cu(111) system, long believed to exhibit a Kondo resonance, instead adopts a magnetic ground state that is protected from Kondo screening by substantial magnetic anisotropy. The zero-bias anomaly in scanning tunneling spectra undergoes significant modification when Co atoms are attached to monoatomic Cu chains. Measurements conducted at 340 mK in a magnetic vector field reveal clear signatures of inelastic spin-flip excitations, with the anisotropy axis tilted away from the surface normal. The magnitude and orientation of this anisotropy are consistent with density functional theory (DFT) calculations. Moreover, quantum Monte Carlo many-body simulations confirm that the Kondo effect is suppressed when SOC is properly accounted for.

Invited Talk TT 6.4 Mon 16:30 H24

Evidence for spinarons in Co atoms on noble metal (111) surfaces — •Artem Odobesko — Physikalisches Institut, Universität Würzburg, Am Hubland, 97074 Würzburg

The zero-bias anomaly in the tunnelling differential conductance of Co atoms on Au(111) [1], long attributed to the Kondo effect, has recently been reinterpreted [2] as evidence of the spinaron – a novel many-body excitation arising from the interplay between spin excitations and conduction electrons. In our study, we used spin-polarized scanning tunneling spectroscopy (STS) on Co atoms on Cu(111) and Au(111) under high magnetic fields, revealing field-induced energy shifts and spin-resolved spectral features that challenge the conventional Kondo interpretation. Instead, our findings provide the first experimental confirmation of the spinaron [3].

We also investigated the role of hybridization with the substrate in spinaron formation, focusing on the reconstructed Au(111) surface. The unique local electronic environments created by the herringbone reconstruction strongly influence the hybridization strength and spectral features of Co adatoms, revealing a clear link between adsorption site, hybridization, and spinaronic excitations. Our results shed light on the fundamental mechanisms driving spinaron formation.

Invited Talk TT 6.5 Mon 17:00 H24

Spinarons: A new view on emerging spin-driven many-body phenomena in nanostructures — •Samir Lounis — Peter Grünberg Institut, Forschungszentrum Jülich & JARA, D-52425 Jülich, Germany — Faculty of Physics, University of Duisburg-Essen and CENIDE, 47053 Duisburg, Germany — Institute of Physics, Martin Luther University Halle-Wittenberg, 06120 Halle (Saale), Germany

Many-body phenomena are crucial in physics, particularly in condensed mat-

ter, influencing electronic, magnetic, thermodynamic, and transport properties. They leave distinct spectroscopic signatures, such as Kondo, excitonic, and polaronic features, arising from specific degrees of freedom. Since more than two decades Cobalt atoms on the (111) surfaces of noble metals have been a paradigm for the Kondo effect in scanning tunnelling spectroscopy experiments [1]. However, our recent first-principles predictions [2] followed by STS experiments in high magnetic fields [3,4] challenge this notion. Our findings reveal that the observed transport anomalies stem from spin excitations of Co atoms, forming a new many-body state – the spinaron – distinct from the Kondo resonance. I will delve into the spinaron origins, their unique properties, and implications explored through the recent atomic manipulation experiments. This work opens pathways to investigate and engineer these hybrid states in nanostructures, offering new insights into fundamental many-body states.

TT 6.6 Mon 17:30 H24

Emergence of spinaronic states in Fe adatoms — Ilias Klepetsanis[1,2], Juba Bouaziz[4], •Philipp Rüssman[1,3], and Samir Lounis[1,2] — [1]Forschungszentrum Jülich & JARA, Germany — [2]University of Duisburg-Essen and CENIDE, Germany — [3]University of Würzburg, Germany — [4]Research Center for Advanced Science and Technology, University of Tokyo, Japan

In recent years, spinarons, predicted from first-principles calculations [1], have been observed in Co adatoms on the Cu(111) surface, using spin-polarized scanning tunnelling spectroscopy (STS) in high magnetic fields [2]. Spinarons leave a non-trivial spectroscopic signature, for long interpreted to originate from the Kondo effect [3]. Here, we employ relativistic time-dependent density functional and many-body perturbation theory, to investigate the case of Fe adatoms on the Cu(111) surface, which carry a large magnetic moment of $3.25\mu_B$ preferring an out-of-plane orientation as dictated by a magnetic anisotropy energy of 2meV. In contrast to the Co adatom, the spinarons in Fe do not overlap with trivial spin-excitations. We discuss the spinaronic response to an out-of-plane magnetic field, the orbital character and the impact of spin-orbit coupling. [1] J. Bouaziz et al., Nat. Commun. 11, 6112 (2020); [2] F. Friedrich et al., Nat. Phys. 20, 28 (2024); [3] V. Madhavan et al., Science 280, 567 (1998)

TT 6.7 Mon 17:45 H24

Revising the Superconductivity in Iron Based Superconductors from the Perspective of Electron Phonon Coupling — •Lanlin Du[1,2] and Sheng Meng[1,2,3] — [1]Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences, Beijing, China — [2]School of Physical Sciences, University of Chinese Academy of Sciences, Beijing, China — [3]Songshan Lake Materials Laboratory, Dongguan, Guangdong, China

There are currently two mainstream superconducting pairing mechanisms, namely electron phonon coupling and spin fluctuation, which are believed to play a dominant role in conventional superconductors like simple metal superconductors and unconventional superconductors like Copper oxides, respectively. Iron based superconductors are believed to connect these two aspects, that is, both mechanisms are important in it. In fact, some studies have shown that electron phonon coupling is also important in cuprates, and even provide evidence for s-wave pairing symmetry in them. Therefore, it is important to consider the role of electron phonon coupling in unconventional superconductors. Here, we revise the superconductivity in Iron based superconductors using Migdal-Eliashberg formalism and electron phonon coupling strength corrected by many body method from the two perspectives of doping and pressurization. Our results are in good agreement with the experiments. Based on this, we predict a new two-dimensional high-Tc Iron based superconductor.

TT 6.8 Mon 18:00 H24

Theoretical model for multiorbital Kondo screening in strongly correlated molecules with several unpaired electrons — •Manish Kumar[1], Aitor Calvo-Fernandez[2], Diego Solar-Polo[1], Asier Eiguren[2], Maria Blanco-Rey[3], and Pavel Jelinek[1] — [1]Institute of Physics, Academy of Sciences of the Czech Republic , Cukrovarnicka 10, Prague 6, CZ 16200, Czech Republic — [2]Department of Physics, University of the Basque Country UPV-EHU, 48080 Leioa, Spain — [3]Department of Polymers and Advanced Materials: Physics, Chemistry and Technology, University of the Basque Country UPV-EHU, 20018 Donostia-San Sebastián, Spain

The mechanism of Kondo screening in strongly correlated molecules with several unpaired electrons on a metal surface is still under debate. Here, we provide a theoretical framework that rationalizes the emergence of Kondo screening involving several extended molecular orbitals with unpaired electrons. We introduce a perturbative model, which provides simple rules to identify the presence of antiferromagnetic spin-flip channels involving charged molecular multiplets responsible for Kondo screening. The Kondo regime is confirmed by numerical renormalization group calculations. In addition, we introduce the concept of Kondo orbitals as molecular orbitals associated with the Kondo screening process, which provide a direct interpretation of experimental dI/dV maps of Kondo resonances. We demonstrate that this theoretical framework can be applied to different strongly correlated open-shell molecules on metal surfaces, obtaining good agreement with previously published experimental data.

TT 7: Correlated Electrons: Electronic Structure Calculations

Time: Monday 15:00–18:00 Location: H31

TT 7.1 Mon 15:00 H31

Wannier interpolation of reciprocal-space periodic and non-periodic matrix elements in the optimally smooth subspace — •Giulio Volpato, Stefano Mocatti, Giovanni Marini, and Matteo Calandra — Department of Physics, University of Trento, Via Sommarive 14, 38123 Povo, Italy

Maximally localized Wannier functions use the gauge freedom of Bloch wavefunctions to define the optimally smooth subspace with matrix elements that depend smoothly on crystal momentum. The associated Wannier functions are real-space localized, a feature often used to Fourier interpolate periodic observables in reciprocal space on ultradense momentum grids. However, Fourier interpolation cannot handle non-periodic quantities in reciprocal space, such as the oscillator strength matrix elements, which are crucial for the evaluation of optical properties. We show that a direct multidimensional interpolation in the optimally smooth subspace yields comparable accuracy with respect to Fourier interpolation at a similar or lower computational cost. This approach can also interpolate and extrapolate non-periodic observables, enabling the calculation of optical properties on ultradense momentum grids. Finally, we underline that direct interpolation in the optimally smooth subspace can be employed for periodic and non-periodic tensors of any order without any information on the position of the Wannier centers in real space.

LCAO fragment orbital projectors for DFT+U — •Christoph Freysoldt, Hao Chen, and Jörg Neugebauer — Max-Planck-Institut für Nachhaltige Materialien GmbH, Max-Planck-Str. 1, 40237 Düsseldorf

DFT+U is an efficient approach to describe correlated mixed-valence transition metal oxides such as Fe_3O_4=$Fe^{II}Fe_2^{III}O_4$. The correlated orbitals are derived from, but not identical to the metal d-orbitals. Most DFT+U implementations employ local projectors with d-orbital symmetry centered on the transition metal atoms to extract the on-site occupation matrix of the correlated orbitals. Unfortunately, such projectors pick up not only intended occupations of localized orbitals, but also contributions from the extended metal-oxygen bonding states involving the O-2p orbitals. The spurious occupations are sensitive to the projector definition and the M-O bond length, and lead to artifacts in energies and structures. To arrive at a more reliable scheme, one must account for inter-atomic orbital overlap when defining the projectors. We propose using fragment orbitals from a linear combination of atomic orbitals (LCAO) that include the orbital mixing with the first ligand shell of each transition metal ion. To obtain analytic Pulay-like forces when atoms are displaced, the projectors are constructed from a simplified tight-binding model that reflects the atomic positions, but does not rely on the self-consistent electronic structure. We present preliminary results for iron oxides that exhibit improved occupations (closer to 0 and 1) and a reduced sensitivity to bonding distances.

TT 7.3 Mon 15:30 H31

Single- and two-particle observables in the Emery model: A dynamical mean-field perspective — •Yi-Ting Tseng[1], Mario Malcolms[2], Henri Menke[1,2], Marcel Klett[2], Thomas Schäfer[2], and Philipp Hansmann[1] — [1]Friedrich-Alexander-University Erlangen-Nürnberg — [2]Max Planck Institute for Solid State Research, Stuttgart

We investigate dynamical mean-field calculations of the three-band Emery model at the one- and two-particle level for material-realistic parameters of high-T_c superconductors[1]. Our study shows that even within dynamical mean-field theory, which accounts solely for temporal fluctuations, the intrinsic multi-orbital nature of the Emery model introduces effective non-local correlations. These correlations lead to a non-Curie-like temperature dependence of the magnetic susceptibility, consistent with nuclear magnetic resonance experiments in the pseudogap regime. By analyzing the temperature dependence of the static dynamical mean-field theory spin susceptibility, we find indications of emerging oxygen-copper singlet fluctuations, explicitly captured by the model. Despite correctly describing the hallmark of the pseudogap at the two-particle level, such

as the drop in the Knight shift of nuclear magnetic resonance, dynamical mean-field theory fails to capture the spectral properties of the pseudogap.
[1] YiTing Tseng *et al.*, arXiv:2311.09023.

TT 7.4 Mon 15:45 H31

Origin of transitions inversion in rare-earth vanadates — •Xuejing Zhang[1], Erik Koch[2], and Eva Pavarini[1] — [1]Peter Grünberg Institute, Forschungszentrum Jülich, 52425 Jülich, Germany — [2]Jülich Supercomputing Centre, Forschungszentrum Jülich, 52425 Jülich, Germany

The surprising inversion of the orbital- and magnetic-order transitions in the RVO_3 series with increasing the rare-earth radius makes the series unique among orbitally-ordered materials [1]. Here, augmenting dynamical mean-field theory with order-parameter irreducible-tensor decomposition [2], we show that this anomalous behavior emerges from an unusual hierarchy of interactions. First, increasing the rare-earth radius, orbital physics comes to be controlled by *xz*-*xz* quadrupolar super-exchange rather than by lattice distortion. Next, for antiferromagnetic spin order, orbital super-exchange terms with different spin rank compete, so that the dipolar spin-spin interaction dominates. Eventually, G-type magnetic order (anti-ferro in all directions) can appear already above the orbital ordering transition and C-type order (anti-ferro in the *ab* plane) right around it. The strict constraints we found also explain why the inversion is rare, and give at the same time criteria to look for similar behavior in other materials [3].

TT 7.5 Mon 16:00 H31

Engineering correlated Dirac fermions and flat bands on SiC with transition metal adatom lattices — •Niklas Enderlein[1], Henri Menke[1,2], Yi-Ting Tseng[1], Michel Bockstedte[3], Janina Maultzsch[1], Giorgio Sangiovanni[4], and Philipp Hansmann[1] — [1]Friedrich-Alexander-University Erlangen-Nürnberg — [2]Max Planck Institute for Solid State Research, Stuttgart — [3]Johannes Kepler University Linz — [4]Julius-Maximilian-University of Würzburg

In our recent study [1] we propose three transition-metal adatom systems on 3C-SiC(111) surfaces as a versatile platform to realize massless Dirac fermions and flat bands with strong electronic correlations. Using density functional theory combined with the constrained random phase approximation and dynamical mean-field theory, we investigate the electronic properties of Ti, V, and Cr adatoms. The triangular surface lattices exhibit narrow bandwidths and effective two-band Hubbard models near the Fermi level, originating from partially filled, localized d-orbitals of the adatoms. Our study reveals a materials trend from a flat band Fermi liquid (Cr) via a paramagnetic Mott insulator with large local moments (V) to a Mott insulator on the verge to a heavy Dirac semimetal (Ti) showcasing the diverse nature of these strongly correlated systems. Specifically, the flat bands in the Cr and the well-defined Dirac cones in the strained metallic Ti lattice indicate high potential for realizing topological and correlated phases.

TT 7.6 Mon 16:15 H31

Antiferromagnetism in iridates revisited: Mott versus Slater physics — Francesco Cassol, Michele Casula, and •Benjamin Lenz — IMPMC, Sorbonne University - CNRS, Paris, France

Since its discovery, the antiferromagnetic low-temperature phase of the iridates Ba_2IrO_4 and Sr_2IrO_4 has been subject to numerous studies. Whereas their underlying spin-orbit entangled ground state of a half-filled $j_{\text{eff}} = 1/2$ orbital is well accepted, the origin and nature of the antiferromagnetism is still debated. Are the materials classical Mott insulators or is the antiferromagnetism rather of Slater type? In this talk, we will revisit the question based on dynamical mean-field theory (DMFT) calculations that include the $j_{\text{eff}} = 1/2$ and $j_{\text{eff}} = 3/2$ states within the DMFT self-consistency. Comparing to both experiment and *ab initio* simulations from literature, we will depict a complex phase diagram at the crossroads between Slater and Mott physics.

15 min. break

TT 7.7 Mon 16:45 H31

Optical conductivity of Sr_2IrO_4 and Ba_2IrO_4: beyond the traditional interpretation of the double peak structure — •Francesco Cassol, Michele Casula, and Benjamin Lenz — IMPMC, Sorbonne University - CNRS, Paris, France

Since the discovery of their exotic spin-orbital entangled insulating ground state, Sr_2IrO_4 and Ba_2IrO_4 have attracted considerable attention. Spurred by the structural similarities with cuprate high T_C superconductors, numerous studies have explored their magnetic and electronic properties. Herein, we investigate the optical transport properties, by computing the optical conductivity beyond the Peierls substitution scheme within dynamical mean-field theory (DMFT) for both compounds. By explicitly including both $j_{\text{eff}} = 1/2$ and $j_{\text{eff}} = 3/2$ states in the DMFT self-consistency, we characterize the nature of the double peak structure found in the optical conductivity at low energy. In contrast with the traditional interpretation, we assign a mixed j_{eff} character to both peaks. Moreover, we accurately capture their temperature dependence, further corroborating our findings.

TT 7.8 Mon 17:00 H31

Non-flat bands and chiral symmetry in magic angle twisted bilayer graphene — •Miguel Sánchez[1], José González[2], and Tobias Stauber[1] — [1]Insituto de Ciencia de Materiales de Madrid ICMM-CSIC. Madrid, Spain — [2]Insituto de Estrrcutura de la Materia IEM-CSIC. Madrid, Spain)

We find that in any effective theory of magic angle twisted bilayer graphene (MATBG) that integrates out high-energy modes, the flat bands are prone to a significant increase in bandwidth. This effect from the Coulomb interaction is comparable to and even exceeding the perturbations due to strain and electron-phonon coupling.

As a result of this band widening, we identify a pattern of explicit symmetry breaking in MATBG from the ideal $U(4) \times U(4)$ symmetry down to the chiral non-flat $U(4)$ group, in contrast to the flat $U(4)$ symmetry that prevails when the bands are very flat.

Our work builds upon and extends a previous study [1]. For instance, we employ an atomistic model of MATBG that treats the full bandwidth accurately. Moreoever, we discuss the implications of our results for the latest experimental and theoretical findings.
[1] Phys. Rev. Lett. **125**, 257602 (2020).

TT 7.9 Mon 17:15 H31

Electronic structure of CrB_2 and implications for the incommensurate antiferromagnetic order — •André Deyerling[1], Alexander Regnat[1], Schorsch Sauther[1], Christian Pfleiderer[1,2,3,4], and Marc A. Wilde[1,2] — [1]Physik Department, TUM School of Natural Sciences, Technische Universität München, Germany — [2]Zentrum für Quantum Engineering (ZQE), Technische Universität München, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), Technische Universität München, Germany — [4]Heinz Maier-Leibnitz Zentrum (MLZ), Technische Universität München, Germany

CrB_2 exhibits antiferromagnetic order below $T_N = 89$ K [1]. Applying pressure leads to the suppression of magnetic order and the onset of superconductivity [2,3,4]. We report ab initio calculations of CrB_2 for different pressures and discuss possible mechanisms leading to the suppression of magnetic order and the onset of superconductivity. In addition we discuss the electronic structure for different possible magnetic ground states and their compatibility with neutron scattering experiments [4] and quantum oscillation measurements [5,6].

TT 7.10 Mon 17:30 H31

Calculating core-hole valence electron interactions from *ab initio* — •Felix Sorgenfrei[1], Olle Eriksson[1,2], and Patrik Thunström[1] — [1]Department of Physics and Astronomy, Uppsala University, Sweden — [2]Wallenberg Initiative Materials Science for Sustainability (WISE), Uppsala University, Uppsala Sweden

One common approach to simulating X-ray absorption spectra (XAS) for strongly correlated systems is the cluster model, where a model Hamiltonian is described with numerous free parameters. However, when different parameter sets yield the same spectra, drawing definitive conclusions becomes challenging. To overcome this, approaches integrating density functional theory (DFT) or DFT+ methods with the cluster model have been developed, allowing most parameters to be determined *ab initio*. Nonetheless, the Coulomb interaction between the core-hole and valence electrons (U_{cv}) remains undetermined from *ab initio* calculations. In this talk, I will present a method to calculate the screened core-valence interaction using *ab initio* linear response DFT, offering a more rigorous and predictive framework for XAS simulations.

TT 7.11 Mon 17:45 H31

SOLAX: A Python solver for fermionic quantum systems with neural network support — Louis Thirion[1], Philipp Hansmann[1], and •Pavlo Bilous[2] — [1]Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany — [2]Max Planck Institute for the Science of Light, Staudtstr. 2, 91058 Erlangen, Germany

We present a new Python library SOLAX [1] designed for configuration interaction (CI) calculations of fermionic quantum many-body systems which require high dimensional expansions in Slater determinant bases. The provided Python classes allow to conveniently encode basis sets, quantum states, and operators within the second quantization formalism. The JAX-based GPU-accelerated back-end performs efficiently the quantum mechanical operations necessary to determine many-body quantum states in finite-size Hilbert spaces.

Along with these core functionalities, SOLAX integrates a neural-network (NN) support for the CI calculation for otherwise prohibitively large expansions in Slater determinant basis sets. We show how NN can be used in SOLAX to identify a priori unknown subsets of the most important Slater determinants and iteratively obtain high-quality approximative many-body quantum states. Our recent developments include also NN-supported construction of spectral functions, which we plan to provide in future versions of SOLAX.

TT 8.1 Mon 15:00 H32

64-pixel Magnetic Micro-Calorimeter array to study X-ray transitions in muonic atoms — •Daniel Kreuzberger, Andreas Abeln, Christian Enss, Andreas Fleischmann, Loredana Gastaldo, Daniel Hengstler, Andreas Reifenberger, Adrian Striebel, Daniel Unger, Julian Wendel, and Peter Wiedemann — for the QUARTET Collaboration, Kirchhoff Institute for Physics, Heidelberg University

The QUARTET collaboration aims to improve the knowledge on the absolute nuclear charge radii of light nuclei from Li to Ne. We use a low temperature Metallic Magnetic Calorimeter (MMC) array for high-precision X-ray spectroscopy of low-lying states in muonic atoms. MMCs are characterized by a high resolving power of several thousand and a high quantum efficiency in the energy range up to 100 keV. Conventional solid-state detectors do not provide sufficient accuracy in this energy range. A high statistics measurement with lithium, beryllium and boron has recently been performed at the Paul Scherrer Institute. We present the experimental setup and the performance of the detector used. We discuss the first preliminary spectra and systematic effects in this measurement. The high statistics data in combination with the achieved energy resolution and calibration accuracy should allow a more precise characterization of the muonic X-ray lines. With the knowledge gained, a significant improvement in the determination of nuclear charge radii is expected.

TT 8.2 Mon 15:15 H32

Magnetocaloric upgrade for the Quantum Design PPMS® — •Marvin Klinger, Jorginho Villar Guerrero, Anna Klinger, Tim Treu, Anton Jesche, and Philipp Gegenwart — EP VI, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg

Achieving millikelvin temperatures presents significant challenges in experimental physics. While many laboratories operate liquid helium cryostats at 2 K, reaching very low temperatures traditionally requires dilution refrigeration - a technique demanding both specialized expertise and substantial resources. We developed an upgrade for the Quantum Design Physical Property Measurement System (PPMS®) that overcomes these limitations. Our system employs adiabatic demagnetization refrigeration (ADR) to achieve temperatures well below 50 mK for multiple hours. The exceptional performance stems from novel quantum ADR materials that overcome disadvantages of traditional hydrated paramagnetic salts [1]. The upgrade consists of a user-friendly insert that integrates seamlessly with existing PPMS® systems. Its modular design allows researchers to easily swap the low-temperature assembly to accommodate different experimental needs, currently supporting electrical transport, stress/strain, and heat capacity measurements. This versatility and accessibility can make sub-50 mK measurements available to a broader scientific community without the complexity of dilution refrigeration.

TT 8.3 Mon 15:30 H32

The noise-o-meter: A novel device to disentangle noise sources in superconducting devices — •Lukas Münch, Daniel Hengstler, Matthew Herbst, David Mazibrada, Andreas Reifenberger, Markus Renger, Christian Ständer, Rui Yang, Andreas Fleischmann, Loredana Gastaldo, and Christian Enss — Kirchhoff-Institute for Physics, Heidelberg University

In many applications of superconducting devices, different intrinsic noise sources are limiting the ultimate performance of the device. Our new device allows to conveniently disentangle the noise of the read-out chain, and to distinguish between magnetic flux noise and other noise sources. It consists of a microfabricated Wheatstone-like bridge of four superconducting inductors, two of which are filled with a sample material, which is read out via a pair of two-stage dc-SQUID read-out chains. The device can be operated in two modes. In the passive mode, the output signals of both read-out chains are cross-correlated, which allows the measurement of the total noise of all intrinsic noise sources within a sample material. In the active mode, the bridge is driven by an AC current to measure the samples complex susceptibility and, therefore, specifically the samples magnetic noise via the fluctuation-dissipation theorem. We used this setup to characterize SiO_2, Ag:Er and Au:Er films in a large temperature range from 20 to 800 mK. We discuss our design considerations and present the results of these measurements. Furthermore, we address the current performance limits of $S_\Phi = 30\,\mathrm{n}\Phi_0/\sqrt{\mathrm{Hz}}$ in passive mode and around 10 ppm for the concentration of magnetic impurities in active mode.

TT 8.4 Mon 15:45 H32

Broadband EPR Spectroscopy of $LiYF_4$ doped with Rare-Earth Ions — •Ana Strinic[1,2,3], Patricia Oehrl[1,2,3], Georg Mair[1,2], Hans Huebl[1,2,3], Rudolf Gross[1,2,3], and Nadezhda Kukharchyk[1,2,3] — [1]Walther-Meißner-Institute, Bavarian Academy of Sciences and Humanities, Garching, Germany — [2]School of Natural Sciences, Technical University of Munich, Garching, Germany — [3]Munich Center for Quantum Science and Technology, Munich, Germany

We report on the study of hyperfine transitions of rare-earth ions doped into the host crystal $LiYF_4$ (RE^{3+}:$^7LiYF_4$) using broadband EPR spectroscopy at millikelvin temperatures. While the studied crystals are intentionally doped with ^{167}Er or ^{143}Nd, we identify impurity traces of other rare-earth ions from their EPR-transitions, based on previously published spin Hamiltonian parameters [1]. Taking into account the electron Zeeman, the hyperfine, and the quadrupole interactions, the high resolution spectra allow for the determination of refined spin Hamiltonian parameters for ^{167}Er and ^{143}Nd, as well as for the identified impurities. Our results demonstrate the advantage of using broadband EPR for material research, not only because precise information on the interactions of the spin system can be obtained, but also because the material purity can be tested. This study is relevant for quantum memory applications, as high purity materials are associated with achieving long coherence times [2].

TT 8.5 Mon 16:00 H32

Electro-optic cavities: Towards local measurement of light-matter coupling — •Michael S. Spencer[1], Joanna M. Urban[1], Maximilian Frenzel[1], Niclas S. Mueller[1], Olga Minakova[1], Martin Wolf[1], Alexander Paarmann[1], and Sebastian F. Maehrlein[1,2,3] — [1]FHI Berlin — [2]HZDR — [3]TU Dresden

Cavity quantum electrodynamics is expected to provide a unique direction for tailoring ground- and excited-state properties in correlated materials. Bringing this together with high-field driving in the terahertz (THz) spectral range opens the door to explore low-energy, field-driven cavity electrodynamics. Despite this potential, leveraging field-driven material control in bulk cavities is hindered by the lack of direct retrieval of intra-cavity fields. Here, we demonstrate novel active cavities, consisting of a Fabry-Pérot cavity filled with an electro-optic crystal, which measure their intra-cavity electric fields on ultrafast timescales. With these, we demonstrate quantitative retrieval of the cavity modes in amplitude and phase. We furthermore design a tunable multi-layer cavity, enabling deterministic design of hybrid cavities for future field-resolved polaritonic systems. Our theoretical modeling reveals the origin of the avoided crossings embedded in the intricate mode dispersion upon cavity tuning and enable fully-switchable polaritonic effects within arbitrary materials hosted by the hybrid cavity. Electro-optic cavities will therefore serve as in-situ probes of light-matter interactions across all coupling regimes, laying the foundation for field-resolved intra-cavity quantum electrodynamics.

Two-stage Pulse Tube Cryocooler with intermediate heat exchanger for accessing regenerator cooling capacity — •Bernd Schmidt[1,2], Jack-André Schmidt[1,2], Xaver Herrmann[1,2], Jens Falter[1], Dirk Dietzel[1,2], and André Schirmeisen[1,2] — [1]TransMIT GmbH, Center for Cryotechnology and Sensors, Giessen, Germany — [2]Institute of Applied Physics, University of Giessen, Germany

Two-stage PTCs achieve minimum temperatures of 2.2 K and have found their way even into sensitive applications where they compete with conventional LHe-bath cryostats. The 1st stage of a PTC is providing quite large cooling power at higher temperatures, ideal to cool radiation shields and precool peripheral elements. In addition, the cooling capacity of the regenerator is often used for precooling. This raises the question how the cooling capacity of a regenerator can best be harnessed. We present a cryocooler design [1], where an additional heat exchanger was incorporated into the 2nd stage regenerator.

This intermediate cooling stage allows to extract 4-5 W of cooling power at temperatures of 8-9 K for a standard two-stage PTC with a cooling capacity of 1.6 W at 4.2 K. The experimental data shows that applying the additional heating power does not adversely influence the performance of the second stage cold

flange. The achieved cooling powers and temperatures are, for instance, ideally suited to cool superconducting wires in current quantum systems.

Experimental investigations of a frequency optimized Pulse Tube Cryocooler cooldown — •Jack Schmidt[1,2], Bernd Schmidt[1,2], and Andre Schirmeisen[1,2] — [1]Justus-Liebig-Universität Gießen — [2]TransMIT GmbH

Working in research often requires lower temperatures to achieve material effects such as superconductivity. This is achieved by using cryogenic liquids or closed cycle cryocoolers. Later have sub genres of working principle and provide different positive and negative aspects. We focus on the usage of Gifford-McMahon-type pulse tube cryocoolers which provide temperatures down to 2.2 K with the usage of Helium. The cooling power at 4.2 K scales up to 5 Watts nowadays with an electrical input power of the compressor around 25 kW. [1] As for mechanical stability the cryostats often become bulky and heavy. Including temperature isolation of the cold parts the cooldown times become very large. As the cryocoolers are mostly optimized for ongoing low temperature operation the cooling process lacks adaptations for an ideal cooldown. Other findings on this topic suggest to adjust valves and frequency. [2] Here we present our findings on the cooling process of a cryocooler to reduce cooldown time while adjusting the frequency. We were able to reduce the cooling time of the cryocooler by 9 % , applying electrical heat the cooldown is reduced by 10 %.

TT 8.8 Mon 17:00 H32

Photoelectron characterization of a Cold field emitter for Ultrafast TEM — •Tim Dauwe[1,2], Nora Bach[1,2], Rudolf Haindl[1,2], Armin Feist[1,2], and Claus Ropers[1,2] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]4th Physical Institute, University of Göttingen, Germany

Ultrafast transmission electron microscopy (UTEM) combines high spatial resolution with capabilities to image structures in the ultrafast temporal regime. This development was substantially advanced by creating femtosecond photoelectron pulses at modified Schottky tip emitters [1]. Further progress is expected by utilizing cold field emission guns (CFEG), which offer particularly high brightness and a narrower kinetic energy spectrum. In this contribution, we present a characterization of laser-triggered photoemission from a CFEG. We use a recent gun design allowing for laser access to the emitter (see Ref. [2]) and analyze beam characteristics in the linear photoemission regime. The CFEG is shown to support sub-nanometer probes and allows for photoelectron energy widths below 0.3eV. We emphasize the characterization of the spectral shape as a function of gun settings and compare it to theoretical models. Our experiments provide new insights for implementing and understanding photoemission from a CFEG, which will promote UTEM experiments at high resolution.

Erbium dopants as luminescence thermometers in nanophotonic silicon waveguides — •Kilian Sandholzer, Stephan Rinner, Justus Edelmann, and Andreas Reiserer — Technical University of Munich, TUM School of Natural Sciences, and Munich Center for Quantum Science and Technology (MCQST), Garching, Germany

The demand for fast and accurate temperature measurements in nanophotonic silicon devices grows as integrated structures for applications become more complicated and denser in classical and quantum technologies. Established approaches use sensors attached close to the components, which limits spatial resolution and increases the footprint of devices [1]. We propose and implement luminescence-based thermometry using directly integrated erbium emitters within nanophotonic silicon waveguides [2]. Coverage from 2 K to 295 K is achieved using two different effects: The thermal activation of non-radiative decay channels via impurities is used for temperatures above 200 K, and the population dynamics of crystal field and spin levels caused by phononic thermalization at lower temperatures. We achieve relative thermal sensitivities of 0.22(4) %/K at room temperature, increasing to 420(50) %/K at 2 K. Combined with spatially selective implantation, our method promises precise thermometry from ambient to cryogenic temperatures with a few-nanometer resolution.

Fast, accurate and local temperature control using qubits — •Riya Baruah[1], Pedro Portugal[1], Joachim Wabnig[2], and Christian Flindt[1,3] — [1]Department of Applied Physics, Aalto University, 00076 Aalto, Finland — [2]Nokia Bell Labs, Cambridge, United Kingdom — [3]RIKEN Center for Quantum Computing, Wakoshi, Saitama 351-0198, Japan

Many quantum technologies operate in the subkelvin regime. It is therefore desirable to develop practical tools and methods for the precise control of the temperature in nanoscale quantum systems. Here, we present a proposal for fast, accurate, and local temperature control using qubits, which regulate the flow of heat between a quantum system and its thermal environment [1,2]. The qubits are kept in a thermal state with a temperature that is controlled in an interplay between work done on the qubits by changing their energy splittings and the flow of heat between the qubits and the environment. Using only a few qubits, it is possible to control the thermal environment of another quantum system, which can be heated or cooled by the qubits. As an example, we show how a quantum system at subkelvin temperatures can be significantly and accurately cooled on a nanosecond timescale.

TT 9: Correlated Magnetism – Low-Dimensional Systems

Time: Monday 15:00–18:15 Location: H33

TT 9.1 Mon 15:00 H33

Pressure and quantum magnetism: Insights from brochantite $Cu_4SO_4(OH)_6$ — •Victoria Ginga[1], Bin Shen[2], Ece Uykur[3], Nico Giordano[4], and Alexander Tsirlin[1] — [1]Felix Bloch Institute, University of Leipzig, Germany — [2]EP VI, EKM, University of Augsburg, Germany — [3]Helmholtz-Zentrum Dresden-Rossendorf, Germany — [4]Deutsches Elektronen-Synchrotron DESY, Germany

Brochantite $Cu_4SO_4(OH)_6$, a widespread natural copper sulfate mineral, exemplifies a low-dimensional quantum magnet due to its geometrically frustrated $S = 1/2$ Cu^{2+} chains. The crystal structure of brochantite ($P2_1/n$) consists of edge-sharing zigzag double chains forming corrugated sheets in the *ab*-plane, with dissimilar Cu-O-Cu bridges fostering complex magnetic interactions. Ferromagnetic ordering within the Cu1-Cu2 and Cu3-Cu4 chains coexists with antiferromagnetic coupling between the chains, thus creating a delicate balance that can be affected by external pressure. We show that brochantite develops antiferromagnetic ordering below $T_N \approx 6$ K at ambient pressure. High-pressure X-ray diffraction data show that the monoclinic structure of brochantite remains stable up to at least 33 GPa, but individual structural parameters and especially bond angles are modified by pressure, thus affecting magnetic frustration in the compound. Magnetization measurements under pressure reveal changes in the Neel temperature and in the position of the susceptibility maximum. Our findings highlight brochantite as a platform for studying the interplay of structural and magnetic properties under extreme conditions.

TT 9.2 Mon 15:15 H33

μSR-investigation of clinoatacamite $Cu_2Cl(OH)_3$ — •Carolin Kastner[1], Fabrice Bert[2], Thomas J. Hicken[3], Jonas A. Krieger[3], Hubertus Luetkens[3], Aaron Schulze[1], Dirk Menzel[1], F. Jochen Litterst[1], Leonie Heinze[4], Kirrily C. Rule[5], Anja U. B. Wolter[6], and Stefan Süllow[1] — [1]IPKM, TU Braunschweig, Braunschweig, Germany — [2]SQM, Université Paris-Saclay, Orsay, France — [3]PSI, Villigen, Switzerland — [4]FZ Jülich GmbH, JCNS at MLZ, Garching, Germany — [5]ANSTO, Kirrawee, Australia — [6]IFW Dresden, Dresden, Germany

Interest in the natural mineral clinoatacamite $Cu_2Cl(OH)_3$ arose due to its chemical and structural relationship to herbertsmithite, a candidate material featuring a quantum spin liquid state on the kagome lattice. In clinoatacamite, the Cu^{2+} spins form a system of distorted kagome layers with three inequivalent antiferromagnetic in-plane couplings and weaker ferromagnetic interlayer exchange. This gives rise to a complex magnetic phase diagram which contains a sequence of magnetic transitions of unknown symmetry.

Here, we present a study of the magnetic phase diagram of single-crystalline clinoatacamite using muon spin spectroscopy (μSR) to gain insight into the microscopic details of the different magnetic phases. For our investigation, the natural, single-crystalline samples were extensively pre-characterized by magnetization and specific heat. We will discuss our findings in the context of the local site symmetry of the different Cu ions.

TT 9.3 Mon 15:30 H33

Complex magnetic excitations in the alternating ferro-antiferromagnetic chain vompound $Cu_2(OH)_3Br$ — •Kirill Povarov[1], Yurii Skourskii[1], J. Wosnitza[1,2], David Graf[3], Zhiying Zhao[4], and Sergei Zvyagin[1] — [1]Hochfeld-Magnetlabor Dresden (HLD-EMFL) and Würzburg-Dresden Cluster of Excellence ct.qmat, HZDR, Dresden — [2]Institut für Festkörper- und Materialphysik, TU Dresden — [3]National High Magnetic Field Laboratory, Tallahassee — [4]Fujian Institute of Research of Structure of Matter, Fujian

We report the intricate spectrum of magnetic excitations in the mixed-chain quantum magnet $Cu_2(OH)_3Br$. Electron spin resonance (ESR) measurements in the frequency range between 0.1 and 1 THz reveal two distinct types of excitations: Low-energy modes of antiferromagnetic resonance (AFMR), and a high-energy excitation multiplet. The latter was argued to stem from mixing between the spinons and magnons, based on the results of zero-field neutron spectroscopy [1]. Peculiarities of their behavior in magnetic fields up to 16 T are discussed.

This work was supported by the Deutsche Forschungsgemeinschaft through the Würzburg-Dresden Cluster of Excellence on Complexity and Topology in Quantum Matter - *ct.qmat* (EXC 2147, project No. 390858490) and the SFB 1143, as well as by HLD at HZDR, member of the European Magnetic Field Laboratory (EMFL).

TT 9.4 Mon 15:45 H33

Synthesis and physical properties of the quasi-spin chain compound Li_2CuO_2 — •Ashiwini Balodhi[1,2] and Min Gyu Kim[2] — [1]Experimentalphysik IV, Ruhr-Universität Bochum, 44801 Bochum, Germany — [2]Department of Physics, University of Wisconsin-Milwaukee, Milwaukee, WI 53201, USA

Li_2CuO_2 serves as an excellent model system for investigating low-dimensional magnetism, owing to its simple $CuOi_4$ square planar coordination along the b-axis (orthorhombic structure). Previous studies on both polycrystalline and single-crystal samples have revealed an antiferromagnetic (AFM) transition at $T_N \sim 9$ K, accompanied by a canted AFM spin structure at T = 2.6 K. To probe the intrinsic magnetic properties of Li_2CuO_2, we synthesized this material using the flux method. We will present detailed magnetic, and heat capacity measurements on flux-grown samples. Magnetization and heat capacity data confirm a long-range antiferromagnetic transition at T_N = 9.3 K. In contrast to earlier studies reporting ferromagnetic components at low temperatures, our results do not indicate any evidence of ferromagnetic ordering in low temperature regime.

This work is supported by the University of Wisconsin-Milwaukee.

TT 9.5 Mon 16:00 H33

Sub-Kelvin magnetic susceptibility insights into the spin chain system $YbAlO_3$ — •Lipsa Behera[1,2], Javier Landaeta[2], Konstantin Semeniuk[2], and Elena Hassinger[1,2] — [1]TUD Dresden University of Technology, Dresden, Germany — [2]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany

Low dimensional quantum magnets offer a rich platform to explore intriguing physics such as Tomonaga-Luttinger liquid, incommensurate phases and quantum phase transitions. What makes them special is the constraint in dimensionality leading to strong correlations. $YbAlO_3$ is an example of a quasi-one-dimensional spin chain system that can be described as a S = 1/2 Heisenberg chain with smaller Ising-like interchain interactions. At 1K it shows a typical spinon spectrum. At low temperature, the phase diagram presents an antiferromagnetic phase below 0.9 K, that changes into a longitudinal spin density wave including a MS/3 plateau, transverse antiferromagnetic phase and the field polarised state with H ||a. Recent thermal conductivity and magnetostriction measurements uncovered a previously unobserved MS/5 plateau phase at B = 0.7 T, motivating detailed sub-kelvin magnetic susceptibility studies. Here, we report ac susceptibility measurements down to 25 mK, which not only reproduces the known phase diagram to a good extent, but also confirm the presence of the magnetization plateau Ms/5. Furthermore, it reveals additional anomalies, embedded in the incommensurate phase, adding up to the complex magnetic behavior of this material.

TT 9.6 Mon 16:15 H33

Evidence of spin-phonon charge coupling in the quasi-1D Ising spin chain system α-CoV_2O_6 — •Debismita Naik and Pradip Khatua — Department of Physical Sciences, Indian Institute of Science Education and Research Kolkata, Mohanpur, West Bengal 741246, India

The quasi-one-dimensional Ising spin chain system α-CoV_2O_6 exhibits fascinating magnetic properties at lower temperatures. The DC magnetization and specific heat confirm the antiferromagnetic long-range ordering temperature T_N = 15 K. From the specific heat, the calculated magnetic entropy above T_N suggests short-range ordering in this low-dimensional compound. The temperature-dependent XRD supports the key finding of magnetoelastic coupling, which is crucial for linking the electrical and magnetic dipoles. Temperature-dependent Raman spectroscopy reveals the presence of spin-phonon coupling below T_N. Additionally, the study highlights an unusual evolution of the Raman modes above T_N which appears to be linked to short-range magnetic ordering. The renormalization of Raman modes and lattice anomalies near T_N illustrate spin-lattice coupling via magnetoelastic and spin-phonon interactions leads to interplay between spin, charge, and phonon degrees of freedom in α-CoV_2O_6. To support the intriguing phenomena, the theoretical charge density difference maps suggest the formation of electrical dipoles between Co and O atoms below T_N arises from p-d hybridization.

TT 9.7 Mon 16:45 H33

Crystal structure, electronic structure and magnetism in the binary compound Cr_3Se_4 — •Helge Rosner[1], Seojin Kim[1], Yurii Prots[1], Vincent Morano[2], Oksana Zaharko[2], Jörg Sichelschmidt[1], Marcus Schmidt[1], and Michael Baenitz[1] — [1]Max-Planck-Institut für Chemische Physik fester Stoffe, 01187 Dresden, Germany — [2]Laboratory for Neutron Scattering and Imaging, 5232 Villigen PSI, Switzerland

Cr_3Se_4 crystallises in a monoclinic lattice, structurally closely related to the rhombohedral chalcogenite delafossite-like systems $ACrX_2$ with A = Na, Cu, Ag and X = S, Se. In contrast to these intrinsically semiconducting materials with a nonmagnetic monovalent A site, in Cr_3Se_4 the distorted triangular $CrSe_2$ layers are separated by a formally trivalent and magnetic ion. In consequence, the inter-layer distance is strongly reduced, making the system more three dimensional, and thus strongly increasing the magnetic ordering temperature.

Here, we present a joint experimental and theoretical study of the binary material Cr_3Se_4, including thermodynamic measurements, high resolution XRD, neutron scattering and density functional band structure calculations. Our data consistently demonstrate that the metallic system undergoes an antiferromagnetic ordering at about 160 K which is strongly coupled to the crystal lattice. The band structure calculations show that the conduction bands originate from strongly hybridised Cr-Se states with sizeable spin-orbit interaction. In a detailed comparison, we will highlight the similarities and differences between Cr_3Se_4 and the chalcogenite delafossites.

TT 9.8 Mon 17:00 H33

First-principles phonon study of $AgCrS_2$, $AgCrSe_2$, and $AgCrTe_2$ — •Seo-Jin Kim, Jörg Sichelschmidt, Michael Baenitz, Yurii Prots, Markus Schmidt, and Helge Rosner — Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany

We study the elastic and dynamic stability of layered triangular lattice systems $AgCrS_2$, $AgCrSe_2$, and $AgCrTe_2$ using density functional theory (DFT). These systems share the same structure but exhibit different properties. Multiferroic $AgCrS_2$ undergoes an additional structural transition to a monoclinic phase and exhibits a collinear double-stripe antiferromagnetic ground state below T_N = 42 K. $AgCrSe_2$ shows noncollinear cycloidal magnetic ordering below T_N = 32 K. To investigate the interplay between magnetism and structure, we analyze the elastic constants and phonon dispersions of these compounds. Our findings reveal that the on-site Coulomb repulsion and additional symmetry alterations in the Cr layer are crucial for achieving dynamical stability in $AgCrS_2$. Furthermore, we analyze $AgCrSe_2$ and $AgCrTe_2$ to understand the general trends in elastic and dynamic properties with chalcogen variation.

TT 9.9 Mon 17:15 H33

Magnetic-field tuning of the spin dynamics in the van der Waals antiferromagnet $CuCrP_2S_6$ (CCPS) — •Joyal John Abraham[1,2], Sebastian Selter[1], Yuliia Shemerliuk[1,2], Saicharan Aswartham[1], Bernd Büchner[1,2,3], Vladislav Kataev[1], and Alexey Alfonsov[1] — [1]Leibniz IFW Dresden, D-01069 — [2]Institute for Solid State and Materials Physics, TU Dresden, D-01062 Dresden — [3]Institute for Solid State and Materials Physics and Würzburg- Dresden Cluster of Excellence ct.qmat, TU Dresden, D-01062

Magnetic van der Waals (vdW) materials have recently attracted significant attention due to their tunable magnetic properties, easy exfoliation, and possible integration into spintronic devices. In this work, we explore with electron spin resonance (ESR) spectroscopy the spin dynamics of the vdW antiferromagnetic (AFM) compound CCPS featuring interpenetrating antipolar Cu^{1+} and (AFM) Cr^{3+} sublattices. Above the AFM ordering temperature $T_N \approx 30$ K ESR reveals prominent ferromagnetic (FM) spin correlations that persist far above T_N, suggesting an intrinsically two-dimensional character of the spin dynamics in CCPS. At $T < T_N$, a complex field dependence of collective excitations of the AFM-ordered spin-lattice was observed featuring two non-degenerate magnon gaps at $H = 0$. A remarkable tuning of the excitations from the AFM-type to the FM-type with increasing field strength was demonstrated. Application of the linear spin wave theory enabled us to quantify the exchange and anisotropic constants. Furthermore, this unusual crossover of AFM-FM excitations is explained using the obtained energy parameters.

TT 9.10 Mon 17:30 H33

Investigation of the insulator to metal transition in the 2d van der Waals magnet $FePSe_3$ — •Saicharan Aswartham, Masoumeh Rahimkhani, Andreas Kreyssig, and Anna Böhmer — Experimentalphysik IV, Ruhr- Universität Bochum, 44801 Bochum, Germany

Layered magnetic van der Waals (vdW) materials offers an interesting playground for the investigation of correlated electronic ground states in two dimensions. $FePSe_3$ belongs to the family of transition metal phosphorus trichalcogenides $TMPX_3$ with an antiferromagnetic ground state with T_N=108 K. Interestingly, under the application of external pressure FePSe3 undergoes insulator to metal transition. Here, we present detailed synthesis and physical properties of $Fe_{1-x}TM_xPSe_3$ with different transition metal substitution. We furtheraim to investigate spin cross over behaviour with the application of chemical pressure in $FePSe_3$.

Modelling low-energy spin excitation measurements in field-induced phases of the spin-ladder antiferromagnet $BiCu_2PO_6$ — Patrick Pilch[1], Kirill Amelin[2], •Gary Schmiedinghoff[3], Anneke Reinold[1], Changqing Zhu[1], Kirill Yu. Povarov[4], Sergei Zvyagin[4], Hans Engelkamp[5], Yin-Ping Lan[6], Guo-Jiun Shu[6], Fang-Cheng Chou[7], Urmas Nagel[2], Toomas Rõõm[2], Götz S. Uhrig[1], Benedikt Fauseweh[1,3], and Zhe Wang[1] — [1]TU Dortmund, 44227 Dortmund, Germany — [2]NICPB, 12618 Tallinn, Estonia — [3]DLR, 51147 Cologne, Germany — [4]HZDR, 01328 Dresden, Germany — [5]Radboud University, 6525 ED Nijmegen, The Netherlands — [6]Taipei Tech, Taipei 10608, Taiwan — [7]NTU, Taipei 10617, Taiwan

We report on terahertz spectroscopic measurements and subsequent theoretical modelling of quantum spin dynamics on single crystals of a spin-1/2 frustrated spin-ladder antiferromagnet $BiCu_2PO_6$ as a function of applied external magnetic fields. Anisotropic spin triplon excitations are observed, which split in applied magnetic fields with a quantum phase transition at $B_{c1} = 21.4\,T$ for fields applied along the crystallographic *a* axis.

We theoretically model the magnetic field dependence of the triplon modes by using continuous unitary transformations to determine an effective low energy Hamiltonian. Through an exhaustive parameter search we find numerically optimized parameters to very well describe the experimentally observed modes, which corroborate the importance of significant magnetic anisotropy in the system.

The talk focuses on the theoretical analysis of the experimental data.

TT 9.12 Mon 18:00 H33

Evidence of multiple phase transition in $Sr_2BB'O_6$ — •Aprajita Joshi, Shalini Badola, Akriti Singh, and Surajit Saha — Indian Institute of Science Education and Research Bhopal, India

The manifestation of phase transition is well mimicked by the lattice, thus by phonons, which requires its correlation with other degrees of freedom (spins, phonons etc.). Often, one can study the behavior of associated phonons with external perturbation to get more insight into the ground state of the material. Thus, any changes in the phase can be tracked with the external stimuli. Keeping this in mind, we explored the structural and magnetic attributes of $Sr_2BB'O_6$ with the help of Raman spectroscopy, using temperature as an external perturbation. The obtained phonon parameter shows the signature of a series of structural phase transitions. Magnetic measurements reveal that it also stabilizes in an antiferromagnetic ground state. An apparent deviation in Raman modes was seen around both the magnetic transitions, acting as a signature of spin-phonon coupling in the system. Additionally, temperature-dependent Raman gave insight into the local distortion in the lattice arising in the magnetically ordered state. This was also corroborated by temperature-dependent XRD measurements.

Uniaxial pressure tuning of the anomalous Hall effect in Mn_3Ge — •Gustavo Lombardi[1], Leonardo Oparacz Kutelak[2], Mario Moda Piva[1], Vinicius Estevo Silva Frehse[3], Guilherme Calligaris[2], Ricardo Donizeth dos Reis[2], and Michael Nicklas[1] — [1]Max Planck Institute for Chemical Physics of Solids, 01187, Dresden, Germany — [2]Brazilian Synchrotron Light Laboratory, 13083-100, Campinas, Brazil — [3]Center for Electronic Correlations and Magnetism, 86159, Augsburg, Germany

The hexagonal Heusler compound Mn_3Ge exhibits an antiferromagnetic structure in which the Mn spins are arranged in a 120° triangular configuration characteristic of a Kagome lattice in the *ab* plane. These Kagome layers are periodically stacked along the *c* axis. This structure gives rise to a large anomalous Hall effect (AHE) due to a non-vanishing Berry curvature. Uniaxial pressure provides an effective method for tuning the AHE in Mn_3Ge. Our results reveal that applying stress along the *a* direction, which induces a distortion in the *ab* plane, significantly modifies the Hall signal. In contrast, stress applied along the *c* axis has no visible effect on the Hall signal. These results, combined with previous hydrostatic pressure data [1], suggest that the strong variations in the AHE are due to changes in the magnetic order in the *ab* plane. We also find that the application of hydrostatic and uniaxial pressure leads to different modifications of the magnetic order, the former inducing an out-of-plane tilt of the Mn spins, while the latter induces rotations of the Mn spins within the *ab* plane.

TT 10.2 Mon 15:15 H36

Terahertz-light induced dynamics in the magnetic Weyl semimetal Mn_3Sn — •Anneke Reinold[1], Sergey Kovalev[1], Tomohiro Uchimura[2], Shunsuke Fukami[2], and Zhe Wang[1] — [1]Department of Physic, TU Dortmund University, Germany — [2]Laboratory for Nanoelectronics and Spintronics, Research Institute of Electrical Communication, Tohoku University, Sendai, Japan

We present a time-resolved spectroscopic study of the strong terahertz (THz) field-driven dynamics in the chiral-structured non-collinear Kagome antiferromagnet Mn_3Sn, a material renowned for anomalous transport properties, topological effects, and promising spintronic applications [1]. The driven charge and spin nonequilibrium dynamics are probed by optical transmission and Faraday rotation with a sub-picosecond time resolution for various experimental conditions. By varying THz and optical polarization, sample orientation, and sample temperature, we carry out a comprehensive investigation of the THz field-driven nonequilibrium dynamics, in order to figure out the contributions due to different mechanisms. Our findings provide insight into the THz field-driven spin dynamics in this Kagome antiferromagnet and demonstrate its potential for THz spintronic applications.

TT 10.3 Mon 15:30 H36

Anomalous Hall and Nernst effect in the Weyl semimetal $Ta_{1+x}Ru_{1-x}Te_4$ — •Mahdi Behnami[1,2,3], Dmitri Efremov[1], Grigory Shipunov[1], Saicharan Aswartham[1], Vilmos Kocsis[1], Marina Putti[3,4], Bernd Büchner[1,2], Helena Reichlova[1,2,5], and Federico Caglieris[4] — [1]IFW Dresden, P.O. Box 270116, 01171 Dresden, Germany — [2]Institut für Festkörper- und Materialphysik, Technische Universität Dresden, 01062 Dresden, Germany — [3]Department of Physics, University of Genoa, 16146 Genova, Italy — [4]CNR-SPIN, 16152 Genova, Italy — [5]Institute of Physics ASCR, v.v.i., Cukrovarnick a 10, 162 53, Praha 6, Czech Republic

The anomalous Nernst effect is a transverse thermoelectric phenomenon driven by a temperature gradient perpendicular to both the heat current and the magnetic order vector. This effect is particularly valuable for probing the topological nature of materials, as it exhibits greater sensitivity to the Berry curvature near the Fermi energy compared to the anomalous Hall effect. In this study, we report that the type-II Weyl semimetal $Ta_{1+x}Ru_{1-x}Te_4$ exhibits both anomalous Hall and Nernst effects. These phenomena can be attributed to the finite Berry curvature generated by the Weyl points in this material.

TT 10.4 Mon 15:45 H36

Electronic transport and classification for topological nodal planes — •Moritz M Hirschmann[1,2], Kirill Alpin[1], Raymond Wiedmann[1], Niclas Heinsdorf[1,3], Wan Yee Yau[1,4], Andreas Leonhardt[1], Douglas H Fabini[5], Johannes Mitscherling[1,6,7], and Andreas P Schnyder[1] — [1]MPI FKF, Stuttgart, Germany — [2]RIKEN CEMS, Wako, Japan — [3]UBC, Vancouver, Canada — [4]MPI CBG, Dresden, Germany — [5]MIT, Cambridge, USA — [6]UC, Berkeley, USA — [7]MPI PKS, Dresden, Germany

Nodal planes are the two-dimensional generalization of nodal points/lines [1], and like them, they may carry a topological charge, for which we devise a symmetry-based classification. When a single or a pair of two nodal planes are topological, Fermi arcs connect the pockets of Weyl points and nodal planes on the surface. While this is similar to Weyl semimetals, their transport properties differ. We find that the large degeneracy of nodal planes is susceptible to a time-reversal breaking that contributes to the anomalous Hall effect. Further, perturbed nodal planes generically enhance the quantum metric contributing to the interband part of the optical conductivity. As an application, we study the hexagonal van der Waals material $CoNb_3S_6$, which exhibits such topological

nodal planes. Recently, this compound has gained interest due to its All-in-All-out magnetic order that exhibits a non-trivial spin-space symmetry [2]. Here, the topological nodal planes dominate the anomalous Hall and Nernst effects.

TT 10.5 Mon 16:00 H36

Quantum geometry of topological nodal planes in Kondo systems — •Yannis Ulrich[1], Andreas Schnyder[1], and Laura Classen[1,2] — [1]Max Planck Institute for Solid State Research, Heisenbergstrasse 1, D-70569 Stuttgart, Germany — [2]Department of Physics, Technical University of Munich, D-85748 Garching, Germany

The geometric properties of the Hilbert space of Bloch states, such as the Berry curvature or quantum metric, play an important role in understanding topological semimetals. They are also fundamental for the understanding of various physical responses, including the (non-)linear Hall effect and (magneto-)optical conductivities. In this talk, I investigate the quantum geometry of two-dimensional topological band degeneracies, i.e., topological nodal planes, with a flat dispersion. Such nodal planes naturally arise in Kondo materials with screw rotation symmetries. Using a periodic Anderson model, I show how nodal planes in these Kondo materials can be tuned via pressure or temperature to be close to the Fermi level with a nearly flat dispersion. I show that such flat nodal planes exhibit a substantial quantum geometry, which in turn leads to nontrivial signatures in the (non-)linear Hall responses. Derivations of the Hall conductivities are presented in the manifestly gauge-invariant language of projectors, emphasizing their advantages in this type of calculation.

TT 10.6 Mon 16:15 H36

Finite-size topological phases from semimetals — •Adipta Pal[1,2] and Ashley M. Cook[1,2] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Max Planck Institute for the Chemical Physics of Solids, Dresden, Germany

Topological semimetals are some of the topological phases of matter most intensely-studied experimentally. The Weyl semimetal phase, in particular, has garnered tremendous, sustained interest given fascinating signatures such as the Fermi arc surface states and the chiral anomaly, as well as the minimal requirements to protect this three-dimensional topological phase. Here, we show that thin films of Weyl semimetals (which we call quasi-(3-1)-dimensional, or q(3-1)d) generically realize finite-size topological phases distinct from 3d and 2d topological phases of established classification schemes: response signatures of the 3d bulk topology co-exist with topologically-protected, quasi-(3-2)d Fermi arc states or chiral boundary modes due to a second, previously-unidentified bulk-boundary correspondence. We show these finite-size topological semimetal phases are realized by Hamiltonians capturing the Fermiology of few-layer Van der Waals material MoTe2 in experiment. Given the broad experimental interest in few-layer Van der Waals materials and topological semimetals, our work paves the way for extensive future theoretical and experimental characterization of finite-size topological phases.

Phonon-mediated surface superconductivity in Weyl semimetals — •Kristian Maeland and Björn Trauzettel — Institute for Theoretical Physics and Astrophysics, University of Würzburg, D-97074 Würzburg, Germany

Recent experiments show that Weyl semimetals can host surface superconductivity in the Fermi arcs, while remaining metallic in the bulk. We study a lattice model of a Weyl semimetal to see if phonons are a candidate pairing mechanism to explain this phenomenon. Specifically, we study the pairing mechanism in detail on the surface and in the bulk. Furthermore, we make predictions about the critical temperature and the momentum dependence of the gap function.

TT 10.8 Mon 17:00 H36

The Weyl-Mott point: Topological and non-Fermi liquid behavior from an isolated Green's function zero — •Rafael Alvaro Flores Calderon[1] and Chris Hooley[2] — [1]Max Planck Institute for the Physics of Complex Systems, Noethnitzer Strasse 38, 01187 Dresden, Germany — [2]Centre for Fluid and Complex Systems, Coventry University, Coventry CV1 2TT, United Kingdom

We present a model in which a Hatsugai-Kohmoto interaction is added to a system of fermions with a Weyl point in their non-interacting dispersion relation, and analyze its behavior as a function of the chemical potential. We show that the model exhibits a Weyl-Mott point, a single isolated Green's function zero, and that this implies an emergent non-Fermi-liquid state at the border of the metallic regime and a gapped topological state for the insulating one. The Weyl-Mott point inherits the topological charge from the original Green's function pole, and is therefore naturally associated with a strongly correlated chiral anomaly.

TT 10.9 Mon 17:15 H36

Observation of quasiparticle lifetime oscillations in WSi_2 — •Ivan Volkau[1], Nico Huber[1], Leo Maximov[1], Andreas Bauer[1,3], Christian Pfleiderer[1,2,3], and Marc A. Wilde[1,3] — [1]Technical University of Munich (TUM) — [2]MCQST, Munich — [3]TUM Zentrum für Quantum Engineering

The observation of quasiparticle lifetime oscillation (QPLOs) in CoSi [1] raises the question whether they are a generic feature observable in many materials or if they require a specific band structure. Here, we report the observation of QPLOs in WSi_2, which has recently generated great interest due to its remarkable characteristics in its transport properties, such as axis-dependent conduction polarity [2] and extremely large magnetoresistance [3]. We present Shubnikov-de Haas (SdH) and de Haas-van Alphen measurements, performed at different orientation of magnetic field up to 18 T and temperatures down to 1.5 K. We analyze the oscillation frequencies, their angular dependence, and their temperature dependence. The detected combination frequencies in the SdH effect exhibit characteristics consistent with QPLOs theory providing another example where the influence of QPLOs is observed.

TT 10.10 Mon 17:30 H36

Anomalous photo-Nernst effect and impact of disorder in $HfTe_5$ films — Maanwinder Singh[1,2], Tobias Meng[3], and •Christoph Kastl[1,2] — [1]Walter-Schottky-Institute, Technical Unversity of Munich, Germany — [2]Munich Center for Quantum Science and Technology — [3]Institute of Theoretical Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, Germany

We discuss optoelectronic transport in thin films of $HfTe_5$, which is a non-magnetic, weakly gapped semimetal at the border of a weak to strong topological insulator transition. We find that focused photoexcitation results in strong a transversal response at finite magnetic field, which we describe in terms of a Berry curvature driven anomalous photo-Nernst effect of three-dimensional massive Dirac fermions [1]. We further use Raman microscopy to reveal significant microscale disorder and strain in contacted films, which has important implications for the interpretation of transport experiments in $HfTe_5$ due to the sensitivity of its electronic structure to external strain [2].

TT 11: Superconductivity: Poster

Time: Monday 15:00–18:00 Location: P4

TT 11.1 Mon 15:00 P4

Chiral and nematic superconductivity in monolayer $NbSe_2$ — •Anton Bleibaum[1], Julian Siegl[1], Wen Wan[2], Marcin Kurpas[3], John Schliemann[1], Miguel M. Ugeda[2,4,5], Magdalena Marganska[1], and Milena Grifoni[1] — [1]Institute for Theoretical Physics, University of Regensburg, 93053 Regensburg, Germany — [2]Donostia International Physics Center, Paseo Manuel de Lardizábal 4, 20018 San Sebastián, Spain — [3]Institute of Physics, University of Silesia in Katowice, 41-500 Chorzów, Poland — [4]Centro de Física de Materiales, Paseo Manuel de Lardizábal 5, 20018 San Sebastián, Spain — [5]Ikerbasque, Basque Foundation for Science, Bilbao 48013, Spain

Superconductivity emerges when there is an effective attractive electron-electron interaction. As proposed by Kohn and Luttinger in 1965, screening of the Coulomb interaction can give rise to long-range Friedel oscillations providing regions of attractive interaction which allow for Cooper pairing. In $NbSe_2$, Coulomb repulsion is sufficient to induce superconductivity, when accounting for screening on the triangular lattice. Using momentum resolved gap equations, we find two quasi-degenerate nematic solutions near the critical temperature T_c. In agreement with tunneling spectroscopy experiments, a complex linear combination forms a fully gaped chiral phase well below T_c. When we allow for an in-plane magnetic field, we find an equal spin pairing component.

TT 11.2 Mon 15:00 P4

Exfoliation and STM/STS Investigations of Monolayer $NbSe_2$ S/F Systems — •Tiark Tiwary[1], Marcel Strohmeier[1], Elke Scheer[1], and Angelo Di Bernardo[1,2] — [1]University of Konstanz, 78457 Konstanz, Germany — [2]University of Salerno, Via Giovanni Paolo II, 132, 84084 Fisciano (SA), Italy

Two dimensional materials have become of great interest in the recent years, because of their promise to enable novel electronic functionality by choosing suitable material combinations. A typical feature of 2D superconductors is their anisotropy of the critical field which is most pronounced in the monolayer limit. To understand more about the behaviour of Ising superconductivity in monolayer $NbSe_2$, STM/STS measurements were performed. To this end, gold-assisted exfoliation was used to obtain large monolayer on a Ti/Au surface. The measurements largely confirmed the previous reports [1, 2] on monolayer $NbSe_2$. To develop devices for superconducting spintronics, the interplay between a ferromagnet and monolayer $NbSe_2$ is investigated. Multiple techniques to gain $NbSe_2$ monolayer were explored. The exfoliation of small monolayers on a Co surface could be achieved.

Cavity Mediated Control on Study of Transient THz Field on Superconductors — Angela Montanaro, Giacomo Jarc, •Nitesh Khatiwada, and Daniele Fausti — Friedrich-Alexander-Universität Erlangen-Nürnberg

Cavity QED has emerged as a new stimulus for studying phase transition in quantum materials. A recent study[1] demonstrating changes in critical temperature for metal insulator phase transition mediated by cavity electrodynamics in 1T-TaS_2 has inspired us to investigate cavity mediated phase transition in superconductors.

[1] Nature 622, 487 (2023).

TT 11.4 Mon 15:00 P4

THz spectroscopy on superconducting ZrN thin films — •Ozan Saritas[1], Frederik Bolle[1], Martin Dressel[1], Roman Potjan[2], Marcus Wislicenus[2], and Marc Scheffler[1] — [1]1. Physikalisches Institut, Universität Stuttgart, Stuttgart, Germany — [2]Fraunhofer Institute for Photonic Microsystems (IPMS), Center Nanoelectronic Technologies (CNT), Dresden, Germany

The recent large-scale preparation of superconducting ZrN thin films is of interest for potential quantum technology applications [1]. Therefore, here we use THz frequency domain spectroscopy to investigate the superconducting electrodynamics of ZrN thin films, with thickness between 20 nm and 50 nm, grown on 300 mm-standard silicon substrates. We have measured the transmission and phase shift of THz radiation passing through the ZrN films, and we have obtained the frequency-dependent dielectric function. We thus acquired characteristic material quantities such as the temperature-dependent superconducting energy gap $2\Delta(T)$ and superfluid density $n_s(T)$. With decreasing thickness, there is a clear trend towards a lower critical temperature T_c, a reduced $2\Delta(T = 0)$, and a lower $n_s(T = 0)$. While the overall behavior is similar to BCS predictions, thinner films exhibit values for the ratio $2\Delta(T = 0)/(k_B T_c)$ that deviate more from the canonical value.

Additionally, a novel analysis of the temperature-dependent shift of Fabry-Perot transmission resonance frequencies of superconducting thin-film samples was performed.

TT 11.5 Mon 15:00 P4

Terahertz investigations on superconducting nitride thin films — •Yayi Lin[1], Frederik Bolle[1], Janine Lorenz[2], Marcello Guardascione[2], Marc Neis[2], Thomas J. Smart[2], Martin Dressel[1], Rami Barends[2], Pavel Bushev[2], F. Stefan Tautz[2], Felix Lüpke[2], and Marc Scheffler[1] — [1]1. Physikalisches Institut, Universität Stuttgart, Stuttgart, Germany — [2]Peter Grünberg Institut, Forschungszentrum Jülich, Jülich, Germany

In recent years, superconducting nitride thin films have garnered significant attention, for example for applications in quantum electronics. Due to the wide range of accessible kinetic inductance, high critical temperature, and correspondingly large energy gap, these materials are readily utilized in microwave resonators, low-temperature amplifiers, and quantum circuits.

We use terahertz (THz) spectroscopy to probe the electrodynamics of superconducting NbTiN ($T_c > 10$ K) and TiN ($T_c > 3$ K) thin films at frequencies below and above their superconducting energy gaps. We combine THz frequency-domain spectroscopy and THz time-domain spectroscopy to cover the frequency range from 100 GHz to 3 THz. We present key properties of several nitride thin films such as critical temperature (T_c), complex optical conductivity ($\hat{\sigma}$), energy gap (2Δ), superfluid density (n_s), and kinetic inductance (L_k). Of particular interest is the absolute value of the superconducting energy gap, which allows comparison with other spectroscopic techniques and predictions based on BCS theory.

TT 11.6 Mon 15:00 P4

Nanoscale Characterization of Defects in Superconducting Nitrides — •Janine Lorenz[1,2,3], Amin Karimi[1], Yorgo Hadad[1], Rami Barends[1], F. Stefan Tautz[1,2,3], and Felix Lüpke[1,4] — [1]Peter Grünberg Institut, Forschungszentrum Jülich, Germany — [2]Jülich Aachen Research Alliance (JARA) - Fundamentals of Future Information Technology, Germany — [3]Institut für Experimentalphysik IV A, RWTH Aachen Universität, Germany — [4]II. Physikalisches Institut, Universität zu Köln, Germany

Due to their elevated critical temperature and high kinetic inductance, Nitride supercondcutors are promising candidates for microwave resonators and low-noise amplifiers that are essential for useful quantum computing. We aim to improve structural and superconducting properties of our 11 nm NbTiN thin films grown by sputter deposition. By implementing a post-deposition thermal annealing protocol in Nitrogen/Hydrogen gas atmosphere we achieve an increase in critical temperature from initially 11.5 K to 18 K. In this work, we apply scanning probe techniques to investigate surface superconductivity and defects that appear as Yu-Shiba-Rusinov states of treated and untreated thin films.

TT 11.7 Mon 15:00 P4

Superconductivity of Reduced Indium Tin Oxide — •Luca Hofmeister, Jan Pusskeiler, Gabriele Untereiner, Martin Dressel, and Marc Scheffler — 1. Physikalisches Institut, Universität Stuttgart, Deutschland

Indium tin oxide (ITO) is a transparent semiconductor commonly used in photovoltaics and flat screen displays. It is possible to induce low temperature superconductivity in ITO via electrochemical reduction in a NaCl solution. [1,2]

We reduced multiple ITO samples at a constant reduction current and measured the temperature dependence of their two-point resistance with a microwave Corbino spectrometer. Depending on the reduction time, the T_c ranges from 2.2 K to 3.7 K, forming a superconducting dome.

Reduction induces a color change of the ITO, which loses some of its transparency for increasing reduction times. Nevertheless, ITO retains some transparency even after very long reduction, thereby making ITO a candidate for usage as a transparent superconducter.

TT 11.8 Mon 15:00 P4

Structural properties of $YBa_2Cu_3O_7$ thin film nanopatterns generated by focused He-ion-beam irradiation — •Robin Hutt[1], Cesar Magen[2], Christoph Schmid[1], Jan Ullmann[1], Simon Koch[1], Javier Pablo-Navarro[2], Ross Carter[1], Paul Zimmermann[1], Frank Schreiber[1], Dieter Koelle[1], Reinhold Kleiner[1], Ivan Zaluzhnyy[1], and Edward Goldobin[1] — [1]Universität Tübingen, Germany — [2]INMA, Universidad de Zaragoza - CSIC, Spain

Irradiation of a $YBa_2Cu_3O_7$ (YBCO) thin film with a focused He ion beam (He-FIB) with spot size $\lesssim 10$ nm changes its properties on the nanoscale. A moderate irradiation dose D supresses the critical temperature T_c locally, thus allowing us to "draw", e.g., Josephson barriers, while a high D destroys (amorphizes) the crystal locally, letting us create highly resistive walls (edges of devices and holes) in one fabrication run. We report on the irradiation of YBCO thin films by He-FIB using single lines and rectangular areas with different doses and investigate the result using transmission electron microscopy (TEM). We visualize the crossover to amorphization at the critical dose D_c and the growth of the amorphous track width with D. Using a simple model, we obtain the value of D_c and FIB spot size with a good accuracy. In the areas irradiated by $D < D_c$ we use strain analysis of the TEM images to detect subtle changes in the crystal structure. This is complemented by spatially-resolved X-ray diffraction data that indicate the swelling of the film in c-direction in irradiated regions. Finally, these observations are correlated with electric transport properties of irradiated areas.

TT 11.9 Mon 15:00 P4

$YBa_2Cu_3O_7$ thin films on Si substrates for SQUID-on-lever scanning probe microscopy — •Simon Koch, Alexander Koller, Christoph Schmid, Reinhold Kleiner, and Dieter Koelle — Physikalisches Institut, Center for Quantum Science (CQ) and LISA$^+$, Universität Tübingen, Germany

Scanning SQUID microscopy (SSM) is a powerful technique for imaging magnetic fields or dissipation processes. The use of the high-T_c cuprate superconductor $YBa_2Cu_3O_7$ (YBCO) combined with custom made Si atomic force microscopy (AFM) cantilevers could enable SSM in the Tesla range and at temperatures up to ~ 80 K with high spatial resolution. However, YBCO has a complex crystal structure and a small coherence length, which leads to a high sensitivity to defects on the atomic scale. High quality YBCO films can only be obtained by epitaxial growth on lattice-matched substrates. Therefore, the challenge with this approch is the integration of YBCO thin films on Si wafers. In recent years, epitaxial $SrTiO_3$ (STO) with perovskite crystal structure has been realized on Silicon [1] and epitaxial STO-on-Si commercial substrates are now available. STO is lattice-matched to YBCO, and therefore provides an ideal starting point for the project.

We present our process for the fabrication of YBCO thin films on STO-on-Si substrates, based on pulsed laser deposition (PLD) and discuss the optimization of growth conditions. We further present our preliminary results regarding film quality and electrical characterization of fabricated structures.

Disorder dependent properties of superconductors — •Marvin Zibula and Götz Seibold — Institut für Physik B-TU Cottbus-Senftenberg, Erich-Weinert Straße 1, 03046 Cottbus

We study the properties of disordered superconductors within the attractive Hubbard model and a disorder potential which interpolates between diluted impurities and Anderson-type disorder with a random potential at each lattice site. In the latter case, we reproduce the results from Ghosal et al. [1], corresponding to the formation of superconducting islands that are not correlated to the underlying charge distribution. However, such a correlation becomes effective upon reducing the impurity concentration. Our results are important for recent optical experiments related to the nonlinear first harmonic response which are more compatible with the diluted model.

TT 11.11 Mon 15:00 P4

Influence of strong correlations on impurity-induced TRSB in a (s+id)-wave superconductor — •Marius Paul and Götz Seibold — BTU Cottbus

In numerical simulations of the extended Hubbard model with nearest-neighbor attraction, which is an actively investigated model for high-Tc-superconductors, there has been made observations of time reversal symmetry breaking in the form of loop currents in the last few years [1,2]. Those loop currents emerge mainly in the vicinity of an $s + id$-state when nonmagnetic disorder is present in the superconductor. While previous work has focused on the investigation of this phenomenon within the Bogoljubov-de Gennes approximation, we will discuss here the influence electronic correlations on the stability of the loop currents. This is accomplished via the time-dependent Gutzwiller approximation extended towards the inclusion of pairing correlations.

Higgs collective mode in superconductors: in- and out-of equilibrium — •Sida Tian[1], Rafael Haenel[1,2], and Dirk Manske[1] — [1]Max Planck Institute for Solid State Research, 70569 Stuttgart — [2]Quantum Matter Institute, University of British Columbia, Vancouver V6T 1Z4, Canada

Collective modes in superconductors encode rich information about the superconducting state. Experimentally probing them requires THz lasers that push the system away from equilibrium. We present a theory of non-equilibrium response based on Keldysh formalism, and introduce a recent developed experimental technique of Non-equilibrium Antistokes Raman Scattering. We further comment on the influence of higher-order fluctuations to collective modes, which will change the collective mode mass. This implies that in circumstances where quantum corrections become relevant such as strong coupling, the Higgs mode will move inside the pair breaking gap.

TT 11.15 Mon 15:00 P4

Nematic susceptibility in heavily hole-doped iron based superconductors — •Franz Eckelt[1], Xiaochen Hong[2], Vilmos Kocsis[3], Vadim Grinenko[4], Bernd Büchner[2], Christian Hess[1], Chul-Ho Lee[5], and Kunihiro Kihou[5] — [1]Bergische Universität Wuppertal, 42097 Wuppertal, Germany — [2]College of Physics and Center of Quantum Materials and Devices, Chongqing University, 401331 Chongqing, China — [3]Leibnitz-Institut for Solide State and Materials Research, 01069 Dresden, Germansy — [4]Tsung-Dao Lee Institute, Shanghai Jiao Tong University, Shanghai 201210, China — [5]National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Ibaraki, 305-8568, Japan

We investigate the elastoresistivity of heavily hole doped iron-based superconductor $Ba_{1-x}K_xFe_2As_2$ in the range x=0.68-0.98 using a piezoelectric measurement technique. We observe a divergent increase in elastoresistance along the [110] direction during cooling for all samples the amplitude of which possesses a strong non-montonic doping dependence. We discuss our results in terms of nematic fluctuations, Fermi surface effects near a Lifshitz transition, and a potential orbital-selective Mott transition.

TT 11.16 Mon 15:00 P4

The Search for 1144 Phases under Pressure — •Leonard Essich, Kristin Kliemt, and Cornelius Krellner — Institute of Physics, Goethe University Frankfurt, Germany

Alternative stacking of 122 Fe-based pnictides has enabled the synthesis of the 1144 phase $ABFe_4As_4$ (A = alkali, B = alkaline earth). Examples include $CaKFe_4As_4$, where a *half-collapsed* tetragonal phase emerges under pressure, and $EuRbFe_4As_4$ or $EuCsFe_4As_4$, where Eu magnetism coexists with superconductivity [1,2]. Theoretical studies predict the stability of further 1144 Fe-arsenides and an extension to phosphides ($AB(TM)_4P_4$ where TM = Fe, Ru, Co, or Ni). Notably, $CaKRu_4P_4$ has been successfully synthesised [1]. This work investigates the synthesis of other 1144 phases under high-pressure conditions, designed to support the incorporation of smaller phosphorus atoms on arsenic lattice positions. Multi-anvil presses offer precise pressure and temperature control, large sample sizes, and adaptable setups for crystal growth research. In this contribution, we present the capabilities of a multi-anvil press, the challenges encountered during sample preparation, and outline the pathway to synthesising 1144 phases. A Walker-type module, previously utilized in our laboratory, contains a 6-8 anvil configuration within a steel cylinder [3]. The choice of pressure-transmitting medium and internal configuration is crucial to achieving the desired outcome in these experiments.

Two-Gap Superconductivity in the Noncentrosymmetric La_3Se_4 — F Košuth[1,2], N Potomová[2], Z Pribulová[1], J Kacmarčík[1], •M Naskar[3], D S Inosov[3], S Ash[4], A K Ganguli[5], J Soltýs[6], V Cambel[6], P Szabó[1], and P Samuely[1] — [1]Centre of Low Temperature Physics, Institute of Experimental Physics, Slovak Academy of Sciences, SK04001 Košice, Slovakia — [2]Centre of Low Temperature Physics, Faculty of Science, P. J. Šafárik University, SK-04001 Košice, Slovakia — [3]Institut für Festkörper und Materialphysik, Technische Universität Dresden, D-01069 Dresden, Germany — [4]Institute for Solid State Research, Leibniz IFW Dresden, D-01069 Dresden, Germany — [5]Department of Chemistry, Indian Institute of Technology Delhi, New Delhi 110016, India — [6]Institute of Electrical Engineering, Slovak Academy of Sciences, Bratislava SK84104, Slovakia

Point-contact Andreev reflection spectroscopy at low temperatures and high magnetic field has been carried out on the noncentrosymmetric superconductor La_3Se_4 (T_c = 8 K). Two superconducting energy gaps Δ_1 and Δ_2, with $2\Delta_1/k_BT_c$ = 5.8 and $2\Delta_2/k_BT_c$ = 2.3, are directly observed in certain spectra. The effects of temperature and magnetic fields help to distinguish a two-gap structure, even in the more common spectra where only a single gap is visible at low temperatures, indicated by a pair of maxima around zero bias. The presence of two-gap superconductivity, consistent with the results from point-contact Andreev reflection spectroscopy, is further confirmed by heat capacity and Hall probe magnetization measurements.

TT 11.18 Mon 15:00 P4

Positive Evidence for Bogoliubov-Fermi Surfaces in Al/InAs Hybrids — •Simon Feyrer[1], Ignacio Lobato[1], Vjeko Dimic[1], Michael Prager[1], Dominique Bougeard[1], Matthias Kronseder[1], Giorgio Biasiol[4], Carlos Balseiro[2], Liliana Arrachea[2], Marco Aprili[3], Christoph Strunk[1], and Leandro Tosi[1,2] — [1]Institute of Experimental and Applied Physics, University of Regensburg, Germany — [2]Centro Atomico Bariloche, Comision Nacional de Energia Atomica, Argentina — [3]Laboratoire: Physic des Solides, Université Paris-Saclay, France — [4]IOM CNR, Laboratorio TASC, Area Science Park Basovizza, Trieste, Italy

We present measurements of a lumped element microwave resonator made out of hybrid Al/InAs superconductor/semiconductor 2D heterostructures. In our

device, the inductor is a narrow wire taylored in the material, dominating the kinetic inductance contribution. The resonance frequency depends on temperature, on power and strongly on in-plane magnetic field. We have observed a change of behavior as the magnetic field becomes larger than B*, consistent with a contribution of the superconducting 2DEG in the InAs affected by the spin-orbit coupling [1]. Using resonators with different geometries we discuss the correlation between the observed anisotropy and the crystal orientation.

TT 11.19 Mon 15:00 P4

Proximity induced superconductivity in non-collinear antiferromagnets (NCAFMs) — •Anshuman Padhi[1], Prajwal Rigvedi Madhusudan Rao[1], Ajin Joy[2], Ajesh K Gopi[1], Jiho Yoon[1], Jae-Chun Jeon[1], Banabir Pal[1], and Stuart S. P. Parkin[1] — [1]Max Planck Institute of Microstructure Physics, 06120, Halle (Saale), Germany — [2]Indian Institute of Science, 560012, Bengaluru, India

Conversion of spin-singlet Cooper pairs to spin-polarised triplet Cooper pairs has been a significant achievement of proximity induced superconducting hybrids. But they often require multilayed stack of mismatched magnetisation interfacing the superconducting condensate, leading to lower tunability, less flexibility on the choice of materials and lesser densities of converted triplet Cooper pairs. Recently, usage of non-collinear antiferromagents have been shown to host long-ranged supercurrents and owing to their atomic distribution of spins in a Kagome lattice are a prime candidate for triplet superconductivity. In this study we aim to fundamentally understand the proximity effect into two-phases of a Mn-based antiperovskite, by analysing the field-dependence of the critical temperature of the superconducting thin-film interfacing them. The unique spin-texture of such materials, with broken inversion symmetry and the presence of uncompensated moments too, can lead to interesting physics w.r.t. the Andreev levels. Thus we fabricate S/I/NCAFM tunneling devices and perform electrical tunneling measurements to study the probable Andreev levels and the impact of the spin-states on them. This exploratory work aims at a deeper level of understanding of Cooper pair interactions in NCAFMs.

TT 11.20 Mon 15:00 P4

Interaction of supercurrents in multiterminal graphene Josephson junctions — •Paul Maier, Romain Danneau, and Detlef Beckmann — Institut für Quantenmaterialien und Technologien, Karlsruher Institut für Technologie

Topological states are predicted to exist in the Andreev bound state spectrum of multiterminal Josephson junction with four or more terminals [1]. Superconductor graphene hybrid structures are especially suitable to realize such devices due to the gate tunability of graphene and the low contact resistance necessary to form Andreev bound states. Understanding the distribution of supercurrent in graphene multiterminal Josephson junctions is one step in the search for these states. We report on the experimental investigation of transport in a four-terminal graphene Josephson junction. We observe magnetic interference patterns in two-terminal measurements and critical current contours in multi-terminal measurements, and compare the results to theoretical simulations.

TT 11.21 Mon 15:00 P4

Control of Andreev Reflection via a Single-Molecule Orbital — •Lorenz Meyer[1], Jose L. Lado[2], Nicolas Néel[1], and Jörg Kröger[1] — [1]Institut für Physik, Technische Universität Ilmenau, D-98693 Ilmenau, Germany — [2]Department of Applied Physics, Aalto University, 02150 Espoo, Finland

Charge transport across a single-molecule junction fabricated from a normal-metal tip, a phthalocyanine, and a conventional superconductor in a scanning tunneling microscope is explored as a function of the gradually closed vacuum gap. The phthalocyanine (2H-Pc) molecule and its pyrrolic-hydrogen-abstracted derivative (Pc) exhibit vastly different behavior. Andreev reflection across the 2H-Pc contact exhibits a temporary enhancement that diminishes with increasing conductance. The hybridization of 2H-Pc with the tip at contact formation gives rise to a molecular magnetic moment that is Kondo-screened in the tip. In contrast, the single-Pc junction lacks Andreev reflection in the same conductance range. Spectroscopy experiments and supporting nonequilibrium Green function calculations highlight the importance of a molecular orbital close to the Fermi energy for rationalizing the observations.

TT 11.22 Mon 15:00 P4

Real-space mapping of Yu-Shiba-Rusinov states around magnetic defects on superconducting surfaces — •Raffaele Aliberti[1,2], Samir Lounis[1,4], Philipp Rüssmann[1,3], and Stefan Blügel[1] — [1]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, Jülich, Germany — [2]RWTH Aachen, Aachen, Germany — [3]Institute for Theoretical Physics and Astrophysics, University of Würzburg, Würzburg, Germany — [4]Faculty of Physics, University of Duisburg-Essen and CENIDE, 47053 Duisburg, Germany

Interfacing magnetic impurities with superconductors generally gives rise to Yu-Shiba-Rusinov (YSR) bound states. Using first-principles, we study the case of Mn impurities deposited on a superconducting Ta (110) surface. We explore both the orbital nature and amplitude of the induced YSR states while investigating their spatial extent, which is characterized by an oscillatory and anisotropic behavior as function of distance with respect to the Mn impurities.In particular, we study the interplay of intrinsic electronic structure properties of the hosting superconductor and that of the impurities, which impacts the resulting "cloud" of YSR states.

We employ the Kohn-Sham Bogoliubov-de Gennes method within the all-electron full-potential relativistic Korringa-Kohn-Rostoker Green function method [1] interfaced with the AiiDA infrastructure for high-throughput automation [2].

TT 11.23 Mon 15:00 P4

Stochastic resonance realized with a superconducting magnetic impurity state — •Philipp Maier[1], Björn Kubala[1,2], Joachim Ankerhold[1], and Ciprian Padurariu[1] — [1]Institute for Complex Quantum Systems and IQST, Ulm University — [2]German Aerospace Center (DLR), Ulm

The phenomenon of stochastic resonance was originally studied in the context of climatic changes and has since been observed in a variety of systems, both classical and quantum. Here, we employ this phenomenon to infer the rates of tunneling processes in the course of quantum electronic transport [1,2]. We theoretically investigate the emergence of stochastic resonance in superconducting junctions, focusing on a system where one electrode hosts a Yu-Shiba-Rusinov state – a discrete bound state within the superconducting gap induced by the magnetic exchange interaction between a magnetic impurity and its superconducting host. Applying the framework of full counting statistics, we demonstrate that stochastic resonance manifests as the reduction of the Fano factor and a resonance of the tunneling current. The frequency of the resonance reveals information about the rate of microscopic electronic processes, e.g. the process responsible for quasiparticle-occupation parity breaking.

TT 11.24 Mon 15:00 P4

Dynamical simulations of single photon detection in superconducting nanowires — •Carlos Alberto Diaz Lopez[1], Joachim Ankerhold[1], Björn Kubala[1,2], and Ciprian Padurariu[1] — [1]Institute of Complex Quantum Systems, University of Ulm, Ulm, Germany — [2]German Aerospace Center (DLR), Ulm, Germany

We use a Python simulation package py-TDGL [1] based on modified Ginzburg-Landau theory [2] to simulate the dynamics of the superconducting condensate in a thin nanowire during the detection of a single-photon. The detection event is modeled phenomenologically as a hot-spot formation: the photon is modeled as an initially localized increase in the electronic temperature, with a Gaussian spatial profile that diffuses outwards while also dissipating in time. Our simulations successfully reproduce the characteristic time-dependent voltage peaks measured in superconducting nanowire single-photon detectors, while providing an accompanying movie-like dynamics of the superconducting order parameter. We propose a method to enhance the prominence of the voltage peaks by optimizing the applied DC current and the intensity of an externally-applied perpendicular magnetic field, with the goal of enabling the detection of single-photons in a broader frequency spectrum.

TT 11.25 Mon 15:00 P4

Simulations of heating effects in dual Shapiro step circuits — •Matthias Meiring, Fabian Kaap, Sergey Lotkhov, and Lukas Grünhaupt — Physikalisch-Technische Bundesanstalt, Bundesallee 100, 38116 Braunschweig

So-called dual Shapiro steps are quantised current steps separated by $2ef$, with e the elementary charge and f the rf drive frequency. They have recently gained renewed interest due to successful experimental demonstrations [1,2,3]. These dual Shapiro steps could bear the potential for a novel quantum current standard. Our measurements of dual Shapiro steps in an Al/AlO_x/Al dc-SQUID connected to a circuit made of high-kinetic-inductance granular aluminium and high-ohmic oxidised titanium revealed an electron temperature, which is substantially higher compared to the case without rf drive. We evaluate thermal heating phenomena in the measured chip layout and present adapted circuit designs, which should reduce heating effects and enhance the step size. Achieving this will lead to more prominent dual Shapiro steps and could thus pave the way to a new quantum current standard based on superconducting circuits.

TT 11.26 Mon 15:00 P4

Broadband kinetic inductance of high impedance superconductors — •Jan Pusskeiler[1], Martin Dressel[1], Thomas Valentin[2], Ameya Nambisan[2], Simon Geisert[2], Ioan Pop[1,2], and Marc Scheffler[1] — [1]1. Physikalisches Institut, Universität Stuttgart — [2]Physikalisches Institut and IQMT, KIT

Kinetic inductance quantifies the intrinsic phase-shifted electrodynamics of superconductors and lies at the heart of superconducting quantum electronics operating at microwave frequencies. Determining the complex impedance Z of disordered and granular superconductors in a frequency range from 10 kHz to 20 GHz using a broadband Corbino reflectometer allows direct observation of the kinetic inductance as a linear contribution to the reactance, $\mathrm{Im}(Z) = L_{\mathrm{kin}} \cdot \omega$. By obtaining the broadband kinetic inductance at temperatures deep in the superconducting state, from 1.15 K up to the critical temperature T_c, we can extrapolate the zero-temperature kinetic inductance.

We study granular aluminum as a high-kinetic inductance superconductor featuring a superconducting dome in the low-temperature phase diagram as a function of normal-state resistivity ρ_{dc}. We report kinetic inductances ranging from 20 pH/sq to 2 nH/sq for granular aluminum thin films with resistivities between 120 $\mu\Omega$cm and 6100 $\mu\Omega$cm. We calculate the superfluid stiffness and observe a $1/\rho_{\mathrm{dc}}$ dependance, as also reported in [1]. Furthermore, we observe absorption features that we interpret as signatures of collective modes of the superfluid condensate.

TT 11.27 Mon 15:00 P4

Characterization of photoresists for deep UV direct writing lithography — •Niels Fiedler[1], Andreas Reifenberger[1], Lukas Münch[1], Alexander Stoll[1], Ludwig Hoibl[2], Andreas Fleischmann[1], and Christian Enss[1] — [1]Kirchhoff Institute for Physics, Heidelberg University — [2]Heidelberg Instruments Mikrotechnik GmbH

Photoresists are integral to the precise pattern transfer processes required for fabricating micro- and nanoscale devices. The structuring of photoresists with optical maskless lithography systems has proven to be extremely versatile and efficient in research and development. Within the framework of the SuperLSI project, Heidelberg Instruments is developing a maskless lithographic platform incorporating a 266 nm Deep UV optical system, designed to achieve patterning resolutions as fine as 200 nm. Identification and thorough characterization of photoresists compatible with the lithographic platform is required. We focus on the performance of a positive (DuPont UV5-0.6) and negative (micro resist technology ma-N 2405) photoresist for the fabrication of superconducting sub-500 nm features. Structural fidelity, etch resistance, and developer compatibility with superconducting materials, such as niobium and aluminum, are evaluated. Achieving reduced linewidths advances quantum sensors like SQUIDs by enabling smaller Josephson junctions (JJs). Initial results for cross-type JJs with areas below 1 μm^2 highlight the potential of optical maskless lithography for flexible wafer-scale fabrication of superconducting devices.

TT 11.28 Mon 15:00 P4

Chemical-mechanical polishing process for the fabrication of cross-type Nb/Al-AlOx/Nb Josephson tunnel junctions — •A. Stoll, N. Fiedler, L. Münch, D. Hengstler, A. Reifenberger, A. Fleischmann, and C. Enss — KIP, Heidelberg University

Josephson tunnel junctions (JJs) are the basic elements of many superconducting electronic devices such as qubits or superconducting quantum interference devices (SQUIDs). Since many applications demand numerous JJs, a reliable wafer-scale fabrication process yielding reproducible, high-quality junctions is essential.

We present the microfabrication process of cross-type Nb/Al-AlOx/Nb Josephson tunnel junctions, emphasizing chemical-mechanical polishing (CMP) for planarization within SiO_2. A layer of SiO_2 is deposited over the structured trilayer, and CMP is used to polish away excess SiO_2, resulting in a planar, smooth, and uniform surface that enhances the accuracy and reliability of the junctions. Quality checks were conducted on junctions of various sizes, as well as the influence of support-like structures around junctions, to evaluate performance and scalability. Electrical characterizations demonstrate high-quality superconducting properties, validating the efficacy of CMP in the planarization of Josephson junction trilayers

This method enhances the scalability and integration of Josephson junctions in complex superconducting circuits, contributing to advancements in quantum computing and superconducting electronics.

TT 11.29 Mon 15:00 P4

High-quality niobium Josephson junctions for superconducting mm-wave qubits — •Urs Strobel[1], Benedict Rothmund[1], Lucas Radke[1], Hannes Rotzinger[1,2], and Alexey V. Ustinov[1,2] — [1]Physikalisches Institut (PHI), Karlsruher Institut für Technologie, 76131 Karlsruhe, Germany — [2]Institut for Quantum Materials and Technologies (IQMT), Karlsruher Institut für Technologie, 76131 Karlsruhe, Germany

Millimeter-wave quantum circuits require a superconductor with an energy gap above 100 GHz , which exceeds the energy gap of the widely used aluminum. Niobium offers much more suitable properties in this frequency range. Implemented in thin film technology on low loss substrates, high quality niobium Josephson junctions should complement the capacitors and inductors required for quantum circuits. We have developed Nb/Al-AlO_x/Nb trilayer Josephson junctions suitable for quantum circuits and characterized them at cryogenic temperatures. We present dc and mm-wave measurement data obtained with these junctions. In addition, we discuss design considerations for prospective mm-wave transmon qubits.

TT 11.30 Mon 15:00 P4

Building a Quantum Wheatstone Bridge — •Thilo Krumrey[1], Alex Kreuzer[1], Hossam Tohamy[1], Hannes Rotzinger[1,2], and Alexey V. Ustinov[1,2] — [1]Physikalisches Institut, Karlsruher Institut für Technologie, 76131 Karlsruhe, Germany — [2]IQMT, Karlsruher Institut für Technologie, 76131 Karlsruhe, Germany

Today's qubits, while still quite noisy, are sufficiently coherent for non-computing applications. We are exploring the possibility of using an arrangement of superconducting qubits to study the quantum version of the Wheatstone resistance bridge[1]. It would allow for comparative measurements of coupling energies using the interference of an excitation gradient across strongly coupled qubits. We propose an implementation of a quantum Wheatstone bridge using superconducting quantum circuits with quarton flux qubits. Here, the large positive anharmonicity and the tunability [2] of the operating frequency are beneficial for our application. We will present circuit simulations results based on the proposed design and compare them with measurements of the circuit at mK temperatures.

TT 11.31 Mon 15:00 P4

Charge Sensitivity of a Quantum Phase Slip Transistor — •Marius Frohn[1], Jan Nicolas Voss[1], Hannes Rotzinger[1,2], and Alexey Ustinov[1,2] — [1]Physikalisches Institut, Karlsruher Institut für Technologie, Karlsruhe, Germany — [2]Institut für Quantenmaterialien und Technologien (IQMT), Karlrsruher Institut für Technologie, Karlsruhe, Germany

Superconducting quantum phase slip (QPS) devices are high-impedance circuits that are promising for quantum sensing applications or the realisation of a current standard. For example, the QPS transistor is a dual circuit to the SQUID and is therefore sensitive to charge rather than flux. We study QPS transistors fabricated from two strongly coupled granular aluminium nanowires. This allows us to use intrinsic electromigration[1] to fine-tune the Coulomb blockade voltage in situ. The current-voltage characteristics at different gate biases and wire resistances provide insight into the charge sensitivity and operating range of the QPS transistor. We present the results of experiments on superconducting nanowire circuits at mK temperatures.

TT 11.32 Mon 15:00 P4

Characterization of Nb Air Bridges for Superconducting Quantum Computing — •Amanda Scoles[1,2], Niklas Bruckmoser[1,2], Leon Koch[1,2], Ivan Tsitsilin[1,2], David Bunch[1,2], Julius Feigl[1,2], Lea Richard[1,2], Vera Bader[1,2], Lasse Södergren[1,2], Christian Schneider[1,2], and Stefan Filipp[1,2] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany

Superconducting qubits are a promising platform for the realization of practical quantum computing. The short gate times, comparatively long lifetimes, and relatively straightforward fabrication process, when compared to other systems, indicate an encouraging future for superconducting quantum circuits. Nevertheless, further optimization of both the fabrication and calibration processes is necessary to fully realize the potential of this platform. In particular, there is a need to enhance qubit coherence, reliability and scalability, which are the current main limitations of this technology.

In this work we investigate Nb air bridges, which provide flexibility in routing of control lines and facilitate the scaling of qubit numbers in planar geometries. We investigate the optimal fabrication parameters in order to maximize the yield of such structures. Additionally, we assess the quality factors of superconducting resonators in the vicinity of air bridges as well as daisy chains of air bridges, to determine the additional loss induced by the air bridge process.

TT 11.33 Mon 15:00 P4

Chiral High-Fidelity State Transfer with Thouless Pumping in Superconducting Circuits — •Lukas Vetter[1,2], Federico Roy[1,2], Jacquelin Luneau[1,2], João H Romeiro[1,2], Max Werninghaus[1,2], Christian MF Schneider[1,2], Peter Rabl[1,2], and Stefan Filipp[1,2] — [1]Technical University of Munich, TUM School of Natural Scienes, Department of Physics — [2]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften

Efficient and robust techniques for state transfer and entanglement generation are vital for the progress of quantum technologies. Thouless pumping enables the topologically protected chiral transfer of excitations in quantum systems, however, dispersion during the protocol leads to losses in transfer fidelity. Here, we introduce a protocol for high-fidelity state transfer based on Thouless Pumping with Bloch Oscillations to suppress dispersion. Our protocol enables the transfer of single and multi-excitation Fock states and Bell states with high fidelity while being robust against perturbations of the Hamiltonian. We describe the effect of Bloch Oscillations using semi-classical equations of motion and show that changing the pumping cycle enables the generation of distant Bell pairs. We experimentally implement our results on a superconducting qubit device by realizing the pumping on a tunable coupler architecture. Our work paves the way for using Thouless pumping in quantum information processing, with applications in topologically robust entanglement generation and multi-qubit gates.

We acknowledge financial support from GeQCoS, MUNIQC-SC, MCQST, OpenSuperQPlus100, and the Munich Quantum Valley.

TT 11.34 Mon 15:00 P4

Vacuum Correlations in Superconducting Quantum Circuits — •Gesa Dünnweber[1,2,3] and Peter Rabl[1,2,3] — [1]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [2]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany

When the quantum vacuum is subjected to time-varying boundary conditions, its inherent fluctuations can be parametrically amplified to create photonic excitations. This phenomenon, known as the dynamical Casimir effect, has been experimentally realized in superconducting quantum devices. Building on these results, we theoretically investigate the correlations induced in such circuits by quantum vacuum interactions. In particular, we analyze a system featuring controlled time-dependence across multiple components and consider potential technological applications.

TT 11.35 Mon 15:00 P4

Gate tunable superconductivity in Al/STO hybrid structures — •Jay Schmidt, Simon Reinhardt, Matthias Kronseder, Nicola Paradiso, and Christoph Strunk — Deptartment of Exp. and Appl. Physics, University of Regensburg, Germany

We present a systematic study on the gate-tunable superconducting properties of Al thin films epitaxially deposited on STO substrates. As a quantum paraelectric, STO exhibits an exceptionally high $\varepsilon \approx 7000$, enabling substantial charge modulation at the Al/STO interface. Metal deposition on STO induces oxygen vacancy formation within the substrate, contributing double electron donors that create an interface 2DEG. Based on measurements of the Hall-effect we extract charge carrier densities in the Al/STO system that are comparable to those in pristine Al films and significantly surpass those observed in LAO/STO 2DEGs. This finding indicates that charge transport is predominantly mediated by Al carriers. $T_C(n)$ and $B_C(T, n)$ exhibit strong tunability under an applied gate voltage with variations up to 15% and 50%, respectively. Notably, the observed T_C values ($\approx$ 0.92 - 1.06 K) are lower than those of pristine Al thin films ($\approx$ 1.4 K) but exceed those of STO, suggesting a bilayer system of superconductors with distinct gap energies coupled through proximity effects. We further investigate the superfluid stiffness, which turns out to be also highly gate-tunable with variations up to 15%. These results underline the potential of Al/STO heterostructures as a versatile platform for studying tunable superconducting phenomena.

TT 11.36 Mon 15:00 P4

Design of a Gate Tunable $\lambda/4$ Josephson Parametric Amplifier in an Al/InAs Hybrid Superconductor/Semiconductor Heterostructure — •Vjeko Dimić[1], Simon Feyrer[1], Alexander Kirchner[1], Giorgio Biasiol[2], Christoph Strunk[1], and Leandro Tosi[1,3] — [1]Institute of Experimental and Applied Physics, University of Regensburg, Germany — [2]CNR-Istituto Officina dei Materiali Laboratorio TASC, Italy — [3]Centro Atomico Bariloche, Comision Nacional de Energia Atomica, Argentina

We present the design of a Josephson parametric amplifier based on a distributed $\lambda/4$ microwave resonator fabricated on a hybrid Al/InAs heterostructure. The 2DEG hosted in the InAs is used to tailor SNS junctions which terminate the resonator and can be tuned using an electrostatic gate deposited on top [1]. We characterize the microwave response of $\lambda/4$ resonators, the losses and the tunability of the resonance frequency resulting from the gate modulation of the Josephson inductance. We show how amplification can be obtained by pumping the gate electrode at twice the resonance frequency.

TT 11.37 Mon 15:00 P4

Design of granular aluminum based kinetic inductance traveling wave parametric amplifiers — Daniel Valenzuela, Christoph Kissling, •Victor Gaydamachenko, Fabian Kaap, Sergey Lotkhov, and Lukas Grünhaupt — Physikalisch-Technische Bundensanstalt, Bundesallee 100, 38116 Braunschweig

Superconducting traveling wave parametric amplifiers (TWPA) are a key ingredient in readout chains, which benefit greatly from lowest possible added noise and several GHz of bandwidth. In the case of kinetic inductance based TWPAs (KI-TWPA), the non-linear kinetic inductance of disordered superconducting thin films is used to enable three- and four-wave mixing processes for signal amplification. A key challenge for the design of KI-TWPAs is to ensure an impedance of 50 Ohm. In addition, unwanted frequency conversion processes have to be phase mismatched, while those generating amplification need to be retained. We tackle both challenges using so-called artificial coplanar waveguides with a multiperiodic capacitance variation. Here, we discuss the design of granular aluminum (grAl) KI-TWPA, our fabrication and process, and show initial experimental results.

TT 11.38 Mon 15:00 P4

Advanced Josephson travelling wave parametric amplifyer analysis with non-linear circuit simulations — •Lars Aaron Anhalt[1,2,3], Daniil Bazulin[1,2], Gleb Krylov[1,2], Yongjie Yuan[4], Diego Contreras[1,2,3], Christian Gnandt[1,2,3], Michael Haider[4], Kirill Fedorov[1,2,5], and Stefan Filipp[1,2,5] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching — [2]School of Natural Sciences, Technical University of Munich, 85748 Garching — [3]Ludwig-Maximilians-Universität in Munich, 80539 Munich — [4]TUM School of Computation, Information and Technology, Technical University of Munich, 85748 Garching — [5]Munich Center for Quantum Science and Technology, 80799 Munich

Broadband, quantum-limited microwave amplifiers are crucial for efficient and fast readout, which enables scaling of superconducting quantum processors. Josephson travelling wave parametric amplifiers (JTWPAs) are the most common solution in the field, providing amplification via copropagation of a pump tone with a signal in a nonlinear medium composed of Josephson junctions. Unwanted conversion processes, as well as stringent requirements on the fabrication processes, still pose challenges to their successful implementation. Here, we demonstrate how circuit simulation with WRSpice can help with the interpretation of experimental measurements of particular JTWPA designs and facilitate further improvements. Our simulations prove to be applicable to a wide range of circuit designs and varying parameters, reproducing competing conversion processes that go beyond analytical results from commonly used coupled mode equations.

TT 11.39 Mon 15:00 P4

Observing measurement-induced transitions in a transmon qudit — •Philippe Gigon[1,2], Zihao Wang[3], Benjamin D'Anjou[1], Alexandre Blais[1], and Machiel Blok[3] — [1]Université de Sherbrooke — [2]Walther-Meißner-Institut — [3]University of Rochester

Numerous experiments have shown that high-power dispersive transmon readout can lead to unexpected state transitions. Significant theoretical efforts have been made to describe these transitions using a simplified model, avoiding the need to account for the full Lindbladian dynamics of the coupled resonator-transmon system [1,2,3,4]. In this study, we employ a semi-classical effective drive model combined with Floquet theory and compare its predictions with experimental results from a transmon qudit. The high controllability and the readout capabilities of the qudit make it the perfect tool to study measurement-induced transitions. Our findings reveal that the semi-classical model accurately predicts critical photon numbers, identifies the states involved in the transitions, and quantifies the affected population.

TT 11.40 Mon 15:00 P4

Collective behavior of qubits coupled to a common wave-guide — •Johannes Friedrich[1,2], Gerhard Huber[1,2], Joan Agustí[1,2], Gesa Dünnweber[1,2], Christian Schneider[1,2], and Stefan Filipp[1,2] — [1]Technical University of Munich, TUM School of Natural Sciences, Physics Department — [2]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften

The behavior of multiple qubits coupled to a common waveguide cannot be understood as the additive behavior of single qubits. Since the waveguide can mediate an all-to-all interaction between qubits via propagating photons, collective radiant states, such as superradiant, subradiant, and twilight states, can be

formed [1,2]. Using superconducting qubits offers control over multiple system parameters such as individual qubit frequency, coupling and spacing and enables the realization of 1D waveguides with large coupling to decoherence ratios, parameters difficult to achieve in atomic systems. Here, we explore parameter regimes beyond time and spatial uniform couplings, providing insights into designing quantum devices with controllable radiative properties.

We acknowledge financial support from GeQCoS, MUNIQC-SC, MC-QST, OpenSuperQPlus100, the Munich Quantum Valley and the Deutsche Forschungsgemeinschaft.

TT 11.41 Mon 15:00 P4

Design of fluxonium qubits inductively coupled to granular aluminum based readout resonators — •Li-Wei Chang, Asen Georgiev, Fabian Kaap, Sergey Lotkhov, Mark Bieler, and Lukas Gruenhaupt — Physikalisch-Technische Bundesanstalt, Bundesallee 100, 38116 Braunschweig, Germany

The fluxonium qubit is a specific type of superconducting qubit, which has garnered significant interest due to its coherence time in the milli-second range, high gate fidelities on the order of 99.9%, and a large anharmonicity up to several GHz. Recent years have also seen a surge in material studies related to this type of qubit, with a particular focus on high kinetic inductance materials such as granular aluminum (grAl). Three basic components form a fluxonium qubit: a Josephson junction, a capacitor, and a so-called superinductor with an impedance larger than the resistance quantum $R_Q = \hbar/4e^2$. We discuss our circuit parameters chosen via numerical simulations to implement a fluxonium with a transition frequency of 0.6 GHz ~ 12 GHz depending on the external magnetic field. To enable dispersive readout, we employ a granular aluminum based readout resonator. This configuration not only provides substantial inductance but also allows inductive coupling to the qubit. We present our methodology to design the circuit parameters, including the dispersive shift, quality factor, and T1 Purcell decay

TT 11.42 Mon 15:00 P4

Understanding loss channels in fluxonium qubits through high-impedance LC resonators — •Matthias Zetzl[1,2,3], Johannes Schirk[1,2,3], Florian Wallner[1,2,3], Ivan Tsitsilin[1,2,3], Niklas Bruckmoser[1,2,3], Christian Schneider[1,2,3], and Stefan Filipp[1,2,3] — [1]Walther-Meißner-Institut, Garching, Germany — [2]Technische Universität München, Munich, Germany — [3]Munich Center for Quantum Science and Technology, Munich, Germany

Current quantum systems based on superconducting qubits are limited by their rate of information loss. Therefore, identifying and mitigating the sources of decoherence of individual qubits is key to improve the performance of these systems. Here, we investigate loss mechanisms in Josephson junction arrays, which are commonly used to implement protected qubits such as "fluxonium" or "zero-pi" qubits. To probe these loss channels, we characterize high-impedance lumped-element LC resonators, comprised of two charge islands connected by a Josephson junction array. While this architecture closely resembles that of "fluxonium" qubits, it allows for a more straightforward characterization by direct transmission measurements of the resonators. By extracting the internal quality factor of the resonators, we can assess the fabrication quality of the junctions in a fast and efficient way, providing a useful tool for all junction based components.

TT 11.43 Mon 15:00 P4

dc-SQUIDs with distributed lossy lines to damp LC resonances — •Nicolas Kahne, Anna Ferring-Siebert, Daniel Hengstler, Fabian Krämer, David Mazibrada, Lukas Münch, Alexander Stoll, Andreas Fleischmann, and Christian Enss — Kirchhoff-Institute for Physics, Heidelberg University

SQUIDs are sensitive superconducting magnetic flux to voltage converters, whose operation is based on the Josephson effect. In particular at mK temperatures this sensitivity can be degraded by LC-resonances in inductances and capacitances of different structures of the SQUID design. To damp the resonances and reduce their influence on the SQUID characteristics, lumped-element resistors are commonly placed into the SQUID circuitry, which need precise simulations to determine the appropriate resistance values and positions.
In this contribution we show results for a dc-SQUID with a new damping strategy, using lossy lines for the input coil and the feed lines. For the input coil we use a thin gold layer which is fabricated in a bilayer process underneath the superconducting coil. For the parallel pair feed lines, on the other hand, we damp inductively through large areas of gold on top which are galvanically decoupled by an insulating layer. We compare the different damping schemes for single dc-SQUIDs and two-stage dc-SQUID setups, regarding the resonance features in their SQUID characteristics and noise contributions. For future designs we also plan tests with SQUID-washers made of lossy lines.

TT 11.44 Mon 15:00 P4

Mapping Locations of Two Level Defects in Superconducting Quantum Circuits — •David Mazibrada[1], Johannes Schwenk[1], Jürgen Lisenfeld[1], Hannes Rotzinger[1,2], Philip Willke[1], and Alexey V. Ustinov[1,2] — [1]Physikalisches Institut, 76131 Karlsruhe, Germany — [2]Institut for Quantum Materials and Technologies, 76131 Karlsruhe, Germany

The development of superconducting quantum circuits has drawn attention to the study of microscopic two-level systems (TLS), as they are a source of decoherence and instability of qubits. Individual TLS can be manipulated using microwave signals, but their specific locations in quantum circuits remain largely unclear. We intend to manipulate the TLS using the electric field of an atomic force microscope tip [1]. This approach should allow us to gain insights into the microscopic nature of the TLS. We will present the assembled atomic force microscope setup and show characterisation data of quantum circuits measured at millikelvin temperatures.

[1] M. Hegedüs, et al., arXiv:2408.16660v1 (2024)

TT 11.45 Mon 15:00 P4

Fully tunable C-shunted Flux Qubits for TLS Research — •Benedikt Berlitz[1], Alexey V. Ustinov[1,2], and Jürgen Lisenfeld[1] — [1]Physikalisches Institut, Karlsruhe Institute of Tech- nology (KIT), Karlsruhe, Germany — [2]IQMT, Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany

Material defects forming two-level-systems (TLS) present a source of decoherence and unwanted degrees of freedom in superconducting quantum systems. The qubits in turn can be used as a tool to study the properties of TLS. We fabricated fully tunable, capacitively shunted superconducting flux qubits specifically to be used as TLS detectors, aiming for good coherence in a wide accessible qubit frequency range. The goal is to gather comparable data of many defects located within the same device. We describe design, fabrication and measurements of the fabricated samples. Studying TLS with these tools will enhance our understanding of the underlying physics of TLS in amorphous ma- terials and hopefully reveal a path to achieving higher coherence with superconducting qubits.

TT 11.46 Mon 15:00 P4

Identification of Noise Sources in Superconducting Microstructures — •Markus Renger, Anton Jarecka, Daniel Hengstler, Matthew Herbst, David Mazibrada, Lukas Münch, Andreas Reifenberger, Christian Ständer, Rui Yang, Andreas Fleischmann, Loredana Gastaldo, and Christian Enss — Kirchhoff-Institute for Physics, Heidelberg University

Improving the performance of superconducting devices often means identifying and eliminating different noise sources. Many noise sources are independent of the specific experimental set-up and transferable across many device categories such as qubits, SQUIDs, and superconducting detectors. We have constructed a stand-alone device with which we can analyze specific noise sources in a representative manner. This device consists of a Wheatstone-like bridge of four micro-fabricated superconducting inductors, two of which filled with sample material, and a pair of two-stage dc-SQUID read-out chains. We can use the method of cross-correlation, to derive the total noise contribution of our device, or AC-drive the Wheatstone bridge to measure the complex AC susceptibility of the sample material. Our experiments are performed at temperatures between $T = 20$ mK and $T = 800$ mK in the frequency range from $f = 100$ mHz to $f = 100$ kHz. We discuss the design of the experimental holder with excellent thermal coupling and shielding. We present the results of multiple measurements on thin films of SiO_2, Ag:Er, as well as Au:Er and perform a detailed comparison. In addition, we demonstrate our device's ability to probe the dynamics of magnetic moments in the sample material.

TT 11.47 Mon 15:00 P4

Dual Tone Spectroscopy of Atomic Tunneling Systems — •Jan Blickberndt, Anton Jarecka, Moritz Maur, Andreas Reiser, Andreas Fleischmann, and Christian Enss — Kirchhoff Institute for Physics, Heidelberg University

Atomic Tunneling Systems (TSs) are intrinsic to disordered structures and thin films, inevitably impacting microstructured devices by causing noise and decoherence in all kinds of applications ranging from Josephson Junctions to cryogenic detector readout chains. Understanding the dynamics of these random fluctuators is essential to mitigate their deteriorative effects on superconducting quantum devices. To investigate the non-equilibrium dielectric behavior of TSs under electric bias, we developed a novel LC resonator setup based on a Wheatstone bridge design. This configuration features two resonance branches that share a common dielectric host material in their capacitors, thereby probing the exact same ensemble of TSs. By applying an external bias field via a cover electrode, we can modulate the energy states of the TSs, enabling their transition between the two resonance modes which allows us to explore ensemble properties as well as the non-linear dynamics of two-level systems. Our current experiments confirm the functionality of the device. To complement the experimental work, we developed a Monte Carlo simulation framework to validate and extend our findings.

TT 11.48 Mon 15:00 P4

Dynamic Control of Dielectric Loss in Amorphus Solids at Low Temperatures — •Marc Hyps, Christian Ständer, Jan Blickberndt, Andreas Fleischmann, Andreas Reiser, and Christian Enss — Kirchhoff Institute for Physics, Heidelberg University

The main influence on the low temperature behaviour of amorphous solids is determined by atomic tunneling systems (TSs). TSs can be described by the phenomenological standard tunneling model (STM). The STM assums the TSs to be broadly distributed in their energy splitting. Experimental investigations of atomic tunneling systems gained recent interest due to their deteriorative effects in superconducting quantum devices, such as increased noise and decoherence. We use newly designed and microfabricated superconducting LC-resonator to study the dielectric rf-response of an amorphous sample in the presence of an electric bias field. The bias field is applied via an electrode placed above the resonator chip wich modifies the energy splitting of the TSs. With this setup we are able to prove the non-equillibrium Landau-Zener dynamics with two different measurement protocols. Aditionally we apply two symetrically detuned pump tones. These resulted in an inversion of the population difference between ground and exited state, hence gain. Also an additional loss contribution was found, hinting towards a coupling to nuclear quadrupol moments.

TT 11.49 Mon 15:00 P4

Enhancement of Low Temperature Dielectric Loss through Vibrational Bias — •Jonathan Herbrich, Christian Ständer, Andreas Fleischmann, Andreas Reiser, and Christian Enss — Kirchhoff Institute for Physics, Heidelberg University

At low temperatures low energy excitations are present in amourphous solids, due to atomic tunneling systems (TSs), leading to different properties compared to their crystalline counterparts. These TSs can be expressed as two level systems with a flatly distributed energy splitting. These properties are well described by the phenomenological standard tunneling modell (STM). Due to their negative influence like noise and decoherance on superconducting quantum devices, these TSs are a subject of recent investigations.

Lately we investigated the dielectric rf-response of an amourphous sample while slowly varying an electric bias field. A microfabricated superconducting LC-resonator, using the sample as a substrate, was used for these measurements. In recent measurements a mechanical strain field was used instead of the electric one. The field is applied by bending the sample with a piezoelectric actuator. As a result, the energy splitting of the TSs is modified, as these couple to the strain field via the deformation potential. Our measurements can be described in a framework based on Landau-Zener transition, origianally developed for the description of electrically biased resonators.

TT 11.50 Mon 15:00 P4

Superconducting Qubits for Measurements with Infrared Photons — •Jonathan Huschle[1], Markus Griedel[1,2], Hannes Rotzinger[1,2], and Alexey V. Ustinov[1,2] — [1]Physikalisches Institut (PHI), Karlsruhe Institut for Technology (KIT) — [2]Institut for Quanten Materials and Technologies (IQMT), Karlsruhe Institut for Technology (KIT)

In superconductors, the impact of photons with energy higher than the energy gap leads to breaking of Cooper pairs, which increases noise level and introduces additional dissipation at microwave frequencies. The coherence of superconducting qubits is particularly sensitive to this influence and can be used as a detector. In the qBriqs project, we develop a setup and measurement protocol for far-infrared photons and identify the influence of broken Cooper pairs using a modified transmon qubit[1]. Here, the capacitance of the qubit is reduced, resulting in an increased charge noise sensitivity. We present the qubit design and measurements at mK temperatures.

TT 11.51 Mon 15:00 P4

Round Robin of the European "Metrology for Superconducting Qubits" (MetSuperQ) Project — •Paul Kugler — KIT, Karlsruhe, Deutschland

Project presentation: The MetSuperQ project addresses the urgent need for metrology support in superconducting circuits, a leading technology for practical quantum computers. The qubit round robin aims to enhance qubit coherence times by studying external influences through round robin measurements at multiple institutes and laboratory settings. This initiative will demonstrate qubit readout and benchmarking, disentangle intrinsic from external sources of decoherence, and raise awareness about the reliability of qubit characterization. By closing the gap in metrology support, this project paves the way for fault-tolerant quantum computers and their scalability.

TT 11.52 Mon 15:00 P4

Quantum Secret Sharing in Multipartite Microwave Networks — •Karolina Weber[1,2], Wun Kwan Yam[1,2], Simon Gandorfer[1,2], Florian Fesquet[1,2], Kedar E. Honasoge[1,2], Maria-Teresa Handschuh[1,2], Achim Marx[1], Rudolf Gross[1,2,3], and Kirill G. Fedorov[1,2,3] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany — [2]School of Natural Sciences, Technische Universität München, 85748 Garching, Germany — [3]Munich Center for Quantum Science and Technology, 80799 Munich, Germany

Quantum secret sharing (QSS) is a quantum cryptography scheme that provides an unconditionally secure way to exchange information in multipartite networks. Here, information about a secret quantum state is shared with n receivers, where the original secret state can be reconstructed if and only if a sufficient number of receivers collaborate. The remaining receivers do not acquire enough information for reconstruction, thereby protecting the secret state from losses, noise, or malicious conspiracies. We experimentally implement the QSS protocol with coherent states in a microwave network with $n = 3$ parties using continuous-variable entanglement and analyze the achieved reconstruction fidelities for different scenarios. We observe that the reconstruction fidelity with 2 collaborating parties exceeds the no-cloning limit, thus, proving the unconditional security of the QSS protocol. Finally, we consider an extension of this experiment towards sharing of qubit states and its applications to blind quantum computing.

TT 11.53 Mon 15:00 P4

Simulation of Non-Markovian Waveguide QED Systems with Tensor-Network Techniques — •Ze Xu — Walther-Meißner-Institute

The coupling of atoms or other two-level emitters to the quantized electromagnetic field is typically modeled using a Markovian master equation, which accounts for both dissipative and coherent photon-mediated interactions. However, this description breaks down in extended optical networks or slow-light waveguides, where significant propagation delays lead to strongly retarded, i.e., non-Markovian, interactions between the emitters. This regime of light-matter interactions remains largely unexplored due to the complexity of modeling non-Markovian effects in a fully quantized framework. In this poster, I will discuss the application of tensor-network techniques for simulating non-Markovian waveguide QED systems with strongly driven emitters, focusing specifically on the case of so-called giant atoms under critical coupling conditions.

TT 11.54 Mon 15:00 P4

Evaluating Spin Ensembles Based on Phosphorus Donors for Quantum Memory Applications — •Andreas Dunaev[1,2], Patricia Oehrl[1,2], Rudolf Gross[1,2,3], and Hans Huebl[1,2,3] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]School of Natural Sciences, Technische Universität München, Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany

Solid-state spin ensembles show great potential for applications in quantum memory devices due to their long coherence times and compatibility with superconducting quantum circuits [1]. Crucial requirements for the application as a memory platform are that the stored information can be accessed and the storage capacity can actively be reset [2]. Here, we discuss an electron spin ensemble of phosphorus donors in silicon coupled to a superconducting resonator in this context. In detail, we present the characterization of this coupled system and demonstrate the storage of classical pulses using a Hahn-echo pulse sequence at temperatures of 4K, moderate magnetic fields, and GHz frequencies. In addition, we introduce the concept of an active reset of the spin ensemble using infrared light. We compare our findings to an input-output model.

TT 11.55 Mon 15:00 P4

Remote Cooling of Spin-ensembles through a Spin-mechanical Hybrid Interface — •Wang Yang[1], Durga Dasari[1], and Joerg Wrachtrup[1,2] — [1]3. Physikalisches Institut, ZAQuant, University of Stuttgart, Allmandring 13, 70569 Stuttgart, Germany — [2]Max Planck Institute for solid state research, Heisenbergstraße 1, 70569 Stuttgart, Germany

We present a protocol for the ground-state cooling of a tripartite hybrid quantum system, in which a macroscopic oscillator acts as a mediator between a single probe spin and a remote spin ensemble. In the presence of weak dispersive coupling between the spins and the oscillator, cooling of the oscillator and the ensemble spins can be achieved by exploiting the feedback from frequent measurements of the single probe spin. We explore the parameter regimes necessary to cool the ensemble, the oscillator, or both to their thermal ground states. This novel cooling protocol shows that, even with only weak dispersive coupling, energy transfer-like effects can be obtained by simply manipulating the probe spin. These results not only contribute to the development of a practical solution for cooling/polarizing large spin ensembles, but also provide a relatively simple means of tuning the dynamics of a hybrid system. The proposed protocol thus has broader implications for advancing various quantum technology applications, such as macroscopic quantum state generation and remote sensing.

TT 11.56 Mon 15:00 P4

Towards SQUID Optomechanical Devices based on $YBa_2Cu_3O_7$ — •Timo Märklin, Kenny Fohmann, Michael Schöllhorn, Mohamad El Kazouini, Christoph Schmid, Benedikt Wilde, Dieter Koelle, Reinhold Kleiner, and Daniel Bothner — Physikalisches Institut, Center for Quantum Science (CQ) and LISA$^+$, Universität Tübingen, Germany

Integrating a superconducting quantum interference device (SQUID) into a superconducting microwave resonator yields a circuit with a flux-tunable resonance frequency. By additionally releasing a part of the SQUID loop from the substrate such that it can oscillate mechanically, one obtains a SQUID optomechanical device in which microwave photons interact with phonons of the mechanical oscillator. If their interaction rate is sufficiently high, one can prepare non-classical states in the mechanical resonator which could build the foundation for experiments testing quantum gravity.

Today's standard material for superconducting frequency-tunable resonators is aluminum. However, the low critical field of aluminum in the range of some 10 mT severely limits the interaction rates achievable in SQUID optomechanical devices, as the interaction rate is directly proportional to an externally applied magnetic field. Therefore, we investigate the high-T_c superconductor $YBa_2Cu_3O_7$ (YBCO) regarding its suitability for SQUID optomechanics, since its high critical field beyond 10 T promises interaction rates higher than those achieved so far. This poster presents our recent progress along the path towards SQUID optomechanical devices based on YBCO.

TT 11.57 Mon 15:00 P4

Analysis of the Mechanical Properties of Nanomechanical String Resonators based on NbTiN — •Burak Bülbüloğlu[1,2], Korbinian Rubenbauer[1,2], Thomas Luschmann[1,2,3], Rudolf Gross[1,2,3], and Hans Huebl[1,2,3] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]School of Natural Sciences, Technical University of Munich, Garching, Germany — [3]Munich Center for Quantum Science and Technology, Munich, Germany

Opto- and electromechanical systems play an intricate part in the fields of quantum sensing and transduction. Aluminum (Al) is a popular material platform in the field of cavity-optomechanics due to its low internal loss rates at microwave frequencies and self-limiting oxide. However, the operation of Al is limited by its critical temperature ($T_c \approx 1.2\,K$ in the bulk). We explore Niobium Titanium Nitride (NbTiN) as an alternative candidate for opto- and electromechanical systems based on thin film technology. NbTiN has a T_c of up to 17 K in bulk and can be used as a material for planar superconducting microwave quantum circuits. Moreover, it has a higher critical current density compared to Al and, thus, can support a larger photon number or microwave drive power. Here, we present doubly-clamped NbTiN nanomechanical string resonators and investigate their mechanical properties. We find stress levels on par with annealed Al, positioning NbTiN strings as a promising platform for the implementation of nano-electromechanical circuits operating at elevated temperatures.

TT 11.58 Mon 15:00 P4

Cavity Optomechanics with a Carbon Nanotube Nanomechanical Resonator — •Katrin Burkert, Akong Loh, Furkan Özyigit, Fabian Stadler, Anton Weber, Niklas Hüttner, and Andreas K. Hüttel — Institute for Experimental and Applied Physics, University of Regensburg, 93040 Regensburg, Germany

Carbon nanotubes (CNTs) are the smallest and lightest nanomechanical resonators. Suspended between Ti/Au electrodes and gated, they can act simultaneously as beam resonators with large Q and as quantum dots. We have realized optomechanical coupling of a SWCNT nanomechanical resonator to a microwave cavity and quantified it through optomechanically induced transparency measurements [1,2]. The nonlinearity of Coulomb blockade in the CNT was exploited to significantly enhance the coupling strength, reaching $g_0 \sim 100$ Hz [1,2]; also back-action of the CNT on the microwave cavity has been demonstrated [1,2]. Ongoing work is directed towards strong coupling and ground state cooling of the nanomechanical resonator. This requires improvements of the microwave cavity [3] and the transfer assembly procedure. Suspended CNTs have been proposed as long-lived nano-electromechanical qubits [4], a topic of high current research interest [5].

Dissipative Microwave Optomechanics with a Carbon Nanotube — •Anton Weber, Katrin Burkert, Akong Loh, Niklas Hüttner, and Andreas K. Hüttel — Institut for Experimental and Applied Physics, University of Regensburg, 93053 Regensburg, Germany

High-frequency nanomechanical resonators are valuable for many measurement applications. We investigate a high quality factor mechanical resonator consisting of a suspended carbon nanotube. The nanotube is actuated by applying an external radiofrequency signal. Its motion can modulate its conductance, allowing for electrical detection [1]. In order to transfer this type of experiment from time-averged, dc measurement to fast GHz detection, the nanotube can be integrated into a microwave reflectometry setup at low temperature. A Quartz tuning-fork based carbon nanotube transfer is used to insert the bottom-up grown CNTs into the top-down designed circuit geometry [2]. The specific electronic and mechanical properties of CNTs require adaptation to the microwave circuit; a stub tuner, formed from coplanar waveguides (CPWs), is used for this purpose. They are particularly suitable for high impedance CNTs, as their resonant frequencies and impedance behavior can be precisely controlled by their geometry. The nanotube vibration modulates the signal reflection, effectively resulting in a dissipatively coupled microwave optomechanical system [3].

TT 11.60 Mon 15:00 P4

Simulation model on the trigger time in superconducting single-photon detectors — •Tim Janocha, Someshvaran Udayakumar, Stefan Kaiser, and Riccardo Bassoli — Technische Universität Dresden, Dresden, Deutschland

Superconducting nanowire single-photon detectors (SNSPDs) are promising quantum communication devices due to their high efficiency, low dark count rates and minimal timing jitter. Here we present a simulation model on the trigger time between photon absorption and detection triggering. Within the framework of the proposed model, the influence of the photon energy, bias current, and strip width are investigated and their influence on the device performance is discussed.

TT 11.61 Mon 15:00 P4

Towards X-ray Spectroscopy with sub-eV Absolute Energy Calibration up to 100 keV — •A. Striebel, A. Abeln, A. Brunold, D. Kreuzberger, D. Unger, D. Hengstler, A. Reifenberger, A. Fleischmann, L. Gastaldo, and C. Enss — Kirchhoff Institute for Physics, Heidelberg University

Metallic magnetic calorimeters (MMCs) are energy-dispersive X-ray detectors which provide an excellent energy resolution over a large dynamic range combined with a very good linearity. MMCs convert the energy of each incident photon into a temperature pulse which is measured by a paramagnetic temperature sensor. The resulting change of magnetisation is read out by a SQUID magnetometer.

To investigate electron transitions in U^{90+} within the framework of the SPARC collaboration, we developed the 2-dimensional maXs-100 detector array. It features 8x8 pixels with a detection area of 1 cm^2, an absorber thickness of 50 μm, a photo efficiency of 18 % at 100 keV, an energy resolution of 40 eV at 60 keV and was successfully operated in a recent beamtime at CRYRING@FAIR. To increase the photo efficiency to above 35 % at 100 keV we develop a new maXs-100 detector with 100 μm thick absorbers.

Currently, the absolute energy calibration is limited not by the detector itself, but by the Struck SIS3316 analog-to-digital converter. We present a technique to precisely determine the ADCs' non-linearity using an Analog Devices EVAL-ADMX1002B ultra low-distortion sine wave generator. This allows to correct for the non-linearity. We discuss the effect of this correction on actual MMC spectra.

TT 11.62 Mon 15:00 P4

Towards Large-Area 256-Pixel MMC Arrays for High Resolution X-ray Spectroscopy — •Andreas Abeln, Daniel Hengstler, Daniel Kreuzberger, Andreas Reifenberger, Andreas Fleischmann, Loredana Gastaldo, and Christian Enss — Kirchhoff Institute for Physics, Heidelberg University

Metallic Magnetic Calorimeters (MMCs) are energy-dispersive cryogenic particle detectors. Operated at temperatures below 50 mK, they provide very good energy resolution, high quantum efficiency as well as high linearity over a large energy range. In many precision experiments in X-ray spectroscopy the photon flux is small, thus a large active detection area is desirable. Therefore, we develop arrays with increasing number of pixels.

In this contribution we present a detector setup featuring a novel dense-packed 16 × 16 pixel MMC array. The pixels provide a total active area of 4 mm × 4 mm and are equipped with 5 μm thick absorbers made of gold. This ensures a stopping power of at least 50 % for photon energies up to 20 keV. The expected energy resolution is 1.4 eV (FWHM) at an operating temperature of 20 mK. For the cost-effective read-out of the 128 detector channels we envisage the flux-ramp multiplexing technique. We present first results of the detector characterization obtained utilizing parallel 2-stage dc-SQUID read-out chains. We discuss the detector performance, focusing on the thermal behavior within the detector as well as to the thermal bath.

TT 11.63 Mon 15:00 P4

MMC-Based Photon and Phonon Detector for Scintillating Crystals at mK **Temperatures** — •Ioana-Alexandra Nitu, Christian Enss, Andreas Fleischmann, Daniel Hengstler, Ashish Jadhav, Cagla Mahanoglu, Andreas Reifenberger, Christian Ritter, and Loredana Gastaldo — Kirchhoff Institute for Physics, Heidelberg University

Scintillating crystals at mK temperatures are used in the search for neutrinoless double beta decay ($0\nu\beta\beta$) and Dark Matter, because they provide the means to discern the interaction of heavy particles, such as α particles, from light ones, such as electrons. The discrimination is achieved by measuring the temperature increase of the crystal and the emitted light simultaneously. This approach is used in the AMoRE experiment where $LiMoO_4$ crystals are employed to search for $0\nu\beta\beta$.

We present the design concept of an integrated photon and phonon (P2) detector, based on low temperature metallic magnetic calorimeters (MMCs). This detector is to be microfabricated on a 3-inch Si wafer; the central wafer area is used for the detection of the scintillation light, while the outer area contains three double-meander MMC detectors to monitor temperature changes in the crystal. We pursue the optimisation of the design and discuss the challenges in the microfabrication of the photon and phonon detector. Preliminary results are presented and compared to the expected performance.

TT 11.64 Mon 15:00 P4

MMC-based X-ray Detector for Transitions in light Muonic Atoms — •Peter Wiedemann, Andreas Abeln, Christian Enss, Andreas Fleischmann, Loredana Gastaldo, Daniel Hengstler, Daniel Kreuzberger, Andreas Reifenberger, Adrian Striebel, Daniel Unger, and Julian Wendel — for the QUARTET Collaboration, Kirchhoff Institute for Physics, Heidelberg University

High energy resolution X-ray spectroscopy of muonic atoms is used for the determination of charge nuclear radii. The QUARTET collaboration aims to improve the accuracy of nuclear charge radii of light elements from Li to Ne up to one order of magnitude by using Metallic Magnetic Calorimeter (MMC) arrays. These Detectors have already demonstrated excellent energy resolution and energy calibration with sub-ev prevision. We present the result obtained with the newly developed MMC array optimized to reach a quantum efficiency of 98% at 19 keV with 4 eV ΔE_{FWHM} We Discuss the performance achieved with this new MMC array at the light of precision X-ray spectroscopy of muonic lithium, beryllium and boron.

TT 11.65 Mon 15:00 P4

Towards Phonon Detection in Superfluid Helium with MMCs — •Axel Brunold, Andreas Fleischmann, and Christian Enss — Kirchhoff Institute for Physics, Heidelberg University

The search for light dark matter requires innovative detection techniques that can probe weakly interacting particles with exceptional sensitivity. One promising approach involves studying elastic scattering interactions between dark matter particles and helium atoms at millikelvin temperatures.

As part of the "Direct search Experiment for Light dark matter", DELight, a pilot experiment is conducted to investigate the behavior of metallic magnetic calorimeters (MMCs) submerged in liquid helium. MMCs have previously demonstrated the capability to detect photons with high energy resolution and linearity; this experiment seeks to explore how these properties translate to the detection of phonons. In this setup, a small copper cell (300 ml) is cooled to below 1 K within a ^{3}He/^{4}He dilution refrigerator and filled with ^{4}He. The liquid helium level, while filling and later on operating the MMC, is monitored with an LC circuit-based level meter. At these millikelvin temperatures, ^{4}He is deep in its superfluid phase, enabling a long mean free path for phonons and rotons. A resistive heater is used to excite phonons, which are then collected by an MMC on a 5 mm x 5 mm silicon substrate. This contribution presents the setup and first results.

TT 11.66 Mon 15:00 P4

MOCCA: A 4k-pixel Molecule Camera for the Position and Energy Resolved Detection of Neutral Molecule Fragments — •Abdullah Özkara[1], Christian Enss[1], Andreas Fleischmann[1], Lisa Gamer[2], Loredana Gastaldo[1], Daniel Hengstler[1], Christopher Jakob[2], Daniel Kreuzberger[1], Ansgar Lowack[1], Oldřich Novotnỳ[2], Andreas Reifenberger[1], Dennis Schulz[1], and Andreas Wolf[2] — [1]Kirchhoff Institute for Physics, Heidelberg University — [2]Max Planck Institute for Nuclear Physics, Heidelberg

The MOCCA detector is a 4k-pixel high-resolution molecule camera based on metallic magnetic calorimeters and read-out with SQUIDs that is able to detect neutral molecule fragments with keV kinetic energies. It will be deployed at the Cryogenic Storage Ring CSR at the Max Planck Institute for Nuclear Physics in Heidelberg, a storage ring built to prepare and store molecular ions in their rotational and vibrational ground states, enabling studies on electron-ion interactions. To reconstruct the reaction kinematics, MOCCA measures the energy and position of the molecule fragments incidenting on the detector, even with multiple particles hitting the detector simultaneously.

For readout, the signals of the 64 pixels of each row are added up and a triggered pixel is identified by its unique signal decay time. Two pixel rows are connected to the same SQUID with opposite polarity. This allows the use of only 32 SQUID channels to read out all 4094 pixels of the detector. We present an improved readout scheme using an exponential decay time spacing. In addition, we compare simulations of this scheme to measured data.

TT 11.67 Mon 15:00 P4

Characterization of Ti/Au Bilayer at mK — •Martin Schwendele, Christian Enss, Andreas Fleischmann, Daniel Hengstler, Ashish Jadhav, Lukas Münch, Andreas Reifenberger, and Loredana Gastaldo — Kirchhoff Institute for Physics, Heidelberg University

Low temperature microcalorimeters reach high energy resolution in a wide energy range thanks to very sensitive thermometers. Magnetic penetration depth thermometers (MPTs) would represent a very interesting alternative with respect to commonly used metallic magnetic calorimeteres (MMCs) and transition edge sensors (TESs).

We present the study of Ti/Au bilayers, typically used in TES as sensible material for MPTs. Films with different ratios between the superconducting layer and the normal conducting layers have been produced using sputtering technique. We discuss the dependence of the transition temperature as a function of the thickness ratio as well as the estimation of the penetration depth as a function of temperature.

kdotpy: A Python application for k·p band structure simulations of zincblende semiconductors — •Wouter Beugeling[1,2], Florian Bayer[1,2], Christian Berger[1,2], Jan Böttcher[3], Leonid Bovkun[1,2], Christopher Fuchs[1,2], Maximilian Hofer[1,2], Saquib Shamim[1,2], Moritz Siebert[1,2], Li-Xian Wang[1,2], Ewelina M. Hankiewicz[3], Tobias Kiessling[1,2], Hartmut Buhmann[1,2], and Laurens W. Molenkamp[1,2] — [1]Physikalisches Institut (EP3), Universität Würzburg, Am Hubland, 97074 Würzburg, Germany — [2]Institute for Topological Insulators, Am Hubland, 97074 Würzburg, Germany — [3]Institut für Theoretische Physik und Astrophysik (TP4), Universität Würzburg, Am Hubland, 97074 Würzburg, Germany

The software project kdotpy aims at simulations of electronic band structures of semiconductor devices with k·p theory. The application implements the widely used Kane model, capable of reliable predictions of transport and optical properties for a large variety of topological and non-topological materials with a zincblende crystal structure.

In this presentation, I present the core functionality and features of kdotpy. I will explain how we have implemented principles of modern software engineering and good scientific practice in this project.

TT 12.2 Mon 17:00 H15

End states in zigzag Haldane model nanoribbons — Simone Traverso, Maura Sassetti, and •Niccolò Traverso Ziani — Physics Department, University of Genova, Italy

As topological materials based on the graphene lattice become experimentally realizable in materials such as germanene, the physics of the bound states that characterize them at step edges and in quasi one-dimensional settings becomes relevant.

In this context, the appearance of topological bound states in zigzag Haldane nanoribbons will be addressed [1]. A reentrant topological phase diagram is found. Together with numerical results, a low energy theory extending the Jackiw-Rebbi paradigm will be presented.

TT 12.3 Mon 17:15 H15

Time-reversal invariant Chalker-Coddington model and the real-space renormalisation group — •Syl Shaw and Rudolf A. Römer — Department of Physics, University of Warwick, Coventry, CV4 7AL, UK

The Chalker-Coddington model has been utilised to great success in understanding the plateau transitions in the quantum Hall effect. Since the model's incep-

tion, it has been extended to a time-reversal invariant symmetry class to describe the quantum-spin Hall effect. Here we adapt a real-space renormalisation group method[1] to respect time-reversal symmetry and use it investigate the phase diagram of the quantum-spin Hall effect. We aim to find distinct phases as a function of both saddle-point height, z and spin-mixing angle ϕ. At the phase boundary between insulator and metal, we compute the value of the critical exponent of the localisation length, ν, with the same real-space renormalisation technique. [1] S. Shaw, R. A. Römer Physica E 165, 116073 (2025)

TT 12.4 Mon 17:30 H15

Utilizing Silicon Qubit Devices for Quantum Electrical Metrology — •Dustin Wittbrodt[1], Johannes Christian Bayer[1], Lars Schreiber[2,3], Janne Lehtinen[4], Marcelo Jaime[1], and Frank Hohls[1] — [1]Physikalisch-Technische Bundesanstalt, Braunschweig, Germany — [2]RWTH Aachen University, Aachen, Germany — [3]Forschungszentrum Juelich, Juelich, Germany — [4]SemiQon Technologies Oy, Espoo, Finland

The 2019 redefinition of the SI system established fixed values for fundamental constants such as the elementary charge (e) and the Planck constant (h), enabling the quantum realization of the units of Ampere, Volt, and Ohm. While the quantum realization of Volt and Ohm is well-established, the realization of the Ampere, whether directly through Single Electron Pumps (SEPs) or indirectly via the Volt and Ohm, has yet to achieve the same level of accuracy. Moreover, further device applications in practical circuits require paralelization approaches to achieve higher current outputs. The international project "Advanced Quantum Technology for Metrology of Electrical Currents" (AQuanTEC) aims to upscale SEPs beyond the 1 nA threshold. To achieve this, AQuanTEC explores several strategies, including the use of silicon devices first designed for spin qubit realization. These devices are highly promising due to their potential scalability, driven by ongoing advancements in integrating large numbers of qubits.

TT 12.5 Mon 17:45 H15

Surface state dominated transport in HgTe topological insulator devices — •Maximilian Hofer[1,2], Christopher Fuchs[1,2], Lena Fürst[1,2], Tobias Kiessling[1,2], Wouter Beugeling[1,2], Hartmut Buhmann[1,2], and Laurens W. Molenkamp[1,2] — [1]Physikalisches Institut, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany — [2]Institute for Topological Insulators, Am Hubland, 97074 Würzburg, Germany

Recently grown three dimensional topological insulators based on tensile strained HgTe exhibit an exceptionally high mobility and very low intrinsic carrier density. The high quality material has made it possible to study the Landau level dispersion at low magnetic fields and identify four distinct transport regimes. We demonstrate that while a contribution from the topological surface states to transport measurements is expected across the full experimentally accessible density range, there exists only a narrow density regime for which the electronic transport is exclusively carried by the topological surface states. We present the corresponding phase diagram for pure topological surface state transport depending on layer thickness and carrier concentration. For thick HgTe films grown pseudomorphically strained on CdTe, the total carrier density needs to be kept between 1.8×10^{11} cm^{-2} and 2.6×10^{11} cm^{-2} to remain in the pure surface state region and avoid contributions from bulk states. The experimental observations are supported by eight band $\boldsymbol{k} \cdot \boldsymbol{p}$ band structure calculations.

TT 12.6 Mon 18:00 H15

Designing a quantum sorter based on two-dimensional topological insulators — •Amanda Teodora Preda[1,2], Iulia Ghiu[2], Lucian Ion[2], Andrei Manolescu[3], and George Alexandru Nemnes[1,2] — [1]Horia Hulubei National Institute for Physics and Nuclear Engineering, Reactorului 30, Magurele- Ilfov, 077125, Romania — [2]University of Bucharest, Faculty of Physics, Atomistilor 405, Magurele-Ilfov, 077125, Romania — [3]Department of Engineering, Reykjavik University, Menntavegur 1, Reykjavik IS-102, Iceland

The idea of a quantum sorter emerged in quantum information, a field that aims to exploit quantum effects and manipulate qubits for information processing. In theory, it was proven that one can propose a universal quantum sorter for any arbitrary observable. To this point, suitable experimental schemes of implementation for this proposal were explored mainly in quantum optics. In our study, we introduce a solid-state version of a quantum sorter, based on a multi-terminal mesoscopic device with multiple output ports, that aims to separate the incoming states by both their spin and transversal mode. In order to maximize the state-separation efficiency of such a device, we chose to exploit the unique transport properties of topological insulators. Employing the tight-binding based simulation package Kwant, we modeled a device that meets the criteria of an irreversible quantum sorter, using the well-established BHZ Hamiltonian to simulate a multi-terminal quantum system made up of both trivial and topological materials.

TT 13: Focus Session: Magnetic Phenomena from Phonon Chirality and Angular Momentum II (joint session MA/TT)

The magnetic moment of the electron lies at the heart of magnetism and spintronics. However, recent research has unveiled the angular momentum and magnetic moment of chiral phonons as fundamental quantities in their own right. These chiral phonons give rise to a plethora of novel lattice phenomena analogous to electronic effects, such as the phonon Hall and phonon Zeeman effects. Moreover, they play a critical role in angular momentum transfer on ultrafast timescales, as seen in the Einstein-de Haas effect. Chiral phonons can also generate effective magnetic fields reaching the tesla scale, inducing magnetization in antiferromagnetic, paramagnetic, and even nonmagnetic materials - a phenomenon reminiscent of the Barnett effect. These advancements showcase phonon chirality and angular momentum as powerful emerging tools for generating and controlling magnetism. This focus session aims to highlight the latest breakthroughs in chiral-phonon magnetism and foster connections between the rapidly evolving field of chiral phononics and the broader magnetism research community.

TT 13.1 Tue 9:30 H16

Continuous-wave terahertz spectroscopy on chiral phonons — •Ji Eun Lee, Luca Eisele, Artem Pronin, and Martin Dressel — 1. Physikalisches Institut, Universität Stuttgart, Germany

We apply continuous-wave frequency-domain terahertz spectroscopy to study chiral phonons at low frequencies. As samples, we use thin films of materials with soft phonon modes, such as SrTiO3 and (doped) PbTe. Our experimental method utilizes both, measurements of transmission with circular-polarized light and Faraday-rotation experiments. In the talk, our approach to the measurements and preliminary results will be summarized.

TT 13.2 Tue 9:45 H16

Spin-lattice coupling in multiscale modeling: from angular momentum transfer to chiral phonons — •Markus Weissenhofer[1,2], Philipp Rieger[1], Sergiy Mankovsky[3], Akashdeep Kamra[5], MS Mrudul[1], Hubert Ebert[3], Ulrich Nowak[4], and Peter M. Oppeneer[1] — [1]Uppsala University, Uppsala, Sweden — [2]Freie Universität Berlin, Berlin, Germany — [3]Ludwig Maximilian Universität, München, Germany — [4]Universität Konstanz, Konstanz, Germany — [5]Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, Kaiserslautern, Germany

Transfer and manipulation of angular momentum is a key aspect in spintronics. Recently, it has been shown that angular momentum transfer between spins and lattice is possible on ultrashort timescales [1]. To contribute to the understanding of this transfer, we have developed a theoretical multiscale framework for spin-lattice coupling, which is linked to ab-initio calculations on the one hand and magnetoelastic continuum theory on the other [2], allowing for the study of a wide range of magnetomechanical phenomena. Here I will discuss how this framework can be used to calculate magnon-phonon coupling parameters, emphasizing the importance of a Dzyaloshinskii-Moriya type interaction for angular momentum transfer [2] and revealing the existence of chiral phonons in iron arising from a chirality-selective coupling [3]. TT 13.3 Tue 10:00 H16

Chiral phonon-induced magnetization reversal in 2D ferromagnets — •Daniel Bustamante Lopez[1] and Dominik Juraschek[2] — [1]Department of Physics, Boston University, Boston, Massachusetts 02215, USA — [2]Department of Applied Physics and Science Education, Eindhoven University of Technology, Eindhoven, Netherlands

In our previous work, we explored magnonic rectification, where a coherently excited chiral phonon generates an effective magnetic field capable of inducing quasistatic magnetization in antiferromagnetic materials. In this study, we extend this concept to ferromagnetic materials, demonstrating that phononic magnetic fields can achieve permanent magnetization reversal. We focus on two-dimensional chromium-based ferromagnetic crystals, including CrI3, CrGeTe3, and CrCl3, and investigate reversal mechanisms such as damping switching and precessional switching. Our findings reveal that phononic magnetic fields enable robust and permanent magnetization reversal within nanoseconds, highlighting their potential for ultrafast magnetic control.

TT 13.4 Tue 10:15 H16

Chiral phonons in coupled magnon-phonon band structure — •Yelyzaveta Borysenko, Daniel Schick, and Ulrich Nowak — University of Konstanz, Konstanz, Germany

Coupling of spin and lattice degrees of freedom in magnetic materials is a key aspect for angular momentum based information processing. During ultrafast demagnetization, spin angular momentum can be transferred into the lattice creating chiral phonons even in simple centrosymmetric materials [1]. Spin-lattice coupling mechanisms involved in such processes can be approached using first principles calculations, which allow to determine leading energy terms for angular momentum exchange for different materials [2, 3]. Coupled spin-lattice dynamics is then described constructing angular momentum-conserving Hamiltonian linked to ab initio calculated model parameters [4].

Here, we linearize the equations of motion and calculate coupled magnon-phonon dispersions. We discuss how different coupling terms, e.g., of anisotropy or Dzyaloshiskii-Moriya type, can modify magnon and phonon dispersions, open up energy gaps, lift the degeneracy of modes, and lead to avoided crossings in the band structure.

TT 13.5 Tue 10:30 H16

Phonon Inverse Faraday effect from electron-phonon coupling — •Natalia Shabala and Matthias Geilhufe — Department of Physics, Chalmers University of Technology, 412 96 Gothenburg, Sweden

The phonon inverse Faraday effect describes the emergence of a DC magnetization due to circularly polarized phonons. From time-dependent second order perturbation theory and electron-phonon coupling we develop a microscopic formalism for phonon inverse Faraday effect. We arrive at a general and material-independent equation [1]. Using this equation for ferroelectric soft mode in $SrTiO_3$ gives an estimate of effective magnetic field which is consistent with recent experiments [2]. Hence, our approach is promising for shedding light into the microscopic mechanism of angular momentum transfer between ionic and electronic angular momentum, which is expected to play a central role in the phononic manipulation of magnetism.

Temperature dependent magnon-phonon coupling in YIG/GGG heterostructures — •J. Weber[1,2], M. Cherkasskii[3], F. Engelhardt[3,4,5], S.T.B. Goennenwein[6], S.Viola Kusminskiy[3,5], S. Geprägs[1], R. Gross[1,2,7], M. Althammer[1,2], and H. Huebl[1,2,7] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]School of Natural Sciences, Technical University of Munich, Munich, Germany — [3]Institute for Theoretical Solid State Physics, RWTH Aachen University, Aachen, Germany — [4]Department of Physics, University Erlangen-Nuremberg, Erlangen, Germany — [5]Max Planck Institute for the Science of Light, Erlangen, Germany — [6]Department of Physics, University of Konstanz, Germany — [7]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany

Magnon-phonon coupling in heterostructures has recently gained interest in the context of angular momentum conversion and angular momentum transport via phonons. A typical experimental setting is a bilayer system, where the magnetization dynamics of a magnetic thin film interacts with the elastic standing wave excitations of a non-magnetic bulk crystal. So far, bulk acoustic wave resonators consisting of a ferrimagnetic yttrium iron garnet (YIG) film deposited on a crystalline gadolinium gallium garnet (GGG) substrate have been studied at room temperature due to the favorable magnetic damping properties of YIG [1]. We present a temperature dependent analysis of the magnon-phonon coupling of a YIG/GGG bulk acoustic wave resonator.

TT 13.7 Tue 11:15 H16

Modeling of the preparation and conservation of coherent phonon (pseudo) angular momentum — •Olga Minakova[1], Maximilian Frenzel[1], Carolina Paiva[2], Joanna M. Urban[1], Michael S. Spencer[1], Martin Wolf[1], Dominik M. Juraschek[2,3], and Sebastian F. Maehrlein[1,4,5] — [1]FHI Berlin — [2]Tel Aviv University — [3]Eindhoven University of Technology — [4]HZDR — [5]TU Dresden

The angular momentum of lattice vibrations - phonon angular momentum - is an underexplored degree of freedom in solid-state systems. Recent experiments have shown that circularly-polarized THz pulses can coherently excite degenerate phonon modes, enabling the preparation of phonon angular momentum states. THz-Kerr effect spectroscopy provides a means to monitor these states by directly measuring vectorial phonon trajectories. To interpret such experiments, it is essential to understand the symmetry properties of the phonon modes that influence the driving and probing processes, as well as the conservation of angular momentum in the crystal lattice. Here, we model the generation and detection of coherent phonon angular momentum, revealing how crystal symmetry dictates the selection rules in the lattice. We show that the form of the Raman tensors associated with the phonon explains the phonon helicity observed in experiments, linking the discrete rotational symmetry of the material to the conservation of pseudo angular momentum in lattice vibrations.

TT 13.8 Tue 11:30 H16

Spin-spin interaction via chiral phonons — •Daniel Schick[1], Markus Weissenhofer[2,3], Akashdeep Kamra[4], and Ulrich Nowak[1] — [1]University of Konstanz, Konstanz, Germany — [2]Uppsala University, Uppsala, Sweden — [3]Free University of Berlin, Berlin, Germany — [4]University of Kaiserslautern-Landau, Kaiserslautern, Germany

Coupling between the magnetic degrees of freedom and phonons has emerged as a topic of great importance for explaining various magnetic phenomena, like ultrafast demagnetization processes [1], and the possibility to affect magnetization dynamics via phonon pumping [2]. We develop a tool to study spin-lattice coupling in atomistic simulations, which conserves total angular momentum. This allows us to precisely retrace the transfer of angular momentum between the spin and lattice systems. We demonstrate the emergence of an effective spin-spin interaction mediated by chiral phonons. This effect can arise from thermal phonons as follows. A spin may precess after coupling to a phonon, with this precession producing chiral phonons, which in turn, affect other spins. A similar effect can be achieved by driving a spin to induce chiral phonons. We discuss the dependence of this interaction on the temperature and strength of the spin-lattice interaction and discuss our findings within the context of phonon-enhanced magnon transport phenomena.

TT 13.9 Tue 11:45 H16

Ultrafast generation of multicolor chiral phonons in magnetic and ferroelectric materials — •Omer Yaniv[1] and Dominik M. Juraschek[2] — [1]Tel Aviv University, Tel Aviv, Israel — [2]Eindhoven University of Technology, Eindhoven, Netherlands

Terahertz pulses are powerful tools capable of initiating coherent vibrational motions in solids. Circularly polarized pulses can further excite chiral phonons. Such phonons carry an angular momentum and are able to generate magnetic moments leading to a varying range of phenomena, including the phonon Hall, phonon Zeeman, and phonon inverse Faraday effects. Our study investigates the coherent driving of phonons using multicolor laser pulses, leading to Lissajous trajectories of the atoms. We demonstrate the generation of such multicolor chiral phonons in BaTiO3, a task that presents significant challenges due to the requirement of an exact 1:2 phonon frequency ratio. Achieving this precise ratio is crucial for the generation of closed atomic Lissajous loops. However, we overcome this challenge by creating phonon polaritons with shifted frequencies through the use of optical cavities. This approach allows us to surpass the limitations imposed by the strict phonon frequency ratio. By carefully tuning the cavity parameters, we demonstrate a new pathway for controlling lattice vibrations at ultrafast timescales. We also explore how multicolor phonons tune magnetic properties in monolayer CrI3, a 2D material with strong spin-orbit coupling and ferromagnetism. By manipulating phonon dynamics, we examine the interaction between lattice vibrations and magnetic order.

TT 13.10 Tue 12:00 H16

Chiral Phonons induced by Magnon-Phonon Coupling — •Hannah Bendin[1], Alexander Mook[2], Ingrid Mertig[1], and Robin R. Neumann[1,2] — [1]Martin Luther University Halle-Wittenberg, Halle (Saale), Germany — [2]Johannes Gutenberg University, Mainz, Germany

Chiral phonons, the quasiparticles of circularly polarized lattice vibrations, have recently been investigated due to a range of emerging phenomena. Notably, chiral phonons carry nonzero angular momentum. However, the systems in which they occur still require extensive research. Chiral phonons may, for example, be

found in lattices with broken inversion symmetry. Alternatively, they can be induced by the coupling to magnons, the quasiparticles of spin excitations, thereby lifting time-reversal symmetry.

Here, we analyze how magnetoelastic coupling gives rise to magnon-phonon hybridization, which, in turn, generates phonon angular momentum. Conversely, we show how the phonon angular momentum and the spin of the magnons affects their coupling strength. This interplay between magnons and chiral phonons allows for the tunability of the phonon angular momentum.

TT 13.11 Tue 12:15 H16

Ultrafast laser-induced carrier and magnetization dynamics in $SrTiO_3$ from real-time time-dependent DFT — •Andri Darmawan, Markus E. Gruner, and Rossitza Pentcheva — Department of Physics, University of Duisburg-Essen

Recent experimental studies indicate electric-field-driven ferroelectricity [1] and multiferroicity [2] in the paradigmatic nonmagnetic band insulator $SrTiO_3$ in the terahertz regime. Following a comprehensive study of the optical [3] and x-ray absorption [4] spectra including quasiparticle and excitonic effects, here we explore the response of $SrTiO_3$ to laser excitation. Using real-time time-dependent density functional theory (RT-TDDFT) as implemented in the Elk code, we investigate both linear and circular polarized laser pulses. A complex site- and orbital-dependent temporal dynamics is observed with opposite sign of fluctuations at O and Ti sites and charge transfer from O $2p$ to Ti $3d$ states for linearly polarized light, that breaks dynamically inversion symmetry. Notably, circularly polarized pulses induce a finite transient magnetic moment which is absent for linearly polarized pulses. Funding by DFG within CRC1242 (project C02) and computational time at magnitUDE, amplitUDE and the Leibniz Supercomputer Center (project pr87ro) are gratefully acknowledged.

Phonon pumping in ferromagnet/nonmagnetic insulator hybrid systems — •Richard Schlitz[1], Luise Holder[1], Johannes Weber[2,3], Mikhail Cherkasskii[4], Fabian Engelhardt[4], Julie Střihavková[5], Matthias Althammer[2,3], Silvia V. Kusminskiy[4,6], Hans Huebl[2,3,7], and Sebastian T. B. Goennenwein[1] — [1]Department of Physics, University of Konstanz, Konstanz, Germany — [2]Walther-Meißner-Institut, BAdW, Garching, Germany — [3]School of Natural Sciences, TUM, Garching, Germany — [4]Institute for Theoretical Solid State Physics, RWTH Aachen University, Aachen, Germany — [5]Faculty of Mathematics and Physics, Charles University, Prague — [6]Max Planck Institute for the Science of Light, Erlangen, Germany — [7]Munich Center for Quantum Science and Technology, München, Germany

In ferromagnetic thin films, magnetization dynamics, e.g., driven by ferromagnetic resonance, can coherently couple to phonons. If a ferromagnetic film is deposited on a crystalline substrate with polished parallel faces, the sample stack forms a bulk acoustic resonator, leading to characteristic modifications of the magnetic resonance signal.

In this work, we show that the magnetoelastic coupling can mediate the hybridization of the coherent magnetization dynamics with longitudinal and transverse phonons, with a particular dependence on the orientation of the magnetic field. We extract the magnetoelastic coupling parameters and compare them with theoretical expectations. Our results show that both longitudinal and transverse phonons can be efficiently excited, depending on the magnetic field orientation.

TT 14: Spin Transport and Orbitronics, Spin-Hall Effects I (joint session MA/TT)

TT 14.1 Tue 9:30 H18

Topological orbital Hall effect caused by skyrmions and antiferromagnetic skyrmions — •Lennart Schimpf, Ingrid Mertig, and Börge Göbel — Institut für Physik, Martin-Luther-Universität Halle-Wittenberg

The topological Hall effect is a hallmark of topologically non-trivial magnetic textures such as magnetic skyrmions. It quantifies the transverse electric current once an electric field is applied and occurs as a consequence of the emergent magnetic field of the skyrmion. Likewise, an orbital magnetization is generated. Here we show that the charge currents are orbital polarized even though the conduction electrons couple to the skyrmion texture via their spin [1]. The topological Hall effect is accompanied by a topological orbital Hall effect even for s electrons without spin-orbit coupling. As we show, antiferromagnetic skyrmions and antiferromagnetic bimerons that have a compensated emergent field [2], exhibit a topological orbital Hall conductivity that is not accompanied by charge transport and can be orders of magnitude larger than the topological spin Hall conductivity.

TT 14.2 Tue 9:45 H18

Optimization of orbital torques in ferrimagnets and their relationship with Gilbert damping — •shilei ding, william legrand, hanchen wang, mingu kang, paul noel, and pietro gambardella — Department of Materials, ETH Zurich, 8093 Zurich, Switzerland

Application of an electric field can induce a non-equilibrium orbital angular momentum in conductive materials whose electronic bands have a k-dependent orbital character. This phenomenon can lead to the current-induced accumulation of orbital momenta in nonmagnetic layers, which can then diffuse into neighboring magnetic layers and interact with the local magnetization through spin-orbit coupling, giving rise to orbital torques. Conversely, the excitation of spin precession in a magnetic layer can give rise to an orbital current, resulting in orbital pumping and dissipation of angular momentum in the nonmagnetic layer. In the first part, I will present the efficacy of converting orbital to spin momenta in ferrimagnetic materials, specifically in the RE-TM ferrimagnet GdyCo100-y. This work underscores the mechanisms that facilitate orbital-to-spin conversion within a magnetic layer at the atomic level. In the second part, I will discuss how the Gilbert damping parameter correlates to spin and orbital torques in magnetic layers adjacent to Pt and CuOx layers, respectively. I will show that CoFe/CuOx bilayers exhibit a favorable combination of efficient orbital torque and minimal increase in Gilbert damping, which is promising for the implementation of orbital torque oscillators with reduced damping compared to spin torque oscillators.

TT 14.3 Tue 10:00 H18

Orbital magnetoresistance in insulating antiferromagnets — •Christin Schmitt[1], Sachin Krishnia[1], Edgar Galíndez Ruales[1], Takashi Kikkawa[2], Duc Tran[1], Timo Kuschel[1], Eiji Saitoh[2], Yuriy Mokrousov[1,3], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg-University Mainz, 55128 Mainz, Germany — [2]Department of Applied Physics, The University of Tokyo, Tokyo 113-8656, Japan — [3]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany

Insulating antiferromagnetic and ferrimagnetic materials are promising candidates for spintronic devices due to their intrinsic properties such as low damping [1]. Recently, orbital angular momentum (OAM) has emerged as a crucial concept in condensed-matter physics. Theoretical and experimental studies have highlighted that the orbital Hall effect (OHE) can enable orbital currents with efficiency orders of magnitude higher than that of spin Hall effects [2]. Here, we investigate magneto-resistance effects in magnetic systems [2,3]. We find that in TmIG the transverse magnetoresistance signal is increased significantly upon replacing Pt, a spin-current generator, by Cu*, a pure orbital-current generator. Further, we explore antiferromagnets with orbital magnetoresistance effects as pure orbital current is crucial for next generation pure orbitronics devices using abundant, cheap and environmentally friendly materials. [1] R. Lebrun, et al., Nature, 561, 222-225 (2018). [2] S. Ding, et al., Phys. Rev. Lett. 125, 177201 (2020). [3] S. Ding et al., Phys. Rev. Lett. 128, 067201 (2022).

TT 14.4 Tue 10:15 H18

Non-reciprocity in magnon mediated charge-spin-orbital current interconversion — •Sachin Krishnia[1], Omar Ledesma-Martin[1], Edgar Galindez-Ruales[1], Felix Fuhrmann[1], Duc Tran[1], Rahul Gupta[1], Marcel Gasser[1,2], Dongwook Go[1,2], Gerhard Jakob[1], Yuriy Mokrousov[1], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Germany — [2]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany

In magnetic systems, angular momentum is carried by the spin and orbital degrees of freedom. Non-local devices can be used to study angular momentum transport. They consist of parallel heavy-metal nanowires placed on top of magnetic insulators like yttrium iron garnet (YIG), facilitating the transmission of information by magnons, generated by the accumulation of spin at the interface, created via the spin Hall effect (SHE) and detected via the inverse SHE (iSHE). It has been demonstrated that these processes have comparable efficiencies when the role of the detector and injector is reversed, which points to reciprocity of the processes. However, we show that by adding Ru as a source of direct and inverse orbital Hall effect (OHE), the system no longer exhibits this reciprocity. Specifically, the generation of magnons via the combination of SHE and OHE

and detection via the iSHE is found to be about 35% more efficient than the inverse process for our system [1]. [1] O. Ledesma et al., arXiv:2411.07044 (2024).

TT 14.5 Tue 10:30 H18

Detection of dynamic x-ray magnetic linear dichroism in NiO — •Timo Kuschel[1], Johannes Demir[1], Olga Kuschel[2], Joachim Wollschläger[2], and Christoph Klewe[3] — [1]Bielefeld University, Germany — [2]Osnabrück University, Germany — [3]Advanced Light Source (ALS), Berkeley, USA

Spin transport through thin antiferromagnetic layers such as NiO has been studied by ferromagnetic resonance (FMR) spin pumping [1], spin Seebeck effect [2], non-local magnon spin transport [3] and x-ray detected FMR (XFMR) [4]. In all these experiments, the spin current has been identified in an adjacent Pt layer [1-3] or FeCo film [4] via inverse spin Hall effect or dynamic x-ray magnetic *circular* dichroism, respectively, after having the NiO layer already passed.

In this contribution, we study Fe_3O_4/NiO/Pt [5] by XFMR and present the identification of dynamic x-ray magnetic *linear* dichroism (XMLD) [6] at the Ni L edges directly in the NiO layer for FMR spin pumping in the adjacent Fe_3O_4 layer. We will analyze the XFMR response depending on the NiO thickness. Further, we will discuss coupling phenomena at the NiO-Fe_3O_4 interface vs. spin transport through the NiO layer as the origin of the dynamic XMLD response.

Manipulating the sign of the interlayer exchange coupling — •Nathan Walker — The Open University, Milton Keynes, UK

We demonstrate, using computer simulations and a non-equilibrium Greens function approach, that the sign of the out-of-equilibrium interlayer exchange coupling (ooeIEC) changes in the presence of an external bias. The system consists of a double barrier connected to an exchange coupled ferromagnetic trilayer. We find a strongly non-linear dependence of the spin current on voltage which results in the exchange coupled tri-layer switching between parallel and antiparallel configurations. Our results are in excellent agreement with earlier theoretical calculations, which predict an approximately 2π topological phase change of the (equilibrium) IEC. We believe that this could act as an energy efficient mechanism for magnetic switching which does not rely on spin-transfer torque (STT). There are potential applications to magnetoresistive random-access memory (MRAM), one of the principal contenders for a universal memory.

TT 14.7 Tue 11:00 H18

Harnessing Orbital Hall Effect in Spin-Orbit Torque MRAM — •J. Omar Ledesma Martin[1,2], Rahul Gupta[1], Chloé Bouard[2], Fabian Kammerbauer[1], Iryna Kononenko[1], Sylvain Martin[2], Gerhard Jakob[1,3], Marc Drouard[2], and Mathias Kläui[1,3] — [1]1 Institute of Physics, Johannes Gutenberg University Mainz, 55099, Mainz, Germany — [2]Staudingerweg 7 — [3]Department of Physics, Center for Quantum Spintronics, Norwegian University of Science and Technology, 7491, Trondheim, Norway

There is considerable potential in the Orbital Hall Effect (OHE) and the Spin Hall Effect (SHE) as electrical means for controlling the magnetization of spintronic devices. Here Ru stands out exhibiting an orbital Hall conductivity four times greater than the spin Hall conductivity of Pt. [1] This work assesses the efficiency of four distinct stacks in devices with perpendicular Magnetic Tunnel Junctions (MTJ). Following the formula Ta/OHE/Pt/[Co/Ni]x3/Co/MgO/CoFeB/Ta/Ru, where the OHE materials are Ru, Nb, and Cr. Additionally, a sample with Pt instead of OHE serves as a reference. The results demonstrate an improvement for the Ru samples, exhibiting higher damping-like torque and significantly lower switching current density compared to both the other samples and the Pt reference. These findings, including first-principle calculations, underscore the potential of Ru as an OHE material for enhancing the performance and power consumption of spintronic devices.

Spin and orbital Hall effect in metal systems: extrinsic vs. intrinsic contributions — •Sergiy Mankovsky and Hubert Ebert — LMU of Munich, 81377 Munich, Germany

Kubo's linear response formalism has been used to study the orbital Hall effect (OHE) for non-magnetic undoped and doped metallic systems, focusing on the impact of different types of disorder. Corresponding first-principles calculations of the orbital Hall conductivity (OHC) were performed making use of the KKR Green function method that allows in particular to monitor the impact of the vertex corrections on the OHC. The doping- and temperature-dependence of the OHC have been investigated and compared with corresponding results for the spin Hall conductivity (SHC). The temperature dependent properties of the OHC and SHC determined by thermally induced lattice vibrations (in non-magnetic materials) and spin fluctuations (in magnetic systems) have been accounted for making use of the alloy analogy model. For elemental systems at finite temperature a dominating role of the intrinsic contribution to the temperature-dependent OH and SH conductivities is found. In contrast, the OH and SH conductivities of doped systems at low temperatures are dominated by the SOC-driven extrinsic contributions strongly decreasing at higher temperatures due to the increasing impact of the electron-phonon scattering.

TT 14.9 Tue 11:45 H18

Simulations of spin transport in YIG — •Ben Schwanewedel, Moumita Kundu, and Ulrich Konstanz — Fachbereich Physik, Universität Konstanz, Konstanz, Germany

Being synthesized first in 1957, YIG has the lowest Gilbert damping among all known materials. This makes it interesting for spintronic applications and long-range spin transport. In YIG's complex unit cell Fe atoms occupy 20 sublattices leading to 20 magnon bands between 0 and 25 THz. We develop an atomistic spin model for YIG based on exchange interactions from Ref. [1], which were determined through neutron scattering. Further parameters were adapted from Ref. [2]. We varify our study through investigation of the magnon dispersion and comparing it to the results of Ref. [1].

We use atomistic spin dynamics simulations for the model above based on the stochastic Landau-Lifshitz-Gilbert equation to unravel its spin dynamics and spin transport properties. The spin transport is triggered by thermal gradients and and local magnetic fields and it is analyzed using an observable which is proportional to the magnon population. Also, magnon dispersions far from equilibrium are evaluated and discussed.

Orbital Hall effect accompanying quantum Hall effect — •Börge Göbel and Ingrid Mertig — Institut für Physik, Martin-Luther-Universität Halle-Wittenberg

The quantum Hall effect emerges when two-dimensional samples are subjected to strong magnetic fields at low temperatures: Topologically protected edge states cause a quantized Hall conductivity in multiples of e^2/h. Here we show that the quantum Hall effect is accompanied by an orbital Hall effect [1]. Our quantum mechanical calculations fit well the semiclassical interpretation in terms of "skipping orbits". The chiral edge states of a quantum Hall system are orbital polarized akin to an orbital version of the quantum anomalous Hall effect in magnetic systems. The orbital Hall resistivity scales quadratically with the magnetic field making it the dominant effect at high fields.

The discussion can be generalized to systems with effective magnetic fields: The topological Hall effect caused by the emergent field of topological spin textures, such as magnetic skyrmions, is accompanied by an orbital Hall effect, as well [2].

TT 14.11 Tue 12:15 H18

Large Spin Hall Angle in Mn-based Antiferromagnetic Alloys — •Nabil Menai[1], Martin Gradhand[2], and Derek Stewart[3] — [1]H. H. Wills Physics Laboratory, University of Bristol, Tyndall Ave, BS8-1TL, UK — [2]Institute of Physics, Johannes Gutenberg University Mainz, Staudingerweg 7, 55128 Mainz, Germany — [3]Western Digital Research Center, San Jose, California 95119, USA

Antiferromagnets (AFMs) have emerged as crucial materials for spintronic technologies for their ability to host spin-dependent transport phenomena, despite their zero net magnetization. Their robustness against external magnetic fields and ultrafast spin dynamics make them ideal for efficient spin-charge interconversion. In this theoretical study, we use density functional theory and Greens function methods to investigate the transport properties of Mn-based binary alloyed AFMs. Our focus is on the total spin Hall conductivity (SHC), accounting for both the intrinsic contributions from Berry curvature and the extrinsic effects from skew scattering and side-jump mechanisms. The objective is to identify AFM materials that exhibits a high spin Hall angle (SHA); with an efficient charge-to-spin Hall current conversion ratio. Our results reveal that doping MnPt with Ir significantly enhances the SHA, achieving a value of 8% at room temperature. In contrast, doping with Pd offers temperature stability with lower SHA values. Additionally, we examine the effects of substituting Mn atoms with magnetic transition metals such as Fe and Ni. These findings underscore the potential of antiferromagnetic alloys for efficient spin current generation.

TT 14.12 Tue 12:30 H18

Competing ordinary and Hanle magnetoresistance in Pt and Ti thin films — •Sebastian Sailler[1], Giacomo Sala[2], Denise Reustlen[1], Richard Schlitz[1], Min-Gu Kang[2], Pietro Gambardella[2], Sebastian T.B. Goennenwein[1], and Michaela Lammel[1] — [1]Department of Physics, University of Konstanz — [2]Department of Materials, ETH Zurich

One of the key elements in spintronics research is the spin Hall effect, allowing to generate spin currents from charge currents. A large spin Hall effect is observed in materials with strong spin orbit coupling, e.g. Pt. Recent research suggests the existence of an orbital Hall effect, the orbital analogue to the spin Hall effect, which also arises in weakly spin orbit coupled materials like Ti, Mn or Cr. In any of these materials, a magnetic field perpendicular to the spin or orbital accumulation leads to additional Hanle dephasing and thereby the Hanle magnetoresistance. Here, we studied the magnetoresistance (MR) of Pt thin films over a wide range of thicknesses. Careful evaluation shows that the MR of our textured samples is dominated by the so-called ordinary MR, while the Hanle effect does not play a significant role. Analyzing the intrinsic properties of Pt films deposited by different groups, we find that next to the resistivity, also the structural properties of the film influence which MR dominates. We further show that this correlation can also be found in orbital Hall active materials like Ti. We conclude that in all materials exhibiting a spin or orbital Hall effect, the Hanle MR and the ordinary MR coexist, and that the sample's purity and crystallinity determines which MR dominates.

TT 14.13 Tue 12:45 H18

Orbital Hanle magnetoresistance in Mn thin films — •Min-Gu Kang, Federica Nasr, Giacomo Sala, and Pietro Gambardella — Department of Materials, ETH Zurich, 8093 Zurich, Switzerland

Momentum-space orbital texture, or orbital character of electrons, enables the orbital Hall effect (OHE), a current-induced flow of nonequilibrium orbital angular momentum in centrosymmetric systems with negligible spin-orbit coupling. This orbital current, which can be orders of magnitude larger than its spin counterpart, offers transformative potential for spin-orbitronics, yet the mechanisms of orbital relaxation remain unclear. In this work, we present temperature-dependent orbital Hanle magnetoresistance and associated orbital relaxation mechanisms in Mn thin films. The results clearly show that the orbital Hanle magnetoresistance depends on the structure of the Mn thin films and can be associated with competing Dyakonov-Perel and Elliott-Yafet orbital relaxation effects. Our study highlights the critical role of orbital relaxation in determining the magnitude of current-induced orbital effects in 3d transition metal films.

TT 14.14 Tue 13:00 H18

Tuning of spin transport properties in 2D ferromagnet VSe_2 by structural polytypes of TaS_2 electrodes — •Biplab Sanyal and Masoumeh Davoudiniya — Department of Physics & Astronomy, Ångströmlaboratoriet, Uppsala University, Box-516, 75120 Uppsala, Sweden

2D magnets and their heterostructures are promising materials for future spintronic applications. Here, we present a study of spin transport through a ferromagnetic monolayer of 1T-VSe_2 with two structural polytypes of TaS_2 electrodes stacked in van der Waals heterostructures. Using density functional theory coupled with the nonequilibrium Green function framework, we explore the impact of TaS_2 electrode polytypes on the device's quantum transport properties. We observe that devices with 1T-TaS_2 electrodes exhibit higher spin-dependent transmission compared to 2H-TaS_2 electrodes. Incorporating MoS_2 as a tunnel barrier, anisotropic tunnel magnetoresistance enhances significantly, reaching 168% for the 1T-device and 1419% for the 2H-device. Spin-transfer torque (STT) analysis shows that its magnitude is highest at 90° (−702 μeV/V for 1T and −1561 μeV/V for 2H devices) and decreases towards 180°. The 1T-device shows superior performance with lower Gilbert damping, reduced critical current density and voltage for magnetization switching, compared to the 2H-device, which requires significantly higher current and voltage. Our predictions reveal the potential of 1T-VSe_2-based heterostructures for advanced spintronic applications.

Solving Many-Body Problems on Quantum Computers — •Benedikt Fauseweh — TU Dortmund University, Otto-Hahn-Str 4, 44227 Dortmund

In this talk, I will provide an overview on the state-of-the art in digital quantum simulations (DQS) for many-body systems [1]. Modern quantum computers present challenges due to the noisy nature of these systems. Novel quantum algorithms, especially hybrid classical-quantum algorithms [2], have been developed to fit the specifications of such devices. For DQS, the prevailing question today is: What problems are amenable to be simulated on noisy quantum computers? I will discuss recent work on simulating quantum many-body dynamics [3], algorithmic advances to detect ground state phase transitions and the potential of stabilizing exotic non-equilibrium phases of matter, e.g., discrete time crystals [4], using quantum-classical feedback.

TT 15.2 Tue 10:00 H31

Fast Initialisation of Bell States in Kerr Cat Qubits — •Miriam Resch[1], Ciprian Padurariu[1], Björn Kubala[1,2], and Joachim Ankerhold[1] — [1]ICQ and IQST, Ulm University, Ulm, Germany — [2]Institute of Quantum Technologies, German Aerospace Center (DLR), Ulm, Germany

Schrödinger cat states play an important role for applications in continuous variable quantum information technologies. As macroscopic superpositions they are inherently protected against certain types of noise making cat qubits a promising candidate for quantum computing [1]. It has been shown recently that cat states occur naturally in driven Kerr parametric oscillators (KPOs) as degenerate ground states with even and odd parity that are adiabatically connected to the respective Fock states by switching off the drive [2]. To perform operations with several cat qubits one crucial task is to create entanglement between them. This can be done by initializing the cats from entangled Fock states or by performing operations directly in cat space. Here we show efficient transformations of multi mode cat states through adiabatic and diabatic switching between Kerr-type Hamiltonians with degenerate ground state manifolds and show how those transformations can be used to directly initialize the cat states as entangled Bell states.

TT 15.3 Tue 10:15 H31

Impurity models in waveguide QED — •Adrian Paul Misselwitz[1,2,3], Jacquelin Luneau[1,2,3], and Peter Rabl[1,2,3] — [1]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [2]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany

In this talk I will discuss photonic impurity models, which emerge from the coupling of two-level atoms to a 1D photonic waveguide in the presence of strong photon-photon interactions. Such models appear, for example, in the context of superconducting microwave circuits, where Josephson junctions give rise to strong Kerr-nonlinearities at the few-photon level. In this case, the resulting competition between photon-photon repulsion and the attractive atom-photon interaction leads to the formation of localized bound states with a well-defined photon number and, under certain conditions, the build-up of long-range, algebraically decaying correlations between the impurity sites. I will show how these strongly-correlated phases of light and matter can be simulated efficiently with the help of large-scale tensor network simulations and discuss a possible explanation of the observed long-range correlations in terms of a simpler, effective Bose-Hubbard model.

TT 15.4 Tue 10:30 H31

Voltage without current — Christina Koliofoti and •Roman-Pascal Riwar — Peter Grünberg Institut, Forschungszentrum Jülich, 52425 Jülich, Germany

Superconductors famously give rise to equilibrium currents without voltages. But can the converse exist? We argue that voltage-dependent Josephson effects generically provide exactly such a classical time crystal behaviour – bringing with them known conceptual issues, such as discontinuous "brick-wall" trajectories, and ill-defined canonical quantization. With the example of quantum phase slip junctions in the presence of electro-motive forces, we resolve these lingering problems. Decoherence provokes a phase transition from a quantum Hamiltonian (non-Lagrangian) system with nonlinear Cooper-pair tunneling to a Lagrangian (non-Hamiltonian) classical time crystal. Our work illustrates that direct canonical quantization of low-energy theories may fail, and that the nonadiabaticity of brick-wall trajectories leads to a temporary break down of the classical theory even for strong decoherence.

TT 15.5 Tue 10:45 H31

Of gyrators and anyons I - Anyons — •Oleksiy Kashuba, Ram Mummadavarapu, and Roman-Pascal Riwar — Peter Grünberg Institut, Forschungszentrum Jülich, 52425 Jülich, Germany

In recent years there have emerged various ideas to create and control topological excitations in superconducting devices. Notably, nontrivial Chern bands were predicted to exist in conventional multiterminal Josephson junctions, but the Chern number is yet to be experimentally verified, and the pathway towards feasible quantum hardware applications is unclear. In this talk, we show how generic multiterminal circuits can be expressed as gyrator networks with quantized gyration conductance, giving rise to anyonic excitations carrying q/p fractional fluxes (q, p integer), measurable via a fractional Aharonov-Casher phase. We further present concepts for error correction protocols, and quantum simulations of interacting fermionic (or generally anyonic) many-body systems—notably, introducing the possibility to mimic fractional quantum Hall physics or to implement local fermionic models that explicitly break the Wigner superselection rule. The latter indicates that a full understanding of multiterminal circuits will require grappling with a virtually unexplored class of parity-breaking quantum field theories.

TT 15.6 Tue 11:00 H31

Of gyrators and anyons II - Gyrators — •Ram Mummadavarapu, Oleksiy Kashuba, and Roman-Pascal Riwar — Peter Grünberg Institut, Forschungszentrum Jülich, 52425 Jülich, Germany

In recent years, significant progress has been made in developing methods to create and control topological excitations in superconducting devices. Among these, the prediction of nontrivial Chern bands in conventional multiterminal Josephson junctions stands out as a particularly promising development. However, despite theoretical predictions, the experimental verification of the nontrivial Chern number remains an open challenge. Based on the realization that multiterminal junctions generically map on special gyrator networks hosting anyons (see also talk "Of gyrators and anyons I"), we here present circuit-specific band-engineering techniques to minimize parasitic anyon interactions. We show in particular how circular scattering in three-terminal quantum dot chains gives rise to a flat topological ground state, where disorder mitigates Chern number fluctuations and the quasiparticle continuum provides a work-around for known limitations to create nontrivial flat bands. Further band-engineering strategies are presented where the superconducting phase is scrambled either via parallelization or dissipative phase transitions.

TT 15.7 Tue 11:30 H31

Minimal SU(2) models for analog simulation in small-scale superconducting quantum devices — •Lucia Valor[1,2,3], Jacquelin Luneau[1,2,3], Klaus Liegener[1,2,3], Stefan Filipp[1,2,3], and Peter Rabl[1,2,3] — [1]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [2]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany

Lattice gauge theories (LGTs) are essential tools for studying fundamental interactions in particle physics and have broad applications in condensed matter physics and quantum information. Quantum simulation of non-Abelian theories remains challenging. Recent research on the analog simulation of LGTs has focused on scalable atomic quantum platforms. In contrast, we propose minimal SU(2) LGT models for analog simulation, tailored for small-scale superconducting quantum hardware. By adopting concepts from quantum optics, our approach emphasises coarse-grained systems that capture internal degrees of freedom and relevant non-Abelian properties with just a few qubits, bypassing the scalability demands of fine-grained models. We explore unique features of these non-Abelian systems and provide a circuit design for their experimental realisation. This work advances the study of non-Abelian gauge theories and introduces a novel method for implementation of LGTs using superconducting qubits.

TT 15.8 Tue 11:45 H31

Secure squeezed state microwave quantum communication with spin ensembles (part 1) — •Florian Fesquet[1,2], Patricia Oehrl[1,2], Kedar E. Honasoge[1,2], Maria-Teresa Handschuh[1,2], Achim Marx[1], Rudolf Gross[1,2,3], Hans Huebl[1,2,3], and Kirill G. Fedorov[1,2,3] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany — [2]School of Natural Sciences, Technical University of Munich, 85748 Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany

Quantum key distribution (QKD) holds the promise of delivering unconditionally secure distribution of classical keys between remote parties. So far, its implementation in the microwave regime, which is frequency-compatible with superconducting quantum circuits, has been missing. Here, we present the realization of a continuous-variable QKD protocol using propagating squeezed microwave states and demonstrate a finite-size security. In order to store these states for quantum memory applications, we investigate a scheme based on the excitation of high-coherence spin ensembles by microwave quantum signals. Here, we focus on a phosphorus donor electron spin ensemble hosted in isotopically engineered silicon. Our measurements indicate a successful coupling of microwave squeezed states to the spin ensemble with an estimated efficiency of 36%.

TT 15.9 Tue 12:00 H31

Secure squeezed state microwave quantum communication with spin ensembles (part 2) — •Patricia Oehrl[1,2], Florian Fesquet[1,2], Tahereh Parvini[1,2,3], Maria-Teresa Handschuh[1,2], Kedar E. Honasoge[1,2], Achim Marx[1], Nadezhda Kukharchyk[1,2,3], Rudolf Gross[1,2,3], Kirill G. Fedorov[1,2,3], and Hans Huebl[1,2,3] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]School of Natural Sciences, Technical University of Munich, Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany

Solid-state spin ensembles offer exceptional coherence times at low temperatures and transition frequencies in the GHz range, which makes them ideal for interfacing with superconducting quantum circuits. Moreover, they are promising candidates for the storage of microwave quantum states, providing great potential for quantum memory and quantum sensing applications. Here, we investigate a phosphorus donor electron spin ensemble hosted in silicon. It is coupled to a superconducting microwave resonator and probed at millikelvin temperatures as well as moderate magnetic fields. We investigate the efficiency of photon absorption for coherent and squeezed microwave signals. To this end, we use continuous wave and pulsed electron spin resonance protocols. We verify our results with an input-output model of our hybrid system and discuss the storage efficiency of microwave signals.

We acknowledge financial support from the Federal Ministry of Education and Research of Germany (project number 16KISQ036).

Quantum thermodynamics of non-Markovian Otto cycles using the principle of minimal dissipation — •Salvatore Gatto[1], Alessandra Colla[2], Heinz-Peter Breuer[1], and Michael Thoss[1] — [1]University of Freiburg — [2]Università degli Studi di Milano

A central challenge in quantum thermodynamics revolves around establishing a consistent and universally accepted definition for work, heat, and entropy production in open quantum systems subjected to thermal reservoirs. A recently developed approach, known as principle of minimal dissipation [1,2], leads to a unique decomposition of the quantum master equation into coherent and dissipative dynamics, allowing to identify uniquely the contributions describing work and heat. In this contribution, we apply this approach to investigate the thermodynamic characteristics of the quantum Otto cycle[3] of a single-impurity Anderson model, with a particular focus on memory effects and strong system-bath couplings. The study uses the hierarchical equations of motion approach (HEOM), which allows a numerically exact simulation of nonequilibrium transport in general open quantum systems involving multiple bosonic and fermionic environments [4].

TT 15.11 Tue 12:30 H31

Non-Hermitian dynamics close to exceptional points — •Aisel Shiralieva, Grigorii Starkov, and Björn Trauzettel — University of Würzburg, Würzburg, Germany

Exceptional points (EPs), which are degeneracies occurring in both open classical and quantum systems, play a crucial role across numerous areas of physics. This work examines the behavior of dissipative systems with N levels, with a particular emphasis on non-Hermitian qubits and qutrits. These systems are of interest due to recent experimental studies involving a driven non-Hermitian superconducting qubit embedded within a three-level structure, where the ground state serves as an "effective bath". Although significant progress have been made in understanding EPs, the precise connection between their occurrences in non-Hermitian Hamiltonians and in the Lindblad formalism remains unclear, especially if quantum jumps are treated as perturbations. Our results reveal how EPs in these two frameworks relate to each other and illustrate how perturbations can either lift the degeneracy or eliminate the EPs entirely in the Lindblad formalism.

TT 15.12 Tue 12:45 H31

Post-measurement Quantum Monte Carlo — •Kriti Baweja[1], David Luitz[1], and Samuel Garratt[2] — [1]Institute of Physics, Nussalle 12 53115, Bonn, Germany — [2]Department of Physics, University of California, Berkeley, CA 94720, USA

We study the effects of extensive measurements on many-body quantum ground and thermal states using Quantum Monte Carlo (QMC). Measurements generate density matrices composed of products of local nonunitary operators, which we expand into operator strings via a generalized stochastic series expansion (SSE). This 'post-measurement SSE' employs importance sampling of operator strings contributing to a measured thermal density matrix. Our algorithm is applied to the spin-1/2 Heisenberg antiferromagnet on a square lattice. Thermal states of this system exhibit SU(2) symmetry, which is preserved through SU(2)-symmetric measurements. We identify two classes of post-measurement states: one where correlations can be efficiently computed using determinis-

tic loop updates, and another where SU(2)-symmetric measurements induce a QMC sign problem in any site-local basis. Using this approach, we demonstrate measurement-induced phenomena, including the creation of long-range Bell pairs, symmetry-protected topological order, and enhanced antiferromagnetic correlations. This method offers a scalable way to simulate measurement-induced collective effects, providing numerical insights to complement experimental studies. Our work opens the door to exploring how measurements influence many-body quantum systems, enabling deeper understanding of their dynamics. [1] arXiv:2410.13844

TT 15.13 Tue 13:00 H31

Zero-temperature magnon-mediated long-range entanglement in Heisenberg chain with magnetic impurity — •Marius Melz and Jamal Berakdar — Martin-Luther-Universität Halle -Wittenberg

The understanding of many-body entanglement in solid-state systems is of interest both for fundamental and practical reasons. In this work, a spin-1/2 Heisenberg chain is coupled to a chiral magnetic impurity, acting as a magnon scatterer. The spatial entanglement structure of the ground state and its effect on the propagation of local magnons is characterized by the spatially resolved bipartition entropy and logarithmic negativity. The ground state exhibits an entanglement transition at a critical magnetic bias field. We find that magnon scattering generates steady-state long-range entanglement between two scattering regions. Furthermore, it is demonstrated that this effect is significantly amplified in the high-entanglement phase.

TT 16: Superconductivity: Properties and Electronic Structure II

Layer-thickness and substrate effects on superconductivity in epitaxial FeSe films on BLG/SiC(0001) — •yongsong wang[1], haojie guo[1], ane etxebarria[2], sandra sajan[1], sara barja[1,2,3,4], and miguel moreno ugeda[1,3,4] — [1]Donostia International Physics Center, San Sebastián, Spain — [2]Department of Polymers and Advanced Materials, University of the Basque Country, San Sebastián, Spain — [3]Centro de Física de Materiales, San Sebastián, Spain — [4]Ikerbasque, Basque Foundation for Science, Bilbao, Spain

The layered nature and simple structure of FeSe reveal this iron-based superconductor as a unique building block for the design of artificial heterostructure materials. While superconductivity develops in ultrathin films of FeSe on $SrTiO_3$ substrates, it remains unclear whether it can be developed on more chemically inert, layered materials such as graphene. Here, we report on the characterization of the structural, chemical and electronic properties of few-layer FeSe on bilayer graphene grown on SiC using low-temperature scanning tunneling microscopy/spectroscopy (STM/STS) and X-ray photoelectron spectroscopy (XPS). STM imaging of our FeSe films with thicknesses up to three layers exhibit the tetragonal crystal structure of bulk FeSe, which is supported by XPS spectra consistent with the FeSe bulk counterpart. While our STS measurements at 340 mK reveal a metallic character for few-layer FeSe on BLG/SiC, they show an absence of superconductivity, as the low-lying electronic structure exhibits a spatially anisotropic dip-like feature robust against magnetic fields. Superconductivity in FeSe/BLG/SiC, however, emerges for thicker films with $T_c = 6$ K.

TT 16.2 Tue 9:45 H32

Lattice dynamical studies in the unconventional superconductor: LiFeAs — •Akshay Tewari[1], Sabine Wurmehl[2], Bernd Büchner[2], Andrea Piovano[3], and Markus Braden[1] — [1]II.Physics Institute, Universität zu Köln, Zülpicher Strasse 77, 50937 Köln, Germany — [2]IFW Dresden, D-01171 Dresden, Germany — [3]ILL, 71 avenue des Martyrs, 38000 Grenoble, France

LiFeAs crystallizes in a tetragonal structure(P4/nmm) and is superconducting below T_c=18K. Unlike other iron pnictides, LiFeAs does not exhibit long-range magnetic order, but has AFM fluctuations at incommensurate positions. Studies suggest that superconductivity in LiFeAs is driven by electronic correlations but a contribution from electron phonon coupling is still debated. We have studied the phonon dispersion of LiFeAs using inelastic neutron scattering on large single crystals to search for anomalies in the dispersion which are signatures of electron phonon coupling. We could determine almost all branches along main symmetry directions by analyzing the data with force-model lattice dynamical calculations. Temperature dependencies of specific phonon modes were also examined. Our experimental results provide significant differences to the DFT calculations previously reported[1,2]. No pronounced instability was observed but strong relative energy shifts of 6% were detected for specific modes in the temperature dependent scans. The overall dispersion fits the lattice dynamical model and is also supported by more recent DFT calculations.

TT 16.3 Tue 10:00 H32

NMR evidence of pseudogap and against spin magnetism in the time-reversal symmetry breaking state of $Ba_{1-x}K_xFe_2As_2$ — •F. Bärtl[1], F. Caglieris[2,3,4], Y. Li[5], Q. Hu[5], Y. Zheng[5], C.-H. Yim[5], J. Wosnitza[1,6], R. Sarkar[2], H.-H. Klauss[2], E. Babaev[7], J. Garaud[8], H. Kühne[1], and V. Grinenko[5] — [1]HLD-EMFL, HZDR, Dresden — [2]University of Genoa — [3]CNR-SPIN, Genoa — [4]IFW, Dresden — [5]TDLI, Shanghai Jiao Tong University — [6]IFMP, TU Dresden — [7]Department of Physics, KTH, Stockholm — [8]Institut Denis Poisson, Université de Tours

Recently, we focused on the investigation of samples from the narrow doping range of $0.7 \leq x \leq 0.8$ in the hole-doped superconductor $Ba_{1-x}K_xFe_2As_2$. Here, the proximity to a Lifshitz transition results in a multiband $s+is$ superconducting state, which spontaneously breaks time-reversal symmetry (BTRS), manifested as spontaneous currents around non-magnetic impurities. This is theoretically predicted and was experimentally revealed by μ^+SR measurements, where the depolarization rate below T_c is only non-zero in the mentioned narrow doping regime. Moreover, the μ^+SR together with Nernst-effect measurements suggest the emergence of the BTRS already at a temperature $T_c^{Z_2} > T_c$, which indicates a behavior beyond mean-field approximation, described by a four-fermion order parameter, hence termed quartic metal. Here, we present ^{75}As NMR spectroscopy and relaxometry measurements of a sample with $x = 0.77$, which contradict the presence of conventional spin magnetism and hint at pseudogap behavior in the critical regime.

TT 16.4 Tue 10:15 H32

Observation of saddle point nesting driven charge order on the surface of a 122-type iron-based superconductors — •Yu Zheng — Tsung Dao Lee Institute, Shanghai Jiao Tong University, 1 Lisuo Road, Shanghai, 201210

Unconventional superconductivity is known for intertwining with other correlated states, making the exploration for new intertwined orders highly important for understanding the mechanism of unconventional superconductivity. Spin and nematic orders are widely observed in the iron-based superconductors (FeSCs). However, evidence for charge order in the phase diagrams of FeSCs is rarely found. Employing STM and DFT, here we demonstrate,through expanding the phase diagram of $Ba_{1-x}K_xFe_2As_2$ to the heavily hole doped regime by surface doping, the formation of a CDW order on the As-terminated surface of $Ba_{0.23}K_{0.77}Fe_2As_2$, whose emergence suppresses superconductivity completely, indicating direct competition between the two. Notably, the wavevector of the charge order matches with the nesting vector between the near-EF saddle points, suggesting saddle-point nesting as its driving mechanism.

TT 16.5 Tue 10:30 H32

Long-term stability of irradiation-induced defects in $YBa_2Cu_3O_{7-\delta}$ thin films — •Bernd Aichner[1], Sandra Keppert[2], Philip Rohringer[1], Marius-Aurel Bodea[2], Benedikt Müller[3], Max Karrer[3], Reinhold Kleiner[3], Edward Goldobin[3], Dieter Koelle[3], Johannes David Pedarnig[2], and Wolfgang Lang[1] — [1]Faculty of Physics, University of Vienna, Wien, Austria — [2]Institute of Applied Physics, Johannes Kepler University Linz, Linz, Austria — [3]Physikalisches Institut, Center for Quantum Science (CQ) and LISA$^+$, University of Tübingen, Tübingen, Germany

Helium ion irradiation is the method of choice for creating sub-100 nm structures in cuprate superconductors suitable for pinning magnetic flux quanta.

In this presentation, we address the stability of irradiation-induced defects for irradiation performed in an ion implanter as well as in a helium ion microscope. Annealing experiments allow us to extract the activation energy for the diffusion of displaced oxygen atoms back to their original sites in the material's crystal structure. Additionally, a long-term study indicates that vortex-matching features caused by a regular array of irradiation-induced defect columns are still present after about six years of sample storage, a strong hint for the stability of the defects created by irradiation. These findings may be an important ingredient for future applications of helium ion irradiation in the production process of superconducting electronics.

TT 16.6 Tue 10:45 H32

Two-fluid model analysis of the terahertz conductivity of YBaCuO samples: Optimally doped, underdoped and overdoped cases — •Christelle Kadlec[1], Wen-Yen Tzeng[2], Chih-Wei Luo[3], Jiunn-Yuan Lin[3], and Michal Šindler[1] — [1]Institute of Physics, Prague, Czech Republic — [2]National Formosa University, Yunlin, Taiwan — [3]National Yang Ming Chiao Tung University, Hsinchu, Taiwan

The conductivity of a high-quality overdoped $Y_{0.7}Ca_{0.3}Ba_2Cu_3O_{7-\delta}$ film and of underdoped and optimally doped films of its parent compound $YBa_2Cu_3O_{7-\delta}$ was measured using time-domain terahertz spectroscopy. In the normal state, the frequency dependence of the complex conductivity is described by the Drude model. Below the critical temperature T_c, the two-fluid model was successfully employed to fit all the spectra, from 5 K up to T_c. The temperature behaviour of fundamental parameters such as the scattering rate $1/\tau$, the superfluid (normal) fraction f_s (f_n) and the complex conductivity σ was investigated at given frequencies. We observed that a fifth of the electrons do not condense to the superfluid fraction even at 5 K for the optimally doped and overdoped samples. The real part of the conductivity $\sigma_1(T)$ exhibits a peak for low frequencies. It can be observed for all three compounds and its exact shape depends on the quality of the sample. A further analysis shows that this peak is a consequence of the competition between the scattering time $\tau(T)$ and the superfluid fraction $f_s(T)$.

TT 16.7 Tue 11:15 H32

Higgs spectroscopy on the interplay of superconductivity and charge density waves — •Liwen Feng[1,2], Tim Priessnitz[2], Thales De Oliveira[3], Jan-Christoph Deinert[3], Sergey Kovalev[3], Hao Chu[4], and Stefan Kaiser[1] — [1]TUD Dresden University of Technology, Germany — [2]Max Planck Institute for Solid State Research, Stuttgart, Germany — [3]Helmholtz-Zentrum Dresden-Rossendorf, Germany — [4]Shanghai Jiao Tong University, China

Superconductivity (SC) and charge density wave (CDW) often coexist. In the framework of Higgs Spectroscopy, we use high-field terahertz pulses to coherently drive the corresponding Higgs and CDW amplitude modes and investigate their interplay directly in the third harmonic generation (THG) signals. Our findings reveal that the interaction between CDW fluctuations and Higgs oscillations lead to a Fano resonance [1]. We will show that we can characterize the interplay by directly investigating the relative phase responses of these modes in the time-domain THG signal [1]. We will discuss competing interactions of SC with long-range CDW order in 2H-$NbSe_2$ [1] and hole-doped cuprate $La_{2-x}Sr_xCuO_4$, interaction with short-range CDW order in the electron-doped cuprate $La_{2-x}Ce_xCuO_4$, and a noninteracting scenario in the Bismuthate superconductor $Ba_{1-x}Rb_xBiO_3$.

TT 16.8 Tue 11:30 H32

Dynamics of non-thermal states in a cuprate superconductor revealed by mid-infrared three-pulse spectroscopy — •Angela Montanaro[1,2,3], Enrico Maria Rigoni[1,2], Giacomo Jarc[1,2], Viktor Kabanov[4], and Daniele Fausti[1,2,3] — [1]University of Trieste, 34127 Trieste, Italy — [2]Elettra Sincrotrone Trieste, 34127 Trieste, Italy — [3]University of Erlangen-Nürnberg, 91058 Erlangen, Germany — [4]Jožef Stefan Institute, 1000 Ljubljana, 25123 Brescia, Italy

Unconventional cuprate superconductors exhibit anomalous high-frequency electrodynamics compared to standard BCS systems. In BCS superconductors, spectral weight redistribution occurs only near the superconducting gap energy, but in cuprates, changes extend to energies two orders of magnitude higher. This implies that high-energy electronic excitations might influence the pairing mechanism.

In this work, we disentangle the effects of high- and low-photon energy excitations in a prototype cuprate system. We set up a technique which combines two pump pulses having substantially different photon energy: a visible pulse much more energetic than the superconducting gap and a mid-infrared pump with photon energy smaller than the gap. Our findings show that the two photoexcitations have a different effect on the condensate electrodynamics. Moreover, we found that the overall response of the system strongly depends on the time-order of the two photoexcitations. This allowed us to constrain the lifetime of photoinjected carriers and ultimately the recovery time of the condensate.

TT 16.9 Tue 11:45 H32

Hidden antiferromagnetism and pseudogap from fluctuating stripes — •Henning Schlömer[1], Annabelle Bohrdt[2], and Fabian Grusdt[1] — [1]Department of Physics, Ludwig-Maximilians-Universität München, Theresienstr. 37, 80333 — [2]University of Regensburg, Universitätsstr. 31, 93053 Regensburg

One of the central mysteries of hole-doped cuprates is the pseudogap phase, whose unusual properties are believed to be essential for understanding high-temperature superconductivity. While a broad variety of theoretical proposals have been put forward in the past decades, a unified view connecting the pseudogap to other observed phases, like antiferromagnetic (AFM) and stripe phases, has remained elusive. In this talk, I will propose a scenario in which the the AFM, stripe, and pseudogap phases all share a common origin: The spins in the material form an ordered AFM background, on top of which fluctuating domain walls exist that can obscure long-range order. I will argue that these fluctuating domain walls are at the heart of the pseudogap phase: They hide magnetic order in real space, leaving only short-range AFM correlations detectable in experiments. Furthermore, these fluctuations can give rise to a topological phase (an odd Z2 spin liquid) that supports a small Fermi surface, consistent with experimental data. At a (hidden) quantum critical point, hidden AFM order fully dissolves, restoring spin symmetry without a divergent correlation length.

TT 16.10 Tue 12:00 H32

Direct evidence of pairing up to the pseudogap energy in cuprate high-temperature superconductors — Jiasen Niu[1,2], Maialen Ortego Larrazabal[3], Thomas Gozlinski[1,2], •Yudai Sato[1,2], Koen M. Bastiaans[4], Tjerk Benschop[1], Jian-Feng Ge[1,5], Yaroslav M. Blanter[4], Genda Gu[6], Ingmar Swart[3], and Milan P. Allan[1,2] — [1]Leiden Institute of Physics, Leiden University — [2]Fakultät für Physik, Ludwig-Maximilians-Universität — [3]Debye Institute of Nanomaterials Science — [4]Kavli Institute of Nanoscience, Delft University of Technology — [5]Max Planck Institute for Chemical Physics of Solids — [6]Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory

In cuprate high-temperature superconductors, a pseudogap state is observed in a specific region of the phase diagram. Since it exists between the Mott insulating and superconducting phases, the origin of the peudogap is thought to be associated with electron pairing and/or a locally ordered state. Despite extensive studies, however, a definitive explanation remains elusive. Shot-noise experiments, which can directly detect electron pairing, hold the potential to resolve this long-standing debate. In this presentation, I will report on local shot-noise measurements on the unconventional superconductor $Bi_2Sr_2Ca_2CuO_{8+\delta}$ using scanning tunneling microscopy. We found that the pseudogap energy is associated with electron pairing, with pairing energies reaching up to 70 meV. Our results exclude the possibility of the pseudogap arising solely from local orders, and instead indicate a clear relation between the pseudogap state and Cooper pair formation.

TT 16.11 Tue 12:15 H32

Spin susceptibility in a pseudogap state with spiral magnetic fluctuations — •Paulo Forni[1], Pietro M. Bonetti[1,2], Henrik Müller-Groeling[1], Demerio Villardi[1], and Walter Metzner[1] — [1]Max Planck Institute for Solid State Research, D-70569 Stuttgart, Germany — [2]Department of Physics, Harvard University, Cambridge MA 02138, USA

We explore the spin susceptibility in the pseudogap phase of the 2D Hubbard model by introducing spin fluctuations into a spiral magnetic state. This analysis is based on an emergent SU(2) gauge theory following the fractionalization of the electron field into a fermionic chargon, carrying charge, and a bosonic spinon, encoding its spin. Chargons are treated within the random phase approximation in a spiral state. Deep in the pseudogap phase, spin fluctuations can be captured by a gradient expansion of the spinon field, leading to a nonlinear sigma model whose stiffnesses are computed from the underlying chargon order. Our results reveal a gapped, nematic, and SU(2)-symmetric spin susceptibility with a broad spectrum of magnetic excitations. These findings align with key features of the pseudogap phenomenology in cuprates, offering a unified theoretical framework to describe its spin and charge degrees of freedom.

TT 16.12 Tue 12:30 H32

Rise and fall of the pseudogap in the Emery model: Insights for cuprates — •Mario O. Malcolms[1], Henri Menke[1,2], Yi-Tin Tseng[2], Eric Jacob[3], Karsten Held[3], Philipp Hansmann[3], and Thomas Schaefer[1] — [1]Max-Planck-Institut für Festkörperforschung — [2]University of Erlangen-Nürnberg — [3]Institute of Solid State Physics, TU Wien

The intriguing properties of layered cuprate superconductors have not lost their fascination since their discovery. The physical mechanisms behind this rich phenomenology -after almost 40 years of intense community effort- are still highly debated. The reason for the latter is deeply routed in the fact that cuprates are strongly interacting quantum many-body systems, many of whose properties cannot be explained by a simple single-particle picture: their electrons are strongly correlated in space and in time. Adding to the complexity of this material class it has been realized early on, that due to the hybridization of copper $d_{x^2-y^2}$- and oxygen $p_{x/y}$-orbitals in the relevant two-dimensional layers, the undoped parent compounds are charge-transfer, rather than (single-orbital) Mott-Hubbard insulators. The adequate minimal theoretical modellization of cuprates, hence, has to include the oxygen p-orbitals on top of the copper-d ones, enabling, among other properties, (Zhang-Rice) singlet-formation between these orbitals. In this work we make significant progress in the universal description of the cuprates' phase diagrams by extending the powerful λ-corrected dynamical vertex approximation (DΓA) to the three-band Emery model.

TT 17: Correlated Electrons: Method Development

Time: Tuesday 9:30–13:15 Location: H33

TT 17.1 Tue 9:30 H33

Accuracy of embedded impurity methods for spin-polarized systems — •Kevin Ackermann and Maurits W. Haverkort — Institute for Theoretical Physics, Heidelberg, Germany

Ab-Initio embedded impurity approaches, such as DFT+DMFT, have proven to be a robust tool in understanding physical properties of materials for quite some time. Still the intersection between the employed mean field method, like Hartree-Fock or DFT, and the many-body impurity remains awkward. One of the issues can be exemplified for spin-polarised systems. For these materials spin is no longer a good quantum number in mean-field approximations and SU(2)-symmetry is explicitly broken by the usual spin-polarized mean-field methods. This automatically turns every spin-flip excitation into a *Hund's* coupling excitation, distorting the many-body spectral function in the process. Standard methods used in quantum chemistry to remedy this, such as restricted open shell Hartree-Fock/Kohn-Sham, average over the different spin potentials or densities. However, there are many flavors of realizing the needed spin averaging. To examine the impact of this choice, we compare ground state properties, such as bond lengths, as well as excitation spectra among a multitude of spin averaging schemes for a range of molecules.

TT 17.2 Tue 9:45 H33

Neural-network-supported Configuration Interaction as impurity solver for DMFT — •Alexander Kowalski[1], Philipp Hansmann[2], Giorgio Sangiovanni[1], and Adriana Pálffy[1] — [1]Institute for Theoretical Physics and Astrophysics, Universität Würzburg, 97074 Würzburg, Germany — [2]Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

Solving a strongly correlated lattice model by means of DMFT involves mapping it to interacting auxiliary Anderson impurity models (AIM) whose solution consumes the majority of computational resources. For the solution, algorithms such as QMC, NRG, DMRG or exact diagonalization can be used, where the latter in particular has the advantage of being able to compute exact results on the real frequency axis but is constrained to a small number of bath sites due to the exponential growth of the Hilbert space. Selected configuration interaction (CI) based approaches that operate in only a subspace of the total Hilbert space can greatly alleviate this problem while still including the most relevant contributions. Recently, a neural network has been shown to improve basis selection in ground state AIM calculations [1]. Here we investigate the use of a similar neural-network-supported CI solver to select the Hilbert space basis for the auxiliary AIM in DMFT.

TT 17.3 Tue 10:00 H33

Neural Quantum States as Dynamical Mean Field Theory solvers — •Jonas B. Rigo[1], Wladislaw Krinitsin[1,2], and Markus Schmitt[1,2] — [1]Forschungszentrum Jülich GmbH, Peter Grünberg Institute, Quantum Control, 52425 Jülich, Germany — [2]University of Regensburg

Neural Quantum Sates (NQS) constitute a variational wave function ansatz, that can provably efficiently represent even highly entangled quantum many-body states. Beyond their representative power, NQS inherit the speed of modern neural networks (NN) and equally profit from the enormous development that NNs have recently received. In this work we show that NQS can efficiently find the ground state of quantum impurity models with large baths, allowing us to compute high quality real-frequency, zero-temperature Green's functions by means of a Krylov-like method. We demonstrate the capability of this approach and its potential as dynamical mean-field theory (DMFT) solver at the example of the Bethe lattice and other benchmarks.

TT 17.4 Tue 10:15 H33

Neural network supported Configuration Interaction calculations in quantum many-body clusters — •Louis Thirion[1], Pavlo Bilous[2], Yorick L. A. Schmerwitz[3,4], Gianluca Levi[3], Elvar Ö. Jónsson[3], Henri Menke[5], Maurits Haverkort[6], Adriana Pálffy-Buss[7], Hannes Jónsson[3], and Philipp Hansmann[1] — [1]University of Erlangen-Nürnberg — [2]Max Planck Institute for the Science of Light, Erlangen — [3]University of Iceland, Reykjavik — [4]Max Planck Institute for Coal Research, Mühlheim — [5]Max Planck Institute for Solid State Research, Stuttgart — [6]University of Heidelberg — [7]University of Würzburg

A novel method is presented for computing the ground state in finite-size quantum many-body systems using configuration interaction (CI) enhanced by machine learning. Our recently developed Python library Solax [1] is used for this purpose. A neural network classifier is trained to select an efficient many-body basis in an iterative procedure. It addresses the exponential growth of the Hilbert space while maintaining accuracy. Validation with the Single Impurity Anderson Model shows a basis reduction by at least an order of magnitude compared to standard truncation schemes [2]. Application to the N_2 molecule with $\leq 2 \times 10^5$ Slater determinants, gives results comparable to full CI calculations with nearly 10^{10} determinants [3]. We aim to extend this method to multi-tier embedding schemes for predicting critical energy scales in heterogeneous catalysis.

TT 17.5 Tue 10:30 H33

Simulating two-dimensional fermionic systems with strong correlations using Neural Quantum States — •Hannah Lange[1,2,3], Annika Böhler[1,2], Christopher Roth[4], and Annabelle Bohrdt[5,2] — [1]LMU Munich — [2]Munich Center for QST, Munich — [3]Max-Planck-Institute for Quantum Optics, Garching — [4]Flatiron Institute, New York — [5]University of Regensburg

Simulating strongly interacting fermionic systems is crucial for understanding correlated phases like unconventional superconductivity, yet it remains a challenge for numerical and experimental methods in many cases. Here, I will discuss the efficiency and accuracy of fermionic neural quantum states (NQS), in particular hidden fermion determinant states (HFDS), for simulating doped quantum magnets. I will show results on the strongly interacting limit of the Fermi-Hubbard model across the entire doping regime. The HFDS achieve energies competitive with matrix product states (MPS) on lattices as large as 8 x 8 sites while using several orders of magnitude fewer parameters. This efficiency enables us to probe low-energy physics across the full doping range: Starting from the low-doping regime, where magnetic polarons dominate, we track their evolution with doping through spin and polaron correlations and compare them with experimental measurements. Furthermore, I will discuss different initializations of NQS, including a hybrid training scheme, which improves the training by incorporating experimental measurements. Our findings open the way for simulating large-scale fermionic systems at any particle filling.

TT 17.6 Tue 10:45 H33

Simulating Fermi Hubbard and t-J Models with Neural Quantum States — •Annika Böhler[1,2], Hannah Lange[1,2,3], Christopher Roth[4], and Annabelle Bohrdt[2,5] — [1]Department of Physics Ludwig-Maximilians-Universität München, Germany — [2]Munich Center for Quantum Science and Technology, Germany — [3]Max-Planck-Institute for Quantum Optics, Munich Germany — [4]Center for Computational Quantum Physics, Flatiron Institute, New York, USA — [5]University of Regensburg, Germany

Simulating strongly correlated electron systems remains a major challenge in condensed matter physics. While these systems offer a rich playground for studying emergent phenomena such as high-temperature superconductivity, they remain challenging to study both experimentally and theoretically, due to the exponential growth of the Hilbert space dimension. Neural Quantum States (NQS) offer a versatile variational framework to address this complexity. In this presentation, I will discuss the application of NQS to the strong interaction limit of the Fermi-Hubbard model. I will explore results obtained using different NQS architectures tailored to encode specific symmetry constraints. Hidden fermion determinant states are employed to efficiently capture fermionic antisymmetry, while other architectures incorporate lattice symmetries to improve accuracy and efficiency. I will show how these models can be extended to study higher SU(N) generalizations of the t-J model, providing a flexible approach to investigate a wide range of strongly correlated quantum systems and their emergent phases.

TT 17.7 Tue 11:00 H33

Investigating Quantum Many-Body Systems with Neural Quantum States — •Fabian Döschl[1,2], Felix A. Palm[1,2,3], Hannah Lange[1,2,4], Fabian Grusdt[1,2], and Annabelle Bohrdt[2,5] — [1]Ludwig-Maximilians-University Munich, Theresienstr. 37, Munich D-80333, Germany — [2]Munich Center for Quantum Science and Technology, Schellingstr. 4, Munich D-80799, Germany — [3]CENOLI, Universite Libre de Bruxelles, CP 231, Campus Plaine, B-1050 Brussels, Belgium — [4]Max-Planck-Institute for Quantum Optics, Hans-Kopfermann-Str.1, Garching D-85748, Germany — [5]University of Regensburg, Universitätsstr. 31, Regensburg D-93053, Germany

Neural Quantum States (NQS) have shown to be a reliable and efficient method for numerically simulating the ground states of two-dimensional quantum systems. Of particular interest for current research are fractional quantum Hall models and lattice gauge theories, both of which present significant challenges for state-of-the-art numerics. In this study, we demonstrate that NQS are capable of effectively simulating such complex systems. We focus on evaluating the strengths and weaknesses of this Ansatz from a physical perspective, providing deeper insights into the potential difficulties encountered during optimization.

15 min. break

TT 17.8 Tue 11:30 H33

X-ray absorption meets Matrix Product States: Application of a MPS-based band Lanczos solver to impurity models with core levels — •Coraline Letouzé[1], Sebastian Paeckel[2], Guillaume Radtke[1], and Benjamin Lenz[1] — [1]Sorbonne Université, Muséum National d'Histoire Naturelle, UMR CNRS 7590, Institut de Minéralogie, de Physique des Matériaux et de Cosmochimie, IMPMC, 75005 Paris, France — [2]Department of Physics, Arnold Sommerfeld Center for Theoretical Physics (ASC), Munich Center for Quantum Science and Technology (MCQST), Ludwig-Maximilians-Universität München, 80333 München, Germany

In strongly correlated materials like transition metal (TM) oxides, core-level spectroscopies such as X-ray Absorption Spectroscopy (XAS) are usually solved on a small cluster made of the valence and core states of the TM ion and its oxygen ligands. This cluster is then diagonalized exactly via the Lanczos algorithm. In the quest to extend this cluster model into an impurity model, beyond the capabilities of Exact Diagonalization, we apply the band Lanczos algorithm on Matrix Product States (MPS). Compared to standard valence-only impurity models, the inclusion of core levels leads to more interacting orbitals connected by an intricate interaction network.

In this talk I will present our results on impurity models for simple TM oxides (NiO, MnO), with a focus on the numerical stability and convergence of the MPS-based band Lanczos solver.

TT 17.9 Tue 11:45 H33

Diagonal isometric tensor product states in two dimensions — •Benjamin Sappler[1,2], Masataka Kawano[3], and Frank Pollmann[1,2] — [1]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 München, Germany — [3]Department of Basic Science, University of Tokyo, Meguro-ku, Tokyo 153-8902, Japan

The numerical simulation of quantum many-body systems is a challenging problem due to the exponential growth of Hilbert space with system size. In one spatial dimension this challenge was answered by the Density Matrix Renormalization Group (DMRG) algorithm, which can be understood as a variational method over Matrix Product States (MPS). One of the reasons for the success of DMRG is the existence of a canonical form for MPS that simplifies and speeds up most algorithms. Isometric tensor product states (isoTPS) generalize the canonical form of MPS to tensor networks in two and higher dimensions and have shown first promising results. Here we introduce an alternative canonical form for isoTPS by rotating the lattice by $\pi/4$ and introducing auxiliary tensors. We implement the time evolving block decimation (TEBD) algorithm on this new canonical form and benchmark the method by computing ground states and the real time evolution of the transverse field Ising model in two dimensions on large square lattices.

TT 17.10 Tue 12:00 H33

Dual Fermion Approach to the Falicov-Kimball Model: a benchmarking of methods — •Akshat Mishra[1], Hugo U. R. Strand[2], and Erik G. C. P. van Loon[1] — [1]NanoLund and Division of Mathematical Physics, Department of Physics, Lund University, Lund, Sweden — [2]School of Science and Technology, Örebro University, SE-701 82 Örebro, Sweden

The Falicov-Kimball model is often said to be the simplest lattice model for electronic correlations. It consists of mobile electrons and immobile impurities and the competition between the kinetic and interaction energy governs the physics. As a function of interaction strength and doping, the model shows uniform metallic and insulating phases as well as charge-density waves. A numerically exact solution of the Falicov-Kimball model is possible using classical Monte Carlo. In this work, we use this as a benchmark for two approximate many-body methods, Dynamical Mean-Field Theory (DMFT) and Dual Fermion (DF). We explore the thermodynamic properties, the electronic structure and the momentum-dependent susceptibility.

TT 17.11 Tue 12:15 H33

Enabling accurate Quantum Chemistry on current and near-term Quantum Hardware with the Transcorrelated Method. — •Werner Dobrautz[1,2], Igor O. Sokolov[5], Ali Alavi[4], Martin Rahm[3], and Ivano Tavernelli[5] — [1]CASUS - HZDR, Görlitz, Germany — [2]ScaDS.AI - TU Dresden, Dresden, Germany — [3]Chalmers University, Gothenburg, Sweden — [4]MPI-FKF, Stuttgart, Germany — [5]IBM Research, Rüschlikon, Switzerland

In this talk I will present how to enable accurate and efficient quantum chemistry calculations on NISQ devices for relevant chemical and physical problems. This is achieved by the use of an exact explicitly correlated method in the form of the transcorrelated (TC) method.

TC methods provide an efficient way of partially transferring the description of electronic correlations from the ground state wavefunction directly into the underlying Hamiltonian. This reduces the necessary quantum resources twofold:

(1) The TC Hamiltonian possesses a more compact ground state wavefunction, which facilitates electronic structure calculations and thus requires shallower quantum circuits.

(2) For ab initio quantum chemistry problems the TC method reduces the required number of qubits, by allowing to obtain highly accurate results with small basis sets.

I will present results on the Hubbard model and small chemical test systems, like the hydrogen molecule and lithium hydride, where results within chemical accuracy to the complete basis set limit and experimental results are within reach with only 4 to 10 qubits.

TT 17.12 Tue 12:30 H33

Cluster extension of the DMF^{2}RG and application to the 2d Hubbard model — •Marcel Krämer[1,2], Michael Meixner[1], Kilian Fraboulet[1], Pietro Bonetti[3], Demetrio Vilardi[1], Nils Wentzell[4], Thomas Schäfer[1], Alessandro Toschi[5], and Sabine Andergassen[2,5] — [1]Max Planck Institute for Solid State Research, Stuttgart, Germany — [2]Institute of Information Systems Engineering, TU Wien, Vienna, Austria — [3]Department of Physics, Harvard University, Cambdrige, USA — [4]Center for Computational Quantum Physics, Flatiron Institute, New York, USA — [5]Institute for Solid State Physics, TU Wien, Vienna, Austria

The DMF^{2}RG has been introduced to overcome the weak-coupling limitation of the fermionic functional renormalization group (fRG). This approach builds on the idea to exploit the dynamical mean-field theory (DMFT) as starting point for the fRG flow, thus capturing **local nonperturbative** correlations via DMFT together with perturbative nonlocal correlations generated during the flow. We show how **nonlocal nonperturbative** correlations can be also incorporated in the DMF^{2}RG scheme by using cellular DMFT (CDMFT) for a 2×2 cluster instead of single-site DMFT as starting point of the flow. Both CDMFT and fRG implementations have been formulated within the single-boson exchange decomposition, which has already proven to be an insightful bosonization scheme. We illustrate the ability of this novel approach to efficiently capture nonlocal nonperturbative correlations to describe d-wave superconductivity in the 2d Hubbard model.

TT 17.13 Tue 12:45 H33

How to stay on the physical branch of self-consistent many-electron schemes — •Herbert Essl, Matthias Reitner, and Alessandro Toschi — TU Wien

We precisely determine the mathematical condition under which the physical solution of the many-electron problem, obtained by self-consistent resummations becomes unstable by increasing interaction strength. The evaluation of the proposed criterion only requires the calculation of two-particle correlation functions. The validity of our predictions has been explicitly verified by performing self-consistent calculations of basic interacting models. Our findings eventually unveil the precise connection linking the misleading convergence of the self-consistent schemes to the multivaluedness of the Luttinger-Ward functionals and to the divergences of the irreducible vertex functions. Further, our analysis explains how the misleading convergence occurs even in parameter regions without vertex divergences. More importantly, it allows us to define a general scheme for stabilizing the physical solution, when it is unstable in conventional self-consistent schemes.

TT 17.14 Tue 13:00 H33

Mapping energy functionals and external potential of V- representable charge densities of interacting quantum systems — •Calin-Andrei Pantis-Simut[1,2], Amanda Teodora Preda[1,2], and George Alexandru Nemnes[1,2] — [1]Horia Hulubei National Institute for Physics and Nuclear Engineering, Reactorului 30, 077125 Magurele-Ilfov, Romania — [2]Faculty of Physics, University of Bucharest, Atomistilor 405, 077125 Magurele-Ilfov, Romania

Quantum systems are shaping the modern information processing technologies. Designing and analyzing these systems yields one of the most outstanding challenges in modern physics. These systems are fairly complex due to the Coulomb interaction between the particles. There are several methods for solving these problems, the most accurate providing solutions beyond mean-field approaches. Here the Exact Diagonalization is regarded as the gold standard for a system containing several particles. Recently, charge densities of such systems have been successfully mapped from randomly generated external potentials, using cGANs models. In this work, we intend to develop a machine learning based-model in order to obtain energy functionals E[n] for several classes of Hamiltonians (e.g. containing spin-orbit interaction), thus enabling the bypass of numerical intensive procedures like Exact Diagonalization. For this task, we employ CNNs to map the energy functionals from the ground state charge density. A more in depth analysis of the inverse problem is employed also in this work. Successfully mapping the external potential is not trivial since not every proposed charge density is V-representable.

TT 18: Focus Session: Strongly Correlated Quantum States in Moiré Heterostructures (joint session TT/HL/MA)

In recent years, significant progress has been made in realizing and exploring correlated quantum states in multilayer moiré heterostructures of graphene or transition metal dichalcogenides. These achievements have been made possible by the high level of control and tunability of these systems. Striking phenomena have been demonstrated experimentally, including unconventional superconductivity, fractional quantum anomalous Hall states, Mott-Wigner states and density waves, as well as kinetic ferromagnetism. Moreover, recently novel spectroscopic experimental techniques have been developed which allow for new ways to explore the dynamical response of these exotic states. This focus session will discuss recent experimental advancements as well as theoretical developments in the field of strongly correlated moiré heterostructures.

Organizers: Dmitri K. Efetov (LMU München), Michael Knap (TU München)

Time: Tuesday 9:30–13:15 Location: H36

Topical Talk TT 18.1 Tue 9:30 H36

The Thermoelectric Effect and Its Natural Heavy Fermion Explanation in Twisted Bilayer and Trilayer Graphene — Dumitru Calugaru[1], Haoyu Hu[2], Rafael Luque Merino[3], Nicolas Regnault[4], Frank Koppens[3], Dmitri K. Efetov[5], and •Bogdan Andrei Bernevig[1] — [1]Dept of Physics, Princeton University, Princeton, USA — [2]DIPC, San Sebastián, Spain — [3]ICFO, Barcelona, Spain — [4]Laboratoire de Physique de l'ENS, Paris, France — [5]LMU Munich, Munich, Germany

We study the interacting transport properties of twisted bilayer graphene (TBG) using the topological heavy-fermion (THF) model, where TBG comprises localized, correlated f-electrons and itinerant, dispersive c-electrons. The Seebeck coefficient of TBG exhibits unconventional traits: negative values with sawtooth oscillations at positive fillings, contrasting typical band-theory expectations. This behavior arises from the dichotomy between heavy (short-lived, correlated f-electrons) and light (long-lived, dispersive c-electrons), with transport dominated by c-electrons due to their stronger dispersion and longer lifetimes. At positive integer fillings, c- (f-)electron bands govern the electron (hole) doping side, resulting in an overall negative Seebeck coefficient. Sawtooth oscillations occur near each integer filling due to gap openings. Our results underscore the importance of electron correlations and lifetime asymmetry, naturally captured by the THF model, in understanding TBG transport properties. These findings align with experiments on twisted bilayer and trilayer graphene and highlight the interplay of heavy and light carriers.

Topical Talk TT 18.2 Tue 10:00 H36

Angle-Tuned Chiral Phase Transition in Twisted Bilayer Graphene — •Laura Classen[1;2], Nikolaos Parthenios[1,2], Cheng Huang[3], Xu Zhang[3], Maksim Ulybyshev[4], Fakher Assaad[3], and Zi Yang Meng[4] — [1]Max Planck Institute for Solid State Research — [2]Technical University of Munich — [3]University of Hong Kong — [4]University of Wuerzburg

The twist angle constitutes an important control knob in twisted bilayer graphene that has become accessible in-situ. It effectively tunes between weakly interacting, decoupled graphene layers and strongly correlated electrons at a magic angle of around 1.1 degree. We propose that this facilitates the realisation of a chiral phase transition of Dirac fermions at charge neutrality in twisted bilayer graphene. We argue that the transition can be described by the Gross-Neveu-Yukawa model that couples Dirac fermions and an XY order parameter field. The quantum critical behavior of this effective model is consistent with quantum Monte Carlo simulations of the continuum model for twisted bilayer graphene.

Topical Talk TT 18.3 Tue 10:30 H36

Quantum Optics of Semiconductor Moire Materials — •Atac Imamoglu — Institute of Quantum Electronics, ETH Zurich

Moire superlattices in two dimensional semiconductors have enabled the observation of a wealth of phenomena driven by strong electronic correlations, ranging from Mott-Wigner states to fractional quantum anomalous Hall effect. In this talk, I will present experiments exploring quantum optical control of strongly correlated electrons.

15 min. break

Topical Talk TT 18.4 Tue 11:15 H36

Probing the Band Structures of Multilayer Graphene Using the Quantum Twisting Microscope — •Martin Lee[1,2], Ipsita Das[1,2], János Papp[1,2], Marc Currle[1], Jiazhuo Li[1,2], Mudit Bhatt[1,2], Jonah Herzog-Arbeitman[3], Jiabin Yu[3], Zhiyuan Zhou[3], Markus Becherer[4], Philipp Altpeter[1], Christian Obermayer[1], Heribert Lorenz[1], Kenji Watanabe[5], Takashi Taniguchi[5], Bogdan Andrei Bernevig[3,6,7], and Dmitri Efetov[1,2] — [1]Fakultät für Physik, Ludwig-Maximilians-Universität, München, Germany — [2]Munich Center for Quantum Science and Technology, München, Germany — [3]Department of Physics, Princeton University, Princeton, New Jersey, USA — [4]School of Computation Information and Technology, Technical University of Munich, Germany — [5]National Institute of Material Sciences, Tsukuba, Japan — [6]Donostia International Physics Center, Donostia-San Sebastian, Spain — [7]IKERBASQUE, Basque Foundation for Science, Bilbao, Spain

Understanding the band-structure is foundational in describing the behavior of electrons in crystalline systems. While the tight-binding model effectively captures the non-interacting band-structures in materials like graphene, it relies on analytically or numerically derived hopping parameters. In this talk, we present the development of a quantum twisting microscope (QTM), which allows the k-resolved tunneling spectroscopy between the electronic states at the 2D tip and the 2D sample by twisting in-situ. Our QTM measurements allow us to extract the hopping parameters that agree with theoretical predictions.

Topical Talk TT 18.5 Tue 11:45 H36

Gate-Tunable Bose-Fermi Mixture in a Strongly Correlated Moiré Bilayer Electron System — •Nathan Wilson[1], Amine Ben Mhenni[1], Wilhelm Kadow[2], Mikołaj Metelski[1], Adrian Paulus[1], Alain Dijkstra[1], Jonathan Finley[1], and Michael Knap[2] — [1]Walter Schottky Institute, TU Munich, Garching, Germany — [2]School of Natural Sciences, TU Munich, Garching, Germany

Quantum gases consisting of species with distinct quantum statistics, such as Bose-Fermi mixtures, can behave in a fundamentally different way than their unmixed constituents. This makes them an essential platform for studying emergent quantum many-body phenomena such as mediated interactions and unconventional pairing. Here, we realize an equilibrium Bose-Fermi mixture in a bilayer electron system implemented in a WS_2/WSe_2 moiré heterobilayer with strong Coulomb coupling to a nearby moiré -free WSe2 monolayer. Absent the fermionic component, the underlying bosonic phase manifests as a dipolar excitonic insulator. By injecting excess charges, we show that the bosonic phase forms a stable mixture with added electrons but abruptly collapses upon hole doping. We develop a microscopic model to explain the unusual asymmetric stability with respect to electron/hole doping. By monitoring excitonic resonances from both layers, we demonstrate stability of the phase over a wide range in the boson/fermion density phase space, in agreement with theoretical calculations. Our results further the understanding of phases stabilized in moiré bilayer electron systems and demonstrate their potential for exploring the exotic properties of equilibrium Bose-Fermi mixtures.

TT 18.6 Tue 12:15 H36

Theory for Optical Control of Correlated States in Moiré Transition Metal Dichalcogenide Heterostructures — •Haoyang Tian and Urban Friedrich Peter Seifert — Institut für Theoretische Physik, Universität zu Köln, Zülpicher Str. 77a, 50937 Köln, Germany

In recent years, moiré transition metal dichalcogenide (TMD) heterostructures have emerged as highly versatile platforms for investigating phases and phenomena of strongly correlated electrons on emergent lattice scales. However, experimental characterization of the precise nature of some interaction-driven long-range ordered states and their excitations has remained a challenge. Given strong light-matter couplings and valley selection rules in TMD materials, ultrafast optical methods may constitute a promising avenue for probing and controlling these states and their collective modes. In this work, we develop a theoretical framework to describe coherent light-matter interactions in moiré TMD heterostructures, and model the system's steady-state and non-equilibrium dynamics during and after photoexcitation with a laser pulse. Thus obtained characteristic signatures of the system's dynamics may allow for new experimental insights.

TT 18.7 Tue 12:30 H36

Single-Particle Spectral Function of Fractional Quantum Anomalous Hall States — •Fabian Pichler[1,2], Wilhelm Kadow[1,2], Clemens Kuhlenkamp[3,1,2], and Michael Knap[1,2] — [1]Technical University of Munich, TUM School of Natural Sciences, Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), München, Germany — [3]Department of Physics, Harvard University, Cambridge, Massachusetts, USA

Fractional quantum Hall states are the most prominent example of states with topological order, hosting excitations with fractionalized charge. Recent experiments in twisted $MoTe_2$ and graphene-based heterostructures provide evidence of fractional quantum anomalous Hall (FQAH) states, which spontaneously break time-reversal symmetry and persist even without an external magnetic field. Understanding the unique properties of these states requires the characterization of their low-energy excitations. To that end, we construct a parton theory for the energy and momentum-resolved single-particle spectral function of FQAH states. We explicitly consider several experimentally observed filling fractions as well as a composite Fermi liquid in the half-filled Chern band. The parton description captures qualitatively our numerical exact diagonalization results. Additionally, we discuss how the finite bandwidth of the Chern band and the non-ideal quantum geometry affect the fractionalized excitations. Our work demonstrates that the energy and momentum-resolved electronic single-particle spectral function provides a valuable tool to characterize fractionalized excitations of FQAH states in moiré lattices.

TT 18.8 Tue 12:45 H36

Tuneability of Superconducting Properties in Transition Metal Dichalcogenide bilayers — •Michael Winter and Tim O. Wehling — I. Institut für Theoretische Physik, Universität Hamburg, Notkestraße 9-11, 22607 Hamburg

In recent years, rising interest sustained in van der Waals materials, particularly in transition metal dichalcogenides (TMDs or TMDCs). This work explores the potential for bilayer [hetero-]structuring in TMDs, which have garnered significant attention due to the discovery and prediction of exotic quantum phases, such as superconductivity and Mott insulating behaviour.

I present predictions derived from a minimal quantum lattice model, incorporating ab initio calculations based on plane-wave density functional theory (DFT), density functional perturbation theory (DFPT), and subsequent electron-phonon interaction calculations. The resulting model allows us to investigate the effects of different material combinations (e.g., MoS_2, $MoSe_2$, WS_2, WSe_2) and electron doping on superconductivity in such [hetero-]bilayer.

TT 18.9 Tue 13:00 H36

Proximity-Induced Spin-Triplet Superconducting Correlations in Transition Metal Dichalcogenides — •Florian Kayatz, Jorge Cayao, and Annica Black-Schaffer — Department of Physics and Astronomy, Uppsala University, Box 516, S-751 20 Uppsala, Sweden

The realization of spin-triplet Cooper pairs is a key ingredient for superconducting spintronics. One promising route to achieve this task is by exploiting the strong intrinsic spin-orbit coupling of transition metal dichalcogenides (TMDs). In this work, we consider a TMD layer coupled to a conventional spin-singlet s-wave superconductor and demonstrate the emergence of spin-triplet superconducting correlations. We find that these spin-triplet pair correlations form in the TMD as a proximity-induced effect but also appear in the superconductor as an inverse proximity effect and as a nonlocal phenomenon that exists between the TMD and superconductor. Furthermore, we relate these emergent superconducting correlations to experimentally observable features in the density of states and conductance.

TT 19: Many-body Quantum Dynamics I (joint session DY/TT)

Time: Tuesday 9:30–13:00 Location: H37

TT 19.1 Tue 9:30 H37

Controlling Many-Body Quantum Chaos — •Lukas Beringer[1], Mathias Steinhuber[1], Juan Diego Urbina[1], Klaus Richter[1], and Steven Tomsovic[1,2] — [1]Institut für Theoretische Physik, Universität Regensburg, D-93040 Regensburg, Germany — [2]Department of Physics and Astronomy, Washington State University, Pullman, WA USA

Controlling chaos is a well-established technique that leverages the exponential sensitivity of classical chaotic systems for efficient control. This concept has been generalized to single-particle quantum systems [1] and, more recently, extended to bosonic many-body quantum systems described by the Bose-Hubbard model [2]. In direct analogy to the classical paradigm, a localized quantum state can be transported along a specific trajectory to a desired target state. In the latter context, this approach reduces to time-dependent control of the chemical potentials, making it suitable for implementation in optical lattice experiments. Highlighted potential applications are rapid, customizable state preparation and stabilization of quantum many-body scars in one-, two-, and three-dimensional lattices. Recent progress includes potential applications to large time-crystal platforms and preparation protocols for entangled states, such as cat-like states.

[2] L. Beringer, M. Steinhuber, J. D. Urbina, K. Richter, S. Tomsovic, Controlling many-body quantum chaos: Bose-Hubbard systems, New J. Phys (2024): 26 073002.

TT 19.2 Tue 9:45 H37

Exact spectral function and nonequilibrium dynamics of the strongly interacting Hubbard model — Ovidiu I. Pâțu[1], •Andreas Klümper[2], and Angela Foerster[3] — [1]Institute for Space Sciences, Bucharest-Măgurele, R 077125, Romania — [2]Fakultät für Mathematik und Naturwissenschaften, Bergische Universität Wuppertal, 42097 Wuppertal, Germany — [3]Instituto de Física da UFRGS, Av. Bento Gonçalves 9500, Porto Alegre, RS, Brazil

Analytical results on the correlation functions of strongly correlated many-body systems are rare in the literature and their importance cannot be overstated. We present determinant representations for the space-, time-, and temperature-dependent correlation functions of the strongly interacting one-dimensional Hubbard model in the presence of an external trapping potential. These representations are exact and valid in both equilibrium and nonequilibrium scenarios like the ones initiated by a sudden change of the confinement potential. In addition, they can be implemented numerically very easily significantly outperforming other numerical approaches. As applications of our results we investigate the single particle spectral functions of systems with harmonic trapping and show that dynamical quasicondensation occurs for both fermionic and bosonic spin-1/2 systems released from a Mott insulator state.

TT 19.3 Tue 10:00 H37

Quantum many-body scars beyond the PXP model in Rydberg simulators — Aron Kerschbaumer[1], Marko Ljubotina[1,2,3], Maksym Serbyn[1], and •Jean-Yves Desaules[1] — [1]Institute of Science and Technology Austria, Klosterneuburg, Austria — [2]Technical University of Munich, Garching, Germany — [3]Munich Center for Quantum Science and Technology, Munich, Germany

Persistent revivals recently observed in Rydberg atom simulators have challenged our understanding of thermalization and attracted much interest to the concept of quantum many-body scars (QMBSs). QMBSs are non-thermal highly excited eigenstates that coexist with typical eigenstates in the spectrum of many-body Hamiltonians, and have since been reported in multiple theoretical models, including the so-called PXP model, approximately realized by Rydberg simulators. At the same time, questions of how common QMBSs are and in what models they are physically realized remain open.

In our work, we demonstrate that QMBSs exist in a broader family of models that includes and generalizes PXP to longer-range constraints and states with different periodicity. We show that in each model, multiple QMBS families can be found. Each of them relies on a different approximate su(2) algebra, leading to oscillatory dynamics in all cases. However, in contrast to the PXP model, their observation requires launching dynamics from weakly entangled initial states rather than from a product state. The new QMBSs we unveil may be experimentally probed using Rydberg atom simulator in the regime of longer-range Rydberg blockades.

TT 19.4 Tue 10:15 H37

Roughening dynamics of quantum interfaces — Wladislaw Krinitsin[1,2], •Niklas Tausendpfund[1,3], Matteo Rizzi[1,3], Markus Heyl[4], and Markus Schmitt[1,2] — [1]Institute of Quantum Control (PGI-8), Forschungszentrum Jülich, Jülich, Germany — [2]Faculty of Informatics and Data Science, University of Regensburg, Regensburg, Germany — [3]Institute for Theoretical Physics, University of Cologne, Köln, Germany — [4]Center for Electronic Correlations and Magnetism, University of Augsburg, Augsburg, Germany

The roughening transition, known from three-dimensional classical spin systems, describes how fluctuations of interfaces transition from being bounded to being extensive when crossing the characteristic roughening temperature. We explore signatures of such phenomena in the dynamics of domain walls in the two dimensional quantum Ising model, where we observe pre-thermal steady states in their evolution well beyond the perturbative limit using Tree Tensor Networks. We formulate an effective model of the interface, which captures qualitative features of a roughening transition. Most notably, it exhibits a Berezinskii Kosterlitz Thouless quantum phase transition from smooth to rough interfaces, whose signatures extend to finite temperatures. These findings can be related to the observed slow thermalization in the full model, opening the way to a bet-

ter understanding of pre-thermalization effects in interface dynamics, which can be easily implemented and tested in experimental setups such as Rydberg atom experiments.

TT 19.5 Tue 10:30 H37

Semigroup Influence Functionals for the Dynamics of Quantum Impurity Models — •Michael Sonner[1], Valentin Link[2], and Dmitry Abanin[3,4] — [1]Max-Planck-Institut für Physik komplexer Systeme, Nöthnitzer Straße 38, D-01187 Dresden, Germany — [2]Institut für Theoretische Physik, Technische Universität Dresden, D-01062 Dresden, Germany — [3]Department of Physics, Princeton University, Princeton, New Jersey 08544, USA — [4]Google Research, Brandschenkestrasse 150, 8002 Zürich, Switzerland

Quantum impurity models~(QIM) consist of a local interacting impurity which is coupled to baths of free fermions. These models exhibit a range of non-trivial phenomena such as the Kondo effect. and play a central role in the dynamic mean field theory (DMFT) approach to correlated matter. However, despite their importance, computing the real time dynamics of QIM remains a challenge. Recently, approaches based on matrix product states (MPS) representation of influence functionals (IF) have been proven effective approaches to this problem. These method work by capturing the, generically non-markovian dynamical effects of the quantum environments on the local impurity in a multi time object, which then is compressed as MPS. Taking explicit advantage of time-translation invariance of the model, we find an infinite MPS or semigroup representation of the IF. I will demonstrate how these ideas can be used to predict QIM dynamics for very long times as well as give direct access to stationary non-equilibrium states.

TT 19.6 Tue 10:45 H37

Quantum Fisher information of monitored random circuits — •Arnau Lira Solanilla, Xhek Turkeshi, and Silvia Pappalardi — Universität zu Köln

We characterize the multipartite entanglement structure of monitored random quantum circuits using the quantum Fisher information. We show that, despite the known phase transition in bipartite correlations, the multipartiteness is bounded. On the other hand, we generate a phase with extensive multipartite entanglement under symmetry preserving random operations by introducing two-qubit measurements. We focus on the limit where no unitary operations are applied, but there is a competition between two noncommuting projective measurements. We exploit a map to bond percolation to precisely calculate the universal scaling of multipartite entanglement.

TT 19.7 Tue 11:00 H37

Entanglement in quantum circuits with SU(2) symmetry — •Tobias Dörstel and Michael Buchhold — Institute for Theoretical Physics, Cologne

Quantum circuits offer a robust framework for studying the out-of-equilibrium dynamics of quantum many-body systems. We investigate one-dimensional monitored quantum circuits with global SU(2) symmetry, serving as digital counterparts to the Heisenberg chain. These circuits consist of unitary qubit SWAPs and non-unitary SWAP-measurements. Entanglement in the chain is governed by the configuration of qubit singlet states, whose count is fixed by the symmetry sector. Varying the measurement rate, unitary operations, and singlet number reveals diverse entanglement behaviors, ranging from volume law to $\log^2(L)$ and $\log(L)$ scaling of half-chain entanglement. We explain these scaling regimes analytically using an SU(2)-symmetric "Page law" and a mapping to loop models with crossings.

15 min. break

TT 19.8 Tue 11:30 H37

Generalized dual-unitary circuits from biunitarity — •Michael A. Rampp, Suhail A. Rather, and Pieter W. Claeys — Max-Planck-Institut für Physik komplexer Systeme, Dresden

We present a general framework for constructing solvable lattice models of chaotic many-body quantum dynamics with multiple unitary directions using biunitary connections. We show that a network of biunitary connections on the Kagome lattice naturally defines a multi-unitary circuit, where three 'arrows of time' directly reflect the lattice symmetry. These models unify various constructions of hierarchical dual-unitary and triunitary gates and present new families of models with solvable correlations and entanglement dynamics. Using multilayer constructions of biunitary connections, we additionally introduce multilayer circuits with monoclinic symmetry and higher level hierarchical dual-unitary solvability and discuss their (non-)ergodicity. Our work demonstrates how different classes of solvable models can be understood as arising from different geometric structures in spacetime.

TT 19.9 Tue 11:45 H37

Magic spreading in doped Clifford circuits — •Jiangtian Yao and Pieter W. Claeys — Max Planck Institute for the Physics of Complex Systems

We study the spreading of magic, or nonstabilizerness, in Clifford circuits with doping by non-Clifford gates. We characterize the spatial extent of magic in classes of Clifford circuits where the growth behavior of entanglement entropy and operator strings are known. The dynamics of magic spreading in such circuits is compared to that of entanglement entropy, and quantitative measures for longer-ranged magic are also explored.

TT 19.10 Tue 12:00 H37

One magnon magnetization dynamics for the kagome lattice antiferromagnet — Henrik Schlüter, •Jannis Eckseler, and Jürgen Schnack — Faculty of Physics, Bielefeld University, Bielefeld, Germany

We present aspects of the one-magnon dynamics of the antiferromagnetic kagome lattice as an example of flat-band dynamics extending the work of [1] to two dimensional systems. We illustrate how localized eigenstates also called localized magnons [2] influence the dynamics of excitations and possibly prevent the system from thermalization. To this end we introduce a $J_1 - J_2$-model for the kagome lattice which guarantees the stability of one out of three localized magnons and lets us distinguish the different flat bands.

[1] F. Johannesmann, J. Eckseler, H. Schlüter, and J. Schnack, Phys. Rev. B 108, 064304 (2023).

TT 19.11 Tue 12:15 H37

Towards a Many-Body Generalization of the Wigner-Smith Time Delay — •Georg Maier[1], Carolyn Echter[2], Juan Diego Urbina[1], Caio Lewenkopf[3], and Klaus Richter[1] — [1]Institut für Theoretische Physik Universität Regensburg, Regensburg, Germany — [2]Mathematische Fakultät Universität Regensburg, Regensburg, Germany — [3]Instituto de Física Universidade Federal Fluminense, Niterói RJ, Brazil

Many body systems with a large number of degrees of freedom are usually described by statistical physics on the theoretical side while experiments usually relay on scattering (e.g. particle physics). Is it possible to relate scattering and statistical physics, or to measure scattering-related observables which directly relate to quantities of statistical physics? At least for single particle systems a close relation exists between the well known Wigner-Smith delay time in scattering theory and the density of states of the scattering system.

I will present a novel ansatz relating a many-body version of dwell-/Wigner-Smith delay time and many body density of states based on the famous Birman-Krein-Friedel-Loyd formula connecting scattering theory and statistical observables in the many-body context. Due to the flexibility of this ansatz it can be used to investigate a wide variety of MB systems. I will discuss interesting scaling behaviors for different systems, like the harmonic trap[1] or the free particle together with the different behavior of bosons, fermions and indistinguishable particles.

[1] C. Echter et. al 2409.08696

TT 19.12 Tue 12:30 H37

Subleading logarithmic behavior in the parquet formalism — •Marcel Gievers[1,2], Richard Schmidt[3], Jan von Delft[1], and Fabian B. Kugler[4] — [1]Ludwig-Maximilians-Universität, München — [2]Max-Planck-Institut für Quantenoptik, Garching — [3]Universität Heidelberg — [4]CCQ, Flatiron Institute, New York

The Fermi-edge singularity in x-ray absorption spectra of metals is a paradigmatic case of a logarithmically divergent perturbation series. Prior work has thoroughly analyzed the leading logarithmic terms. Here, we investigate the perturbation theory beyond leading logarithms and formulate self-consistent equations to incorporate all leading and next-to-leading logarithmic terms. This parquet solution of the Fermi-edge singularity goes beyond the previous first-order parquet solution and sheds new light on the parquet formalism regarding logarithmic behavior. We present numerical results in the Matsubara formalism and discuss the characteristic power laws. We also show that, within the single-boson exchange framework, multi-boson exchange diagrams are needed already at the leading logarithmic level.

TT 19.13 Tue 12:45 H37

Ballistic transport in a disordered, boundary-driven XXZ spin chain. — •Johannes S Hofmann[1], Adam McRoberts[2], and Roderich Moessner[1] — [1]Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Str. 38, 01187 Dresden, Germany — [2]International Centre for Theoretical Physics, Strada Costiera 11, 34151, Trieste, Italy

Recent experiments on Google's sycamore NISQ device on spin transport realised ballistic transport in a edge-driven XXZ chain without disorder; and theoretical works on the classical variant demonstrated the survival of ballistic regime in the easy-plane upon the introduction of bond disorder. Here, we consider various generalisations of this set-up.

TT 20: 2D Materials: Electronic Structure and Exitations I (joint session O/HL/TT)

Time: Tuesday 10:30–13:00 Location: H8

TT 20.1 Tue 10:30 H8

Line-moiré phases of an epitaxial honeycomb monolayer AgTe/Ag(111) — •Romana Ganser, Muthu P. T. Masilamani, Begmuhammet Geldiyev, Maximilian Ünzelmann, and Friedrich Reinert — Experimentelle Physik VII and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, Germany

We present angle-resolved photoemission spectroscopy (ARPES) measurements on tunable one-dimensional moiré phases of an epitaxial honeycomb monolayer AgTe/Ag(111) [1]. In this model system, the moiré structure can be tuned almost continuously in contrast to hardly controllable twist angles in bilayer van-der-Waals heterostructures [2]. We experimentally observe moiré minibands and band gaps of 120 - 170 meV suggesting sizable superlattice potentials. By comparing the experimental data to simple model calculations, we analyze the local character of the potential. This provides important information of interface hybridization effects on the band structure, which may not be limited to the system at hand but rather a broad range of moiré interfaces.

Photoemission Time Scale Determination: the Effect of Crystal Dimensionality and Electronic Correlation — •Fei Guo[1], Dmitrii Usanov[2], Eduardo B. Guedes[2], Mauro Fanciulli[3], Arnaud Magrez[1], Michele Puppin[1], and Hugo Dil[1,2] — [1]Institute of Physics, Ecole Polytechnique Federale de Lausanne, CH-1015 Lausanne, Switzerland — [2]Photon Science Division, Paul Scherrer Institut, CH-5232 Villigen, Switzerland — [3]Laboratoire de Physique des Matériaux et Surfaces, CY Cergy Paris Université, Cergy-Pontoise, 95031, France

Spin polarization of photoelectrons from spin-degenerate dispersive initial states originates from the interference of multiple photoemission channels, measuring the spin polarization with spin- and angle-resolved photoemission spectroscopy (SARPES) allows the estimation of the phases of the interfering channels, and hence the Eisenbud-Wigner-Smith (EWS) time delay of photoemission, which is the amount of time required by the photoelectron to evolve into a free particle final state. While not directly measurable for solid-state photoemission, this time scale has been measured for gaseous photoionization, which is generally in the attosecond (10^-18s) range.

We present investigations with multiple materials of different properties, and by comparing with previous studies, we propose a relationship between the EWS time delay, electronic correlation mechanism, and dimensionality.

TT 20.3 Tue 11:00 H8

Disorder effects in the Band Structure of Transition Metal Dichalcogenide alloys $A_xB_{1-x}Se_2$ (A, B= Cr, Mo, W) — •Sarath Sasi[1], Aki Pulkkinen[1], Laurent Nicolaï[1], Raphaël Salazar[1], Christine Richter[2,3], Karol Hricovini[2,3], and Ján Minár[1] — [1]New Technologies Research Centre, University of West Bohemia, Pilsen, Czech Republic — [2]LPMS, CY Cergy Paris Université, Neuville-sur-Oise, France — [3]Université Paris-Saclay, CEA, CNRS, LIDYL, Gif-sur-Yvette, France

Recent advances in materials synthesis have enabled the creation of 2D TMDC alloys, which offer unique opportunities for tailoring electronic and optoelectronic properties to meet diverse application demands.[1].This study investigates the band structure evolution of $A_xB_{1-x}Se_2$ alloys (A, B = Cr, Mo, W) across varying composition fractions (x). Using the Coherent Potential Approximation (CPA)[2], which accurately models scattering in disordered systems, theoretical calculations were performed with the *SPR-KKR* package[3]. Results reveal that some of the TMDC alloys maintain their band structures without significant disorder effects. Angle-Resolved Photoemission Spectroscopy (ARPES) measurements align closely with one-step model photoemission calculations, confirming theoretical predictions. These insights provide a foundation for tailoring electronic properties, advancing their applicability in next-generation devices.

TT 20.4 Tue 11:15 H8

Unveiling Doping-Induced Electronic Modifications in Antiferromagnetic MPS_3 van der Waals Materials — •Till Willershausen[1], Jonah Elias Nitschke[1], Patrick Merisescu[2], David Janas[1], Lasse Sternemann[1], Michele Capra[1], Mira Arndt[1], Valentin Mischke[1], and Mirko Cinchetti[1] — [1]TU Dortmund University — [2]Bath University

Antiferromagnetic van der Waals (vdW) materials, with scalability to monolayer thickness, semiconducting properties, and intrinsic antiferromagnetic ordering, hold promise for spintronic and quantum technology applications. We investigate alkali metal doping effects on the MPS_3 family (M = Mn, Ni, Co, Fe) of 2D antiferromagnetic vdW materials, revealing doping-induced changes in their electronic structure. X-ray Photoelectron Spectroscopy (XPS) shows shifts in oxidation states in $NiPS_3$, $CoPS_3$, and $FePS_3$, while $MnPS_3$ displays no significant changes, indicating distinct charge transfer. Further investigation with Angle-Resolved Photoelectron Spectroscopy (ARPES) reveals new alkali-metal induced bands appearing above the previous valence band maximum. This analysis highlights doping-induced modifications and contrasts in transition metal behavior in MPS_3, providing insights into doping mechanisms and electronic tunability.

TT 20.5 Tue 11:30 H8

Enhanced electron-phonon coupling in few-layer $MoTe_2$ from micro-ARPES — •Thomas P. van Waas[1], Julia Issing[2], Marco Gibertini[3], Christophe Berthod[2], Anna Tamai[2], Felix Baumberger[2,4], and Samuel Poncé[1,5] — [1]European Theoretical Spectroscopy Facility, Institute of Condensed Matter and Nanosciences, Université catholique de Louvain, Belgium — [2]Department of Quantum Matter Physics, University of Geneva, Switzerland — [3]Dipartimento di Scienze Fisiche, Informatiche e Matematiche, University of Modena and Reggio Emilia, Italy — [4]Swiss Light Source, Paul Scherrer Institut, Switzerland — [5]WEL Research Institute, Belgium

Bulk orthorhombic T_d-$MoTe_2$ is a type-II Weyl semimetal with a superconducting critical temperature of T_c = 0.1 K. Transport measurements show a monotonic increase in T_c as the thickness of multilayer $MoTe_2$ is reduced, reaching T_c = 7.6 K in the monolayer. We investigate photoemission kinks in the electron pocket of exfoliated mono- bi-, and trilayer $MoTe_2$ from micro-focused angle-resolved photoemission spectroscopy. We use a custom code to quantify the electron self-energy $\Sigma_n(E)$ for a parabolic non-interacting dispersion, and obtain from $\Sigma_n(E)$ the Eliashberg spectral function $\alpha^2F_n(\omega)$ using the maximum entropy method. We find two dominant phonon modes in $\alpha^2F_n(\omega)$ for the mono- and trilayer, with a large enhancement of the lower-frequency phonon mode in the former. We also provide tentative results for the bilayer, where quantification is more challenging due to a small splitting of the electronic bands.

TT 20.6 Tue 11:45 H8

Electronic structure of V-doped WSe_2 — •Jana Kähler[1,2], Florian K. Diekmann[1,2], Matthias Kalläne[1,2,3], Tim Riedel[1,2], Adina Timm[1,2], Anja Yalim[1,2], Jens Buck[1,2], Meng-Jie Huang[2], Jules M. Knebusch[1,2], Luka Hansen[1,3], Jan Benedikt[1,3], and Kai Rossnagel[1,2,3] — [1]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany — [2]Ruprecht Haensel Laboratory, Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg — [3]Kiel Nano, Surface and Interface Science KiNSIS, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany

Spintronics represents a promising and energy-efficient alternative to conventional electronics, with significant potential applications, e.g., in areas such as classical and quantum computing. The vanadium-doped layered transition metal dichalcogenide 2H-WSe_2 is a promising candidate to fulfill the desired properties as a room-temperature magnetic semiconductor with gating tunability. Here, we present a comprehensive electronic structure study of chemical vapor transport-grown pristine and V-doped WSe_2 by soft X-ray, VUV and 11eV-laser ARPES, highlighting the influence of a low V doping concentration on the electronic structure of WSe_2.

TT 20.7 Tue 12:00 H8

Unraveling magnetic ordering in a van der Waals correlated material — Tommaso Pincelli[1,2], •Tania Mukherjee[1,2], Lawson Lloyd[2], Shuo Dong[2,3], Yoav William Windsor[1,2], Martin Wolf[2], Laurenz Rettig[2], and Ralph Ernstorfer[1,2] — [1]Technische Universität Berlin, 10623 Berlin, Germany — [2]Fritz-Haber-Institute of the Max Planck Society, 14195 Berlin, Germany — [3]Beijing National Laboratory for Condensed Matter Physics, China

Layered van der Waals (vdW) materials offer a compelling platform to investigate various emergent quantum properties in low dimensions. Fe_3GeTe_2 (FGT), a vdW ferromagnetic metal, is well-known for exhibiting exotic phenomena, ranging from skyrmion formation to heavy fermion behavior. However, an understanding of the magnetic ordering, a key feature for spintronic applications, still remains elusive in this material. In particular, the interplay of both local magnetic moments and an itinerant mechanism in the formation of ferromagnetic ordering in FGT, a non-f-electron correlated system, remains to be clarified. Using time- and angle-resolved photoemission spectroscopy (trARPES) and first-principles calculations, we provide evidence for an ordering mechanism in FGT by observing a pronounced reduction in the Stoner exchange gap. This stands in contrast to earlier temperature-dependent ARPES studies of the electronic structure of FGT, which favored a localized excitation model over the weak-coupling itinerant picture. We also observe the impact of phononic excitations which further confirm our findings.

TT 20.8 Tue 12:15 H8

Spin structure of the unoccupied surface state at AgTe/Ag(111) — •Carolin Benfer, Marcel Holtmann, and Markus Donath — Physikalisches Institut, Universität Münster, Germany

The AgTe/Ag(111) surface alloy has recently been investigated as a model system for the role of orbital angular momentum in the formation of spin effects in the electronic structure [1]. Two *p*-like surface states were detected in ARPES measurements, one shows a Rashba-type spin splitting, while the other one does not. This behavior is attributed to the symmetries of the orbital wave functions of the electrons. For the unoccupied states a third surface state has been predicted. Following the symmetry arguments given in [1], a Rashba-type spin splitting of the state is expected.

We use inverse photoemission (IPE) to directly study the unoccupied state of the surface alloy. Low-energy electron diffraction and scanning tunneling microscopy measurements confirm a homogeneous monolayer film of the surface alloy, which is growing in a honeycomb structure. Angle-resolved IPE measurements detect the predicted surface state with free electron-like dispersion. Spin-resolved IPE measurements reveal a Rashba-type spin structure.

TT 20.9 Tue 12:30 H8

Orbital mixing as key mechanism for ferromagnetism in van der Waals CrI3 — •Alessandro De Vita[1,2], Srdjan Stavrič[3], Roberto Sant[4], Nicholas B. Brookes[4], Giancarlo Panaccione[5], Silvia Picozzi[3], Ralph Ernstorfer[1,2], and Tommaso Pincelli[1,2] — [1]Institut für Optik und Atomare Physik, Technische Universität Berlin, Straße des 17 Juni 135, 10623 Berlin, Germany — [2]Fritz Haber Institute of the Max Planck Society, Faradayweg 4-6, 14195 Berlin, Germany — [3]Consiglio Nazionale delle Ricerche CNR-SPIN, c/o Università degli Studi G. D'Annunzio, 66100 Chieti, Italy — [4]ESRF, The European Synchrotron, 71 Avenue des Martyrs, CS40220, 38043 Grenoble Cedex 9, France — [5]Istituto Officina dei Materiali (IOM)-CNR, Laboratorio TASC, in Area Science Park, S.S.14, km 163.5, I-34149 Trieste, Italy

Van der Waals ferromagnets constitute a versatile platform where exotic quantum states can be realized; among them, CrI3 is a prototypical and widely studied 2D ferromagnet, with promising applications in spin- and orbitronics. Despite that, key information on its electronic occupation and stabilization of the magnetic configuration are missing. By means of complementary absorption and photoemission spectroscopies, and density functional theory calculations, we give a description of the orbital character of bulk CrI3, and demonstrate that the emergence of ferromagnetism in this material is underpinned by the orbital mixing between I p and Cr eg states. Our results have clear impact on the understanding of how microscopic interactions at the orbital level stabilize ordered states in van der Waals ferromagnets.

TT 20.10 Tue 12:45 H8

Resonant Photoemission Studies of Transition Metal Sulfides and Selenides — •Yashasvi Mehra[1,2,3], Samuel Beaulieu[4], Mauro Faniculli[1,2], Olivier Heckmann[1,2], Karol Hricovini[1,2], Aki I.O. Pulkkinen[3], Jan Minar[3], and Maria Christine Richter[1,2] — [1]Université Paris-Saclay, CEA, LIDYL, Gif-sur-Yvette, France — [2]CY Cergy Paris Université, CEA, LIDYL, Gif-sur-Yvette, France — [3]University of West Bohemia, NTC, Pilsen, Czech Republic — [4]Universite de Bordeaux CNRS CEA, CELIA, UMR5107, F33405 Talence, France

By performing resonant ARPES measurements and SPR-KKR photoemission calculations on Transition Metal Selenide, Sulfide and the Vanadium intercalated NbS2 systems, we study the interplay between different decay mechanisms in resonant conditions, radiation-less Raman Auger and Classical Auger emissions. Through a method proposed by Cini and Sawatzky we can determine the on-site Coulomb interaction per element in some cases. On the theoretical front the calculations are performed using the SPR-KKR method, which is based on one-step model, that incorporates the effect of all matrix elements which accounts for the photoemission process. Furthermore, we analyze calculated ARPES, XAS, element and orbital resolved band structure underlining agreement with experimental results and helping with its interpretation.

TT 21: Quantum Dots and Wires: Transport (joint session HL/TT)

Time: Tuesday 11:15–13:00 Location: H13

TT 21.1 Tue 11:15 H13

Transport properties of quantum dots for single-electron pumps — •Johannes C. Bayer, Thomas Gerster, Dario Maradan, Frank Hohls, and Hans W. Schumacher — Physikalisch-Technische Bundesanstalt, 31668 Braunschweig, Germany

A single-electron pump (SEP) is a device emitting a well-defined number of n electrons per cycle of an external drive. With driving frequency f and elementary charge e, this results in a current of $I = nef$. Since the revision of the SI system, the elementary charge e hereby is an exact value, so that SEPs provide a suitable basis for a quantum current standard. The accuracy of this current is directly related to erroneous cycles, where the emitted number of electrons deviates from n. Our SEP devices are based on electrostatically defined quantum dots in GaAs/AlGaAs two-dimensional electron gases. In such devices, the tunnel barriers as well as the energy levels are controllable via gate voltages. Based on multiple quantum dot devices we here investigate relations between transport properties and SEP operation characteristics.

TT 21.2 Tue 11:30 H13

Non-Markovian higher-order electron pump: improvement of efficiency — •Lukas Litzba, Jürgen König, and Nikodem Szpak — Fakultät für Physik, Universität Duisburg-Essen, Lotharstraße 1, Duisburg 47057, Germany

We consider an electron pump that consists of a non–interacting quantum dot and electron baths. Our pumping setup utilizes only higher–order tunneling processes, which are purely quantum mechanical and have no classical analog. In order to study higher order tunneling–mechanism and non–Markovian effects, we extend the exact Heisenberg equation and the Laplace transform technique to time–dependent Hamiltonians and apply this technique to our model. Thereby, we identify parameter ranges which lead to a significant increase of the current flowing through the quantum dot and an improvement of the energetic efficiency of these processes.

TT 21.3 Tue 11:45 H13

Fast Machine-Learning assisted characterisation of current quantisation — •Wang Ngai Wong[1], Yannic Rath[1], Nikolaos Schoinas[1], Shota Norimoto[1], Masaya Kataoka[1], Alessandro Rossi[1,2], and Ivan Runnger[1,3] — [1]National Physical Laboratory, Teddington, TW11 0LW, UK — [2]Department of Physics, SUPA, University of Strathclyde, Glasgow G4 0NG, UK — [3]Department of Computer Science, Royal Holloway, University of London, Egham, TW20 0EX, UK

Characterisation of single-electron pumps (SEPs) has long been bottlenecked by the process of fine-tuning measurement parameters to study their novel properties. This limits potential experimental parameters to those that can remain static throughout the fine-tuning process. We demonstrate a novel method assisted by machine learning which has led to an eightfold speedup in the measurement process (see Appl. Phys. Lett. 125, 124001 (2024)), and in so doing opens the door to further characterisation experiments which are impossible using conventional methods. Our method is based around an active learning cycle to navigate the information landscape of the gate voltage parameter space, while also significantly reducing the number of measurement points required. This is paired with a post-processing approach which allows us to accurately predict and characterise the small operational regimes significantly more efficiently than conventional sweeps across the parameter space. We exploit the framework to characterise the behaviour of multiplexed GaAs multi-pump devices across a range of magnetic fields.

TT 21.4 Tue 12:00 H13

Novel Mixed-Dimensional Reconfigurable Field Effect Transistors — •Sayantan Ghosh[1,2], Muhammad Bilal Khan[1], Phanish Chava[1], Kenji Watanabe[3], Takashi Taniguchi[3], Slawomir Prucnal[1], René Hübner[1], Thomas Mikolajick[2], Artur Erbe[1,2], and Yordan M Georgiev[1,4] — [1]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]Technische Universität Dresden, Dresden, Germany — [3]National institute for Material Science, Tsukuba, Japan — [4]Institute of Electronics, Bulgarian Academy of Sciences, Sofia, Bulgaria

The limitations of CMOS downscaling drive the exploration of alternative device concepts like reconfigurable FETs (RFETs), which can dynamically switch between n- and p-polarity through electrostatic gating. This work introduces a novel mixed-dimensional RFET utilizing 1D silicon (Si) nanowires combined with 2D hexagonal boron nitride (hBN) as a dielectric and encapsulating layer. hBN*s insulating properties, chemical stability, and absence of dangling bonds make it ideal for its use as a dielectric in 1D electronics. The RFET fabrication employs electron beam lithography, reactive ion etching, and flash lamp annealing for precise silicide formation. Mechanically exfoliated hBN flakes (5-10 nm) were integrated using dry stamping transfer, with thickness characterized by microscopy techniques. Device characterization reveals improved subthreshold swing, on-current, and ION/IOFF ratio due to hBN*s 2D passivation, highlighting its potential for advanced nanowire-based RFET architectures.

TT 21.5 Tue 12:15 H13

Kondo effect for half-filling of the third shell of a quantum dot — •Olfa Dani[1], Johannes C. Bayer[1], Timo Wagner[1], Gertrud Zwicknagl[2], and Rolf J. Haug[1] — [1]1Institut für Festkörperphysik, Leibniz Universität Hannover, Hannover, Germany — [2]2Institut für Mathematische Physik, Technische Universität Braunschweig, Braunschweig, Germany

In this work, we investigate the electrical transport in the third shell [1] of a gate-defined GaAs quantum dot. The exact number of electrons in the quantum dot (N_e) is determined using a quantum point contact as a sensitive charge detector, detecting single-electrons tunneling through the system [2]. N_e is varied by changing the applied gate voltage.

The addition energy E_c for N_e = 7 - 11 shows a triangular behavior with a maximum at half-filling of the shell. This observed behavior is described analytically with Hund's rule exchange interaction. Besides, for successive numbers of electrons occupying the quantum dot N_e = 7 to 11, a Zero-bias anomaly (ZBA) characteristic for the Kondo effect is observed [3]. The width of the ZBA exhibits a triangular behavior, with a maximum at N_e = 9, similar to E_c. The broadening of the ZBA is attributed to the contribution of the Kondo resonance as well as Hund's satellite peaks, originating from the degenerate orbitals observed in the spectral function.

TT 21.6 Tue 12:30 H13

Beyond full counting statistics and Langevin theory: The quantum polyspectra approach to multi-detector measurements — •Armin Ghorbanietemad, Markus Sifft, and Daniel Hägele — Ruhr University Bochum, Faculty of Physics and Astronomy, Experimental Physics VI, Germany

The quantum polyspectra approach to quantum measurements has recently been shown to cover the full range between weak and strong quantum measurements [1 - 3]. It provides thus a more general approach to quantum measurements than the full counting statistics used in nano-electronics or the Langevin-approach used in spin noise spectroscopy. This approach draws its strength from comparing higher order spectra of the measurement record with model spectra calculated from quantum expressions that are calculated on the level of a Lindblad master equation. Here, we generalize the polyspectra approach to include the case of the simultaneous measurements of more than one quantity of a quantum system. The approach regards measurement induced damping, measurement backaction, and the quantum Zeno effect. We give a few examples of multi-detector polyspectra that were calculated by a multi-detector extension of our SignalSnap and QuantumCatch library [4, 5].

TT 21.7 Tue 12:45 H13

Revealing Hidden States in Quantum Dot Array Dynamics: Quantum Polyspectra Versus Waiting Time Analysis — •Markus Sifft[1], Johannes C. Bayer[2], Daniel Hägele[1], and Rolf J. Haug[2] — [1]Faculty of Physics and Astronomy, Ruhr University Bochum, GER — [2]Institute of Solid State Physics, Leibniz Universität Hannover, GER

We show how by virtue of the recently introduced quantum polyspectral analysis of transport measurements [1,2], the complex transport measurements of multi-electron QD systems can be analyzed. This method directly relates higher-order temporal correlations of a raw quantum point contact (QPC) current measurement to the Liouvillian of the measured quantum system. By applying this method to a two-electron double QD system, we uncover dynamics between singlet and triplet states, indistinguishable in the QPC current, without requiring the identification of quantum jumps or prior assumptions about the number of quantum states involved. Our findings demonstrate that system models in such cases of hidden dynamics are inherently non-unique. Furthermore, we compare our method to a traditional analysis via the waiting-time distribution. Our method achieves parameter estimates with up to 50% lower errors, while also being applicable in scenarios with low signal-to-noise, where traditional counting methods falter. Our approach challenges previous assumptions and models, offering a more nuanced understanding of QD dynamics and paving the way for the optimization of quantum devices. TT 22: Many-body Systems: Equilibration, Chaos, and Localization (joint session DY/TT)

Time: Tuesday 14:00–15:30 Location: H37

TT 22.1 Tue 14:00 H37

Power-law banded random matrices as models for quantum many-body Hamiltonians — •Wouter Buijsman[1], Masudul Haque[2,1], and Ivan M. Khaymovich[3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]TU Dresden, Institute of Theoretical Physics, Dresden, Germany — [3]Nordita, Stockholm, Sweden

Hamiltonians of one-dimensional, disordered single-particle sytems with long-range hoppings can naturally be modeled by power-law banded random matrices. In this picture, the phase diagram of power-law banded random matrices show an ergodic, weakly ergodic, and localized phase. Motivated by modern developments on ergodicity breaking and localization in interacting quantum many-body systems, we study many-body interpretations of such random matrices. We discuss a number of ways to label the basis states with many-body configurations, and compare the physical properties of the resulting Hamiltonians. Specifically, we study the scaling of the many-body entanglement entropy with system size for eigenstates at both the bulk and the edge of the spectra. Using a scaling analysis on the full sets of eigenstates, we subsequently provide a quantitative picture of the phase diagram. We elaborate on the physical relevance of this interpretation of random matrix models for quantum many-body systems.

TT 22.2 Tue 14:15 H37

Escaping the Krylov space during reorthogonalization — •Max Pieper, Jannis Eckseler, and Jürgen Schnack — Universität Bielefeld

Krylov complexity [1] is often used as a measure of complexity in quantum many-body-systems. During its calculation, the Lanzcos algorithm is used to construct an operator basis. Due to the poor orthogonality of the resulting basis reorthogonalization is often employed [2]. We investigate how using reorthogonalization causes the Lanczos algorithm to accumulate non-Krylov basis elements. We suspect this to negatively affect the Krylov algorithm.

TT 22.3 Tue 14:30 H37

An estimate of the equilibration time based on the operator growth hypothesis — •Merlin Füllgraf, Jiaozi Wang, and Jochen Gemmer — Universität Osnabrück

We study the equilibration times T_{eq} of local observables in quantum chaotic systems by considering their auto-correlation functions. Based on the recursion method, we suggest a scheme to estimate T_{eq} from the corresponding Lanczos coefficients. We numerically find that, if an observable follows the *operator growth hypothesis*, a finite number of Lanczos coefficients is sufficient for a reasonable estimate of the equilibration time. This implies that equilibration occurs on a realistic time scale much shorter than the life of the universe. The numerical findings are further supported by analytical arguments.

TT 22.4 Tue 14:45 H37

Effects of chaos in Bose-Hubbard systems with few degrees of freedom. The smallest possible heat engine? — •Viviane Bauer, Nico Fink, and James Anglin — Physics Department and Research Center OSCAR, RPTU Kaiserslautern-Landau

Microscopic engines are a research focus in both biochemistry and nanotechnology. While other forms of engines besides heat engines are also being considered, the fully microscopic limit of a heat engine is a fundamentally important problem in physics. What happens to thermodynamics when not only the working fluid and mechanism of a heat engine, but even the hot and cold reservoirs are microscopic?

To realize such microscopic heat baths, we turn to the process of chaotic ergodization, studied in Bose-Hubbard dimers and trimers.

One realization we currently study is based on two Bose-Hubbard trimers, which allow energy and particle transport between them. The particle transport is furthermore coupled to a mass, so our engine works against a force to lift it. Moreover, we have identified a dynamic mechanism which can stabilize this lifting process. The result is a system which operates just like a heat engine, except for being fully microscopic. The structure of coupled chaotic subsystems both supports and requires an understanding of the fully microscopic heat engine in terms of open-system control.

TT 22.5 Tue 15:00 H37

Impurity coupled to the SYK bath — •Anastasia Enckell and Stefan Kehrein — Institute for Theoretical Physics, Georg-August-Universität Göttingen, Germany

System-plus-bath models play an important role in addressing fundamental questions in condensed matter physics. One challenging aspect is modelling the bath, which is often approached using free-particle or open quantum system frameworks. Here, we explore the Sachdev-Ye-Kitaev (SYK) model as a new kind of quantum bath with unique properties, including the absence of quasiparticles, maximal chaos, and non-integrability, which make it a valuable framework for studying system-plus-bath interactions. We study the time evolution of the occupation of an impurity coupled to the SYK bath following a quench. From the Kadanoff-Baym equations for a noninteracting impurity, we see that the only relevant property for the impurity occupation is a combination of hybridisation and density of states of the bath. These parameters can be adjusted in order to model the impurity coupled to any bath of interest. Using this approach, we can study the impurity dynamics coupled to the SYK bath by making suitable changes to the hybridisation in impurity plus Fermi bath setting, which significantly simplifies the task. We observe oscillatory dynamics of the impurity at zero temperature, with the oscillations decreasing as the temperature increases. This behaviour contrasts with that of a free-particle bath and suggests interesting underlying physics.

TT 22.6 Tue 15:15 H37

Thermal-relaxation asymmetry in fluctuating hydrodynamics — •Felipe Pereira-Alves and Aljaž Godec — Mathematical bioPhysics Group, Max Planck Institute for Multidisciplinary Sciences, 37077 Göttingen, Germany

It was theoretically predicted and recently experimentally confirmed that small systems, such as trapped colloidal particles quenched far from equilibrium, heat up faster than they cool down. The phenomenon was coined thermal-relaxation asymmetry. The proposed physical explanation of the asymmetry instigated intriguing questions about its existence in the thermodynamic limit. Here we investigate thermal relaxation dynamics in far-from-equilibrium temperature quenches on the level of fluctuating hydrodynamics of short- and long-range (logarithmically) interacting many-body systems. We prove the existence of a strict asymmetry for any temperature quench for both, short- and long-range interactions. Remarkably, in contrast to small systems, there is no "close-to-equilibrium" regime of quenches for which heating and cooling are symmetric. Notably, we find that relaxation is self-similar up to the relaxation time, and uncover intricate differences between short- and long-range interactions.

TT 24: Unconventional Superconductors

Time: Wednesday 9:30–13:00 Location: H31

Invited Talk TT 24.1 Wed 9:30 H31

Possible Origin of High-Field Reentrant Superconductivity in UTe_2 — •Toni Helm — Hochfeld-Magnetlabor Dresden (HLD-EMFL) and Würzburg-Dresden Cluster of Excellence ct.qmat, Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany

Due to its potentially spin-triplet-superconducting ground state, UTe_2 (fondly called Ute) has triggered a wave of enthusiasm among condensed-matter researchers since the discovery of superconductivity below 1.6 K in this anisotropic heavy-fermion paramagnet. As the quality of single crystals improved, e.g., T_c was pushed to 2.1 K, some of the fog about Ute's mysterious properties has cleared. Nevertheless, the excitement has only become stronger as Ute exhibits signatures of multiple superconducting phases with distinct order parameters stabilized by different tuning parameters such as pressure, magnetic field, or field orientation. Particularly, strong magnetic fields applied to Ute appear to not only suppress superconductivity, as expected for a textbook superconductor, but also enhance and enable additional phases in a rare and very unconventional phase diagram.

In this talk, we will look at Ute's high-field properties and review recent results concerned with the field-induced superconducting phases in this special compound. In particular, we will focus on what is known so far about the reentrant superconductivity that sets in for specific field orientations at field values beyond approximately 40 T. Latest results from experiments in fields up to 70 T have certain implication to the possible origin of the extremely field-robust reentrant superconductivity in UTe_2.

[1] T. Helm et al., Nat. Commun. 15 (2024).

TT 24.2 Wed 10:00 H31

Fermi surface studies on UTe_2 — •F. Husstedt[1,2], B. V. Schwarze[1], J. P. Brison[3], G. Knebel[3], G. Lapertot[3], M. Kimata[4], D. Aoki[4], T. Helm[1], and J. Wosnitza[1,2] — [1]Hochfeld-Magnetlabor Dresden (HLD-EMFL) and Würzburg-Dresden Cluster of Excellence ct.qmat, HZDR, Germany — [2]Institut für Festkörper- und Materialphysik, TU Dresden, Germany — [3]Centre CEA de Grenoble, France — [4]Institute for Materials Research, Tohoku University, Japan

To date, the presence of three-dimensional (3D) Fermi surfaces in the heavy-fermion superconductor UTe_2 is strongly debated. We had access to high-quality UTe_2 single crystals with $T_c = 2$ K to perform angle-dependent measurements of the magnetic torque, magnetotransport, and Hall effect. The observed quantum oscillations provide further insight into the electronic structure of UTe_2. We measured de Haas-van Alphen frequencies that show a very good agreement with previous reports. Consistent with two-dimensional Fermi-surface cylinders, we also observed a 100 T Shubnikov-de Haas (SdH) frequency for field oriented along the crystallographic *a* axis. We investigated the angular dependence of this frequency in the *a*-*b* plane as well as in the *a*-*c* plane to clarify if it may originate from a 3D Fermi surface. The temperature dependence of the 100 T SdH frequency reveals an effective mass much lower than the ones reported for the fundamental frequencies.

TT 24.3 Wed 10:15 H31

Investigating the strain dependence of the lower and upper superconducting critical fields in Sr_2RuO_4: A novel approach using elastocaloric effect measurements — •Aleksei Frolov[1], You-Sheng Li[1], Naoki Kikugawa[2], Andreas W. Rost[3], Andrew P. Mackenzie[1,3], and Michael Nicklas[1] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]National Institute for Materials Science, Japan. — [3]Scottish Universities Physics Alliance, School of Physics and Astronomy, University of St Andrews, St Andrews, UK

Elastocaloric measurements under uniaxial stress are an extremely sensitive technique that provides rich thermodynamic information. This is especially true when studying materials, such as the unconventional superconductor Sr_2RuO_4 [1]. In particular, the investigation of the elastocaloric effect in an applied magnetic field is challenging and pioneering, but highly relevant.

We have performed high resolution elastocaloric measurements on Sr_2RuO_4 in a magnetic field along the [001] axis with uniaxial stress applied in the [100] direction at low temperatures. We have studied the strain dependence of the lower and upper superconducting critical fields. Both show a dome-like shape with a maximum close to the Van Hove strain. We discuss the advantages and limitations of the elastocaloric technique compared to conventional probes such as electrical resistivity and susceptibility, highlighting its contribution to the understanding of unconventional superconductivity in Sr_2RuO_4.

TT 24.4 Wed 10:30 H31

Why scanning tunneling spectroscopy of Sr_2RuO_4 sometimes does not see the superconducting gap — •Adrian Valadkhani[1], Jonas Profe[1], Andreas Kreisel[2], Peter Hirschfeld[3], and Roser Valenti[1] — [1]Goethe University, Frankfurt am Main, Germany — [2]University of Copenhagen, Copenhagen, Denmark — [3]University of Florida, Gainesville, USA

Scanning tunneling spectroscopy (STS) and scanning tunneling microscopy (STM) are perhaps the most promising ways to detect the superconducting gap size and structure in the canonical unconventional superconductor Sr_2RuO_4 directly. However, in many cases, researchers have reported being unable to detect the gap at all in STM conductance measurements, while in others they were able to find the gap. Recently, an investigation of this issue on various local topographic structures on a Sr-terminated surface found that superconducting spectra appeared only in the region of small nanoscale canyons, corresponding to the removal of one RuO surface layer. In this talk, we analyze the electronic structure of various possible surface structures using ab initio density functional theory (DFT), and argue that bulk conditions, favorable for superconductivity, can be achieved, when removal of the RuO layer suppresses the RuO4 octahedral rotation locally. Our findings are supported by a paper recently published using numerical methods beyond DFT-random phase approximation (RPA) and functional renormalization group (FRG). We further propose alternative terminations to the most frequently reported Sr termination where superconductivity surfaces should be observed.

TT 24.5 Wed 10:45 H31

Complex impedance scanning tunneling microscopy as a probe for unconventional superconductors — •Amber Mozes[1], Sanghun Lee[2], Tjerk Benschop[1], Koen Bastiaans[1], and Milan Allan[1,2] — [1]Leiden University, Leiden, The Netherlands — [2]LMU, Munich, Germany

In many unconventional superconductors, the superconducting state is spatially inhomogeneous, and macroscopic superconductivity is suppressed. To understand what causes this suppression of superconductivity, we are developing a probe to measure the local complex impedance. We combine scanning tunneling microscopy (STM) with microwave microscopy. This could, in principle, allow to locally probe the impedance response and relate this to inhomogeneity in free carrier density whenever macroscopic homogeneity is suppressed. More specifically, it would be possible to measure the kinetic inductance of a superconductor, governed by the Meissner effect, as well as local resistivity from non superconducting carriers. Implementation of complex impedance measurements in STM requires a microwave impedance matching circuit to enable simultaneous DC and AC readout of the tip-sample response. I will present our recently developed chip circuits that are in situ replaceable, enabling sample specific circuit design, with the aim to impedance match for superconducting sample properties.

TT 24.6 Wed 11:00 H31

Tunneling spectroscopy on superconducting thin films of non-centrosymmetric niobium rhenium — •Marcel Strohmeier[1], Carla Cirillo[2], Andriy Smolyanyuk[3], Karsten Held[3], Carmine Attanasio[4], Angelo Di Bernardo[1,4], and Elke Scheer[1] — [1]Department of Physics, University of Konstanz, 78457 Konstanz, Germany — [2]CNR-Spin, c/o University of Salerno, 84084 Fisciano (SA), Italy — [3]Institute of Solid State Physics, TU Wien, 1040 Vienna, Austria — [4]Department of Physics 'E.R. Caianiello', University of Salerno, 84084 Fisciano (SA), Italy

In recent years, non-centrosymmetric superconductors have attracted increasing attention as they reveal various properties of unconventional superconductivity. With the absence of inversion symmetry and an asymmetric Rashba-type spin-orbit coupling (SOC) a mixed spin-singlet and spin-triplet pairing state is predicted in these materials. In our talk, we focus on the non-centrosymmetric compound $Nb_{0.18}Re_{0.82}$, whose superconducting order parameter remains under debate. Its favorable combination of material properties such as structural disorder, strong SOC and relatively high critical current densities makes NbRe an promising candidate for applications in superconducting single-photon detection and gate-controlled supercurrent devices. We present low-temperature scanning tunneling microscopy measurements on polycrystalline NbRe fabricated by magnetron sputtering. Using high-energy resolution N-I-S spectroscopy, we probe the local density of states in thin films of varying thickness and crystallinity to gain insights into the intrinsic pairing symmetry of the superconductor.

Unconventional Superconductivity in Epitaxial $KTaO_3$-Based Heterostructures — •Denis Maryenko — RIKEN Center for Emergent Matter Science, Wako, Japan

Spin-orbit coupling (SOC) is a driving force behind the emergence of novel quantum phenomena. Among these, superconductivity is particularly exciting due to its potential to form unconventional superconducting states that challenge conventional theories. The perovskite $KTaO_3$, with its inherently strong SOC, has recently gained attention as a promising material platform for exploring these phenomena. However, achieving precise control over interfacial electronic states to realize a conductive layer in $KTaO_3$ remains a significant challenge.

In this work, we present out recent progress on epitaxially grown $KTaO_3$-based heterostructures, with a focus on the $LaTiO_3$-$KTaO_3$ (110) interface[1]. Our findings reveal a systematic emergence of superconductivity in these structures. We demonstrate that the superconducting state, signaling unconventional Cooper pairing, can be tuned by electric and magnetic fields. This study sheds light on the interplay between superconductivity and SOC in low-dimensional systems, contributing to the broader understanding of quantum materials with strong spin-orbit interaction.

TT 24.8 Wed 12:00 H31

Topological Fermi Arcs and Surface Superconductivity in $PtBi_2$ — •Julia Besproswanny[1], Sebastian Schimmel[1], Sven Hoffmann[1], Gregory Shipunov[2], Saicharan Aswartham[2], Joaquin Puig[3], Yanina Fasano[3], Danny Baumann[2], Ricardo Vocaturo[2], Jorge I. Facio[3], Oleg Jansen[2], Jeroen van den Brink[2], Bernd Büchner[2], and Christian Hess[1] — [1]University of Wuppertal, 42119 Wuppertal, Germany — [2]IFW Dresden, 01069 Dresden, Germany — [3]Centro Atómico Bariloche, Instituto Balseiro, 8400 Bariloche, Argentina

t-$PtBi_2$ is a topological Weyl semimetal, as evidenced by band structure and quasiparticle interference (QPI) investigations [1]. It also exhibits unconventional surface superconductivity [2,3], with ARPES revealing a superconducting energy gap only on the Fermi arc states [3]. Low-temperature scanning tunneling microscopy and spectroscopy (STM/STS) reveals locally varying sample-dependent superconductivity revealed by the energy gap. In some cases the scale of the gap suggests BCS critical temperatures as high as 70-130 K. We study the temperature and magnetic field dependence of the the energy gap, demonstrating its persistence up to 50 K. Furthermore, QPI measurements in the superconducting state indicate an interplay between topological Fermi arcs and superconductivity.

TT 24.9 Wed 12:15 H31

Unconventional Superconductivity in Trigonal $PtBi_2$: Ginzburg–Landau Theory — Harald Waje[1], Ion Cosma Fulga[2], Jeroen van den Brink[2,3], and •Carsten Timm[1,3] — [1]TU Dresden, 01062 Dresden, Germany — [2]Leibniz Institute for Solid State and Materials Research Dresden (IFW), 01069 Dresden, Germany — [3]Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, 01062 Dresden, Germany

Trigonal $PtBi_2$ is a Weyl semimetal that exhibits unconventional surface superconductivity carried by the Fermi arcs [1]. Recent results indicate that the superconducting gap might be nodal, i.e., exhibiting topologically protected Majorana cones. There are three possible superconducting order parameters, corresponding to the three irreducible representations A_1, A_2, and E of the noncentrosymmetric point group C_{3v}. The gap has s-wave ($l = 0$), i-wave ($l = 6$), or d-wave ($l = 2$) symmetry, respectively. We set up a Ginzburg–Landau theory for these order parameters, which also includes coupling to an applied magnetic field. Finally, we discuss some effects described by this theory, such as field-induced pair-density waves.

TT 24.10 Wed 12:30 H31

Symmetry-Preserving First-Order Superconductor-to-Superconductor Transition in Heavy-Fermion $CeRh_2As_2$ — •Fabian Jakubczyk[1,2], Julia Link[1,2], and Carsten Timm[1,2] — [1]TU Dresden, 01062 Dresden, Germany — [2]Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, 01062 Dresden, Germany

Locally noncentrosymmetric materials are attracting significant attention due to the unique phenomena associated with sublattice degrees of freedom. The recently discovered heavy-fermion superconductor $CeRh_2As_2$ has emerged as a compelling example of this class, garnering widespread interest for its remarkable H-T phase diagram, which features field-induced multi-phase superconductivity with non-trivial angular dependencies and large critical fields, as well as antiferromagnetic order, and potential higher multipole orders. To investigate the complex interplay of the ordered phases in $CeRh_2As_2$ including the impact of a magnetic field, we develop a theoretical framework based on group-theoretical considerations, combined with Bogoliubov–de Gennes and Ginzburg–Landau methods. This approach enables us to propose probable symmetries of the superconducting states and elucidate their close relationship with magnetism in this material. Intriguingly, we find that the dominant first-order transition can be interpreted as a transition between coexistence phases of the same symmetry but with distinct admixtures of individual order parameters. Our approach accurately reproduces current experimental phase diagrams, both if the transition to a magnetic phase occurs below the superconducting critical temperature and if it occurs above.

TT 24.11 Wed 12:45 H31

Cause and Effect - Understanding the Fundamental Principles Determining the Gap Structure in Fluctuation Driven Superconductors — •Jonas Profe[1], Olivier Gingras[2], Antoine Georges[3,2,4,5], and Roser Valenti[1] — [1]Institut für Theoretische Physik, Goethe-Universität Frankfurt, Max-von-Laue-Str. 1, 60438 Frankfurt am Main, Germany — [2]Center for Computational Quantum Physics, Flatiron Institute, 162 Fifth Avenue, New York, New York 10010, USA — [3]College de France, 11 place Marcelin Berthelot, 75005 Paris, France — [4]Centre de Physique Theorique, Ecole Polytechnique, CNRS, Institut Polytechnique de Paris, 91128 Palaiseau Cedex, France — [5]DQMP, Universite de Geneve, 24 quai Ernest Ansermet, CH-1211 Geneve, Suisse

Describing and understanding unconventional superconductors is one of the major challenges of modern condensed matter physics. Here, central questions are, what determines which symmetry the superconducting order will have in a material and how can we engineer specific superconducting orders? In this talk, we disentangle how the effective pairing interaction and the electronic structure influence the resulting superconducting order for attractive interactions mediated by fluctuations. For this, we analytically dissect the linearized gap equation in order to extract as much information as possible. We then exemplify how one can utilize this understanding to design models showing specific ordering tendencies in both a single and a multi-orbital setting.

TT 25: Superconductivity: Supercurrent Diode Effect

Time: Wednesday 9:30–12:30 Location: H32

TT 25.1 Wed 9:30 H32

Gate Tunable Anomalous Josephson and Supercurrent Diode Effect — •Johanna Berger[1], Simon Reinhardt[1], Christian Baumgartner[1], Lorenz Fuchs[1], Tim Ascherl[1], Andreas Costa[2], Sergei Gronin[3], Geoff Gardner[3], Tyler Lindemann[3], Michael Manfra[3], Jaroslav Fabian[2], Denis Kochan[2,4], Christoph Strunk[1], and Nicola Paradiso[1] — [1]Institut für Experimentelle und Angewandte Physik, University of Regensburg, 93040 Regensburg, Germany — [2]Institut für Theoretische Physik, University of Regensburg, 93040 Regensburg, Germany — [3]Purdue University, West Lafayette, Indiana 47907 USA — [4]Institute of Physics, Slovak Academy of Sciences, 84511 Bratislava, Slovakia

The discovery of the supercurrent diode effect by Ando et al. [1] and its observation in a rich variety of systems caused an increasing interest in the physics of non-reciprocal superconductivity.

Here, we study Josephson junctions in hybrid Al/InGaAs/InAs structures, which harbor strong Rashba spin-orbit interaction. In combination with a Zeeman field, this gives rise to an anomalous phase shift φ_0 in the current-phase relation (CPR). The presence of high harmonics in the CPR gives rise, in addition, to the supercurrent diode effect [2,3,4]. Using an asymmetric superconducting quantum interferometer we simultaneously measure the φ_0-shift and supercurrent diode effect on a single junction [5]. By electrostatic gating of the junction, we reveal the link between the φ_0-shift and supercurrent diode effect.

TT 25.2 Wed 9:45 H32

Unconventional Josephson Supercurrent Diode Effect Induced by Chiral Spin-Orbit Coupling — •Andreas Costa[1], Osamu Kanehira[2], Hiroaki Matsueda[2], and Jaroslav Fabian[1] — [1]University of Regensburg, Germany — [2]Tohoku University, Japan

First-principles calculations have recently predicted that chiral materials lacking mirror symmetries—such as twisted van-der-Waals homobilayers—can feature unconventional radial Rashba coupling with spins aligned fully parallel (instead of tangentially) to momentum.

In this talk, we will address Josephson transport through vertical superconductor/ferromagnet/superconductor junctions hosting crossed (radial and tangential) Rashba fields at the interfaces and demonstrate that their interplay with ferromagnetic exchange can lead to supercurrent rectification even when the magnetization is collinear with the current. This so-called unconventional supercurrent diode effect (SDE) originates from spin precessions inside the ferromagnet, which imprint polarity-dependent transmission probabilities on the Cooper pairs being well-distinct from the conventional SDE, and provides a sensitive probe of chiral spin textures.

This work has been supported by DFG Grants 454646522 and 314695032 (SFB 1277).

TT 25.3 Wed 10:00 H32

Tunable Field-Free Unidirectional Diode Effect in Single-Crystal Superconducting Device — •Tobias Faeth[1], Damien Berube[2], Killian Rigaux[2], Yuqiang Fang[3], Anyuan Gao[2], Thao Dinh[2], Yufei Liu[2], Jianxiang Qiu[2], Houchen Li[2], Charles Reichhardt[4], Cynthia Reichhardt[4], Fuqiang Huang[3], and Suyang Xu[2] — [1]Max Plack Instiute for Microstructure Physics, Halle (Saale), Germany — [2]Harvard University, Cambridge, USA — [3]Bejing University, Beijing, China — [4]Los Alamos National Laboratory, Los Alamos, USA

Superconducting diodes could become critical components of multiple technologies, from energy-efficient superconducting computing to large scale effective quantum computing, memories and switches. In this talk, we report a device made out of a 2D superconductor, that exhibits field-free, tunable, and perfectly rectifying diode effect. Starting from finite field differential conductance experiments, we demonstrate diode efficiencies up to 30% at 100mT. Measuring nonlinear resistances, we characterize magnetochiral anisotropy (MCA) and calculate a MCA coefficient of $\gamma = 6.0 \times 10^8\ \mathrm{T^{-1}A^{-1}}$, the highest ever reported. Setting the field back to 0, we investigate a novel geometry, while carrying out differential conductance measurements. In the new geometry, we find $I_c^+ = 0$ while $I_c^- = 2\mu A$, a 100% diode efficiency. We hypothesize this effect is attributed to uneven vortex flow under opposite biases. We substantiate this model with computations that confirm increased diode efficiency under the novel geometry.

TT 25.4 Wed 10:15 H32

Tunable Diode effect in a Superconducting Tunnel Junction with Biharmonic Drive — •David Scheer[1], Rubén Seoane Souto[2], Fabian Hassler[1], and Jeroen Danon[3] — [1]Institute for Quantum Information, RWTH Aachen University, 52056 Aachen, Germany — [2]Instituto de Ciencia de Materiales de Madrid, Consejo Superiorde Investigaciones Científicas (ICMM-CSIC), 28049, Madrid, Spain — [3]Department of Physics, Norwegian University of Science and Technology, NO-7491 Trondheim, Norway

A Josephson diode is a superconducting circuit element that enables nonreciprocal transport, allowing a dissipationless supercurrent to preferentially flow in a single direction. Existing methods for achieving the required symmetry breaking mostly rely on specifically-designed materials or carefully-engineered circuits composed of multiple Josephson junctions. In this talk, we demonstrate that applying a biharmonic drive to a conventional superconducting tunnel-junction induces a diode effect through harmonic mixing processes that shift the supercurrent region. We show that, in a conventional tunnel junction, unit efficiency is achievable while maintaining a large supercurrent. Moreover, the relative phase between the two driving tones determines the directionality of the diode, which can be tuned in situ.

TT 25.5 Wed 10:30 H32

Spin-Resolved Josephson Diode Effect in Strongly Polarized SFS Junctions — •Danilo Nikolić, Niklas L. Schulz, and Matthias Eschrig — Institut für Physik, Universität Greifswald, Felix-Hausdorff-Strasse 6, 17489 Greifswald, Germany

We present a systematic study of equal-spin Cooper pair formation at the interface between a superconductor (S) and a helical ferromagnet (F) [1]. The theory is done in the framework of the quasiclassical Green's function formalism [2-4]. However, assuming the large splitting between the spin bands in F, the standard quasiclassical approach cannot be applied directly and requires a modified description [5-8]. Applying this approach, we account for the long-ranged (equal-spin) Josephson current-phase relation (CPR) in an SFS weak link considering a helimagnetic state in F. Remarkably, the CPR takes a nontrivial form leading to both the anomalous and Josephson diode effects. These effects have clear physical interpretations based on the coupling between the superconducting phase and the adiabatic spin gauge field (geometric phase) induced by inhomogeneous magnetization of F.

Spin and Charge Josephson Diode Effect in Diffusive Superconductor-Ferromagnet Heterostructures — •Niklas L. Schulz, Danilo Nikolić, and Matthias Eschrig — Institut für Physik, Universität Greifswald, Felix-Hausdorff-Strasse 6, 17489 Greifswald, Germany

Long-range equal-spin triplet supercurrents in the presence of a nontrivial spin texture are of fundamental importance for applications of superconducting spintronics [1]. In this work we investigate quantum geometric phases in a Josephson trilayer consisting of a strongly spin-polarized ferromagnet connected to BCS su-

perconductors by ferromagnetic insulating barriers. For non-coplanar spin textures of the device, spin-geometric phases arise, which enter the current-phase relation additionally to the superconducting phase difference [2]. In general, such spin-geometric phases are induced by gauge fields entering the transport equation [3] and in the considered case these are caused by spin-dependent U(1) gauge fields. The resulting current-phase relation in such devices allows for the observation of a Josephson diode effect in the charge current for symmetric systems and a diode effect in the spin current for asymmetric configurations. In certain cases, the device also allows to switch between fully spin-polarized supercurrents across the ferromagnet by reversing the Josephson phase.

Josephson diode fabricated by a focused He-Ion beam in a $YBa_2Cu_3O_7$ thin film. — •Edward Goldobin, Alireza Jozani, Christoph Schmid, Reinhold Kleiner, and Dieter Koelle — Universität Tübingen, Germany

We report on the fabrication of a Josephson diode with high asymmetry and size $\approx 1\ \mu m^2$. The device is fabricated from $YBa_2Cu_3O_7$ thin films by creating nanopatterns using a focused He-ion beam (He-FIB). He-FIB irradiation of different doses allows us to "write" both Josephson barriers as well as amorphous resistive walls (circuit boundaries) on a sub-micron scale [1]. We have fabricated sub-μm Josephson junctions of in-line geometry that have rather skewed $I_c(H)$ dependences. At the optimal value of the applied magnetic field H, the ratio of positive and negative critical current I_c reaches ≈ 7. Such a high asymmetry is key for achieving good figures of merit, e.g. a wide rectification window, large stopping forces and a high rectification efficiency [2]. The rectification of an ac current into an average dc voltage $\langle V \rangle$ was investigated experimentally by measuring rectification curves $\langle V \rangle(I_{ac})$ at $T = 4.2$ K. Average dc voltages as high as 212 μV were achieved for the optimum value of the driving amplitude I_{ac}. Further, the diode was loaded, which allowed us to measure the input and the output power and, therefore, experimentally demonstrate the efficiency, which reaches 80% in some regimes [3].

TT 25.8 Wed 11:30 H32

Investigation of Josephson junctions with Weyl-Kondo semimetals — •Ronja Fischer-Süsslin[1], Roman Hartmann[1], Thành Tran[1], Diana Kirschbaum[2], Xinlin Yan[2], Andrey Prokofiev[2], Angelo Di Bernardo[1,3], Silke Paschen[2], and Elke Scheer[1] — [1]FB Physik, Universität Konstanz, Konstanz, Deutschland — [2]Institut für Festkörperphysik, TU Wien, Wien, Österreich — [3]Dipartimento di Fisica, Università di Salerno, Fisciano, Italy

A superconducting diode, i.e., a device with a polarity dependent supercurrent amplitude, would provide new functionalities for superconducting circuits. The superconducting diode effect (SDE) was observed in 2020 [1] in an artificial superlattice with inversion symmetry breaking and is now investigated in both Josephson junctions and junction-free superconductors. We have fabricated and investigated Josephson junctions composed of Nb electrodes and the Ce-based Weyl-Kondo semimetals $Ce_3Bi_4Pd_3$ [2] and $CeRu_4Sn_6$ [3] as weak links. These topologically nontrivial materials are promising candidates to investigate the SDE due to their noncentrosymmetry and strong spin-orbit coupling, which are also responsible for the purely electric-field-driven nonlinear spontaneous Hall response [2,3].

TT 25.9 Wed 11:45 H32

Cooper pair diode in Coulomb blockade Pb islands on graphene — •Stefano Trivini[1,3], Jon Ortuzar[1], Katerina Vaxevani[1], F Sebastian Bergeret[3,4], and Jose Ignacio Pascual[1,2] — [1]CICnanogune, Donostia, Spain — [2]Ikerbasque, Basque Foundation for Science, Bilbao, Spain — [3]Centro de Física de Materiales (CFM),San Sebastián, Spain — [4]Donostia International Physics Center (DIPC), Donostia-San Sebastián, Spain

Non-reciprocity, essential for current rectification in electronics, is challenging to achieve in superconducting devices without external magnetic fields. Current methods rely on non-centrosymmetric materials or magnetochiral effects, limiting their versatility. We investigate small Pb islands on graphene where Coulomb and superconducting correlations coexist. Approaching the STM tip to Josephson regimes, we observe Resonant Cooper Pair Tunneling (RCT) peaks in the current-voltage characteristics. RCT values change with gating. We test this in a current-biased STM junction and find a CP current asymmetric with polarity. This is a realization of non-reciprocal transport of CP, tunable with a gate.

TT 25.10 Wed 12:00 H32

Magnetoelectric phenomena and radial Rashba diode effect in noncentrosymmetric superconductors — •Denis Kochan — Department of Physics, National Cheng Kung University, Tainan, Taiwan — Institute of Physics, Slovak Academy of Sciences, Bratislava, Slovakia

The superconducting diode effect is a magneto-electric phenomenon where an external magnetic field imparts a non-zero center-of-mass momentum to Cooper pairs, either facilitating or hindering the flow of electric current depending on its direction. One possible mechanism leading to SDE is a lack of inversion symmetry that facilitates spin splitting of the electronic bands by the underlying spin-orbit coupling (SOC). When breaking also the time-reversal by a weak magnetic/exchange field the Cooper pairs condensate displays intriguing magneto-electric and magneto-chiral effects.

This talk will present a theoretical overview and key experimental observations, particularly supercurrent diode effect and Josephson inductance anisotropy in InAs-quantum well-based junctions [1], zero-pi-like transitions and anomalous Josephson effect in non-centrosymmetric systems [2], enhanced vortex pinning and squeezing in Rashba-based superconductors [3]. The new kid on the block is the radial Rashba SOC giving rise to a novel Radial Rashba spin-diode effect [4].

TT 25.11 Wed 12:15 H32

The Josephson diode effect with Andreev and Majorana states — •Sayan Mondal[1], Pei-Hao Fu[2], and Jorge Cayao[1] — [1]Department of Physics and Astronomy, Uppsala University, Box 516, S-751 20 Uppsala, Sweden — [2]Science, Mathematics and Technology, Singapore University of Technology and Design, Singapore 487372, Singapore

We consider a Josephson junction formed by Rashba superconductors and investigate the Josephson diode effect as the system transitions from a trivial to a topological phase under an applied external Zeeman field [1]. The component of the Zeeman field parallel to the spin-orbit axis introduces asymmetry in the Andreev bound states, which in turn leads to an asymmetry in the Josephson current, giving rise to the diode effect. In this study, we analyze the forward and backward currents, which differ due to the presence of the parallel Zeeman field. We discover that the diode's efficiency as a function of the Zeeman field exhibits a rich structure strongly dependent on the Andreev bound states. This dependence reveals clear signatures of the topological phase of transition. Notably, in the topological phase, the diode efficiency develops an oscillatory pattern reflecting Majorana bound states' formation. We have also verified that the functionality of the obtained Josephson diode is robust against finite temperatures, below the superconducting gap. Our findings help us understand the realization of Josephson diodes in topological superconductors and can also be useful for identifying the emergence of Majorana bound states.

TT 26.1 Wed 9:30 H33

Temperature-magnetic field phase diagram of the honeycomb Kitaev system $Na_2Co_2TeO_6$ — •Sebastian Erdmann[1], Prashanta Mukharjee[1], Chanhyeon Lee[2], Kwang-Yong Choi[3], and Philipp Gegenwart[1] — [1]Experimental Physics VI, University of Augsburg, Germany — [2]Institute for Materials Research, Tohoku University, Japan — [3]Department of Physics, Sungkyunkwan University, Republic of Korea

Co-based honeycomb magnets have recently attracted considerable interest as promising candidates for the realization of the bond-directional Kitaev exchange [1]. $Na_2Co_2TeO_6$ belongs to this class of materials and displays antiferromagnetic order below 27 K [2]. We investigate a series of phase transitions in $Na_2Co_2TeO_6$ below 4 K, induced by the application of magnetic fields along the a- and a*-axes. The H-T phase diagram is determined by low-temperature measurements of the specific heat and magnetic Grüneisen parameter, supplemented

by literature results. We also compare the thermodynamic behavior upon field tuning to similar studies on other Kitaev materials, such as the prototype system α-$RuCl_3$.[3]

TT 26.2 Wed 9:45 H33

Anisotropic magnetetoelastic coupling in $Na_3Co_2SbO_6$ — •Prashanta K. Mukharjee[1], Lichen Wang[2], Anton Jesche[1], Julian Kaiser[1], Matthias Hepting[2], Pascal Puphal[2], Masahiko Isobe[2], Bernhard Keimer[2], Philipp Gegenwart[1], and Alexander A. Tsirlin[3] — [1]Experimental Physics VI, Center for Electronic Correlations and Magnetism, University of Augsburg, 86159 Augsburg, Germany — [2]Max-Planck-Institute for Solid State Research, Heisenbergstraße 1, 70569 Stuttgart, Germany — [3]Felix Bloch Institute for Solid-State Physics, University of Leipzig, 04103 Leipzig, Germany

Research on 3d-based Co^{2+} materials has intensified as they offer the potential to explore novel regimes of honeycomb magnets, including different versions of the extended Kitaev model. In this study, we investigate the thermodynamic properties of the Kitaev candidate $Na_3Co_2SbO_6$ using complementary thermodynamic measurements, including magnetometry, calorimetry, and high-resolution dilatometry. Our results reveal significant in-plane lattice effects both in the zero-field magnetically ordered phase and in the field-induced states, highlighting a robust anisotropic spin-lattice coupling. Notably, we observe a sign change in both thermal expansion and the structural Grüneisen parameter, which points to a quantum critical endpoint. These findings shed new light on the critical behavior and spin-lattice interactions in $Na_3Co_2SbO_6$ contributing to the understanding of its anisotropic magnetic behaviour.

TT 26.3 Wed 10:00 H33

Revisiting magnetic phases of the Kitaev quantum spin liquid $Na_3Co_2SbO_6$ — •Kranthi Kumar Bestha[1,2], Manaswini Sahoo[1,2], Niccolò Francini[3], Robert Kluge[1], Ryan Christopher Morrow[1], Andrey Maljuk[1], Sabine Wurmehl[1], Sven Luther[4], Hannes Kühne[4], Bernd Büchner[1,2], Laura Teresa Corredor Bohorquez[1], Lukas Janssen[1], and Anja U. B. Wolter[1] — [1]Institute for Solid State Research, Leibniz IFW Dresden 01069, Dresden, Germany — [2]Institute of Solid State and Materials Physics, TU Dresden, 01062 Dresden, Germany — [3]Institute of Theoretical Physics, TU Dresden, 01062 Dresden, Germany — [4]Hochfeld-Magnetlabor Dresden (HLD-EMFL), Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany

The quest for the elusive Kitaev Quantum Spin Liquid phase (KQSL) in Kitaev candidates has resulted in the discovery of unexpected exotic magnetic phases due to competing Kitaev, Heisenberg and off-diagonal interactions in real materials. Honeycomb cobaltate, $Na_3Co_2SbO_6$ (NCSO) has attracted much interest due to the predictions of its proximity to the KQSL phase. Using magnetic and thermodynamic methods, we mapped out the magnetic phase diagram of high-quality NCSO single crystals for all three main crystallographic directions. We observe a $J_{eff} = \frac{1}{2}$ ground state with antiferromagnetic order (T_N = 7 K) and multiple field-induced metamagnetic transitions in three field directions. The observed anisotropy and field-induced transitions are modeled within an extended $JK\Gamma\Gamma'$ model. Our work uncovers new exotic magnetic phases both in-plane and out-of-plane field directions.

TT 26.4 Wed 10:15 H33

Magnetic-field induced phase transition crossover in the triangular lattice antiferromagnet $Ba_3CoSb_2O_9$ — •Sanjay Kumar[1], Rashi Nathawat[1], Arvind Kumar Yogi[2], and Satyapal S. Rathore[3] — [1]Functional Ceramics and Smart Materials Lab, Department of Physics, Manipal University Jaipur, Jaipur - 303007, India. — [2]UGC-DAE Consortium for Scientific Research, Indore - 452001, India. — [3]Department of Physics, Cluster University of Jammu, Jammu - 180001, India.

The effect of magnetic field on the ground state properties of triangular lattice antiferromagnet (TLAF) compound $Ba_3CoSb_2O_9$. The temperature-dependent X-ray diffraction (10 to 300 K) shows no structural changes. The temperature and field-dependent susceptibility indicate that TLAF orders antiferromagnetically below $T_N \sim 3$ K. The susceptibility follows a Curie-Weiss law (above 100 K) with q_{CW} = -133.2 K. The frustration index (f ~ 44) indicates a highly frustrated system. Magnetization curves (dM/dH) at 2 K reveal field-induced spin-flop transitions near H ~ 9 T. Magnetic susceptibility shows a broad peak at T_{max} = 5 K, becoming more pronounced with increasing field. A spin-glass signature appears near $T_g \sim 6.5$ K but vanishes at higher fields. Interestingly, the magnetic ground state in this compound shows a crossover from the various possible spin orders. A significant shoulder-like hump in heat capacity near $T_c \sim 15$ K suggests structural changes, deviating from the typical λ-anomaly. The change in magnetic properties is attributed to the interplay between antisite defects, quantum fluctuations, and geometric frustration in TLAF.

TT 26.5 Wed 10:30 H33

First-principles modeling of Ni-based honeycomb compounds — •Thore Martens and Alexander Tsirlin — Leipzig University, Germany

In recent years, there has been an increasing interest in Kitaev materials for spins higher than 1/2. Using Density functional theory (DFT), anisotropic spin couplings as well as single-ion anisotropy are calculated and compared for several Ni-based honeycomb compounds: $KNiAsO_4$, $BaNi_2(AsO_4)_2$, $BaNi_2(PO_4)_2$ and $Na_3Ni_2BiO_6$. Most of these investigated compounds share a particularly large antiferromagnetic J_3 and a weaker ferromagnetic J_1 as leading couplings giving rise to a zig-zag magnetic structure. The dependence of these couplings on U from LSDA+U as well as full calculations on the tensor elements of J_1 are performed. From this, potential Kitaev interactions are obtained for the four Ni-compounds.

TT 26.6 Wed 10:45 H33

Exploring Geometrical Frustration in Ho_3ScO_6-II: Magnetic Properties and Structural Insights — •Abanoub Hanna[1], Cintli Aguilar Maldonado[1], and Bella Lake[1,2] — [1]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Hahn-Meitner Platz 1, D-14109 Berlin, Germany — [2]Institut für Festkörperphysik,Technische Universität Berlin, Berlin, Germany

Geometrical frustration occurs in magnetic compounds when the arrangement of magnetic ions in triangular or tetrahedral lattices leads to competing interactions, resulting in non-classical magnetic states. This study examines the cubic compound Ho_3ScO_6-II, which crystallizes in a bixbyite-type structure with a centrosymmetric cubic space group Ia3* and exhibits no magnetic ordering above 1.8 K, underscoring its geometrically frustrated nature. Unlike its polymorph Ho_3ScO_6-I, which shows long-range magnetic order at 4.4 K, Ho_3ScO_6-II lacks magnetic anisotropy and presents a Curie-Weiss temperature of approximately -20 K and an effective magnetic moment (μ_{eff}) of 9.8 μB, indicating significant antiferromagnetic interactions. Additionally, the study compares Ho_3ScO_6-II with Er_3ScO_6, which is isostructural and exhibits magnetic ordering around 2.1 K that is suppressed under external magnetic fields. This comparison highlights the contrasting behaviours of these compounds, contributing to a deeper understanding of frustrated magnetism within the RE_3ScO_6 system (RE = Ho, Er). The findings provide valuable insights into the unique structural and magnetic properties of Ho_3ScO_6-II and suggest potential applications in spintronic devices and quantum computing.

TT 26.7 Wed 11:15 H33

Continuous Similarity Transformations for the Easy-Axis XXZ Model on the Honeycomb Lattice — •Matthias R. Walther[1], Dag-Björn Hering[2], Vanessa Sulaiman[2], Maximilian Bayer[1], Götz S. Uhrig[2], and Kai P. Schmidt[1] — [1]Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, Staudtstraße 7, 91058 Erlangen, Germany — [2]Condensed Matter Theory, Technische Universität Dortmund, Otto-Hahn-Straße 4, 44221 Dortmund, Germany

Neutron scattering experiments on $YbCl_3$ show that it realizes the antiferromagnetic Heisenberg model on a honeycomb lattice [1]. While key features are captured by linear spin-wave theory (LSWT), a full dispersion cannot be reproduced. We apply continuous similarity transformations (CSTs) [2-4] to the easy-axis antiferromagnetic XXZ-model on the honeycomb lattice. This allows us to derive an effective model which takes the relevant magnon-magnon interactions beyond LSWT into account targeting a quantitative description of the single-particle properties. The CST flow equations are truncated in momentum space by the scaling dimension d so that all contributions with $d \leq 2$ are taken into account. The resulting quartic magnon-conserving effective Hamiltonian is analyzed in the zero-, one-, and two-magnon sector.

TT 26.8 Wed 11:30 H33

Magnetic Frustration and Weak Mn Magnetic Ordering in $EuMn_2P_2$ — Sarah Krebber[1], Marvin Kopp[1], Jens Müller[1], Jörg Sichelschmidt[2], Michael Baenitz[2], Kurt Kummer[3], Cornelius Krellner[1], and •Kristin Kliemt[1] — [1]Physikalische Institut, Goethe Universität Frankfurt, Deutschland — [2]Max-Planck-Insitut für Chemische Physik fester Stoffe, 01187 Dresden, Deutschland — [3]European Synchrotron Radiation Facility, 38043 Grenoble, France

$EuMn_2P_2$ is a member of the Eu-based 122-systems with a trigonal $CaAl_2Si_2$ crystal structure. The magnetic properties of the Eu ion in this compound are located in triangular layers of Eu^{2+}. Several quantaties indicated the presence of A-type antiferromagnetic Eu order at ≈ 18 K, with magnetic moments oriented in the a-a plane. Nevertheless, no magnetic order of Mn was observed [1,2]. This is intriguing, given that the analogous compounds $EuMn_2As_2$ and $EuMn_2Sb_2$ exhibit phase transitions attributed to Mn magnetic order at elevated temperatures

(T_N = 135 K, T_N = 128 K) [3,4].
In this study, we present the results of electron spin resonance (ESR), heat capacity, magnetization, nuclear magnetic resonance (NMR) and electrical resistivity measurements on $EuMn_2P_2$ single crystals, which exhibite a weak magnetic ordering attributed to Mn magnetism.

TT 26.9 Wed 11:45 H33

Exploring the Anisotropic Shastry-Sutherland Model by Strain Tuning of $SrCu_2(BO_3)_2$ — •Francisco Lieberich[1,4], Pascal Puphal[2], Ekaterina Pomjakushina[3], and Elena Gati[1,4] — [1]MPI-CPfS, Dresden, Germany — [2]MPI-FKF, Stuttgart, Germany — [3]PSI, Villigen, Switzerland — [4]TUD, Dresden, Germany

The Shastry-Sutherland model is a hallmark of frustrated magnetism and is realized by $SrCu_2(BO_3)_2$, where competing intra-dimer and inter-dimer interactions J and J' stabilize a dimerized ground state. The Shastry-Sutherland model can be generalized to an anisotropic model with two sets of inequivalent couplings J_1, J_2 and J_1', J_2'. This model is predicted to host novel ground states [1] and may address the debate [2] on the nature of the plaquette phase of $SrCu_2(BO_3)_2$. Experimentally, anisotropic strains break the lattice symmetry of $SrCu_2(BO_3)_2$ and may therefore be used to tune the anisotropy in the Shastry-Sutherland model. We use the AC elastocaloric effect, a thermodynamic probe of strain-tuned quantum materials [3], to map out the entropic landscape of $SrCu_2(BO_3)_2$ under large anistropic strains. By comparing the results under [100] and [110] strain, we disentangle the effects of symmetry-breaking and symmetry-conserving strains on $SrCu_2(BO_3)_2$. Our phase diagrams reveal features consistent with hydrostatic-pressure studies [4], alongside new effects that may arise from symmetry breaking.

Supported by the DFG through SFB 1143.

TT 26.10 Wed 12:00 H33

Search for Precursors of Multi-Magnon Bound States in Li_2CuO_2 Single Crystals in Specific Heat Data — •Stefan-Ludwig Drechsler[1], Eli Zoghlin[2], Wolfram Lorenz[1], and Ulrich Roessler[1] — [1]IFW-Dresden, Dresden, Germany — [2]J. Hopkins University, Baltimore, Maryland, USA

We report specific heat c_p-data for high quality single crystals of the edge-sharing chain cuprate Li_2CuO_2 collected in a wide temperature region from 20 to 70 K well above the Ne'el transition $T_N \approx 9.2$ to 9.4 K at ambient magnetic field. The c_p is analyzed within a sensitive c_p/T^3-plot adopting and generalizing an analytical expression [1] by adding precursor multi-magnon bound state (PMMBS) of any order. This way, the problem of missing intensity around 40 K can be resolved. The obtained excitation energies of PMMBS are in accord with recent inelastic neutron scattering data for Li_2CuO_2 [2] regarding single-magnon, two-magnon and three-magnon bound states. The results are discussed within the context of a recenly proposed Bose condensation scenario of MMBS [3] at very low temperature and ambient field.

TT 26.11 Wed 12:15 H33

Anisotropic Spin Ice on a Breathing Pyrochlore Lattice — •Gloria Isbrandt[1,2], Frank Pollmann[1,2], and Michael Knap[1,2] — [1]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 München, Germany

Spin ice systems have long captivated researchers due to their exotic magnetic properties and emergent excitations. Recently, breathing pyrochlore compounds have been identified as a platform for studying novel phases, including fracton physics and quantum spin liquids. We explore a spin ice model on a breathing pyrochlore lattice, introducing sublattice-dependent anisotropic interactions that are potentially realizable experimentally, for example, through uniaxial strain. We theoretically uncover a rich phase diagram by varying the strain and show how these anisotropic constraints reduce the ground state degeneracy across the different phases. Our numerical simulations reveal that, at low temperatures, the models undergo a crossover into a constrained spin ice manifold, characterized by an entropy density that falls below the celebrated Pauling entropy of conventional spin ice. Moreover, we observe glassy dynamics in spin correlations when probing the out-of-equilibrium behavior, suggesting slow relaxation and memory effects. This model provides a new perspective on spin ice physics, offering a potentially robust platform for studying fracton phenomena and experimental exploration of constrained magnetism and emergent glassy dynamics.

TT 26.12 Wed 12:30 H33

Efficient Optimization and Conceptual Barriers with Projected Entangled-Pair States — •Erik Weerda[1], Daniel Alcalde[1,2], Konrad Schröder[1], and Matteo Rizzi[1,2] — [1]University of Cologne, Cologne, Germany — [2]Forschungszentrum Jülich

Finite projected entangled-pair states (PEPS) are becoming a widely used tool in the computational study of strongly correlated systems. However, no standard set of computational tools has yet emerged to exploit the power of this approach. In this work we investigate a promising approach to ground state search with PEPS based on sampling methods. Along with presenting strategies for more effi cient optimisation, we also discuss conceptual barriers associated with this approach. A benchmark illustrates the power of these tools in the study of ground states of frustrated magnetic models.

TT 27: Focus Session: Nonlinear Spectroscopy of Collective Excitations in Quantum Magnets (joint session TT/MA)

In recent years, significant progress has been made in understanding strongly correlated quantum magnets, with a particular focus on fractionalized states of matter such as quantum spin liquids. These achievements in understanding have been made possible by remarkable developments in both materials science and experimental techniques. In particular, improvements in both traditional experimental tools (e.g., inelastic neutron scattering, Raman scattering, resonant X-ray scattering, etc.) and the introduction of innovative techniques such as 2D coherent THz spectroscopy and sophisticated noise experiments have advanced studies of quantum matter to qualitatively new levels of insight. This focus session will discuss these recent advancements in nonlinear spectroscopy techniques along with theoretical inroads in describing the nonlinear spectroscopic signatures of complex quantum magnets.

Organizers: Simon Trebst (Universität zu Köln), Johannes Knolle (TU München)

Time: Wednesday 9:30–12:45 Location: H36

Topical Talk TT 27.1 Wed 9:30 H36

Detecting Anyons Using Nonlinear Pump-Probe Spectroscopy — •Max McGinley[1,2], Michele Fava[2], and Sid Parameswaran[2] — [1]Cambridge University, UK — [2]Oxford University, UK

Topologically ordered two-dimensional systems can host excitations that possess statistics that interpolate between bosonic and fermionic—so called anyons. In this talk, I will explain how the presence of such anyonic excitations can be inferred from nonlinear spectroscopic quantities. In particular, we consider pump-probe spectroscopy, where a sample is irradiated by two light pulses with an adjustable time delay between them. The relevant response coefficient exhibits a universal form that originates from the statistical phase acquired when anyons created by the first pulse braid around those created by the second. This behaviour is shown to be qualitatively unchanged by non-universal physics including non-statistical interactions and small finite temperatures. In magnetic systems, the signal of interest can be measured using currently available terahertz-domain probes, highlighting the potential usefulness of nonlinear spectroscopic techniques in the search for quantum spin liquids. I will discuss future prospects for inferring properties of collective excitations using analogous techniques.

Topical Talk TT 27.2 Wed 10:00 H36

Two-Dimensional Nonlinear Dynamic Response of Frustrated Magnets — •Wolfram Brenig — Institute for Theoretical Physics, Technical University Braunschweig, D-38106 Braunschweig, Germany

Two-dimensional nonlinear (2DNL) coherent optical spectroscopy is of great interest in order to deconvolute excitation continua in correlated magnets, potentially allowing to analyze individual quasiparticles, including those of fractionalized magnets. We discuss the relevant response functions for the coupling of spin systems to electric fields and analyze the 2DNL dynamical susceptibilities for two scenarios of frustrated magnetism, namely for a quantum spin-liquid (QSL) as well as for a case of incommensurate spiral long-range order (ICO). For the former, we consider the Kitaev magnet, which hosts a quantum spin-liquid, featuring fractionalization in terms of mobile Majorana fermions and static flux-visons. We show that the 2DNL response does not only probe characteristic features of both fractional excitations, but also allows to extract single quasiparticle lifetimes from its multi-particle continua. These properties will be discussed over a wide range of temperatures. For the case of 2DNL response from a magnet with ICO, we chose the J_1-J_3 spin-model on the square lattice. Here, some features of the 2DNL spectra are found to be remarkably similar to those of the QSL case. Going beyond a bare quasiparticle approach, we will also comment on the impact of final-state interactions.

Work done in collaboration with Olesia Krupnitska and profiting from interactions with Roser Valentí, Natalia Perkins, Marius Möller, Anna Keselman, and David Kaib.

Topical Talk TT 27.3 Wed 10:30 H36

Imaging Magnetization Dynamics and Collective Spin Excitations in Compensated Magnets on Ultrafast Timescales — •Benjamin Stadtmüller — Experimentalphysik II, Institute of Physics, Augsburg University, 86159 Augsburg, Germany

Fundamental to the advancement of spintronics and quantum technologies is the ability to encode, manipulate and store information in the spin angular momentum of electrons on ever faster timescales. In this contribution, we therefore discuss the ultrafast magnetic response of compensated magnets, which are interesting candidates for applications due to their robustness against external fields and their fast manipulation speed. We start with the ultrafast magnetization dynamics of conventional antiferromagnets (AFMs), for which the possibility of optical excitation of collective magnon modes on ps timescales has already been demonstrated. For the case of NiO, we show that these timescales can be further reduced by exploiting the strong non-equilibrium excitation with fs laser pulses. These conditions lead to a significant loss of magnetic order and to the excitation of collective magnon modes. We then turn to the ultrafast optical response of the recently discovered class of altermagnets with their d-wave-like spin split band structure. By combining theoretical calculations with ultrafast magneto-optical experiments, we demonstrate the generation of a macroscopic spin polarization in the otherwise fully compensated altermagnet RuO_2, which can additionally be controlled by the excitation geometry [1]. [1] M. Weber and S. Wust et al. arXiv: 2408.05187

Topical Talk TT 27.4 Wed 11:15 H36

Revealing Dynamics of Hidden Sectors with Nonlinear Spectroscopy — •Yoshito Watanabe[1], Simon Trebst[1], and Ciarán Hickey[2,3] — [1]Institute for Theoretical Physics, University of Cologne, Cologne, Germany — [2]School of Physics, University College Dublin, Belfield, Dublin 4, Ireland — [3]Centre for Quantum Engineering, Science, and Technology, University College Dublin, Dublin 4, Ireland

Nonlinear spectroscopy, especially in its two-dimensional coherent spectroscopy (2DCS) form, is an emerging and promising tool for studying the dynamics of quantum materials. Unlike traditional linear probes, 2DCS employs a multi-pulse approach that reveals intricate dynamics, including the ability to resolve fractional excitation continua as sharp spinon-echo signals and to study interactions between excitations, phenomena often obscured in traditional measurements.

In this work, we focus on the potential of 2DCS to detect and characterize quadrupolar excitations in quantum magnets. Using exact diagonalization and establishing an effective Hamiltonian that reflects the dynamics of hidden sectors and higher-order excitations, we identify distinct spectroscopic features, including new signatures associated with quadrupolar excitations. These results provide a guide for the experimental detection and characterization of hidden dynamics in quantum materials.

Topical Talk TT 27.5 Wed 11:45 H36

Theory of Nonlinear Spectroscopy of Quantum Magnets — Anubhav Srivastava[1,2], •Stefan Birnkammer[1], GiBaik Sim[3], Michael Knap[1], and Johannes Knolle[1,4] — [1]Technical University of Munich, Garching, Germany — [2]Indian Institute of Science, Bengaluru, India — [3]Hanyang University, Seoul, Korea — [4]Imperial College London, London, United Kingdom

Two-dimensional coherent spectroscopy (2DCS) is an established method for probing molecules and has been proposed in the THz regime as a new tool for probing exotic excitations of quantum magnets but the precise nature of coupling between pump field and spin degrees of freedom has remained unclear. Here, we develop a general response theory of 2DCS and show how magneto-electric as well as polarization couplings contribute to 2DCS in addition to the standardly assumed magnetization. We propose experimental protocols to distill individual coupling contributions, for example from exchange-striction or spin current mechanism. We provide example calculations for the paradigmatic twisted Kitaev chain material $CoNb_2O_6$ and highlight the crucial role of contributions from cross-coupling between polarization and magnetic nonlinear susceptibilities. Our work paves the way for systematic studies of light-matter couplings in quantum magnets and for establishing 2DCS as a versatile tool for probing fractional excitations of exotic magnetic quantum phases.

TT 27.6 Wed 12:15 H36

Quantitative Prediction of the Dynamics of In-Gap States in Correlated Materials as Seen in Pump-Probe PES, XAS and RIXS Experiments: A NiO Case Study — •Sina Shokri and Maurits W. Haverkort — Universität Heidelberg, Institut für Theoretische Physik, Philosophenweg 19, Heidelberg 69120 Germany

Attosecond pump-probe experiments allow one to study and steer quantum materials on their fundamental time-scales. For atoms and small molecules one can theoretically predict the electronic and vibrational dynamics induced by ultrafast light pulses [1,2]. In solids a theoretical understanding is much harder. The coupling to many continuous degrees of freedom can result into rapid loss of coherence. Quantitative predictions how coherently driven excitations decohere is highly non-trivial. Correlated Mott- Hubbard or charge transfer insulators can show a variety of long lived excitonic excitations within the optical gap. With attosecond pump-probe spectroscopy it is possible to investigate the propagation and decay of such excitations, as recently shown by two-photon photo-emission spectroscopy of NiO. These experiments show photo-induced, long-lived in-gap states with coherent oscillations [3]. In this talk we will show, using non-linear response theory, how to quantitatively predict the dynamics of in-gap states in correlated materials after an optical excitation. We will furthermore show how this dynamics can be probed with different pump-probe experiments including photo-emission spectroscopy, x-ray absorption spectroscopy and resonant inelastic x-ray scattering.

TT 27.7 Wed 12:30 H36

Higher-Order Susceptibilities in Extended Kitaev Models Computed Via Krylov-Space Based Methods — •David Kaib, Marius Möller, and Roser Valenti — Institut für theoretische Physik, Goethe-Universität Frankfurt

Recently, it was proposed that techniques measuring higher-order dynamical response, such as two-dimensional coherent spectroscopy (2DCS), could provide more distinguishable signatures in analyzing the excitations of different systems. This is particularly true when linear response reveals only a featureless continuum, which could arise from various different types of excitations, or, for example, static disorder. The numerical evaluation of nonlinear response functions can, however, be computationally very demanding. Here, we propose an efficient Lanczos-based method that computes higher-order susceptibilities directly in the frequency domain. As an application case, we consider extended Kitaev models, that are relevant to α-$RuCl_3$ and related materials. We compare the nonlinear response from our method to the one obtained within linear spin-wave theory, showcasing that nonlinear response measurements can distinguish whether an observed excitation continuum is of conventional two-magnon type or has a different origin.

TT 28: Many-body Quantum Dynamics II (joint session DY/TT)

Time: Wednesday 9:30–13:00 Location: H37

TT 28.1 Wed 9:30 H37

The Sound of Entanglement — •Benjamin Orthner[1], Clemens Wenger[5], Johannes Kofler[2], Richard Küng[2], Enar de Dios Rodríguez[3], Martin Ringbauer[4], Alexander Ploier[2], and Philipp Haslinger[1] — [1]Vienna Center for Quantum Science and Technology, Atominstitut, TU Wien, Vienna, Austria — [2]Johannes Kepler University Linz, Austria — [3]Internationale Forschungszentrum Kulturwissenschaften, Kunstuniversität Linz, Austria — [4]University of Innsbruck, Austria — [5]Universität für Musik und darstellende Kunst Graz, Austria

This contribution presents *The Sound of Entanglement*, a project at the intersection of quantum physics, music, and visual art. At its core lies a Bell experiment setup, where polarization-entangled photon pairs are generated through spontaneous parametric down-conversion in a β-BBO crystal. The experiment acts as a quantum conductor, utilizing the quantum correlations between the photons to coordinate and influence the choices of live musicians in real-time, creating a performance guided by principles beyond classical physics.

This work seeks to make these abstract concepts more accessible and engaging to broader audiences by transforming them into tangible, sensory experiences. By combining live music with a dynamic light show, both controlled by the experiment, this project illustrates how advancements in technology, like those shaping the second quantum revolution, can redefine artistic expression and bridge the gap between science and art.

TT 28.2 Wed 9:45 H37

A Solvable Model for Full Eigenstate Thermalization — •Felix Fritzsch and Pieter W. Claeys — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

The Full Eigenstate Thermalization Hypothesis (Full ETH) aims to characterize thermalization in many-body quantum systems in terms of the dynamics of higher-order spatiotemporal correlation functions, going beyond the current standard ETH paradigm. In this talk, we introduce a solvable random matrix model for many-body quantum dynamics in which the asymptotic dynamics of generalized out-of-time-order correlation functions can be exactly obtained in the thermodynamic limit. The dynamics of this model naturally maps to dynamics on the lattice of non-crossing partitions, combinatorial structures underlying the mathematics of Free Probability and Full ETH. We demonstrate how local observables approach asymptotic freeness at late times and explicitly characterize all relevant time scales. We confirm our analytical results with numerical simulations performed directly in the thermodynamic limit.

TT 28.3 Wed 10:00 H37

Scrutinizing the Mori memory function for transport scenarios — •Scott Daniel Linz, Jiaozi Wang, Robin Steinigeweg, and Jochen Gemmer — Department of Mathematics/Computer Science/Physics, University of Osnabrück, D-49076 Osnabrück, Germany

Diffusion is a phenomenological hydrodynamic transport behavior that holds over a wide range of materials. Within condensed matter physics there is the opinion that as long as the area under the current-current correlation function converges in time, one has a criterion for diffusive behavior of the corresponding spatiotemporal density dynamics. Attempts to derive this statement are notoriously challenging. We will first demonstrate that it is possible to construct correlation functions of some local density, where the area under a current-current correlation function converges, but the system is not diffusive. After this is demonstrated, we shall introduce a method based on the recursion method and the Mori memory formalism, that yields insight into whether or not a process is truly diffusive. The only disadvantage of this strategy is that one would have to know the behavior infinitely many Lanczos coefficients, whereas in practice one can only calculate a finite number of them in most cases. In the cases examined in this talk, however, the convergence or lack thereof becomes apparent to the naked eye with the finite amount of coefficients that were calculated.

TT 28.4 Wed 10:15 H37

Long-time Freeness in the Kicked Top — •Elisa Vallini and Silvia Pappalardi — University of Cologne, Köln, Germany

Recent work highlighted the importance of higher-order correlations in quantum dynamics for a deeper understanding of quantum chaos and thermalization. The full Eigenstate Thermalization Hypothesis, the framework encompassing correlations, can be formalized using the language of Free Probability theory. In this context, chaotic dynamics at long times are proposed to lead to free independence or "freeness" of observables. We investigate these issues in a paradigmatic semiclassical model - the kicked top - which exhibits a transition from integrability to chaos. Despite its simplicity, we identify several non-trivial features. By numerically studying 2n-point out-of-time-order correlators, we show that in the fully chaotic regime, long-time freeness is reached exponentially fast. These considerations lead us to introduce a large deviation theory for freeness that enables us to define and analyze the associated time scale. The numerical results confirm the existence of a hierarchy of different time scales, indicating a multifractal approach to freeness in this model. Our findings provide novel insights into the long-time behavior of chaotic dynamics and may have broader implications for the study of many-body quantum dynamics.

TT 28.5 Wed 10:30 H37

Periodically and aperiodically Thue-Morse driven long-range systems: from dynamical localization to slow dynamics — •VATSANA TIWARI — Indian Institute of Science Education and Research Bhopal, Bhopal, India

In this talk, I will discuss the impact of time-periodic and aperiodic field on power-law random banded matrix (PLRBM) model where variation in the power-law exponent yields a delocalization-to-localization phase transition. We investigate the periodically driven PLRBM model with the help of the static measures such as level spacing ratio and generalized inverse participation ratio and report the drive-induced multifractal to localization transition. The transport study of the periodically driven system demonstrates the transition from diffusive to logarithmically slow relaxation at dynamical localization point. Extending our analysis to the aperiodic Thue-Morse driving, we find that specific driving parameters leads to the *exact dynamical localization* in a disordered-free long-range model regardless of the long-range parameter. In the disordered case, the localized phase exhibits a long prethermal plateau followed by diffusion to an infinite temperature state, while the delocalized phase shows immediate diffusion. Additionally, we compare this with a quasi-periodic model that also undergoes a localization-delocalization transition, noting that, unlike the delocalized side of the disordered long-range model, it features a prolonged plateau followed by diffusion to the infinite temperature state.

TT 28.6 Wed 10:45 H37

Symmetry-Resolved Out-of-Time-Order Correlators with Projected Matrix Product Operators — •Martina Gisti, David Luitz, and Maxime Debertolis — Institute of Physics, University of Bonn, Nußallee 12, 53115 Bonn, Germany

Out-of-Time-Order Correlators (OTOCs) are key measures of quantum many-body chaos and information spreading. We systematically analyse OTOCs as a function of particle number for interacting spinless fermions in one dimension. With the concept of generalized operator charge, we develop a formalism for the time evolution of symmetry-projected matrix product operators, which we use to resolve the scrambling behaviour by particle number sector. Our results reveal a crossover from ballistic to diffusive dynamics at early times and a saturation regime at late times.

TT 28.7 Wed 11:00 H37

Revealing ultrafast phonon mediated inter-valley scattering through transient absorption and high harmonic spectroscopies — •Kevin Lively[1], Shunsuke Sato[2,3], Guillermo Albareda[2,4], Angel Rubio[2], and Aaron Kelly[2] — [1]Deutsches Zentrum für Luft- und Raumfahrt — [2]Max Planck Institute for the Structure and Dynamics of Matter — [3]University of Tsukuba — [4]Ideaded

Processes involving ultrafast laser driven electron-phonon dynamics play a fundamental role in the response of quantum systems in a growing number of situations of interest, as evinced by phenomena such as strongly driven phase transitions and light driven engineering of material properties. To show how these processes can be captured from a computational perspective, we simulate the transient absorption spectra and high-harmonic generation signals associated with valley selective excitation and intraband charge-carrier relaxation in monolayer hexagonal boron nitride. We show that the multitrajectory Ehrenfest dynamics approach, implemented in combination with real-time time-dependent density-functional theory and tight-binding models, offers a simple, accurate, and efficient method to study ultrafast electron-phonon coupled phenomena in solids under diverse pump-probe regimes which can be easily incorporated into the majority of real-time ab initio software packages.

TT 28.8 Wed 11:30 H37

Chiral basis for qubits and decay of spin-helix states — •Frank Göhmann — Fakultät für Mathematik und Naturwissenschaften, Bergische Universität Wuppertal, 42097 Wuppertal, Germany

In a recent cold-atom experiment by the Ketterle group at MIT one-dimensional spin-helix states could be prepared and their time evolution induced by the XXZ Hamiltonian could be observed. The experiment allows to adjust the anisotropy parameter of the latter. For the special case of the XX model we describe the spatio-temporal decay of a transversal spin helix explicitly. The helix pattern stays stable in space, but has a non-trivial time-dependent decay amplitude which is of scaling form and is governed by a universal function that can be

represented as a semi-infinite determinant related to the discrete Bessel kernel. This representation is valid for all times, is numerically utterly efficient and allows us to obtain the long-time asymptotics of the function. Our work is a rare example of a quench that has been experimentally realized and for which the full time dependence could be calculated exactly.

V. Popkov, X. Zhang, F. Göhmann and A. Klümper, *Chiral basis for qubits and spin helix decay*, Phys. Rev. Lett. **132** (2024) 220404 (5pp)

TT 28.9 Wed 11:45 H37

Towards the chaotic melting at low energies in large systems — •Mathias Steinhuber[1], Jonas Rigo[2], Juan Diego Urbina[1], Klaus Richter[1], and Markus Schmitt[1,2] — [1]University of Regensburg, Regensburg, Germany — [2]Forschungszentrum Jülich GmbH, Peter Grünberg Institute, Quantum Control (PGI-8), Jülich, Germany

Thinking in a classical phase space picture, a many-body ground state should be localized around the minimum of the classical mean-field energy landscape with stable integrable features. But here, we investigate many-body ground states on chaotic features, as the phase space picture is actually fragile if we increase the system size and keep the quantum scale (the effective Plank constant $\hbar_{\text{eff}}$) fixed. With the new degrees of freedom, we disturb the energy landscape in the classical limit more and more such that classical chaos is present even for low energies. We show this phenomenon, called 'chaotic melting' [1,2], is indeed happening in the Bose-Hubbard system with disorder. By using neural quantum states we can push quantum calculations for ground states to large systems and find signatures of chaos at the ground state. An intriguing application for these large systems is that the Bose-Hubbard Hamiltonian with disorder is an effective model for transmon arrays which are a prime candidate for quantum computer hardware. Therefore we also gain access to quantum states describing a possible quantum computer with chaotic features.

TT 28.10 Wed 12:00 H37

Period n-tupling in driven two level systems — •Dhruv Deshmukh and Joachim Ankerhold — Institute for complex quantum systems, Ulm University, Germany

This talk presents the necessary and sufficient conditions for realizing period n-tupling phenomena in periodically driven two-level systems. For the specific case of a two-level system driven linearly by a sinusoidal drive, we numerically identify the drive parameters that enable period n-tupling. Experimental results verifying period doubling in an NV centre driven by a microwave drive, are given. Further, we show that period quadrupling drives yield pulses which are much faster than the standard (Rabi) $\pi/2$ and π pulses built from weak drives. These stronger and faster pulses can be utilized for qubit manipulation, enabling faster gates and more efficient pulse sequences. Moreover, they inspire a new strategy for constructing efficient pulses using a Floquet theory approach to optimal control. Furthermore, the drive parameters could also be set to achieve period-1 (stroboscopic) dynamical freezing. The fragility of such phenomena can be exploited for sensing applications, as illustrated with an example in magnetometry.

TT 28.11 Wed 12:15 H37

Efficient computation of cumulant evolution and full counting statistics: application to infinite temperature quantum spin chains — •Angelo Valli[1,2], Cătălin Pascu Moca[2,3], Miklós Antal Werner[1,4], Márton Kormos[1,2], Žiga Krajnik[5], and Tomaž Prosen[6] — [1]Budapest University of Technology and Economics, Muegyetem rkp. 3., 1111 Budapest, Hungary — [2]HUN-REN BME Quantum Dynamics and Correlations Research Group — [3]University of Oradea, 410087, Oradea, Romania — [4]HUN-REN Wigner Research Centre for Physics, P.O. Box 49, 1525 Budapest, Hungary — [5]New York University, 726 Broadway, New York, NY 10003, USA — [6]University of Ljubljana, Jadranska 19, 1000 Ljubljana, Slovenia

We propose a numerical method to efficiently compute quantum generating functions (QGF) for a wide class of observables in one-dimensional quantum systems at high temperature. We obtain high-accuracy estimates for the cumulants and reconstruct full counting statistics from the QGF. We demonstrate its potential on spin S=1/2 anisotropic Heisenberg chain, where we can reach time scales hitherto inaccessible to state-of-the-art classical and quantum simulations. Our results are in excellent agreement with a recent Google Quantum AI experiment [2] and challenge the conjecture of the Kardar-Parisi-Zhang universality for isotropic integrable quantum spin chains.

TT 28.12 Wed 12:30 H37

Machine learning approach to study the properties of ground and excited states in the 1D Bose-Hubbard model — •Yilun Gao[1], Alberto Rodríguez González[2,3], and Rudolf A. Römer[1] — [1]Department of Physics, University of Warwick, Coventry, CV4 7AL — [2]Departamento de Física Fundamental, Universidad de Salamanca, E-37008 Salamanca, Spain — [3]Instituto Universitario de Física Fundamental y Matemáticas (IUFFyM), Universidad de Salamanca, E-37008 Salamanca, Spain

Many-body quantum interacting systems continue to play a key role in theoretical developments of modern condensed matter physics. Various numerical techniques have been used to explore the features of these many-body systems. Exact diagonalization methods, which most results going beyond ground state properties are based on, can only deal with small system sizes $L \lesssim 15$ because the Hilbert dimensions grow exponentially in L. Recently, deep learning has emerged as a numerical technique that uses strategies of artificial intelligence to predict the physics of such systems. Here we focus on the Bose-Hubbard chain and use HubbardNet [1] to investigate the physics of ground and excited states. We show that the energies and wavefunctions predicted by HubbardNet agree well with the ones calculated by exact diagonalization over a broad range of interaction strengths. We investigate the properties of the eigenstates via their finite-size generalized fractal dimensions. [1] Ziyan Zhu, et al., HubbardNet: Efficient predictions of the Bose-Hubbard model spectrum with deep neural networks, Phys. Rev. Res., **5**, 043084 (2023)

TT 28.13 Wed 12:45 H37

Entanglement Transitions in Quantum Games through Reinforcement Learning — •Giovanni Cemin[1], Marin Bukov[1], and Markus Schmitt[2,3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]University of Regensburg, Regensburg, Germany — [3]Forschungszentrum Jülich, Institute of Quantum Control, Jülich, Germany

In this research, we investigate the dynamics of entanglement in Cliord circuits by employing a reinforcement learning (RL) algorithm in competition with a random agent. The RL agent is designed to strategically place gates that decrease entanglement, while the random agent aims to increase entanglement. This interaction between the two agents results in an entanglement transition, the nature of which is induced by the level of information accessible by the RL agent. By systematically varying the information provided to the RL agent, we analyze its impact on the transition characteristics. Our findings provide new insights into the interplay between entanglement manipulation and information constraints, shedding light on the fundamental mechanisms governing quantum circuit dynamics.

TT 29: 2D Materials: Electronic Structure and Exitations II (joint session O/HL/TT)

Time: Wednesday 10:30–12:45 Location: H11

TT 29.1 Wed 10:30 H11

The Bell-Shaped Component in Diffraction from 2D Materials — •Birk Finke[1], Christian Brand[1], Karim Omambac[1,2], Pascal Dreher[1], Hannah Kohler[1], Frank-J. Meyer zu Heringdorf[1,3,4], and Michael Horn-von Hoegen[1,3] — [1]Universität Duisburg-Essen — [2]Polytechnique Montréal Canada — [3]Center for Nanointegration Duisburg-Essen — [4]Interdisciplinary Center for Analytics on the Nanoscale

In 2D materials, the formation of moiré superlattices with graphene or hBN on crystalline surfaces alters electronic, vibrational, and chemical properties. Here we analysed an unusual broad diffraction background observed in low energy electron diffraction from 2D material systems, which is called the bell-shaped component (BSC). Employing SPA-LEED, LEEM, and μ-LEED we propose the origin to be the inelastic scattering of the low energy electrons at the vertically polarized ZA-phonons of the weakly bound graphene and hBN layers on Ir(111) and SiC(0001). For these systems the ZA-phonon branch exhibits a parabolic dispersion with a finite phonon frequency of a few meV at the Γ point. This results in a high phonon density at low energy, but high momentum causing the strong intensity of the BSC in diffraction. In the framework of kinematic scattering theory, we performed simulations of the inelastic diffuse scattering which quantitively confirm our proposal.

TT 29.2 Wed 10:45 H11

Combining DFT and ML to Explore the Electronic Properties of Nanoporous Graphene — •Bernhard Kretz and Ivor Lončarić — Institut Ruder Bošković, Zagreb, Croatia

Nano-porous graphene (NPG) holds great potential in electronics due to its tunable electronic properties. However, establishing a comprehensive understanding of how structural parameters influence these properties remains a challenge.

This work employs density functional theory (DFT) calculations combined with machine learning (ML) to systematically investigate both static and dynamic electronic properties across a set of 460 NPG structures derived from four distinct templates.

Our DFT results reveal correlations between structural features and band gaps within subsets of our NPG structures. Notably, we identify certain NPG configurations exhibiting band gap behavior analogous to armchair graphene nanoribbons. To predict the dynamic response of our NPG structures, we train two distinct ML networks: one for predicting forces and total energies, and another one for predicting band gaps. Using the former allows us to perform temperature-dependent molecular dynamics simulations for all 460 NPG structures, while the latter enables us to predict band gap evolution under varying operating temperatures, a crucial factor for semiconductor device performance. Our findings identify several NPG structures exhibiting band gaps suitable for semiconductor applications while demonstrating sufficient thermal stability to function effectively at typical operating temperatures.

Invited Talk TT 29.3 Wed 11:00 H11

Polaritons in two-dimensional materials and hybrids probed by electron beams — •Nahid Talebi — Institute for Experimental and Applied Physics, Kiel University, Leibnizstr. 19, 24118 Kiel

Polaritonic quasiparticles in two-dimensional (2D) materials have garnered significant attention in recent years, emerging as a promising platform for studying novel photon- and phonon-mediated correlations between various material excitations. In this work, we employ electron beams to investigate exciton and plasmon polaritons in diverse 2D materials, including transition-metal dichalcogenides, perovskites, hexagonal boron nitride, borophene, and hybrid systems. By comparing cathodoluminescence and photoluminescence spectroscopy, we uncover differences in the selection rules governing the excitation of quasiparticles by coherent light versus electron beams. Furthermore, leveraging a recently developed method that utilizes electron-driven photon sources inside an electron microscope for Ramsey-type spectroscopy, we examine the coherence of cathodoluminescence emitted by exciton polaritons (Nature Physics 19, 869 (2023)) and defects in hexagonal boron nitride (arXiv:2404.09879). These results provide new insights into the temporal coherence of the radiation from 2D materials excited by coherent and incoherent excitations.

TT 29.4 Wed 11:30 H11

Electron-phonon interaction in polar two-dimensional materials — •Gerrit Johannes Mann, Thorsten Deilmann, and Michael Rohlfing — Institute of Solid State Theory, University of Münster, Germany

Electron-phonon interaction is a crucial effect in solid state physics, in particular in two-dimensional materials. We recently developed a generally applicable ab-initio implementation on top of density functional theory that combines finite differences calculations with the perturbative Allen-Heine-Cardona framework in order to calculate the temperature-dependent renormalization of the electronic bandstructure due to electron-phonon interaction using a basis set of localized Gaussian orbitals. Our implementation circumvents the limiting problems of previous implementations and allows to evaluate Debye-Waller contributions beyond the rigid-ion approximation, which are usually neglected [1].

Incorporating effects from macroscopic electric fields into our implementation allows us to extend our calculations to the class of polar materials. In this presentation we discuss our results for two-dimensional transition-metal dichalcogenides, where the renormalization of the electronic bandstructure due to electron-phonon interaction can be as large as several hundreds of meV.

TT 29.5 Wed 11:45 H11

Structural modulations of unidirectional charge density waves in rare earth tellurides — •Eunseo Kim[1], Sanghun Lee[1], Junho Bang[1], Hyungryul Yang[1], Jongho Park[2], Changyoung Kim[2], Dirk Wulferding[2], Doohee Cho[1], Makoto Hashimito[3], Donghui Lu[3], and Sunghun Kim[4] — [1]Department of Physics, Yonsei University, Seoul 03722, Republic of Korea — [2]Department of Physics and Astronomy, Seoul National University, Seoul 08826, Republic of Korea — [3]Stanford Synchrotron Radiation Lightsource, SLAC National Accelerator Laboratory, Menlo Park, CA 94025, USA — [4]Department of Physics, Ajou University, Suwon 16499, Korea

Charge density waves (CDWs) in rare earth tellurides (RTe_3) provide a unique platform for exploring the interplay between lattice deformations and electronic order. Using scanning tunneling microscopy and spectroscopy (STM/S), we investigate unique surface features in two different materials, $GdTe_3$ and $DyTe_3$, that influence the CDW behavior. In $GdTe_3$, twin domain boundaries provide a static platform for observing the spatial "melting" of unidirectional CDWs and the emergence of bidirectional CDWs. Our spatial lock-in analysis demonstrates the attenuation of CDW order parameters and the proliferation of topological defects at these boundaries, correlating with enhanced local density of states near the Fermi level. In $DyTe_3$, nanowrinkles act as topological interfaces, hosting phase-winding CDWs and confining one-dimensional metallic states. These findings emphasize the role of local structural distortions in shaping CDW phenomena, offering insights into manipulating quantum states via lattice engineering.

TT 29.6 Wed 12:00 H11

Ultrafast Charge Separation on the Nanoscale Induced by a Uniform Field — •Jan-Philip Joost and Michael Bonitz — Kiel University, Institute for Theoretical Physics and Astrophysics, 24098 Kiel, Germany

When illuminated by white light, atoms, molecules, and materials absorb only certain characteristic energy contributions based on their absorption properties. Here, we show that this effect can be translated from energy to space: a spatially uniform laser pulse can create strongly localized carrier excitations and spatial charge separation on the sub-nanometer scale within a few femtoseconds, possibly opening new avenues for nanoelectronics. A promising candidate are small graphene heterostructures, which exhibit a pronounced space dependence of the DOS with strongly localized topologically protected states [1]. Direct evidence for this effect is presented by performing extensive NEGF simulations for these systems that take into account strong coupling and dynamical screening [2]. Further, we demonstrate multiple ways to excite targeted areas of the nanostructures, such as a proper choice of the laser energy, polarization, or carrier-envelope phase. Moreover, we find that the observed effects greatly benefit from surface screening, while in free-standing systems the targeted charge excitation is restricted by strongly bound excitons. The findings are expected to be applicable for a broad class of nanoscale monolayer clusters of graphene or TMDCs.

[1] J.-P. Joost et al., Nano Lett. **19**, 9045 (2019)

TT 29.7 Wed 12:15 H11

Two-dimensional breathing Kagome lattice of antimony atoms on a SiC substrate — •Bing Liu[1], Kyungchan Lee[1], Jonas Erhardt[1], Manish Verma[1], Stefan Enyner[1], Cedric Schmitt[1], Philipp Kessler[1], Lukas Gehrig[1], Chris Jozwiak[2], Aaron Bostwick[2], Martin Kamp[1], Eli Rotenberg[2], Jörg Schäfer[1], Simon Moser[1], Giorgio Sangiovanni[1], and Ralph Claessen[1] — [1]Physikalisches Institut, Universität Würzburg, 97074 Würzburg, Germany — [2]Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA

The Kagome lattice, characterized by flat electronic bands, which represents a class of candidate materials for charge order, time-reversal symmetry-breaking and exotic superconductivity. In this work, we report the successful synthesis of a breathing Kagome lattice of Sb on SiC surface. Band mapping reveals a significant gap opening at the K point near the Fermi level, driven by different hopping parameters within the breathing Kagome lattice. Scanning tunneling microscopy measurements of this phase confirm a well-ordered 2x2 lattice reconstruction, consistent with the breathing Kagome unit cell. Furthermore, DFT calculations elucidate the role of the Sb p-orbitals. Specifically, near the Fermi level the physics is dominated by px and py orbitals, which are sensitive to hopping and possibly electron correlation, giving rise to an energy gap, and by their splitting reflect the breathing Kagome lattice situation. Our findings demonstrate a pathway for constructing two-dimensional Kagome lattices on semiconductor surfaces, and are encouraging further research into their spin and electronic properties.

TT 29.8 Wed 12:30 H11

Ultrafast lattice dynamics of monolayer ReS_2 — •Victoria C. A. Taylor[1], Yoav W. Windsor[1,2], Samuel Lai[3], Hyein Jung[1,2], Fang Lui[3], and Ralph Ernstorfer[1,2] — [1]Fritz-Haber-Institut der Max-Planck-Gesellschaft, 14195 Berlin, Germany — [2]Technische Universität Berlin, 10623 Berlin, Germany — [3]Stanford University, Stanford, CA 94305, USA

Within the transition metal dichalcogenide (TMDC) material family, TMDCs containing rhenium stand out due to their low crystal symmetry. Instead of the common hexagonal structure, ReS_2 exhibits in-plane 1D chains of rhenium ions due to a Peierls-like distortion. This highly anisotropic crystal structure results in a range of material properties, such as anisotropic effective carrier masses, polarization dependent optical absorption, and extremely weak interlayer coupling.

We present femtosecond electron diffraction (FED) measurements of monolayer ReS_2. FED is a direct probe of photoexcited lattice dynamics, providing quantitative information on coherent and incoherent atomic vibrations on femtosecond timescales. In ReS_2 monolayers we observe a strong and complex lattice response to photoexcitation. In particular, we observe a rapid (<1 ps) collective response, indicative of a concerted change in ionic positions within the unit cell. We measure the fluence dependence of this response and investigate the effect of the pronounced polarization dependence of the optical excitation, which results from the material's in-plane anisotropy.

TT 30: Nanomechanical systems (joint session HL/TT)

The session covers the physics of nanomechanical systems.

Time: Wednesday 15:00–15:45 Location: H17

TT 30.1 Wed 15:00 H17

Optimizing an Integrated Photonic Racetrack Resonator for Optomechanical Synchronization — •Agnes Zinth[1] and Menno Poot[1,2,3] — [1]Department of Physics, TUM School of Natural Sciences, Technical University of Munich, Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany — [3]Institute for Advanced Study, Technical University of Munich, Garching, Germany

In the field of optomechanics, synchronization will be an essential tool in fields like sensing and quantum technologies. Towards this goal, we develop a photonic integrated optomechanical device consisting of a silicon nitride racetrack cavity with partly suspended waveguide that can vibrate freely. A second beam is added to improve the optomechanical coupling. The observed mechanical modes do not match in frequency, so we use a predisplaced beam instead [1]. The remaining frequency distance can be tuned by the laser power. As the light propagates in the predisplaced beam and only past the PhC beam, it shifts further than the photonic crystal one due to thermal effects. To synchronize them with optomechanical backaction, we also need to enhance the optical cavity. Therefore, we modify the transition from supported to suspended parts. Two different approaches lead to the desired improved optical quality. Currently, we are investigating their impact on the mechanics. We believe that, in the next generation of devices, we can synchronize the racetrack and photonic crystal beam.

[1] Geometric tuning of stress in predisplaced silicon nitride resonators. Nano Letters, 22(10), 4013-4019.

TT 30.2 Wed 15:15 H17

Quantum Mechanics in Two-Dimensional Dynamic Spaces — •Benjamin Schwager and Jamal Berakdar — Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Germany

In the study of systems with reduced dimensions one encounters quantum particles under spatial constraints. Their dynamics have to be modeled based on a configuration space that is a Riemannian manifold, in general, and the resulting quantum wave equations contain correction terms in dependence of its geometric properties. We consider particles which are confined to a flexible thin material shell by studying the Schrödinger equation on moving domains. The model assumes a static observer and couples the deformation dynamics of the material to the quantum dynamics it hosts via additional potential fields. Effects caused by the interplay of geometry and the temporal evolution of the underlying configuration space will be discussed.

TT 30.3 Wed 15:30 H17

Towards cavity optomechanics using 2D materials — •Petricia Sara Peter[1,2], Lukas Schleicher[1,2], Anne Rodriguez[1,2], Leonard Geilen[2,3], Alexander Musta[2,3], Benedict Brouwer[2,3], Alexander Holleitner[2,3], and Eva Weig[1,2] — [1]Chair of Nano and Quantum Sensors, TU Munich, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany — [3]Walter Schottky Institute, TU Munich, Germany

Two-dimensional (2D) materials, such as hexagonal boron nitride (hBN), are promising candidates for advancing cavity optomechanics due to their low mass, high mechanical strength, and unique optical properties. This work focuses on the fabrication of freely suspended hBN membranes on silicon oxide (SiO_2) and silicon nitride (Si_3N_3) substrates, utilizing a water-assisted wet transfer technique. Compared to the dry transfer method, this approach minimizes inhomogeneous stress and preserves optimal mode shapes, improving mechanical quality factors. A Michelson interferometer is used to measure the mechanical properties of the resulting drumhead resonators, including vibrational resonances, mode shapes, and quality factors. These results provide important insights into the performance and quality of the resonator, laying the groundwork for incorporating 2D materials into cavity optomechanical studies.

TT 31: Topology: Quantum Hall Systems

Time: Wednesday 15:00–16:45 Location: H31

Invited Talk TT 31.1 Wed 15:00 H31

Quantum Skyrmion Hall Effect — •Ashley Cook — MPI-PKS, Dresden, Germany

Motivated by recent discovery of additional topologically non-trivial phases of matter in lattice models beyond established classification schemes, we generalise the framework of the quantum Hall effect (QHE) to that of the quantum skyrmion Hall effect (QSkHE). This involves one key generalisation: considering particles on a two-sphere, which see a U(1) monopole, one can project to the lowest Landau level (LLL). Upon performing such a projection, the position coordinates become proportional to SU(2) generators by quenching of kinetic energy. An almost point-like LLL corresponds to matrix representation size for the SU(2) generators of N by N, with N small. The key generalisation is that such an almost point-like LLL with small orbital degeneracy can still host an intrinsically 2+1 dimensional topologically non-trivial many-body state. Equivalently, in regimes in which spin has previously been treated as a label (small N), spin encodes some finite number of spatial dimensions, in general. This many-body state can play the role, in the QSkHE, that a charged particle plays in the QHE.

TT 31.2 Wed 15:30 H31

Electric Field Induced Second-Order Anomalous Hall Transport in an Unconventional Rashba System — •Ankita Bhattacharya and Annica Black-Schaffer — Uppsala University, Sweden

Nonlinear responses in transport experiments may unveil information and generate new phenomena in materials that are not accessible at linear order due to symmetry constraints. While the linear anomalous Hall response strictly requires the absence of time-reversal symmetry, the second order, thus nonlinear, Hall response needs broken inversion symmetry. Recently, much effort has been made to obtain a second-order Hall voltage in response to a longitudinal ac driving current, both to obtain information about band geometric quantities and for its useful technological applications in rectification and frequency doubling. Typically, additional material engineering is required in noncentrosymmetric systems to obtain second-order responses since it obeys a stringent crystallographic symmetry constraint. To circumvent this, an alternative route is to apply a dc electric field. In our work, we uncover an electric field induced second-order anomalous Hall effect in an inversion-broken system possessing unconventional Rashba bands. We establish that the quantum metric, a geometrical feature of electronic wave functions providing information on non-trivial structure of Bloch bands, is responsible for providing the nonlinear Hall response. We are able to find a highly tunable electric field induced second-order anomalous Hall transport in probably the simplest system in 2D, which should be uncomplicated to verify experimentally due to multiple materials already being proposed.

TT 31.3 Wed 15:45 H31

Topological Thermal Hall Effect in the Geometrically Frustrated Magnet Gd_2PdSi_3 — •Parisa Mokhtari[1,2], Daiki Yamaguchi[1], Rinsuke Yamada[1], Akiko Kikkawa[3], Philipp Gegenwart[2], Yasujiro Taguchi[3], Yoshinori Tokura[1,3], and Max Hirschberger[1,3] — [1]Department of Applied Physics and Quantum-Phase Electronics Center, The University of Tokyo, Bunkyo-ku, Tokyo 113-8656, Japan — [2]Experimental Physics VI, Center for Electronic Correlations and Magnetism, University of Augsburg, 86135 Augsburg, Germany — [3]RIKEN Center for Emergent Matter Science, Wako, Saitama 351-0198, Japan

Geometrical frustrated Skyrmion lattices exemplify nontrivial topological states with non-zero scalar spin chirality and a finite Berry curvature in real space. In 2019, T. Kurumaji *et al.* reported a large topological Hall effect in the skyrmion phase in Gd_2PdSi_3 related to the spin chirality of the ground state [1].

In this talk, I will present the thermal Hall conductivity of the frustrated triangular-lattice magnet Gd_2PdSi_3. By entering the skyrmion lattice ground state, the field-dependent thermal Hall effect sharply increases against the adjacent incommensurate phases, similar to the electric Hall conductivity behaviour. Eventually, I will investigate the relationship of Hall entropy to the charge current and discuss the non-dissipativity of topological quantum transport in the geometrically frustrated magnet Gd_2PdSi_3.

[1] T. Kurumaji *et al.*, Science **365**, 914 (2019).

TT 31.4 Wed 16:00 H31

Orbital Magnetization of Dirac Electrons on Curved Surfaces — •Maximilian Fürst — Universität Regensburg

Orbital magnetic response of 2D, (almost) free electrons has extensively been studied in the past, starting from the discovery of Landau levels of Schrödinger [1]/(massless) Dirac [2] electrons with a linear/squareroot dispersion in the field strength B. Apart from Landau diamagnetism, this leads to De-Haas-van-Alphen type oscillations of the susceptibility, that are periodic in 1/B [3]. Confining

(massless) Dirac electrons on a curved surface predominantly leads to unusual oscillations of the susceptibility with periodicity in B. We discuss three example surfaces (Sphere, Cone, Pseudosphere) in a coaxial magnetic field.

TT 31.5 Wed 16:15 H31

Probing Fractional Statistics through Aharonov-Bohm Oscillations in Hanbury-Brown-Twiss Geometry — •Felix Puster, Matthias Thamm, and Bernd Rosenow — Institut für Theoretische Physik, Universität Leipzig, Brüderstraße 16, 04103 Leipzig, Germany

Since the theoretical prediction of anyonic excitations in the fractional quantum Hall effect, experimental evidence for their fractional statistics has been highly sought. In recent years, experiments have determined fractional braiding phases, providing clear evidence for fractional exchange phases. However, the braiding phase fixes the exchange phase of the particles only up to modulo Pi, leaving ambiguity in its exact value. Therefore, experiments capable of determining the exchange phase unambiguously are desired. To this end, we revisit the Hanbury-Brown-Twiss (HBT) geometry in the fractional quantum Hall regime. Our calculations extend previous theoretical work by incorporating an Aharonov-Bohm (AB) phase, finite temperature, and a finite distance between the tunneling points. We compute the current and current-current correlation functions and find that the anyonic exchange phase enters the AB oscillations in both quantities as an additive shift. While this shift is expected for the current-current correlations due to two-particle interference, for the current we interpret it as another example of time domain braiding of anyons – a phenomenon previously reported in geometries with tunneling of anyons across a quantum point contact.

TT 31.6 Wed 16:30 H31

Dipole Representation of Composite Fermions in Graphene's Quantum Hall Systems — •Sonja Predin — Scientific Computing Laboratory, Institute of Physics Belgrade, University of Belgrade, Pregrevica 118, 11080 Belgrade, Serbia

The even-denominator fractional quantum Hall effect has been observed in graphene's fourth Landau level (N = 3) [1]. Motivated by recent studies [2] on pairing and the nature of the ground state in this system, we extend the dipole representation of composite fermions to adapt it to graphene's quantum Hall systems, focusing on half-filled Landau levels. We derive an effective Hamiltonian incorporating particle-hole symmetry. At the Fermi level, the energetic instability of the dipole state is driven by the interplay between topology and symmetry, pushing the system towards a critical state. While paired states are considered, our findings demonstrate that a boost-invariant state lacking well-defined pairing instabilities is energetically favorable stable state, suggesting the absence of pairing instabilities in this system.

TT 32: Superconductivity: Yu-Shiba-Rusinov and Andreev Physics

Time: Wednesday 15:00–16:30 Location: H32

TT 32.1 Wed 15:00 H32

Ab-initio Investigation of YSR States of Fe Adatoms Interacting with Rashba-Split Surface States on $BiAg_2$ — •Ilias Klepetsanis[1,2], Philipp Rüssmann[1,3], and Samir Lounis[1,2] — [1]Forschungszentrum Jülich & JARA, Germany — [2]University of Duisburg-Essen and CENIDE, Germany — [3]University of Würzburg, Germany

One of the most sought after topics in modern condensed matter physics research, has been the creation of topological superconductivity systems that are able to host Majorana states. A plethora of material configurations have been proposed to that end, with emphasis on the interplay between magnetism, SOC and superconductivity. Here, we investigate the behaviour of Fe adatoms deposited on a $BiAg_2$ surface with a superconducting Nb substrate, using the Bogoliubov-de-Gennes full-potential relativistic Korringa-Kohn-Rostoker Green function method [1]. We explore the emergence of Yu-Shiba-Rusinov (YSR) states and their dependence on the adatom deposition site and magnetic moment rotation, as well as the effect of the strong spin-orbit coupling from the substrate. We construct chains of Fe adatoms and study the YSR state behaviour with an increasing chain length and its correlation with the magnetic ground state. Finally we explore the possibility of non-trivial end-states emerging on the Fe chain.

TT 32.2 Wed 15:15 H32

Shiba States in Magnet/Superconductor Heterostructures from First Principles — •Arnold Kole, Andrés Botello-Méndez, and Zeila Zanolli — Utrecht University, Utrecht, The Netherlands

The search for topological superconductors (TSC) with potential applications in quantum computing motivates the study of hybrid systems combining superconductivity, magnetism, and spin-orbit coupling. Previous work has shown the presence of in-gap states in these systems [1]. Of particular interest are Yu-Shiba-Rusinov (YSR) states, that arise due to interactions of magnetic impurities with a superconductor [1]. It has been proposed that these can be used to engineer topological superconductivity [1].

We demonstrate the emergence of topologically trivial in-gap YSR states in $CrCl_3$ islands on superconducting $NbSe_2$ [2]. Using Density Functional Theory (DFT), we show an increase of the Cr 3d density-of-states at the edge and an enhanced exchange interaction between the $CrCl_3$ edge and the $NbSe_2$ substrate [2]. This means that the $CrCl_3$ edge acts as a one-dimensional chain of magnetic impurities interacting with the superconducting $NbSe_2$. This can explain the emergence of the YSR states. Finally, we systematically show that these findings are robust to changes in computational details such as stacking, magnetic configuration and Hubbard U parameters [3].

TT 32.3 Wed 15:30 H32

Spin Dynamics in a Josephson Junction Between Two Superconducting Magnetic Impurity States — Fabian Ziesel[1], Björn Kubala[1,2], Joachim Ankerhold[1], and •Ciprian Padurariu[1] — [1]ICQ and IQST, Ulm University, Germany — [2]Institute of Quantum Technologies, German Aerospace Center (DLR), Ulm, Germany

We study the Josephson effect in a junction formed between two superconducting magnetic impurities. Such a junction was recently realized using a scanning tunneling microscope tip functionalized with a magnetic impurity that probes a second impurity on the sample [1]. Our work extends a recent theoretical investigation [2] by considering the mutually coupled dynamics between the impurity spins and the Josephson phase. We suggest that the Josephson effect can be exploited to manipulate the relative magnetic orientation of the impurities due to a Josephson-induced exchange interaction that arises.

Our theoretical approach treats the Josephson and spin dynamics equally. We identify a key experimental signature of spin dynamics: a small d.c. bias results in excess d.c. current due to the coupling between spins and the Josephson phase. We also discuss spin control, exemplified by inducing a spin-flip of an impurity using an adiabatic voltage pulse.

TT 32.4 Wed 15:45 H32

Yu-Shiba-Rusinov Spectroscopy of Triple Quantum Dot Molecules — •Vladislav Pokorný[1] and Martin Žonda[2] — [1]FZU - Institute of Physics, Czech Academy of Sciences, Na Slovance 2, 182 00 Prague, Czech Republic — [2]Faculty of Mathematics and Physics, Charles University, Ke Karlovu 5, 121 16 Prague, Czech Republic

We study a system of three quantum dots in triangular geometry with equal distances connected to a common superconducting lead and coupled via interdot Coulomb interaction. We provide complete ground state phase diagrams for the half-filled system in various regimes and study the behavior of the in-gap Yu-Shiba-Rusinov states. We use the superconducting impurity Anderson model to describe the system and solve it using a combination of effective methods based on the superconducting atomic limit and the continuous-time hybridization expansion quantum Monte Carlo. The results can provide deep insight into experiments involving trimers made of magnetic molecules on superconducting substrates.

TT 32.5 Wed 16:00 H32

Experimental Signal of Multiple Andreev Reflexion in Spin Splitted Tunneling Junctions — •David Caldevilla-Asenjo[1], Sara Catalano[2,3], Pietro Cattaneo[4], Fernando Sebastian Bergeret[1], Maxim Ilyn[1], and Celia Rogero[1] — [1]Centro de Fisica de Materiales (CSIC-UPV/EHU),20018 Donostia San Sebastian — [2]Materials Physics Center (MPC), Paseo Manuel de Lardizabal 5,20018 Donostia, Spain. — [3]IKERBASQUE, Basque Foundation for Science,

48009 Bilbao, Basque Country, Spain. — [4]Politecnico di Milano, 20133, Milano, Italy

A ferromagnetic insulator in contact with a superconductor induces an effective exchange field, resulting in a spin splitting of the BCS density of states [1,2]. In this work, we study planar Josephson Junctions where one electrode is in contact with a thin layer of the ferromagnetic insulator europium sulfide. Samples are grown in situ by using the hard-mask technique in UHV. We characterized the junctions through DC transport measurements at a base temperature of 10mK, observing Josephson coupling and Multiple Andreev Reflection according to the transparency of the barrier. We propose a theory model to interpret the junction spectra taking into account the exchange field. Our results provide an experimental and theoretical description of ingap transport processes in superconducting junctions proximitized by a ferromagnetic insulator [3].

TT 32.6 Wed 16:15 H32

Nonequilibrium Josephson and Andreev Transport in Quantum Dot Junctions — •Jordi Picó-Cortés[1], Gloria Platero[2], Andrea Donarini[1], and Milena Grifoni[1] — [1]Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany — [2]Instituto de Ciencia de Materiales de Madrid (CSIC) 28049 Madrid, Spain

We investigate nonequilibrium transport through superconducting nanojunctions using a Liouville space approach [1]. The formalism allows us to study finite-gap effects, and to account for both quasiparticle and Cooper-pair tunneling. With focus on the weak-tunneling limit, we study the stationary dc and ac current up to second order (cotunneling) in the hybridization energy. For the particular case of a strongly interacting quantum dot sandwiched between two superconductors, we identify the characteristic virtual processes that yield the Andreev and Josephson current and obtain the dependence on the gate and bias voltage for the dc current, the critical current, and the phase-dependent dissipative current. In particular, the critical current is characterized by regions in the stability diagram in which its sign changes from positive to negative, resulting in a multitude of $0-\pi$ transitions. The latter signal the interplay between strong interactions and tunneling at finite bias.

TT 33: Correlated Magnetism – Spin Liquids

Time: Wednesday 15:00–18:15 Location: H33

TT 33.1 Wed 15:00 H33

An Atlas of Classical Pyrochlore Spin Liquids — •Daniel Lozano-Gómez[1,2], Owen Benton[3], Michel Gingras[2], and Han Yan[4] — [1]Technische Universität Dresden, Dresden, Germany — [2]University of Waterloo, Waterloo, Canada — [3]Queen Mary University of London, London, United Kingdom — [4]The University of Tokyo, Kashiwa, Japan

The pyrochlore lattice magnet has been one of the most fruitful platforms for the experimental and theoretical search for spin liquids. Besides the canonical case of spin ice, works in recent years have identified a variety of new quantum and classical spin liquids from the generic nearest-neighbor anisotropic spin Hamiltonian on the pyrochlore lattice. Despite the rich variety of SLs realized in this lattice, a general framework for the classification and characterization of these is still lacking. In this work, we develop such a theoretical framework to allocate interaction parameters stabilizing different classical SLs and derive their corresponding effective generalized emerging Gauss's laws at low-temperatures. Combining this with Monte Carlo simulations, we systematically identify all classical SLs for the general nearest-neighbor anisotropic spin Hamiltonian on the pyrochlore lattice. We uncover new SL models with exotic forms of generalized Gauss's law and multipole conservation laws. Our work serves as a treasure map for the theoretical study of classical and quantum spin liquids, as well as for the experimental search and rationalization of exotic pyrochlore lattice magnets.

TT 33.2 Wed 15:15 H33

Higher-Rank Spin Liquids and Spin Nematics from Competing Orders in Pyrochlore Magnets — •Niccolò Francini, Lukas Janssen, and Daniel Lozano-Gómez — Institut für Theoretische Physik and Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, 01062 Dresden, Germany

Pyrochlore magnets have proven to provide an excellent arena for the realization of a variety of many-body phenomena such as classical and quantum order-by-disorder, as well as spin liquid phases described by emergent gauge field theories. These phenomena arise from the competition between different symmetry-breaking magnetic orders. In this work, we consider a subspace of the most general bilinear nearest-neighbor Hamiltonian on the pyrochlore lattice, parameterized by the local interaction parameter $J_{z\pm}$, where three symmetry-breaking phases converge. We demonstrate that for small values of $|J_{z\pm}|$, a conventional $\mathbf{q} = 0$ ordered phase is selected by a thermal order-by-disorder mechanism. For $|J_{z\pm}|$ above a certain finite threshold, a novel spin-nematic phase is stabilized at low temperatures. Instead of the usual Bragg peaks, the spin-nematic phase features lines of high intensity in the spin structure factor. At intermediate temperatures above the low-temperature orders, a rank-2 U(1) classical spin liquid is realized for all $J_{z\pm} \neq 0$. We fully characterize all phases using classical Monte-Carlo simulations and a self-consistent Gaussian approximation.

TT 33.3 Wed 15:30 H33

Raman Circular Dichroism of Chiral Quantum Spin Liquids — •Eduard Koller[1,2,3], Valentin Leeb[1,3], Natalia Perkins[4], and Johannes Knolle[1,3,5] — [1]Technical University of Munich, Germany — [2]Institute for Advanced Study, TUM, Germany — [3]Munich Center for Quantum Science and Technology, Germany — [4]School of Physics and Astronomy, University of Minnesota, USA — [5]Blackett Laboratory, Imperial College London, United Kingdom

We investigate the Raman circular dichroism (RCD) of chiral Quantum spin liquids as a probe of the topological properties of fractionalised spin excitations. Starting from the Loudon Fleury formalism we show that the scattering Intensity is directly related to the light matter coupling formalism of spinon bands. We reveal that the RCD signal arises as a result of the Berry curvature and Quantum geometry contributions. We show application to different model quantum spin liquids.

TT 33.4 Wed 15:45 H33

Low-Temperature Features of the Quantum Spin Liquid Candidate PCTO Crystal Structure — •Alexander Mistonov[1], Abanoub Hanna[2], Elaheh Sadrollahi[1], Heidi Savey-Bennett[3], Martin von Zimmermann[4], Elizabeth Blackburn[5], Bella Lake[2], and Jochen Geck[1] — [1]Technische Universität Dresden — [2]Helmholtz-Zentrum Berlin — [3]The University of Manchester — [4]Deutsches Elektronen-Synchrotron DESY — [5]Lund University

$PbCuTe_2O_6$ (PCTO) is well known as a promising candidate for quantum spin liquid compounds. Magnetic ordering does not occur down to 0.02 K [1]. Additionally, diffuse continua are observed in magnetic spectra [2]. At the same time, heat capacity and dielectric response demonstrate signatures of an order-disorder ferroelectric (FE) transition at ~ 1 K [3]. According to thermal expansion measurements, this transition is believed to be accompanied by structural changes. We have performed a high-energy single-crystal X-ray diffraction experiment using a dilution refrigerator to investigate it for the first time. We have observed Bragg peaks that are forbidden for the reported high-temperature crystal structure (space group $P4_132$ [4]) and studied their evolution. In the current work, we share our findings from below and above the FE transition.

TT 33.5 Wed 16:00 H33

What is carrying the heat in the thermal Hall effect of honeycomb magnets? — •Ralf Claus, Jan Bruin, Yosuke Matsumoto, Pascal Reiss, Akmal Hossain, Lichen Wang, Pascal Puphal, Bernhard Keimer, and Hidenori Takagi — Max-Planck-Institut für Festkörperforschung, D-70569 Stuttgart

The observation of a half-integer quantized thermal Hall effect in the honeycomb magnet α-$RuCl_3$ was interpreted as an experimental hallmark for Kitaev majorana fermions. However, follow-up studies only partly reproduced this result and have offered alternative explanations such as phonons or topological magnons. To narrow down the nature of the heat carrying quasiparticles, we conducted a comparative study of the longitudinal (κ_{xx}) and transversal (κ_{xy}) heat transport on α-$RuCl_3$ and $Na_3Co_2SbO_6$ (NCSO). Both share the same crystal symmetries and have comparable magnetic phase diagrams. However, one key difference is that for applied in-plane magnetic fields $B > 3$ T NCSO is in a fully spin-polarized phase convincingly excluding the presence of any majorana fermions. Remarkably, we observed a finite κ_{xy} in NCSO up to $B \approx 10$ T, which displays striking similarities in shape, angle-dependence, and magnitude to that of α-$RuCl_3$. Furthermore, the field dependences of κ_{xx} and of the thermal Hall angle (κ_{xy}/κ_{xx}) across all α-$RuCl_3$ and NCSO samples suggest a substantial phononic contribution to κ_{xy}. Ultimately, we propose that topological magnons are responsible for generating the Hall temperature gradient which in turn is significantly enhanced by phonon-magnon interaction.

TT 33.6 Wed 16:15 H33

Variational Monte Carlo Simulations of Two-dimensional Quantum Spin Liquids — •Florian Michael and Benedikt Fauseweh — TU Dortmund University, Dortmund, Germany

In this project we use state-of-the-art variational algorithms to train neural quantum states for the quantum spin liquid phase of the J1-J2 Heisenberg model on a square lattice. Specifically, this approach makes use of a hybrid architecture of a restricted Boltzmann machine and pair-product states, capturing both global and local correlations efficiently. To further increase the precision of the wave function representation as well as mitigate finite-size effects, we apply quantum number projections and impose twisted boundary conditions.

The project is implemented within the NetKet framework, leveraging the automatic differentiation and just-in-time compilation of JAX as well as GPU accelerated high-performance clusters. The goal is to further advance the application of neural quantum states in quantum many-body physics and gain new insights on properties of quantum spin liquids that are currently difficult to simulate due to their long-range entanglement and absence of magnetic order.

TT 33.7 Wed 16:30 H33

Quantum simulation of fermionic, non-Abelian lattice gauge theories in (2+1)D — •Gaia De Paciani[1,2], Lukas Homeier[1,2,3], and Fabian Grusdt[1,2] — [1]Department of Physics and Arnold Sommerfeld Center for Theoretical Physics (ASC), Ludwig-Maximilians-Universität, München, Germany — [2]Münich Center for Quantum Science and Technology (MCQST), München, Germany — [3]University of Colorado, Boulder, Colorado

Understanding and simulating non-Abelian quantum spin-liquids and dimer models is an open challenge in the condensed matter and high energy physics landscape. Recent advancements in the field of quantum simulations have significantly expanded its potential for applications, particularly in the context of lattice gauge theories (LGTs). Nevertheless, maintaining gauge invariance throughout a simulation remains a critical challenge, especially for large-scale non-Abelian LGTs. We propose a novel approach to simulate non-Abelian U(N) LGTs with dynamical fermionic matter in (2+1) dimensions, enhancing the reliability of the simulation through the suppression of the occupation of gauge invariant sectors. We present a comprehensive framework to simulate gauge-invariant dynamics and we propose two experimental platforms – utilizing ultracold alkaline-earth-like atoms and Rydberg-dressing – to implement these models, enabling the quantum simulation of large-scale non-Abelian gauge theories in near-term experiments.

15 min. break

Invited Talk TT 33.8 Wed 17:00 H33

Emergent Dynamical Gauge Fields in Generic Kitaev Spin Liquids: From Monolayer to Multilayers — •Aprem Joy and Achim Rosch — Institute for Theoretical Physics, University of Cologne

Emergent gauge fields and fractional excitations are long sought-after in modern condensed matter physics. The Kitaev spin liquid and its potential realization in the so called “Kitaev materials" have been at the frontier of this search. The Kitaev spin liquid realizes an emergent static Z2 gauge field with vison excitations strongly interacting with Majorana fermions, by virtue of its gauge flux. While static in the idealized Kitaev model, single visons and vison pairs become dynamical degrees of freedom in the presence of perturbations. We develop a concise theory of the universal properties of single visons in weakly perturbed Kitaev models. We focus both on single-layer and multi-layer systems, motivated by the layered structure of materials. When Kitaev models are stacked on top of each other, weakly coupled by Heisenberg interaction, a rich zoo of mobile gauge excitations emerge whose dynamics is strongly constrained by topology and residual conservation laws, resulting in sub-dimensional mobilities, reminiscent of fractons. Furthermore, we show how vison dynamics in Kitaev materials can lead to novel signatures in relaxation experiments.

[1] A. Joy and A. Rosch, Phys. Rev. X 12, 041004 (2022);

TT 33.9 Wed 17:30 H33

Pressure-dependent magnetism of the Kitaev candidate Li_2RhO_3 — •Efrain Insuasti Pazmino[1], Bin Shen[2], Ramesh Dhakal[3], Friedrich Freund[2], Philipp Gegenwart[2], Steve M. Winter[3], and Alexander A. Tsirlin[1] — [1]Leipzig University, Germany — [2]University of Augsburg, Germany — [3]Wake Forest University, USA

In the search for a Quantum Spin Liquid (QSL) state in real materials, hydrostatic pressure is employed to move honeycomb Kitaev compounds closer to or farther from a QSL state. The candidates studied so far have exhibited long-range magnetic ordering at lower temperatures. However, the candidate Li_2RhO_3 does not show a magnetic transition at low temperatures but instead exhibits spin freezing. Magnetic couplings obtained through theoretical super-exchange and Exact Diagonalization calculations evolve away from the Kitaev limit as pressure increases. Interestingly, the freezing temperature determined in our magnetization measurements remains constant under increasing pressure and does not correlate with the changes in magnetic couplings. An analysis of simulations and experiments suggests that spin freezing could arise from extrinsic factors such as stacking faults and crystal defects. Furthermore, the J_3 coupling was found to be unusually small in comparison with other Kitaev materials. Our work shows commonalities in the pressure evolution of the Kitaev iridates and rhodates where the decrease in the bond angle suppresses the Kitaev coupling while enhancing the off-diagonal anisotropy.

This work was supported by DFG via TRR360 (492547816).

TT 33.10 Wed 17:45 H33

Frustrated multipolar degrees of freedom: The quadrupolar Kitaev model — •Partha Sarker and Urban Friedrich Peter Seifert — Institute for Theoretical Physics, University of Cologne, Zülpicher Straße 77, D-50937 Köln

Frustrated multipolar exchange interactions between spin-S local moments ($S > 1/2$) have been suggested to possibly give rise to quantum spin liquid-like ground states featuring an emergent gauge structure and fractionalized excitations. However, only little is known about characteristic features and experimental signatures of such "multipolar spin liquids". To this end, in this work we turn to the "Quadrupolar Kitaev model" of $S = 1$ moments on a honeycomb lattice as a drosophila, for which recent numerical studies have found a deconfined ground state with topological order. As the model, similar to the spin-S generalization of the Kitaev honeycomb model, is not exactly solvable, we use a combination of mean-field theory and exact symmetry analysis to investigate competing ground states, including multipolar liquids, and their (fractionalized) excitations.

TT 33.11 Wed 18:00 H33

Phases of the Anyonic Hubbard Ladder for Fibonacci Anyons — •Nico Kirchner[1], Adam Gammon-Smith[2], and Frank Pollmann[1] — [1]Technical University of Munich, TUM School of Natural Sciences — [2]School of Physics and Astronomy, University of Nottingham

Two-dimensional systems such as quantum spin liquids may exhibit anyonic excitations that feature exchange statistics beyond the bosonic and fermionic cases. A fundamental question regarding such quasiparticles is how the richer exchange statistics influence their mutual interactions and which phases may arise in systems of anyons as a consequence. To study this topic, we consider the particular case of Fibonacci anyons subject to an anyonic Hubbard model with nearest-neighbor repulsion on a two-leg ladder. Focusing on half-filling, for low interaction strengths a metallic phase is found, whereas for strong repulsion, the anyons form a charge-density wave in real space. Within this regime, the effective interactions arising from the exchange statistics give rise to multiple distinct phases that can be distinguished using the scaling of the entanglement entropy and the spectra of matrix product state transfer matrices.

TT 34: Superconductivity: Theory

Time: Wednesday 15:00–18:30 Location: H36

TT 34.1 Wed 15:00 H36

Eliashberg theory and band-off-diagonal superconductivity — •Bernhard Putzer[1,2] and Mathias S. Scheurer[1] — [1]Institute for Theoretical Physics III, University of Stuttgart, 70550 Stuttgart, Germany — [2]Institute for Theoretical Physics, University of Innsbruck, Innsbruck A-6020, Austria

In contrast to the mean field approximation of BCS theory, the Migdal-Eliashberg approach is a more sophisticated framework to describe phonon-mediated superconductivity. Allowing strong coupling between electronic and bosonic fields opens the door to investigate the effects of inter-band processes on the superconducting state in a controllable setting. We derive and solve the Eliashberg equations for a two-band model, inspired by twisted graphene systems, finding an entirely band-off-diagonal superconducting order parameter. By including full momentum and Matsubara fre- quency dependence, we uncover a mixing of even- and odd-frequency states induced by the band splitting. As a result, the superconductor exhibits very unconventional spectral properties for electron-phonon pairing; this includes a region with a nodal spectrum and a region with finite gap, which is, however, much smaller than the order parameter magnitude. Our findings have consequences for recent experiments on the superconducting state in twisted bilayer and trilayer graphene.

TT 34.2 Wed 15:15 H36

From charge fluctuations to pairing instabilities: Nonperturbative enhancement of the electron-phonon coupling driven by electronic correlations — •Emin Moghadas[1], Matthias Reitner[1], Alexander Kowalski[2], Giorgio Sangiovanni[2], Sergio Ciuchi[3,4], and Alessandro Toschi[1] — [1]Institute of Solid State Physics, TU Wien, Vienna, Austria — [2]Institut für Theoretische Physik und Astrophysik and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, Würzburg, Germany — [3]Dipartimento di Scienze Fisiche e Chimiche, Università dell'Aquila, Coppito-L'Aquila, Italy — [4]Istituto dei Sistemi Complessi, CNR, Roma, Italy

We present a thorough investigation of the nonperturbative electronic mechanisms, which could lead to significant enhancements of the electron-phonon coupling in strongly correlated electron systems. Using dynamical mean-field theory (DMFT) for the single band Hubbard model on the square lattice, we analyze corrections to second-order electron-phonon processes arising from electronic fluctuations near the Mott metal-to-insulator transition (MIT). In this regime, the isothermal charge response becomes particularly large at small momenta, indicating tendencies towards phase-separation instabilities and enabling a substantial enhancement of the effective electron-phonon coupling. Eventually, we critically discuss the impact of our findings on observable spectral quantities as well as possible implications for the emergence of pairing instabilities.

TT 34.3 Wed 15:30 H36

Detailed analysis of the superconducting gap with Dynes pair-breaking scattering — •Anastasiya Lebedeva and František Herman — Comenius University in Bratislava

In our work, we study the energy gap behavior within the Dynes superconductor theory. This model generalizes the Bardeen-Cooper-Schrieffer (BCS) approach by including the pair-breaking disorder, introducing the tunneling in-gap states up to a Fermi level. Elaborating on the self-consistent gap equation, we obtain useful results which are also interesting from the experimental point of view. For example, the derived relations may serve to estimate the pair-breaking impurities concentration in the superconductor i.a. using only the energy gap and the critical temperature values of the material. Moreover, we offer the heuristic gap-to-temperature dependence providing up to 5%-precision in the whole temperature range. It is a more convenient tool compared to the cumbersome numerics used by now.

This work has been supported by the Slovak Research and Development Agency under the Contract no. APVV-23-0515, by the European Union's Horizon 2020 research and innovation program under the Marie Skłodowska-Curie Grant Agreement No. 945478.

TT 34.4 Wed 15:45 H36

Superconducting modes in the presence of Coulomb repulsion — •Joshua Althüser and Götz Uhrig — TU Dortmund, Otto-Hahn-Str. 4, 44227 Dortmund, Deutschland

We numerically study the collective excitations present in BCS-superconductors including screened Coulomb interactions. By varying the screening strength, we analyze its impact on the system. We use a formulation of the effective phonon-mediated interaction between electrons that depends on the energy transfer between particles, rather than being a constant in a small energy shell around the Fermi edge. We compute the system's Green's functions using the iterated equations of motion (iEoM) approach, which ultimately enables a comprehensive analysis of collective excitations. For weak couplings, we identify the well-known amplitude (Higgs) mode at the quasiparticle continuum's lower edge and the phase (Anderson-Bogoliubov) mode at zero energy for a neutral system, which shifts to higher energies as the Coulomb interactions are switched on. As the phononic coupling is increased, the Higgs mode emerges from the continuum, and additional phase and amplitude modes appear, persisting even with active Coulomb interactions.

TT 34.5 Wed 16:00 H36

Obstructed pairs with zero superfluid stiffness — •Tamaghna Hazra and Jörg Schmalian — Karslruhe Institute of Technology

We present a microscopic pairing mechanism in which the kinetic energy of pairs is much lower than the kinetic energy of electrons. This results in interaction-driven localization of charge without extrinsic disorder and is characterized by a vanishing superfluid stiffness. Localized pairs gain more kinetic energy from resonating between sublattices in a bosonic compact localized state, than from delocalizing throughout the material. This is grounded in a microscopic model building on a structural motif shared by many oxide superconductors - strongly interacting localized electrons realize spin degrees of freedom on the vertices and doped charge lives on the edges of the Bravais lattice. In the strong-coupling limit, local unconventional pairs realize the bosonic analogue of flat bands supported on line graphs. We discuss the experimental implications of this pairing mechanism, with concrete falsifiability criteria, and emphasize the broad scope of this recipe in connection to diverse families of strongly correlated materials which share the key ingredients that go into it.

TT 34.6 Wed 16:15 H36

Electronic structure and superconductivity in nickelates and cuprates: Insights from DMFT and DΓA — •Eric Jacob[1], Mario Malcolms de Oliveira[2], Thomas Schäfer[2], Paul Worm[1], Liang Si[3,1], and Karsten Held[1] — [1]Institute of Solid State Physics, TU Wien, 1040 Vienna, Austria — [2]Max-Planck-Institut für Festkörperforschung, 70569 Stuttgart, Germany — [3]School of Physics, Northwest University, Xi'an 710127, China

The infinite-layer nickelates and cuprates represent two compelling families of materials for exploring unconventional superconductivity and correlated electronic phenomena. I will discuss recent advances in understanding the electronic structure of infinite-layer nickelates, focusing on insights from dynamical mean-field theory (DMFT) and their comparison with experimental findings ([1]) from angle-resolved photoemission spectroscopy (ARPES). This helps [2] constrain possible scenarios for their electronic states. In particular, there is only one Ni orbital crossing the Fermi surface. Additionally, I will present ongoing investigations into superconductivity in both nickelates and cuprates, based on the dynamical vertex approximation ($D\Gamma A$ [3], [4]).

Funding through the FWF project I5398 is gratefully acknowledged.

TT 34.7 Wed 16:30 H36

Towards an *ab initio* theory of high-temperature superconductors: a study of multilayer cuprates. — •Benjamin Bacq-Labreuil[1,2], Benjamin Lacasse[1], André-Marie Tremblay[1], David Sénéchal[1], and Kristjan Haule[3] — [1]Institut quantique, Université de Sherbrooke, Canada — [2]IPCMS, Université de Strasbourg, France — [3]Center for Materials Theory, Rutgers University, USA

Significant progress towards a theory of high-temperature superconductivity in cuprates has been achieved via the study of effective models. Yet, material-specific predictions for high-temperature superconductors, while essential for constructing a comprehensive theory, remain out of reach. By combining cluster dynamical mean-field theory and density functional theory in a charge-self-consistent manner, here we show that the goal of material-specific predictions for high-temperature superconductors from first principles is within reach. We demonstrate the capabilities of our approach by performing an in-depth study of two representatives ($Ca_{(1+n)}Cu_nO_{2n}Cl_2$ and $HgBa_2Ca_{(n-1)}Cu_nO_{(2n+2)}$) of the still mysterious multilayer cuprates. We shed light on the microscopic origin of many salient features of multilayer cuprates, in particular the n-dependence of their superconducting properties. Our work establishes a framework for comprehensive studies of high-temperature superconducting cuprates, enables detailed comparisons with experiment, and, through its *ab initio* settings, unlocks opportunities for theoretical material design of high-temperature superconductors.

TT 34.8 Wed 17:00 H36

Enhanced entanglement in the pseudogap — •Frederic Bippus[1], Juraj Krsnik[1], Motoharu Kitatani[2,3], Anna Kauch[1], Gergö Roosz[4], and Karsten Held[1] — [1]Institute of Solid State Physics, TU Wien, Vienna, Austria — [2]Department of Material Science, University of Hyogo, Ako, Hyogo, Japan — [3]RIKEN Center for Emergent Matter Sciences (CEMS), Wako, Japan — [4]HUN-REN Wigner Research Centre for Physics, Budapest, Hungary

We show significantly enhanced entanglement in the pseudogap regime of the Hubbard model using the dynamical vertex approximation (DGA) [1], a nonlocal extension to the dynamical mean-field theory. The pseudogap, a partially gapped electronic state, is observed near the superconducting transition in cuprates and nickelates. Leveraging DGA, we compute the quantum variance-a lower bound to the quantum Fisher information [2] from the spin susceptibility directly on the imaginary Matsubara axis. By circumventing the need for ill-controlled analytical continuation, our approach provides a robust framework for probing entanglement depth. The results show good agreement with experimental data [3]. Additionally, Ornstein-Zernike fits provide analytical insights.

This work is supported by the SFB Q-M&S (FWF project ID F86).

TT 34.9 Wed 17:15 H36

Time evolution of surface state wave packets in nodal noncentrosymmetric superconductors — •Clara Johanna Lapp[1,2], Julia Link[1,2], and Carsten Timm[1,2] — [1]Institute of Theoretical Physics, TU Dresden, 01062 Dresden, Germany — [2]Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, 01062 Dresden, Germany

Nodal noncentrosymmetric superconductors can host zero-energy flat bands of Majorana surface states within the projection of the nodal lines onto the surface Brillouin zone. Thus, these systems can have stationary, localized Majorana wave packets on certain surfaces, which may be a promising platfrom for quan-

tum computation. However, for such applications it is important to find ways to manipulate the wave packets in order to move them without destroying their localization or coherence. As the surface states have a nontrivial spin polarization, applying an exchange field, e.g., by introducing a magnetic insulator at the surface, makes the previously flat band slightly dispersive. We aim to use an adiabatic change of the exchange field to move wave packets on the surface. We therefore investigate the time evolution of a maximally localized wave packet under the influence of such an exchange field employing exact diagonalization as well as quasiclassical approximations.

TT 34.10 Wed 17:30 H36

Interplay of superconductivity and altermagnetism: A symmetry perspective — •Kirill Parshukov[1], Niclas Heinsdorf[1,2], Benjamin T. Zhou[2], Marcel Franz[2], and Andreas P. Schnyder[1] — [1]Max Planck Institute for Solid State Research, Stuttgart, Germany — [2]The University of British Columbia, Vancouver BC, Canada

The interplay between altermagnetism and superconductivity gives rise to several interesting phenomena, including unconventional Josephson effects, diode effects, Cooper pair splitting, and topological superconductivity. In this talk, I investigate how altermagnetic symmetries can lead to new superconducting states with interesting topological properties. Since the superconducting gap functions must transform as irreducible co-representations of the spin-point groups, I first construct all possible superconducting basis functions. Importantly, because the spin-point group symmetries act simultaneously on the spin and the lattice, the spin and spatial parts of the basis functions are coupled in an intricate manner. I illustrate this by considering several examples in two dimensions, including the superconducting states of an altermagnet with four Dirac points [1].

TT 34.11 Wed 17:45 H36

Emergence of a condensate with finite-energy Cooper pairing in hybrid exciton/superconductor systems — •Viktoriia Kornich — University of Würzburg, Würzburg, Germany

I will consider a setup consisting of excitons formed in two valleys, with proximity-induced Cooper pairing, different in the conduction and valence bands. Due to the combination of a Coulomb interaction within excitons and superconducting proximity effects, Cooper pairing between electrons from valence and conduction bands from different valleys is formed. Thus, the gap between these electrons can be much larger than the usual superconducting pairing energies. This Cooper pairing has both even- and odd-frequency contributions. I will show that there is a phase transition into the formation of a robust macroscopic condensate of such Cooper pairs and then will suggest a detection scheme of it via Higgs modes.

TT 34.12 Wed 18:00 H36

Third-harmonic generation currents in pair-density wave superconductor — •Pascal Derendorf[1], Peayush Choubey[2], and Ilya Eremin[1] — [1]Institut für Theoretische Physik III, Ruhr-Universität Bochum, Bochum, Germany — [2]Indian Institute of Technology-Roorkee, Roorkee, India

We investigate the signatures of a unidirectional pair-density wave (PDW) state in the third harmonic generation (THG) using an effective microscopic model, developed previously in Refs. [1,2]. The system possesses a unidirectional PDW state with d-wave symmetry in thermodynamic equilibrium ground state without extra need for an additional perturbation such as external Zeeman field or leading charge density wave order. We extend this model under the non-equilibrium by including a periodic driving in the form of external ac-field. The signatures of the emerging massive modes on the THG are derived via a gauge-invariant effective action approach. We discuss the emerging signatures in the third harmonic generation and their origin.

TT 34.13 Wed 18:15 H36

Describing superconductivity through interpretable artificial intelligence — •Herzain I. Rivera-Arrieta, Lucas Foppa, and Matthias Scheffler — The NOMAD Laboratory at the Fritz Haber Institute of the Max Planck Society, Berlin, Germany

Superconductivity is governed by an intricate interplay among electronic structure, lattice vibrations, and pressure effects, among many other phenomena [1]. Thus, a (single) physical model might not be enough to describe superconductivity. Interpretable artificial intelligence (AI) can provide valuable insights into the underlying mechanisms driving superconductivity, e.g., in conventional superconductors. Herein, we compile a dataset containing approximately 1,000 materials [2] and a diverse range of compositional, structural, electronic, and phonon-related properties. Then, we employ the symbolic-regression SISSO and subgroup discovery AI approaches [3, 4], to identify the few, key physicochemical parameters correlated with a superconductor's critical temperature. This approach is a step towards identifying the "materials genes" [5] of superconductivity.

Conductive surface states in single-crystalline FeSi — •Philip Schröder, Gilles Gödecke, Julius Grefe, Stefan Süllow, and Dirk Menzel — Institut für Physik der Kondensierten Materie, Technische Universität Braunschweig, Mendelssohnstr. 3, 38106 Braunschweig, Germany

The small-gap semiconductor FeSi exhibits an insulating ground state over a wide temperature range [1]. Notably, electric resistivity measurements imply the opening of a metallic transport channel at lowest temperatures, which historically has been attributed to conductivity among impurity levels [2]. However, recent transport studies on high-quality flux-grown FeSi single crystals discuss the conductive behavior in terms of metallic [3] and magnetic [4] surface states. We present (magneto-)resistance measurements on tri-arc Czochralski-grown FeSi single crystals in dependence of the sample thickness. The controlled manipulation of the surface-to-volume ratio by successive grinding of the specimen under investigation allows for separation of the bulk resistivity and the superimposed contribution of the surface channels. An effective two-channel model has been applied to approximate the upper limit of the surface conductivity.

TT 35.2 Wed 15:00 P3

Fabrication and characterization of topological insulator-based SET — •Omargeldi Atanov, Junya Feng, and Yoichi Ando — Physics Institute II, University of Cologne, Cologne, Germany

When a topological insulator (TI) Josephson junction is driven through a topological phase transition, the ground-state parity of the system is expected to change, potentially due to the fusion of Majorana bound state (MBS) pairs. Measuring the individual parity of MBS pairs is a critical step in understanding the mechanisms behind these parity changes and for more complex braiding operations. We present the fabrication and characterization of single-electron transistors (SETs) based on bulk-insulating BiSbTeSe2 flakes, which also serve as the material for TI Josephson junctions. This approach simplifies the process flow of the devices and improves fabrication yield. Initial characterization of devices demonstrates well-formed Coulomb diamonds that confirms the robust charge quantization and SET performance. These results pave the way for integrating SETs with TI Josephson junctions and measuring MBS parity in the near future.

TT 35.3 Wed 15:00 P3

Bulk and surface electron scattering in disordered Bi_2Te_3 probed by quasiparticle interference — •Vladislav Nagorkin[1,2], Sebastian Schimmel[1,2], Paul Gebauer[3], Anna Isaeva[1,4,5,6], Danny Baumann[1], Andreas Koitzsch[1], Bernd Büchner[1,3], and Christian Hess[1,2] — [1]IFW Dresden, Germany — [2]Bergische Universität Wuppertal, Germany — [3]TU Dresden, Germany — [4]University of Amsterdam, The Netherlands — [5]TU Dortmund, Germany — [6]Research Center "Future Energy Materials and Systems", UA Ruhr, Germany

We present low temperature scanning tunneling microscopy and spectroscopy studies of the electronic properties of the topological insulator Bi_2Te_3. The high-resolution differential conductance maps were measured in a relatively large energy range and allowed to reveal the quasiparticle interference in this material. We interpret our experimental data by comparing them with the modeled quasiparticle interference patterns with the use of the spin-selective joint density of states approach including the intricate three-dimensional spin texture of this material. Based on that, the topological properties are clearly demonstrated by the linear energy dispersion of the dominant scattering vector and the absence of the backscattering. In addition, non-dispersive scattering modes were detected and interpreted by scattering involving both surface and bulk states. This allowed us

to approximate the bulk energy gap range in our samples. Finally, we show that the abovementioned findings are robust against the external magnetic field of magnitude up to 15 T.

TT 35.4 Wed 15:00 P3

Planar Hall and Anomalous Planar Hall Effects up to Room Temperature in t-$PtBi_2$ — •Ankit Kumar — IFW Dresden

In topological semimetals, Hall measurements provide an important charge transport footprint of the non-trivial geometric properties of the electronic wavefunctions. In Weyl semimetals, the planar Hall effect (PHE) – the appearance of a transverse voltage when coplanar electric and magnetic fields are applied – is a direct consequence of the longitudinal linear magnetoconductance associated with the chiral anomaly of Weyl fermions, and is quantified by the large Berry curvature of Weyl nodes. The anomalous Hall effect is fully determined only by the location in the Brillouin zone and topological charge of the Weyl nodes. Time-reversal invariance prohibits any anomalous Hall signal in the large class of non-magnetic Weyl semimetals thereby leaving the PHE as the only Hall diagnostic tool of Weyl physics, at least in the linear regime. This complicates the identification of non-magnetic topological semimetals by charge transport experiments.

TT 35.5 Wed 15:00 P3

Instabilities driven by electron-electron interactions — •Eva López Rojo, Julia Link, and Carsten Timm — TU Dresen, Germany

We develop a formalism to study the effect of strong electron-electron interactions in a Weyl semimetal. In this poster, we present the findings for the case of two doped Weyl cones with opposite chirality. For this purpose, we employ a path integral formalism to study different instabilities that could take place. Instead of the charge density wave proposed in the literature, the leading instability for strong inter-valley interactions is found to be a spin density wave, which still has the potential to host axion physics.

TT 35.6 Wed 15:00 P3

The Effect of Interface Disorder on the Tunnel Conductance Across Weyl Semimetal Interfaces — •Haoyang Tian[1], Vatsal Dwivedi[2], Adam Yanis Chaou[2], and Maxim Breitkreiz[2] — [1]Institut für Theoretische Physik, Universität zu Köln, Zülpicher Str. 77a, 50937 Köln, Germany — [2]Dahlem Center for Complex Quantum Systems and Fachbereich Physik, Freie Universität Berlin, 14195 Berlin, Germany

The chiral anomaly in Weyl semimetals is responsible for various anomalous transport phenomena. In tunnel junctions between Weyl semimetals with staggered Weyl node projections, the chiral anomaly leads to a magnetic-field activated magnetotransport. In this work, we discuss the effect of interface disorder on the magnetotransport across such a tunnel junction employing a semiclassical Boltzmann approach. Our results show that, compared to conventional transport channels, the topological connectivity of interface Fermi arcs ensures that anomalous magnetotransport exhibits stronger robustness against disorder. Additionally, interface disorder enhances magnetic breakdown, a quantum tunneling effect, between the Fermi arcs.

TT 35.7 Wed 15:00 P3

Impact of decoherence on the Kitaev honeycomb model — •Alexander Sattler and Maria Daghofer — Universität Stuttgart, 70550 Stuttgart, Germany

Quantum spin liquids (QSL) are phases of matter with unique properties, including quantum fluctuations, frustration, entanglement, fractionalized excitations, and the absence of long-range order. A rare example of an exactly solvable, strongly interacting two-dimensional model with a QSL ground state is the Kitaev honeycomb model (KHM). This model describes spin-1/2 particles on a honeycomb lattice with direction-dependent Ising-like interactions. The KHM with open boundaries supports edge-localized Majorana zero modes that are robust to certain types of disorder. Quantum systems are inherently coupled to their environment, necessitating the study of the KHM properties in open systems, where environmental interactions, such as decoherence, can influence their features. To study this, we analyze the KHM in a cylindrical geometry while modeling environmental coupling using the Lindblad master equation to simulate decoherence. By examining changes in the dispersion relation, entropy, fidelity, purity and spectral gap over time, we evaluate how environmental interactions affect the properties of the KHM.

TT 35.8 Wed 15:00 P3

Andreev reflection and interferometry of fractional quantum Hall edge states — •Tom Menei, Daniele Di Miceli, and Thomas L. Schmidt — Department of Physics and Materials Science, University of Luxembourg

Recent experimental work has demonstrated that it is possible to couple superconductors (SCs) to quantum Hall (QH) systems, both at integer and fractional filling fractions. Due to the strong required magnetic fields and the presence of disorder and Abrikosov vortices in the SC, the theoretical modeling of such QH/SC interfaces is not trivial, especially in the case of fractional QH states. In our work, we use the Laughlin edge state theory and realistic models of the superconductor to derive the coupling mechanism at QH/SC interfaces. We explore the effects on normal and Andreev reflection and discuss possible experimental implications.

TT 35.9 Wed 15:00 P3

Variational Trial States for Fractional Chern Insulators — •Giacomo Amadore — LMU, Munich, Germany

Early on, Laughlin's wave functions and other variational trial states provided deep physical insights into the nature of fractional quantum Hall (FQH) systems. One particularly fruitful approach in motivating such trial states is based on the composite fermion description of the FQH problem in the continuum. In contrast, variational states describing fractional Chern insulators in lattice systems remained scarce. While existing methods can construct lattice analogs of familiar FQH states, these states are not generally expected to be the ground state of simple discretized FQH Hamiltonians, but instead a parent Hamiltonian is only constructed a posteriori. To address this limitation, we propose a conceptually different approach motivated by the possibility to study FQH physics in optical lattice experiments realizing the Hofstadter-Bose-Hubbard model. We derive trial states for the ground state of this specific Hamiltonian by turning hard-core bosons into composite fermions through the attachment of a single flux quantum and deriving an effective Hamiltonian for the composite fermions coupled to a dynamical gauge field. To benchmark our findings, we compare the variational energies of different ansätze to (quasi-)exact numerical results. We anticipate that our preliminary results provide a promising starting point for further variational studies and investigations of lattice analogs of FQH systems.

TT 36: Nanotubes, BEC, Cryocoolers: Poster

Time: Wednesday 15:00–18:00 Location: P3

TT 36.1 Wed 15:00 P3

Quantum Dot Spectroscopy in Suspended MoS_2 Nanotubes — •Stefan B. Obloh[1], Robin T. K. Schock[1], Jonathan Neuwald[1], Matthias Kronseder[1], Matjaž Malok[2], Maja Remškar[2], and Andreas K. Hüttel[1] — [1]Institute for Experimental and Applied Physics, University of Regensburg, 93040 Regensburg, Germany — [2]Solid State Physics Department, Institute Jožef Stefan,1000 Ljubljana, Slovenia

MoS_2 as a semiconductor has attracted a lot of attention due to its 2D nature, strong spin-orbin coupling, broken inversion symmetry, and spin-split bands. By tuning the carrier density in MoS_2 with ionic liquid gating, intrinsic superconuctivity has been achieved [1]. Recent works were able to demonstrate single level transport in planar [2,3] and nanotube-based [4] devices. A remaining challenge lies in reducing the effects of substrate inhomogenity and surface charges, resulting in disordered quantum dots. To mitigate this, one can suspend the tubes above the substrate or shield them from the amorphous SiO_2. We show quantum dot transport measurements of suspended nanotubes as well as insights into fabrication challenges regarding this approach.

TT 36.2 Wed 15:00 P3

MoS_2 Nanotubes as 1D Superconductors? — •Konstantin D. Schneider[1], Robin T. K. Schock[1], Stefan Obloh[1], Matthias Kronseder[1], Matjaz Malok[2], Maja Remskar[2], and Andreas K. Hüttel[1] — [1]Institute for Experimental and Applied Physics, University of Regensburg, 93040 Regensburg, Germany — [2]Solid State Physics Department, Institute Jožef Stefan, 1000 Ljubljana, Slovenia

Due to its intrinsic two dimensional nature, planar MoS_2 is at the center of manifold research efforts. Previous work has shown that MoS_2 exhibits superconducting properties in single and multi layer flakes when increasing its charge density by heavily doping the MoS_2 surface using a liquid-ion gate [1-3].

Clean and defect-free MoS_2 nanotubes, as grown via chemical transport reaction [4,5], should provide an even better test bed for the interplay of a tubular geometry and Ising superconductivity. In addition, with ionic doping mostly affecting the outermost shell of a multi-wall nanotube, the material system lends itself intrinsically for core-shell semiconductor/superconductor hybrid structures

at strong spin-orbin interaction. Here, we present our ongoing work towards this objective [6,7].

TT 36.3 Wed 15:00 P3

Simulations to enhance the conductivity of graphene-based macromaterials — •Florian Fuchs[1,2,3], Fabian Teichert[1,2,3], and Jörg Schuster[1,2,3] — [1]Fraunhofer Institute for Electronic Nanosystems (ENAS), Chemnitz, Germany — [2]Center for Microtechnologies,Chemnitz University of Technology, Chemnitz, Germany — [3]Center for Materials, Architecture and Integration of Nanomembranes (MAIN), TU Chemnitz, Germany

Our aim is to enhance the conductivity of graphene-based macromaterials. These materials consist of many graphene flakes, which are arranged layerwise. A twofold strategy is pursued to improve the material: 1) optimizing the flake properties and the size of the macromaterial, and 2) intercalating molecules in-between the graphene layers.

A network model enables us to estimate the conductivity of the macromaterial for large model systems consisting of thousands of flakes. Particular emphasis will be given in our contribution on the variation of the layer numbers, which is of relevance for printed graphene paths.

To study the impact of intercalants, we perform density functional theory calculations. We concentrate on different fluorides and chlorides, where we vary the cation type and the anion number. The charge carrier density after intercalation is studied and related to more fundamental physical properties such as orbital overlaps and charge transfer.

TT 36.4 Wed 15:00 P3

Quantum Solvation of Flexible Molecules at Low Temperatures from Path Integral Simulations — •Katharina Leitmann[1], Harald Forbert[1,2], and Dominik Marx[1] — [1]Lehrstuhl für Theoretische Chemie, Ruhr-Universität Bochum, 44780 Bochum, Germany — [2]Center for Solvation Science ZEMOS, Ruhr-Universität Bochum, 44780 Bochum, Germany

Protonated methane (CH_5^+) is a fluxional molecule whose sensitivity to its environment makes it an excellent probe for studying molecular interactions at low temperatures. We investigated CH_5^+ microsolvation in *para*-hydrogen clusters $(pH_2)_n$ subject to bosonic exchange at 1 K using a hybrid simulation approach that combines Path Integral Molecular Dynamics (PIMD) for CH_5^+ and bosonic Path Integral Monte Carlo (PIMC) to establish Bose-Einstein statistics of the $(pH_2)_n$ quantum solvation environment.

Our simulations, based on highly accurate High-dimensional Neural Network Potentials parametrised using coupled cluster theory (CCSD(T)), demonstrate stable solvation of CH_5^+ at least up to $n = 12$ pH_2 molecules, which we found to build the first solvation shell. We revealed, that the structure of CH_5^+ is not significantly perturbed by the solvation with pH_2. But we revealed significant fluctuations in the large amplitude motion of CH_5^+ associated to the phenomenon of partial hydrogen scrambling as a function of cluster size n. Further, we investigated the superfluid properties of pH_2 clusters. Analysing the superfluid fraction and bosonic permutation patterns, indicates the manifestation of superfluidity.

TT 36.5 Wed 15:00 P3

Generating a photonic Bose-Einstein condensate in a waveguide — •Lukas Schamriss[1,2,3], Louis Garbe[1,2,3], and Peter Rabl[1,2,3] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany — [2]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany

We aim to propose a superconducting device designed to generate a photonic Bose-Einstein condensate (BEC). The core component is a coupler that induces a pure three-wave mixing interaction linking a waveguide which hosts the condensate to a LC-mode for dissipating energy from the waveguide. This interaction induces an incoherent photon-number conserving thermalization process in the waveguide. Generally, this system is a minimal example for generating a thermalization mechanism for microwave photons which is a key ingredient for the preparation of finite-temperature equilibrium states on superconducting hardware for analog quantum simulations.

TT 36.6 Wed 15:00 P3

Loop current states and their stability in small fractal lattices of Bose-Einstein condensates — •Georg Koch and Anna Posazhennikova — Institut für Physik, Universität Greifswald, 17487 Greifswald , Germany

We consider a model of interacting Bose-Einstein condensates on small Sierpinski gaskets. We study eigenstates which are characterised by cyclic supercurrents per each triangular plaquette ("loop" states). For noninteracting systems we find at least three classes of loop eigenmodes: standard; chaotic and periodic. Standard modes are those inherited from the basic three-site ring of condensates with phase differences locked to $2\pi/3$. Standard modes become unstable in the interacting system but only when the interaction exceeds a certain critical value u_c. Chaotic modes are characterised by very different circular currents per plaquette, so that the usual symmetry of loop currents is broken. Circular supercurrents associated with chaotic modes become chaotic for any finite interaction, signalling the loss of coherence between the condensates. Periodic modes are described by alternating populations and two different phase differences. The modes are self-similar and are present in all generations of Sierpinski gasket. When the interaction is included, the circular current of such a mode becomes periodic in time with the amplitude growing linearly with the interaction. Above a critical interaction the amplitude saturates signalling a transition to a macroscopic self-trapping state originally known from a usual Bose Josephson junction. We perform a systematic analysis of this rich physics.

TT 36.7 Wed 15:00 P3

Sub-50 mK Adiabatic Demagnetization Refrigeration with Frustrated Yb-Oxide Magnets in the PPMS — •Anna Klinger, Jorginho Villar Guerrero, Marvin Klinger, Tim Treu, Anton Jesche, and Philipp Gegenwart — Experimental Physics VI, Center for Electronic Correlations and Magnetism, University of Augsburg

Accessing temperatures in the millikelvin (mK) regime is a prerequisite for quantum-matter research and quantum technologies. Adiabatic demagnetization refrigeration (ADR) is a simple and sustainable alternative to ^{3}He/^{4}He dilution refrigeration. We have shown recently, that geometrically frustrated Yb-oxides feature important advantages compared to the traditionally utilized hydrated paramagnetic salts for mK-ADR [1,2]. We report the development of Yb-oxide-based customized ADR cooling platforms for the use in the Quantum Design Physical Property Measurement System (PPMS) ®. Temperatures below 50 mK and hold times of several hours are demonstrated. Our ADR insert offers multiple experimental capabilities, including electrical transport, stress/strain and heat capacity measurements.

Experimental and Numerical Investigations of the Temperature and Mass Flow Behaviour in the Cold Heat Exchanger of a Single Stage GM-type Puls Tube Cooler — •Elias Eisenschmidt[1,3], Jack-Andre Schmidt[2,3], Bernd Schmidt[2,3], Hardy Weisweiler[1,3], and Andre Schirmeisen[2,3] — [1]Technische Hochschule Mittelhessen, Giessen, Germany — [2]Justus-Liebig-University, Giessen, Germany — [3]TransMIT-Center for Adaptive Cryotechnology and Sensors, Giessen, Germany

GM-type PTCs play an important role in cooling sensitive electronics. Especially due to the recent developments in quantum computing, low vibration regenerative cooling is needed more than ever. [1]

The refrigeration power is usually calculated using a sinusoidal approximation of the mass flow, temperature and pressure of the working fluid inside a pulse tube cooler. However, several measurements have been carried out to gain insight into the actual time-dependent gas properties. It has been shown that the temperature and pressure curve differ significantly from a sinusoidal assumption. [2]

The goal of this work is to measure the time dependent mass flow and temperature behaviour of the helium gas in the cold end of the cooler, using a RTD and a CTA probe.

TT 36.9 Wed 15:00 P3

Optimisation of Rotary Valve Size and Timing for High Massflow GM-Type Pulse Tube Cryocoolers — •Xaver Herrmann[1], Jack-André Schmidt[1,2], Bernd Schmidt[1,2], Jens Falter[2], and André Schirmeisen[1,2] — [1]Instiute of Applied Physics, Justus-Liebig University, Giessen, Germany — [2]TransMIT-Center for Adaptive Cryotechnology and Sensors, Giessen, Germany

Closed-cycle cryocoolers have become a reliable and important tool for low temperature scientific research, such as IR astronomy, SNSPDs or surface science[1]. Here we focus on Gifford-McMahon (GM) type pulse tube cryocoolers (PTC), which offer low maintenance and long measurement periods[2]. A crucial component of a GM type PTC is the rotary valve. Losses in the rotary valve are a sizable fraction of overall losses in a GM type PTC [3,4]. This poster will focus on the effects of valve size and timing for a two stage high input power system(11 kW). Both valve size and timing show a strong effect on cooling performance of the first cooling stage. An increase of up to 90

TT 37: Correlated Electrons: Poster

Time: Wednesday 15:00–18:00 Location: P4

TT 37.1 Wed 15:00 P4

Unveiling the Origin of Magnetic Anisotropy in $CeSb_2$ — •Jan T. Weber[1,2], Kristin Kliemt[1], Sergey L. Bud'ko[2,3], Paul C. Canfield[2,3], and Cornelius Krellner[1] — [1]Physikalisches Institut, Goethe-Universität Frankfurt, Max-von-Laue Straße 1, 60438 Frankfurt am Main, Germany — [2]Ames National Laboratory, U.S. DOE, Ames, Iowa 50011, USA — [3]Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011, USA

$CeSb_2$ is a well-established Kondo-lattice system, crystallizing in the orthorhombic $SmSb_2$ structure (space group 64) [1] and forming plate-like crystals. Extensive past studies have revealed a rich magnetic phase diagram for fields within the plane and a strong suppression of magnetization out of plane [2-5]. However, the in-plane magnetization anisotropy remains poorly understood. Nearly identical lattice parameters present challenges in aligning the crystals within the plane, and unexpected magnetization curves - seemingly inconsistent with symmetry arguments - pose additional questions.

In this contribution, we present rotational magnetization measurements together with magnetic measurements as a function of field, temperature and orientation, providing new insights into the in-plane anisotropy addressing these open questions.

Single Crystal Growth and Characterisation of $EuMn_2Si_2$ and $EuMn_2Ge_2$ — •Janina Strahl, Kristin Kliemt, and Cornelius Krellner — Institute of Physics, Goethe University, Frankfurt (Main), Germany

$EuMn_2Si_2$ exhibits a thermally driven valence transition at around 530 K of the europium ions from Eu^{3+} at low temperatures to $Eu^{\sim 2.5+}$ at high temperatures [1]. The isoelectronic and isostructural substitution of silicon with germanium leads to a stabilization of the divalent state of Eu in $EuMn_2Ge_2$ with reported ferromagnetic Eu ordering below 13 K [2]. Both rare earth intermetallic 122 compounds crystallize in the tetragonal $ThCr_2Si_2$ structure type and show antiferromagnetic ordering of the manganese sublattices above room temperature. In literature [1,2], additional Mn spin-reorientation transitions in polycrystalline $EuMn_2Si_2$ samples at low temperatures were observed. In this contribution, we present the single crystal growth and magnetic properties of both compounds. We found antiferromagnetic ordering of the Eu ions in single crystalline $EuMn_2Ge_2$ below 8.5 K and evidence that previously reported Mn reorientation transitions are absent in pure $EuMn_2Si_2$ single crystals.

TT 37.3 Wed 15:00 P4

Single Crystal Growth and Characterization of a New Yb-based Heavy Fermion Compound — •Fabian Fiedler[1], Florian Stoll[1], Kristin Kliemt[1], Manuel Brando[2], and Cornelius Krellner[1] — [1]Physikalisches Institut, Goethe-Universität Frankfurt, 60438 Frankfurt am Main, Germany — [2]MPI CPfS, 01187 Dresden, Germany

A system near a quantum-critical point usually shows anomalous thermodynamic and transport properties at low temperatures [1,2].

Presently there are only rare cases of such systems with a ferromagnetic ground state together with pronounced Kondo interactions. Especially Yb-based intermetallic compounds with their possible unstable 4f-shell are of interest due to their low magnetic ordering temperatures.

We found a candidate system for Yb-based ferromagnetic quantum criticality with a large and diverging Sommerfeld coefficient below 10 K. We used substitution in order to manipulate the ground state. Here we report on the single crystal growth as well as the structural and physical characterization of these systems.

TT 37.4 Wed 15:00 P4

Negative Pressure Studies on $CeRh_2As_2$ with La Substitution — •Sushma Lakshmi Ravi Sankar[1,2], Arushi Yadav[1], Manual Brando[1], Joachim Wosnitza[2], and Seunghyun Khim[1] — [1]Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany — [2]Technische Universität Dresden, 01069 Dresden Germany

$CeRh_2As_2$ is a Kondo-lattice system with novel phase diagrams involving a superconducting and an unknown ordered state appearing below T_c and T_0, respectively. Recent observations of a suppression of T_c and T_0 under external pressure [1] motivated an investigation of a negative pressure study, which can be achieved by a La substitution with Ce. We have succeeded in growing single crystals of ($Ce_{1-x}La_xRh_2As_2$) up to x ~ 0.1. We found a negative pressure effect as the La substitution leads to an increase in the a- and c- lattice parameters (unit cell volume increase by ~ 0.15% with x = 0.1) while maintaining the $CaBe_2Ge_2$-type crystal structure. Resistivity measurements showed that both T_c and T_0 decrease with the La substitution to be almost suppressed at x ~ 0.08, while the resistivity maximum is slightly shifted to a lower temperature. At the same time, the residual resistivity ratio decreases from 2.24 at x = 0 to 1.46 at x = 0.1, indicating additional disorder introduced by the La substitution. This suggests that both the negative pressure effect and the increased disorder should be considered in understanding the evolution of T_c and T_0 with the La substitution.

TT 37.5 Wed 15:00 P4

Terahertz Time-domain Spectroscopy on the Topological Kondo Insulator SmB_6 — •Zekai Chen, Debankit Priyadarshi, Erik de Vos, and Manfred Fiebig — Department of Materials, ETH Zurich, Zurich, Switzerland

We present a terahertz time-domain spectroscopy (THz-TDS) measurement on the topological Kondo insulator samarium hexaboride (SmB_6). These results are aimed at providing insight into the co-existence of a topologically conductive surface state and the opening of a bandgap below the Kondo temperature. Previous work on Kondo insulators has shown that the Kondo quasiparticles disintegrate near a quantum critical point (QCP) in response to THz radiation, leading to a delayed echo-pulse-like response in the time domain [1]. In contrast to these materials, SmB_6 exhibits an additional in-gap state that could be related to its topological surface conductivity. In the presented experiment, this in-gap state is resonantly probed with THz radiation. Our measurement concentrates on studying the emergence of the in-gap state through correlated electron interaction.

[1] Nat. Phys. 14, 1103 (2018).

TT 37.6 Wed 15:00 P4

Cyclotron Resonance on SmB_6 Probed by Superconducting Coplanar Microwave Resonators — •Anastasia Bauernfeind and Marc Scheffler — 1. Physikalisches Institut, Universität Stuttgart, Stuttgart, Germany

Samarium hexaboride (SmB_6) is a homogeneously mixed-valent, narrow-gap semiconductor typically classified as a topological Kondo insulator. Its resistivity increases sharply as the temperature decreases, showing activated behavior that saturates below approximately 5 K. Experimental evidence suggests that topological surface states dominate low-temperature transport. Two notable studies on quantum oscillations in SmB_6 have sparked intense debate about their origin: one observes behavior consistent with a two-dimensional (2D) Fermi surface attributed to surface states, while the other reports a three-dimensional (3D) bulk Fermi surface, despite the insulating nature of the bulk at low temperatures. In our research, we perform cyclotron resonance experiments on SmB_6 using superconducting coplanar waveguides, a powerful method for investigating the Fermi surface of various materials. By tracing the evolution of the cyclotron frequency (up to 20 GHz) as a function of magnetic field, we can determine the type of charge carriers, the effective mass, and the properties of the associated electronic bands. Combined with temperature-dependent measurements (down to 20 mK) and power-dependent studies, this approach provides valuable insights into the electronic structure of the strongly correlated material SmB_6.

TT 37.7 Wed 15:00 P4

Bonding in UO_2^{2+} Dumbbell Structures: The Influence of a Non-Orthogonal Atomic Basis Set and the U 5f, 6d, 7s, and 6p Orbitals — •Henrik Hahn, Michelangelo Tagliavini, Kevin Ackermann, Sarah L. Goerlitz, Johann Collard, Ruth Kaiser, and Maurits W. Haverkort — Institute for Theoretical Physics (ITP), Heidelberg University, Philosophenweg 19, 69120, Heidelberg, Germany

Actinide compounds exhibit a wide range of complex properties, making their theoretical description a significant challenge. This complexity arises primarily from the open 5f shell, which introduces strong electronic correlations, as well as the close proximity of multiple subshells with different angular momentum (l) values due to the large principal quantum numbers (n) of actinides. In this study, we investigate the U-O bond in UO_2^{2+}, a well-known coordination structure of U^{2+} ($5f^0$). Notably, the stronger σ bond derived from the 5f z^3 orbital lies higher in energy than the weaker π bonds formed by the 5f xz^2 and yz^2 orbitals - an unusual ordering. Through a detailed analysis of the underlying LDA Hamiltonian in a non-orthogonal basis, we provide an explanation for this behavior. Our findings demonstrate that fully understanding the bonding and properties of actinides requires a many-orbital model that transcends the conventional assumption that the low-energy physics is governed solely by the 5f shell. This broader perspective is essential for capturing the intricate electronic structure and bonding characteristics of these materials.

TT 37.8 Wed 15:00 P4

Quantum-Spin Impurities Coupled to a Chern Insulator: Topological Remnants — •David Alan Krüger[1] and Michael Potthoff[1,2] — [1]University of Hamburg, Hamburg, Germany — [2]The Hamburg Centre for Ultrafast Imaging, Hamburg, Germany

Treating quantum-spin impurities as classical vectors is a frequently used approximation to study the impact of local magnetic impurities on the formation of subgap bound states in insulators. Recently, the classical-spin approximation has been exploited for a "local" topological characterization of the ground-state bundle over the manifold of impurity-spin configurations, as opposed to the bundle over the Brillouin zone. This has been achieved by computing spin-Chern numbers $C^{(S)}$ as the corresponding topological invariants.

Here, we numerically solve a system with a single or two quantum spin-$\frac{1}{2}$ locally exchange coupled to a Chern insulator given by the QWZ model. Via Lanczos tridiagonalization, the system is mapped onto a gapped Kondo-impurity model. Local ground-state properties and local single-particle as well as magnetic excitations spectra are obtained by means of an adaptive natural-orbital configuration-interaction technique.

We study the interplay of possible remnants of the classical-spin topology, the intrinsic QWZ topology, and the finite-size Kondo effect. To this end we trace subgap excitations as a function of the local exchange-coupling strength and the mass parameter.

TT 37.9 Wed 15:00 P4

Chiral Kondo Lattice Analyzed via Variational Cluster Approach — •Benjamin Heinrich and Maria Daghofer — Institute for Functional Matter and Quantum Technologies, University of Stuttgart, Germany

Moiré systems composed of van der Waals heterostructures provide an experimentally accessible platform to realize a wide range of strongly correlated electron phenomena. Using transition metal dichalcogenide materials, such as an AB-stacked $MoTe_2/WSe_2$ bilayer, gives rise to an effective multi-orbital Hubbard model on the honeycomb lattice, which can be tuned via doping and the introduction of charge transfer energy through external voltages. Including strong Ising spin-orbit coupling leads to chiral Kondo exchange between localized and itinerant electrons in different layers near half-filling.[1]

To gain a better understanding of experimentally observed phenomena, including magnetic ordering, numerical modeling is performed using the variational cluster approach. This methodology, closely related to cluster dynamical mean-field theory, has been proven effective for studying analogous systems exhibiting Kondo lattice behavior.

TT 37.10 Wed 15:00 P4

Influence of Band Mixing on FCI and CDW — •Marco Schönleber and Maria Daghofer — Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany

Fractional quantum hall physics with vanishing magnetic fields has become an increasingly important research topic in recent years due to new findings in the field of moiré materials. Experimental signatures of these phases are often observed in combination with signatures of charge ordered or other symmetry broken phases. This indicates that band mixing might play an elementary role in the complete description of this phase of matter. For this purpose, an extended Hubbard model on a triangular lattice with $\nu = 1/3$ and $\nu = 2/3$ is considered. This allows the formation of bands of non-trivial topology as well as the formation of commensurate charge density waves. The analysis is carried out by exact diagonalisation. By varying the band gap, it can be shown that the stability of the charge order depends on this, whereby the degree of filling plays a decisive role.

TT 37.11 Wed 15:00 P4

Quantum Monte Carlo simulations of generalized Dicke-Ising models — •Anja Langheld, Max Hörmann, and Kai Phillip Schmidt — Department Physik, Staudtstraße 7, Friedrich-Alexander Universität Erlangen-Nürnberg, D-91058 Erlangen, Germany

Recently, we introduced a wormhole algorithm for the paradigmatic Dicke-Ising model to gain quantitative insights on effects of light-matter interactions on correlated quantum matter [1]. This method enabled us to determine the quantum phase diagram for ferro- and antiferromagnetic interactions on the chain and square lattice alongside the criticality of its second order quantum phase transitions. The continuous superradiant phase transitions are in the same universality class as the Dicke model, leading to a well-known peculiar finite-size scaling which can be understood in terms of scaling above the upper critical dimension.

Going one step further we now introduce new ingredients to the matter Hamiltonian like geometric frustration, long-range interactions and disorder to study the interplay between a variety of correlated matter phenomena and light-matter interactions.

TT 37.12 Wed 15:00 P4

Chiral quantum phase transition in moiré Dirac materials — •Ana García-Page[1] and Laura Classen[1,2] — [1]Max-Planck-Institute for Solid State Research, Stuttgart 70569, Germany — [2]Department of Physics, Technical University of Munich, Garching 85749, Germany

Strong enough interactions induce a semimetal-to-insulator transition in Dirac materials, which can be viewed as the solid-state analogue of the chiral phase transition in quantum chromodynamics1-4. Moiré Dirac materials such as twisted bilayer graphene offer a new opportunity to study this transition because they facilitate tuning the effective interaction via a twist angle5-6. Motivated by this, we explore the quantum phase transition of a 2D Dirac material which spontaneously develops a gap that breaks an Ising symmetry7. We model it via an effective Gross-Neveu-Yukawa theory and employ the functional renormalization group method to map out the phase diagram. We analyze the quantum critical behavior at the transition and investigate the effect of a chemical potential which introduces a finite charge density.

NMR in Pulsed Magnetic Fields - Recent Developments — •Hannes Kühne[1] and Yoshihiko Ihara[2] — [1]HLD-HZDR, Dresden — [2]Department of Physics, Hokkaido University

NMR measurements in the highest pulsed magnetic fields have been developed at dedicated large-scale research facilities for some time and are becoming increasingly available for user experiments. On the poster, I will give an overview of the current developments, possibilities and peculiarities of NMR experiments in pulsed magnetic fields. In particular, the implementation of NMR experiments with dynamically controlled flat-top field pulses has recently been reported, enabling the measurement of broadband NMR spectra and relaxation times up to the ms range [1]. Furthermore, through several examples on low-dimensional spin systems, I will present opportunities to work on scientific questions that can be uniquely addressed using this technique [2].

TT 37.14 Wed 15:00 P4

Magnetic Anisotropy and Low-Energy Spin Dynamics in van der Waals Magnets $M_2P_2S_6$ Probed by Electron Spin Resonance — Joyal J. Abraham[1,2], Yurii Senyk[1,2], Yuliia Shemerliuk[1], Sebastian Selter[1,2], Saicharan Aswartham[1], Bernd Büchner[1,2,3], Vladislav Kataev[1], and •Alexey Alfonsov[1,3] — [1]Leibniz IFW Dresden, 01069 Dresden, Germany — [2]TU Dresden, 01062 Dresden, Germany — [3]Würzburg-Dresden Cluster of Excellence ct.qmat, 01062 Dresden, Germany

In the past recent years magnetic van der Waals (vdW) materials have become increasingly attractive for the fundamental investigations since they provide immense possibility to study intrinsic magnetism in a low-dimensional limit. The weak vdW forces hold together the atomic monolayers in vdW crystals, which results in a poor interlayer coupling, and therefore renders these materials intrinsically two dimensional. That makes them particularly attractive for probing the low-dimensional physics while investigating bulk crystals. On the other hand, a remarkable success in exfoliation of this class of materials due to the lack of significant interlayer chemical bonds unlocks vast potential for applications in the fields of advanced electronics, optoelectronics, and spintronics. In this work we present the results of the electron spin resonance investigation of such magnetic vdW materials $M_2P_2S_6$ (M = Mn, Ni, Cu, Cr) performed in the broad range of temperatures, magnetic fields and excitation frequencies, and discuss their low-energy spin dynamics as well as magnetic anisotropy responsible for the stabilization of the magnetic order.

TT 37.15 Wed 15:00 P4

Magnetic Properties of a Trillium Lattice Compound $Li_2NiGe_3O_8$ — •Annarose Jose Palliyan[1,2], Nazmul Islam[2], Ralf Feyerherm[2], and Bella Lake[2,1] — [1]Institut für Festkörperphysik, Technische Universität Berlin, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany

Frustrated magnets are interesting materials that exhibit exotic properties due to the competing localized spins [1]. Certain lattices are intrinsically predisposed to show frustration due to the arrangement of their magnetic ions and one such lattice is the trillium lattice [2]. The trillium lattice is composed of a three-dimensional chiral network of corner sharing equilateral triangles. $Li_2NiGe_3O_8$ is a trillium lattice candidate where each Ni^{2+} ion is shared between three equilateral triangles. Polycrystalline samples of $Li_2NiGe_3O_8$ were synthesized by solid - state reaction method. The magnetic properties of this complex spinel oxide were studied by magnetization, susceptibility and heat capacity measurements down to He-3 temperatures. Our studies shows the presence of weak antiferromagnetic interactions in this material with no long-range order. A three-level schottky anomaly was observed in this material because of the splitting of the S = 1 triplet state.

TT 37.16 Wed 15:00 P4

Geometric Magnetic Frustration in $Mn_3Al_2Si_3O_{12}$ — •Marwa Abouelela[1,2], Nazmul Isalam[2], Ralf Feyerherm[2], and Bella Lake[1,2] — [1]Institut für Festkörperphysik, Technische Universität, Berlin, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Berlin, Germany

Geometric magnetic frustration in triangular lattices has garnered significant interest in recent research [1]. $Mn_3Al_2Si_3O_{12}$ exhibits geometrical frustration, where Mn^{2+} ($3d^5$) ions form a hyperkagomé structure [2]. In this study, the spessartine was synthesized at high temperatures, and its magnetic susceptibilities and heat capacities were investigated at low temperatures. Temperature-dependent magnetic susceptibility measurements revealed an antiferromagnetic ordering of the Mn^{2+} ions below T_N=6.5K, with a Curie-Weiss temperature of -26.7K. The high ratio of Curie-Weiss temperature to Néel temperature suggests strong frustration in the system.

TT 37.17 Wed 15:00 P4

Static and Dynamic Properties of Quantum Magnets: Results from Numerical Linked Cluster Expansion — •Alexander Schwenke and Wolfram Brenig — Institute for Theoretical Physics, Technical University Braunschweig, D-38106 Braunschweig, Germany

We consider static and dynamic properties of two-dimensional frustrated quantum antiferromagnets utilizing the numerical linked cluster expansion (NLCE). In particular, we are interested in spin-$^1/_2$ models showing quantum phase transitions versus internal parameters, e.g., the J_1-J_2 model on the square lattice or the triangular lattice XXZ model in external magnetic fields.

For the NLCE, we employ a single-site representation focussing on three topics: First, we present results for thermodynamic quantities, namely the internal energy and the specific heat at finite temperature. Second, we study the ground-state energy per site as a function of competing exchange coupling constants focussing on its second derivative. Finally, we investigate the dynamics of the system following a quantum quench.

TT 37.18 Wed 15:00 P4

Magnetism in i-Tb-Cd Quasicrystals — •Andreas Kreyssig[1,2], P. Das[2], G. S. Tucker[2], A. Podlesnyak[3], Feng Ye[3], Masaaki Matsuda[3], T. Kong[2], S. L. Bud'ko[2], P. C. Canfield[2], R Flint[2], P. P. Orth[2,4], T. Yamada[5], and A. I. Goldman[2] — [1]Experimental Physics IV, Ruhr University Bochum, Bochum, Germany — [2]Ames Laboratory, U.S. DOE, and Department of Physics and Astronomy, Iowa State University, Ames, USA — [3]Neutron Scattering Division, Oak Ridge National Laboratory, USA — [4]Department of Physics, Harvard University, Cambridge, USA — [5]Department of Applied Physics, Tokyo University of Science, Tokyo, Japan

i-Tb-Cd orders as icoshedral quasicrystal with the magnetic Tb^{3+} ions arranged in Tsai-type clusters. We studied the magnetic correlations and excitations by elastic and inelastic neutron scattering on single-grain isotopically enriched samples. The measurements of the crystalline electric field excitations demonstrated that the Tb^{3+} moments are directed along the local fivefold axes of the Tsai-type clusters. We calculated the magnetic diffuse scattering for the low-energy configurations using an Ising-type model for the moment arrangements on a single Tb^{3+} icosahedron. By comparison with our diffuse neutron scattering signals, we identified the most likely moment configuration in a single cluster. We further studied the role of intercluster interactions for magnetic frustration and the magnetic scattering.

This work was supported by the U. S. DOE, BES, DMSE, Contract DE-AC02-07CH11358, and resources at HFIR and SNS, U. S. DOE.

TT 37.19 Wed 15:00 P4

Chiral spin liquid in external magnetic field: Phase diagram of the decorated-honeycomb Kitaev model — •Sabastian Granberg Cauchi and Matthias Vojta — TU Dresden, Germany

Studies of Kitaev models on different lattices have shown signatures of topological phase transitions as a function of external magnetic field direction and magnitude. These transitions are often accompanied by a change in the statistics of the low-energy anyonic excitations. In particular, the antiferromagnetic Kitaev system yields a field-induced spin liquid, of arguably gapless U(1) or Abelian character. The existence of field-induced spin liquids on different lattices has consequently been intensely investigated. Here, we determine the phase diagram of the decorated-honeycomb Kitaev model for different inter- and intra-triangle coupling ratios and magnetic fields using a mean-field theory derived from Kitaev's Majorana parton decomposition.

TT 37.20 Wed 15:00 P4

Low-energy description of the SU(3) Hubbard model on the triangular lattice — •Linus Hein — Ludwig-Maximilians-Universität München

It has been a longstanding goal to better understand strongly correlated fermionic systems. Extensive studies have been conducted on these systems, particularly on the square lattice Hubbard model. To find out which of the results are artefacts of this fine-tuned model, it is sensible to analyze slightly modified models with for instance enlarged symmetry. We consider an SU(3) antiferromagnet on a tripartite triangular lattice near one third filling. Previous works explored a non-linear sigma model and its emerging Goldstone modes. Building on these results, we derive a linear spin-wave description of the low-energy excitations. Furthermore, we consider the hole-doped system and derive an effective Hamiltonian to describe the emergent magnetic polarons. Thereby, we broaden our understanding of strongly correlated fermionic systems, in a setting that can be experimentally explored using e.g. ultracold atom experiments.

TT 37.21 Wed 15:00 P4

Temperature Dependent Infrared Spectroscopy on the Frustrated Spin-Ladder System $BiCu_2PO_6$ — •Johanna Strauss[1], Renjith Mathew Roy[1], Maxim Wenzel[1], Haidong Zhou[2], Martin Dressel[1], and Komalavalli Thirunavukkuarasu[3] — [1]1. Physikalisches Institute, University of Stuttgart, Germany — [2]Department of Physics, University of Tennessee Knoxville, Knoxville, USA — [3]3. Department of Physics, Florida A and M University, Tallahassee, USA

Spin systems with frustrated geometries are of significant interest due to their potential to exhibit quantum spin liquid behaviour. This study focuses on $BiCu_2PO_6$ which exhibits no magnetic ordering down to 0.1 K. Various experimental studies on this zig-zag spin-ladder compound reveal that the magnetism in this material arise from complex exchange coupling mechanisms that are not completely understood yet. However, it is clear that the magneto-structural correlations play a major role. Here, we present our attempt to employ infrared spectroscopy to determine the optical conductivity and phonons along planes parallel and perpendicular to the spin-ladders at temperatures ranging from 300 K to 10 K and look for signatures on the nature of spin-phonon coupling.

TT 37.22 Wed 15:00 P4

Magnetic Phase Diagrams of the Frustrated Langbeinite Material $Tl_2Mn_2(SO_4)_3$ — •Manuel Tönnissen[1], Alexander Bäder[1], Ladislav Bohatý[2], Petra Becker-Bohatý[2], Oliver Breunig[1], and Thomas Lorenz[1] — [1]II. Physikalisches Institut, Universität zu Köln — [2]Institut für Kristallographie, Universität zu Köln

Antiferromagnetic Heisenberg spins on the so-called trillium lattice form a highly frustrated 3-dimensional spin system [1]. This theoretical model can be realizied in cubic, low-symmetry space group $P2_13$ materials. One family of materials that partially crystallizes in this space group are langbeinites. Recent studies report that the langbeinite $K_2Ni_2(SO_4)_3$ with S=1 Ni^{2+} ions show close proximity to a field-driven quantum spin-liquid behavior, although there is magnetic order in zero field [2] [3]. Here we focus on the different magnetic phases of the related langbeinite $Tl_2Mn_2(SO_4)_3$ with S=5/2 Mn^{2+} ions. By conducting specific-heat, magnetocaloric-effect, and magnetization measurements, we derive B-T phase diagrams for different orientations of the magnetic field. Our data reveal the presence of at least 3 magnetic phases below a temperature of about 1.5 K for the magnetic field along the [1 1 1] direction and even 4 magnetic phases for fields applied along the [1 1 0] or [0 0 1] directions.

This work is supported through CRC1238 (projects A02 and B01).

Magnetic Order in the Low-Dimensional Quantum Magnet $Cu_2(OH)_3Br$ — •S. Luther[1], Z. Wang[2], A. Reinold[2], Z. Zhao[3], J. Wosnitza[1,4], and H. Kühne[1] — [1]Hochfeld-Magnetlabor Dresden, HZDR — [2]Fakultät Physik, TU Dortmund — [3]Fujian Institute of Research on the Structure of Matter, Chinese Academy of Sciences — [4]Institut für Festkörper- und Materialphysik, TU Dresden

Low-dimensional quantum magnets, such as the quasi-two-dimensional spin system $Cu_2(OH)_3Br$, can host exotic phenomena and ground states. We will present results of high-field magnetization and nuclear magnetic resonance (NMR) spectroscopy that probe the microscopic details of the magnetic structure at finite magnetic fields. In $Cu_2(OH)_3Br$, the Cu^{2+} ions in the distorted crystal structure form alternating ferromagnetic and antiferromagnetic spin-1/2 chains with finite interchain coupling, leading to a Néel temperature of 9.3 K at zero field. Here, we investigate the phase diagram for $H||b$, where a splitting of the NMR spectral lines below T_N and elevated fields reveals a commensurate long-range antiferromagnetic order. Maxima in the temperature-dependent spin-lattice relaxation rate $1/T_1$ at different magnetic fields indicate the transition temperature to the ordered phase. An anomaly in the high-field magnetization at low temperatures and around 16 T suggests the suppression of the magnetically ordered phase.

TT 37.24 Wed 15:00 P4

ESR Investigations of $AgCrSe_2$, $AgCrS_2$ and Cr_3Se_4 — •Jörg Sichelschmidt, Pierre Chailloleau, Michael Baenitz, Seo-Jin Kim, Helge Rosner, Vicky Hasse, and Marcus Schmidt — Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany

We investigated the Electron Spin Resonance (ESR) of Cr in the layered triangular lattice systems $AgCrSe_2$, $AgCrS_2$ and the structurally related Cr_3Se_4. These materials display a variety of interesting physical properties such as unconventional magnetic ordering [1], a spin-polarized surface state [2], an unconventional anomalous Hall effect [3] in $AgCrSe_2$ or multiferroic behavior in $AgCrS_2$, or directional Kondo transport [4]. At low temperatures, all these materials show a divergent ESR spin relaxation, which is typical for low-dimensional spin systems and indicates an increasing importance of Cr^{3+} spin correlations. This also leads to the formation of internal fields, as evidenced by the marked decrease in the resonance field. The relatively narrow Cr^{3+} ESR spectra allow to determine an ESR intensity which reflects the static susceptibility probed locally at the site of the Cr spins.

Electronic Structures of $AgCrS_2$, $AgCrSe_2$, and Cr_3Se_4 — •Seo-Jin Kim, Jörg Sichelschmidt, Michael Baenitz, Marcus Schmidt, and Helge Rosner — Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany

We study the electronic structures of triangular lattice systems $AgCrS_2$, $AgCrSe_2$, and the related compound Cr_3Se_4 using density functional theory (DFT). Although $AgCrSe_2$ and $AgCrS_2$ are isostrucural, they exhibit different physical properties. $AgCrSe_2$ is a self-doped p-type semiconductor characterized by spin-polarized surface states[1], the cycloidal magnetic ordering[2], and the unconventional anomalous Hall effect[3] and directional Kondo transport[4]. In contrast, $AgCrS_2$ is an insulator that undergoes symmetry lowering to a monoclinic phase and exhibits a collinear double-stripe antiferromagnetic ground state below $T_N = 42$ K. This study aims to present a comprehensive analysis of the electronic structures of these compounds. Additionally, we extend our investigation to the structurally related compound Cr_3Se_4.

Synthesis and Physical Properties of 2D van der Waals Magnets $Fe_{1-x}TM_xPX_3$ (TM: Transition Metals) — •Masoumeh Rahimkhani, Saicharan Aswartham, Andreas Kreyssig, and Anna Böhmer — Experimentalphysik IV, Ruhr-Universität Bochum, 44801 Bochum, Germany

Transition-metal phosphochalcogenides ($TMPX_3$) belong to the family of layered van-der-Waals materials in which TM is a transition-metal and X is a chalcogenide. These materials exhibit various electric, optical, and magnetic properties. $FePSe_3$ belongs to this family of $TMPX_3$ with interesting magnetic and electronic properties. Here, we describe the preparation of $FePSe_3$ and its substitution series with different transition metals through solid-state synthesis and CVT. The samples are characterized by X-ray diffraction and scanning electron microscope for structural and phase analysis. Further on, the magnetic and electronic properties will be investigated.

TT 37.27 Wed 15:00 P4

Single-Crystal Study of Kagome Magnets CrRhAs and CrNiAs — •Franziska Breitner, Bin Shen, Anton Jesche, and Philipp Gegenwart — Experimental Physics VI, Center for Electronic Correlations and Magnetism, University of Augsburg, 86159 Augsburg, Germany

CrRhAs and CrNiAs are metals with distorted kagome lattice of magnetic Cr atoms [1]. While CrRhAs is an antiferromagnet with a reported Néel temperature of 165 K for polycristalline samples, CrNiAs is ferromagnetic with T_C=170 K. More recently, interesting properties such as anomalous Hall effect were predicted for CrRhAs [2].

We report the first growth of CrRhAs and CrNiAs single crystals utilizing the flux method and present their specific heat, magnetic susceptibility and electrical transport. Magnetoresistance and Hall effect for CrRhAs indicate no anomalous behaviors. For CrNiAs we also investigate the influences of hydrostatic pressure as well as partial substitution of As with P on the ferromagnetic transition.

Supported by DFG-TRR 360*492547816 and the Alexander von Humboldt Foundation.

TT 37.28 Wed 15:00 P4

Inelastic Scattering in Anisotropic Heisenberg Models on Square and Honeycomb Lattice Via Continuous Similarity Transformations — •Vanessa Sulaiman[1], Dag-Björn Hering[1], Matthias R. Walther[2], Kai P. Schmidt[2], and Götz S. Uhrig[1] — [1]Condensed Matter Theory, Technische Universität Dortmund, Otto-Hahn-Straße 4, 44221 Dortmund, Germany — [2]Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, Staudtstraße 7, 91058 Erlangen, Germany

We apply a continuous similarity transformation (CST) [1,2] with a magnon-conserving generator to the antiferromagnetic anisotropic XXZ model. For the square lattice, the resulting effective Hamiltonian has already been analyzed [3]. We extend the approach by applying the CST to observables as well. Using the continuous fraction representation, we calculate spectral densities for these observables on the square and honeycomb lattice. These are then compared to experimental data from RIXS measurements [4], for example with single-layered $Ca_2CuO_2Cl_2$.

TT 37.29 Wed 15:00 P4

Stochastic Simulation of Spin Transport — •Franz Pöschl[1,4], Xin Zhang[1,2,3], Aristo Kevin Ardyaneira P[1,2,3], and Peter Rabl[1,2,3] — [1]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [2]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany — [4]Ludwig-Maximilians Universität München, Fakultät für Physik, Geschwister-Scholl-Platz 1, 80539 München

Simulating out of equilibrium steady states of large systems is a hard task. It is therefore necessary to develop novel approaches permitting to simulate the dynamics of those systems efficiently. In our work, we use the Discrete Truncated Wigner Approximation which is a semiclassical approach mapping hamiltonians and dissipative processes into a classical phase space. This mapping allows to compute stochastic trajectories and to evaluate the evolution of the system. In this poster I will present this method and show how it can be employed to study the out-of-equilibrium phases of the XXZ spin model and to derive its transport properties.

TT 37.30 Wed 15:00 P4

Anisotropic Magnetoresistance and Hall Effect of $Sr_4Ru_3O_{10}$ — •Simone Seipel[1], Lara Pätzold[1], Zahra Ghazinezhad[1], Augustus A. Nugroho[2], Markus Braden[1], and Thomas Lorenz[1] — [1]II. Physikalisches Institut, Universität zu Köln, Germany — [2]Bandung Institute of Technology, Indonesia

The layered transition-metal oxide $Sr_4Ru_3O_{10}$ is a member of the Ruddlesden-Popper series with a layered orthorhombic crystal structure. It is a ferromagnetic metal with $T \simeq 105$ K and shows an additional metamagnetic transition below 50 K, of which a deeper understanding is still missing. Here, we present a single-crystal study of the anisotropic magnetization and electrical transport properties. For in-plane electric currents ($j||ab$) and $B||c$, we present normal and anomalous Hall effect data. The latter shows a non-monotonic temperature dependence and a characteristic sign change at low temperature which similarly occurs in the magnetoresistance $\rho_{xx}(B||c)$. Such a behavior is known from the sister compound $SrRuO_3$ and associated with Weyl points in the band structure [1]. In addition, we studied the out-of-plane resistivity that is highly anisotropic ($\rho_c >> \rho_{ab}$) due to the layered crystal structure and strongly changes at the metamagnetic transition. Based on magnetoresistance data $\rho_c(B||ab)$ we derive the magnetic-field induced metamagnetic transition at low temperatures and discuss the angular dependence of the transition fields and the magnetoresistance for in-plane magnetic fields.

TT 37.31 Wed 15:00 P4

Thermal Transport in Swedenborgite $CaBaCo_4O_7$ — •Reza Firouzmandi[1], Matthias Gillig[1], Yasujiro Taguchi[2], Yoshinori Tokura[2], Yusuke Tokunaga[2], Vilmos Kocsis[1], and Bernd Büchner[1] — [1]IFW-Dresden, Dresden, Germany — [2]RIKEN-CEMS, Wako, Japan

The interplay between electronic, magnetic, and lattice degrees of freedom in multiferroic materials gives rise to novel transport phenomena, including the thermal Hall effect (THE), thermal analog of the Hall effect, where heat flow is deflected under an external magnetic field. Here, we investigate the thermal transport properties of the multiferroic Swedenborgite $CaBaCo_4O_7$, a compound featuring alternating Kagome and triangular layers of edge-sharing CoO_4 tetrahedra in a mixed valence state. The longitudinal thermal conductivity exhibits anomalies associated with magnetic ordering, while the transverse thermal conductivity (κ_{xy}) reveals an anomalous thermal Hall effect that vanishes at low temperatures, resembling the magnon thermal Hall effect. These results provide

insight into the role of spin-lattice coupling in the thermal transport of frustrated magnetic systems.

TT 37.32 Wed 15:00 P4

Strain dependance of the antiferromagnetic transition of $Ca_{1-x}Sr_xCo_2As_2$ with a substitution induced structural collapse — •Michael Paul, Maik Golombiewski, Teslin R. Thomas, N.S. Sangeetha, Andreas Kreyssig, and Anna E. Böhmer — Experimentalphysik IV, Ruhr-Universität Bochum, 44801 Bochum, Germany

The tetragonal structure of $SrCo_2As_2$ undergoes a gradual collapse with the substitution of Sr by Ca atoms. This collapse is accompanied by the emergence of antiferromagnetic order with a transition temperature T_N of up to 55 K [1]. It has been shown that T_N can be tuned with biaxial strain that is created by cooling a thin $Ca_{1-x}Sr_xCo_2As_2$ sample that is glued to a quartz substrate [2].
A more controlled application of uniaxial force to the sample can be achieved with the use of the cryogenic stress cell Razorbill FC100. The modification of the antiferromagnetic transition of $Ca_{1-x}Sr_xCo_2As_2$ is investigated by applying uniaxial stress to the sample with this device.
We acknowledge the support by the Deutsche Forschungsgemeinschaft (DFG) under CRC/TRR 288 (Project A02).

Single crystal synthesis of $FeSb_2$ and investigation of its electronic transport properties — •Maximilian van de Loo, Maik Golombiewski, Andreas Kreyssig, and Anna E. Böhmer — Experimentalphysik IV, Ruhr-Universität Bochum, 44801 Bochum, Germany

$FeSb_2$ is a diamagnetic narrow band gap semiconductor with interesting electronic transport properties [1]. Huge thermoelectric power factor and a paramagnetic crossover have been reported at low temperatures [1, 2] and attempts to influence and understand these properties by doping have been made [3]. A metal-semiconductor crossover along the b axis can be observed under certain growth conditions. We have synthesized single crystals of $FeSb_2$ via self-flux growth and successfully realized substitutions $(Fe_{1-x}TM_x)Sb_2$ with different transition metals (*TM*). The samples were characterized with electron microscopy, energy-dispersive x-ray spectroscopy, powder x-ray diffraction and Laue diffraction measurements, as well as electrical resistivity measurement. The appearance of the metal-semiconductor crossover has been investigated by varying the growth conditions.

We acknowledge support by the Deutsche Forschungsgemeinschaft (DFG) under CRC/TRR 288 (Project A02).

TT 37.34 Wed 15:00 P4

Feshbach resonance in a strongly repulsive ladder of mixed dimensionality: a possible scenario for bilayer nickelate superconductors — •Hannah Lange[1,2,3], Lukas Homeier[1,3], Eugene Demler[4], Fabian Grusdt[1,3], and Annabelle Bohrdt[3,5] — [1]LMU Munich — [2]Max-Planck-Institute for Quantum Optics, Garching — [3]Munich Center for QST, Munich — [4]ETH Zurich — [5]University of Regensburg

Since the discovery of superconductivity in cuprate materials, the minimal ingredients for high-Tc superconductivity have been an outstanding puzzle. Motivated by the recently discovered nickelate bilayer superconductor LNO under pressure, we study a minimal bilayer model, in which, as in LNO, inter- and intralayer magnetic interactions but no interlayer hopping are present: a mixed-dimensional (mixD) t-J model. The single and coupled mixD ladders we study feature a crossover from tightly bound pairs of holes (closed channel) at small repulsion, to more spatially extended, correlated pairs of individual holes (open channel) at large repulsion. We derive an effective model for the latter, in which the attraction is mediated by the closed channel, in analogy to atomic Feshbach resonances. Using density matrix renormalization group (DMRG) simulations we reveal a dome of large binding energies at around 30% doping, accompanied by a change of the Fermi surface volume. Our work provides a microscopic theory of pairing in the doped mixD system with dominant repulsion and our predictions can be tested in state-of-the-art quantum simulators.

TT 37.35 Wed 15:00 P4

Fluctuation Spectroscopy on $La_2NiO_{4+\delta}$ RRAM devices — •Demian Ranftl[1], Yingxin Li[2], Tristan Stadler[1], Eszter Piros[2], Aleksandra Koroleva[3], Lambert Alff[2], Mónica Burriel[3], and Jens Müller[1] — [1]Institute of Physics, Goethe University, Frankfurt am Main, Germany — [2]Institute of Materials Science, TU Darmstadt, Darmstadt, Germany — [3]Laboratory in Materials Science and Physical Engineering, Université Grenoble Alpes, Grenoble, France

Memristive devices, whose resistance is programmable and retainable, are considered to be most promising for the next generation of non-volatile memory. Low-frequency current noise spectroscopy is a non-invasive investigative tool for probing the effect of defects on resistive switching [1, 2]. Annealing $La_2NiO_{4+\delta}$ films under inert (Ar) or oxidising (O_2) atmospheres results in devices with filamentary and interfacial-type resistive switching respectively [3]. In this work we explore the effect of the switching mechanism, readout voltage and area dependency on the noise characteristics of LNO-based RRAM.

Resistance Fluctuation (Noise) Spectroscopy in EuS and $LiCu_3O_3$ — •Philipp Swoboda[1], Demian Ranftl[1], Nazia Kaya[1], Katharina Zoch[1], Kristin Kliemt[1], Simon Moser[2], Cornelius Krellner[1], and Jens Müller[1] — [1]Institute of Physics, Goethe-University Frankfurt, Frankfurt (Main), Germany — [2]Institute of Physics, University Würzburg, Würzburg, Germany

Noise spectroscopy gives insights into the low-frequency dynamics of charge carriers in condensed-matter systems, which is energy-resolved information that can't be obtained from mean values alone. Here the interest lies in $1/f^{\alpha}$-noise, which can be described as a superposition of independent two-level processes. For instance it has been used to identify energy scales of thermally-activated switching processes like fluctuating polar nanoregions (PNR) in the past [1, 2]. In general the processes observed by resistance fluctuation are sensitive to slow dynamics. Examples are the slowing down of charge carriers in the vicinity of a metal insulator transition and the freezing of PNR at the onset of glassy dynamics. This work aims to use noise spectroscopy as a function of temperature and magnetic field in order to investigate how magnetic polarons influence the colossal magnetoresistance in the ferromagnetic semiconductor EuS, as well as to investigate the exotic electron glass phase in $LiCu_3O_3$.

TT 37.37 Wed 15:00 P4

Single spin-flip dynamics in the Ising model — •Luca Cervellera and Björn Sothmann — Faculty of Physics and CENIDE, University Duisburg- Essen, 47057 Duisburg

The surface of Si(001) consists of buckled Si dimers with alternating orientation in the ground state. At around 190 K, the system undergoes an order-disorder phase transition which can be described in terms of an antiferromagnetic 2D Ising model with anisotropic couplings [1]. Here, we aim at understanding the switching dynamics of a single Ising spin by means of Monte Carlo simulations of the temperature-dependent dynamics using different algorithms which allow us to analyze the waiting-time distribution and full counting statistics of spin flips.

TT 37.38 Wed 15:00 P4

Quantum Monte-Carlo study of the bond- and site-diluted transverse-field Ising model — •Calvin Krämer, Max Hörmann, and Kai Phillip Schmidt — Lehrstuhl für Theoretische Physik V, Staudtstraße 7, Universität Erlangen-Nürnberg, D-91058 Erlangen, Germany

We study the transverse-field Ising model on a square lattice with bond- and site-dilution at $T = 0$ by quantum Monte Carlo simulations. By tuning the transverse field h and the dilution p, the phase diagram of both models is explored. Finite-size scaling of the order parameter and averaged Binder ratios is employed to determine the positions of critical points and the critical exponents β and ν along the critical lines and at the multi-critical point. Dynamical properties in the vicinity of the quantum critical point are analyzed through the local susceptibility. We complement these findings by stochastic analytical continuation [1] of imaginary-time Green's functions, providing momentum-resolved insights into the behavior of excitations. [1] Anders W. Sandvik, Phys. Rev. B 57, 10287

TT 37.39 Wed 15:00 P4

Typical medium theory for disordered electronic systems on simple lattices with Cauchy distribution of on-site potentials — Andreas Ostlin[1], Hanna Terletska[2], Dylan Jones[1], and •Liviu Chioncel[1,3] — [1]Institute of Physics, University of Augsburg, Augsburg, Germany — [2]Middle Tennessee State University, Murfreesboro, Tennessee, USA — [3]ACIT, University of Augsburg, Augsburg, Germany

Effective medium approaches using single-site averaging procedures of various kinds contributed substantially in understanding the density of states of electronically disordered systems in models and materials. The nature and the conditions for appearance of single-particle (Anderson) localization seems to be qualitatively understood, yet discussions concerning special applied methods and quantitative results for the critical conditions are still ongoing. Here we present results using the typical medium theory for the one-particle and two-particle Green's function (conductivities) for the special case of Cauchy-distribution.

TT 37.40 Wed 15:00 P4

Excitations and Their Decay: Calculating the Non-Lorentzian Line Shape of Excited States at the Ti $L_{2,3}$ edge in $SrTiO_3$ — •Sarah L. Görlitz[1], Sina Shokri[1], Widad Louafi[2], Martin Brass[1,3], Marc Merstorf[1], Jonas Hoecht[1], Michelangelo Tagliavini[1], Kevin Ackermann[1], and Maurits W. Haverkort[1] — [1]Institut for Theoretical Physics, Heidelberg University, 69120 Heidelberg — [2]Laboratory of Theoretical Physics, Faculty of Exact Sciences, University of Bejaia, 06000 Bejaia, Algeria — [3]Institute of Solid State Physics, TU Wien, 1040 Vienna, Austria

Understanding electron dynamics in real materials following photon excitations is a challenging task. Ultrafast pump-probe and multi-color experiments require precise control, while strong electron correlations in excited states complicate the theoretical description. Accurate calculations must reproduce absorption line shapes for single-photon absorption, often non-Lorentzian due to multi-channel decay processes.

In this work, we calculate the line shape of Ti 2p → 3d core excitations in $SrTiO_3$. While crystal-field models predict seven delta-function peaks, the real spectrum reveals distinct line widths and non-Lorentzian line shapes. Incorporating Auger-Meitner decay, fluorescence decay, and coupling to the valence-conduction bath continuum, we establish a framework to explain these broadenings. This approach is critical for predicting higher-order response functions, essential for modeling resonant inelastic X-ray scattering (RIXS) and ultrafast spectroscopies, providing insights into the interplay of decay processes and electron dynamics.

TT 37.41 Wed 15:00 P4

Role of interlayer coupling and anisotropy in 1T-TaS_2 studied by ellipsometry — •Achyut Tiwari[1], Renjith M. Roy[1], Christian Prange[1], Yuan Yan[2], Bruno Gompf[1], and Martin Dressel[1] — [1]1. Physikalisches Institut, Universität Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart, Germany — [2]School of Physics, Nankai University, Tianjin, 300071 China

The layered transition metal dichalcogenide 1T-TaS_2 has attracted considerable attention due to its rich electronic phase diagram, characterized by multiple charge density wave (CDW) phases. With decreasing temperature, the material transitions from a metallic incommensurate phase to a metallic nearly commensurate phase and finally to an insulating commensurate phase featuring the star-of-David lattice distortion. The metal-insulator transition (MIT) is a first-order phase transition that exhibits hysteresis during cooling and heating, with an additional intermediate phase in the 215 K-280 K range upon heating. Here, temperature-dependent ellipsometry revealed pronounced anisotropy between in-plane and out-of-plane responses, attributable to significant interlayer interactions. The temperature-dependent out-of-plane dielectric constant exhibited marked changes across the MIT, highlighting the role of interlayer coupling. Furthermore, the effective medium approximation confirmed the existence of the intermediate phase during heating, providing a microscopic description. These findings underscore the importance of interlayer coupling in layered materials and elucidate on the previously unexplored intermediate phase of 1T-TaS_2.

TT 37.42 Wed 15:00 P4

The Interplay Between Diagonal and Off-Diagonal Electron-Phonon Coupling in two-dimensional systems — •jadson lucas portela e silva[1,2], gabriel rein[2], sebastião a. s. júnior[1], willdauany c. f. da silva[1], fakher f. assaad[2], and natanael c. costa[1] — [1]instituto de física universidade federal do rio de janeiro, rio de janeiro, brasil — [2]institut für theoretische physik und astrophysik, universität würzburg, würzburg, germany

The interplay between diagonal and off-diagonal electron-phonon coupling in two-dimensional systems is explored using the Holstein-Su-Schrieffer-Heeger (HSSH) model through non-perturbative Monte Carlo simulations on a square lattice at half-filling. Electron-phonon coupling is crucial in determining exotic phases like charge-density waves (CDW), valence bond solids (VBS), and superconductivity. The HSSH model uniquely combines features of the Holstein and SSH models, where the former modulates the on-site potential energy, and the latter modifies the electron's kinetic energy through lattice displacements. The study constructs phase diagrams by analyzing charge-charge, bond-bond, and pairing correlation functions. Key findings include a competition between CDW and VBS phases, similar to one-dimensional systems. However, unlike the 1D case, no metallic phase is observed between these states, likely due to perfect nesting and van Hove singularities in the density of states, which destabilize the Fermi liquid state. Further exploration beyond half-filling shows that melting of CDW and VBS phases leads to superconductivity.

TT 37.43 Wed 15:00 P4

Picosecond periodic oscillation modulated by Higgs amplitude mode in a superconductor-metal hybrid metasurface — •Siyu Duan[1,2], Jingbo Wu[1], Caihong Zhang[1], Kebin Fan[1], Biaobing Jin[1], and Zhe Wang[2] — [1]School of Electronic Science and Engineering, Nanjing University, Nanjing, China — [2]Department of Physics, TU Dortmund University, Dortmund, Germany

We report on a time-resolved terahertz spectroscopic study of a superconductor-metal hybrid metasurface that is fabricated by introducing superconducting microbridges into metallic resonators. By exploiting the nonlinear response of the superconducting NbN microbridges to a multicycle narrowband terahertz excitation pulse, we observe a picosecond periodic oscillation of terahertz transmission spectra. This oscillation contains components of the fundamental frequency of the narrowband excitation pulse and its second harmonic, which we ascribe tentatively to an excited Higgs mode oscillation. Furthermore, we can modulate the amplitude and duration of periodic oscillations by changing the field strength of the terahertz excitation pulse and the sample temperature.

TT 37.44 Wed 15:00 P4

Density Functional Theory-based Multiplet Ligand Field Theory Calculations of Ultrafast Pump-Probe Electron Dynamics in Correlated Materials — •Ruth Kaiser, Sina Shokri, and Maurits W. Haverkort — Heidelberg University, Institute for Theoretical Physics, Philosophenweg 19, 69120 Heidelberg, Germany

Ultrafast pump-probe spectroscopy allows one to study and steer quantum materials on their fundamental time-scales. In correlated molecules and solids a theoretical understanding is challenging and quantitative predictions how coherently driven excitations decohere is highly non-trivial. We have developed a recipe for quantitatively predicting pump-probe spectra, starting with a Hamiltonian on a basis of local Wannier orbitals derived from density-functional calculations, describing the charge-transfer in the system and, on top of that, we include the full local Coulomb repulsion [1]. Using non-linear response theory, we then calculate the time-resolved spectra, such as photo-emission spectroscopy, x-ray absorption spectroscopy and resonant inelastic x-ray scattering, which captures the pump-probe dynamics. Our routine can be used for different types of correlated materials, such as Mott-Hubbard and Charge-Transfer insulators as well as molecules [2, 3]. Furthermore, we show examples where we implemented our method for real materials like NiO and SF_6 and compare our results with experiments.

TT 37.45 Wed 15:00 P4

Understanding Resonant Inelastic X-ray Spectroscopy Using Dynamical Mean-Field Theory and Model Hamiltonians — •Lukas Hellmann, Aleksandrs Zacinskis, Sina Shokri, Michelangelo Tagliavini, Kevin Ackermann, and Maurits W. Haverkort — Universität Heidelberg, Institut für Theoretische Physik, Philosophenweg 19, Heidelberg 69120 Germany

Using model Hamiltonians with local Coulomb interactions, we demonstrate how resonant inelastic X-ray scattering spectra (RIXS) can be interpreted within the framework of the dynamical mean-field approximation. Our approach incorporates both valence correlations and core-valence Coulomb repulsion, enabling a detailed examination of spectral features across the metal-insulator transition. The calculated RIXS spectra reveal two distinct types of excitations: (1) locally excited excitons exhibiting a resonant enhancement at constant energy loss, and (2) a fluorescence regime characterized by resonant intensity enhancement at constant emitted energy. We analyze the transition in intensity between these two excitation regimes and discuss its implications for understanding electronic dynamics. All calculations are performed directly on the real frequency axis using the software package Quanty (www.quanty.org). This methodology not only provides accurate predictions for RIXS spectra but also offers a versatile framework for studying the dynamics of other correlated systems.

TT 37.46 Wed 15:00 P4

Material Specific Real Frequency LDA+DMFT Calculations of Transition Metals — •Johann Collard, Michelangelo Tagliavini, Kevin Ackermann, Sina Shokri, Aleksanders Zacinskis, Lukas Hellmann, and Maurits W. Haverkort — Institute for Theoretical Physics, Heidelberg University, Philosophenweg 19, 69120, Heidelberg, Germany

3d transition metals exhibit a wide range of intriguing properties. At the same time their accurate theoretical description is challenging task due to the presence of correlated electrons in their open d-shells. Ab-initio approaches, such as LDA+DMFT (Local Density Approximation + Dynamical Mean-Field Theory), have proven successful in capturing many material-specific properties and electron correlation effects. Most existing DMFT algorithms rely on Quantum Monte Carlo simulations, which operate on imaginary frequencies. While effective for static property calculations, these methods require analytical continuation to compute spectral functions, a process that is ill-posed and thus computationally challenging. In this work, we demonstrate how real-frequency DMFT, as implemented in Quanty, can directly compute spectral functions within the LDA+DMFT framework for real materials. This approach avoids the complications of analytical continuation, providing a more straightforward and reliable means of exploring the spectral properties of 3d transition metals.

TT 37.47 Wed 15:00 P4

An Accessible Implementation and Detailed Test of Real-Frequency Dynamical Mean-Field Theory — •Aleksandrs Zacinskis, Sina Shokri, Kevin Ackermann, Michelangelo Tagliavini, and Maurits W. Haverkort — Heidelberg University, Institute for Theoretical Physics, Philosophenweg 19, 69120 Heidelberg, Germany

Dynamical Mean-Field Theory (DMFT) has become a powerful tool for studying materials with correlated electrons. However, most DMFT solvers operate on imaginary Matsubara frequencies, making the extraction of accurate spectral functions challenging due to the need for analytical continuation.

Here, we perform DMFT calculations using a real-frequency solver implemented in Quanty [1]. This implementation utilizes a one-particle basis of natural impurity orbitals [2] to investigate several correlated model systems with local interactions. We systematically examine critical metal-insulator transition interaction strengths and the chemical potential as a function of filling, comparing different bath discretization schemes and numerical cut-offs to manage Hilbert space size.

Our results demonstrate robust and satisfactory convergence at moderate computational costs, validating the reliability of this approach. All calculations were performed using the open-source quantum many-body code *Quanty* (www.quanty.org), emphasizing its accessibility for broader applications in correlated electron systems.

TT 37.48 Wed 15:00 P4

Engineering Correlated Electrons in Adatom Lattices on Semiconductors — •Tim Kullick[1], Niklas Enderlein[1], Henri Menke[1,2], Giorgio Sangiovanni[3], and Philipp Hansmann[1] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg — [2]Max Planck Institute for Solid State Research, Stuttgart — [3]Julius-Maximilian-Universität of Würzburg

Adatom lattices on (111) surfaces of zinc-blende structured semiconductors have proven to be versatile, experimentally realizable platforms for hosting flat bands with strong electronic correlations near the Fermi energy. A recent study [1] revealed transition metals on 3C-SiC(111) surfaces to be intriguing adatom systems, showcasing the diverse nature of strongly correlated systems. Together with earlier theoretical and experimental studies on adatom lattices on the Si(111) surfaces, this recent work underlines the great potential of this material family. In the present project we explore other promising material candidates on SiC and other substrates that might realize (one-, two-, and three-band) Hubbard models at different fillings and a potential impact of spin-orbit coupling. Combined with estimates of the quasiparticle interaction via cRPA, we point out new material directions in this increasingly vivid field.

TT 37.49 Wed 15:00 P4

Calculating Moments for Many-Electrons Systems — •Elaheh Adibi and Erik Koch — Peter Grünberg Institute and Institute for Advanced Simulation, Forschungszentrum Jülich, 52425 Jülich, Germany

We present a combinatorial approach to calculate the M^{th} moment of an N-electron system, defined as $\langle E^M \rangle = \mathrm{Tr}\, H^M$. Working in the basis of Slater determinants $|\boldsymbol{\alpha}\rangle = \prod c^\dagger_{\alpha_i}|0\rangle$, matrix elements $\langle\boldsymbol{\alpha}|H^M|\boldsymbol{\alpha}\rangle$ may only be non-zero for terms where the orbital indices of the creation operators in H^M are permutations of the orbital indices of the annihilators. The trace for a given permutation can then be evaluated combinatorially, without having to deal with the many-body Hilbert space explicitly. Since all permutations related by cyclic rotations give the same contribution, we classify them into groups and evaluate the trace only for a single group member. For the special case of all orbitals in the permutation being different, the calculation simplifies further, as in this irreducible case all permutations written in terms of cycles with a given number of descents give the same contribution to the moment. Relating the groups of permutations for the irreducible and the reducible terms allows us to efficiently evaluate the moments.

TT 37.50 Wed 15:00 P4

Exact t^1_{2g} Superexchange Hamiltonians for Complex Orbital Ordering — •Amit Chauhan, Xue-Jing Zhang, and Eva Pavarini — Peter Grünberg Institute, Forschungszentrum Jülich, 52425 Jülich, Germany

We derive exact superexchange interactions for t^1_{2g} systems with spin-orbit coupling. To this end we extend the formalism developed in [1], which we have successfully used in [2,3] to study the origin of orbital ordering. As first application we consider the case of cubic and tetragonal lattices and study the stability of complex orbital ordering in the presence of spin-orbit interaction and crystal-field splitting.

Scaling and convergence behaviour of linked-cluster expansions — •Harald Leiser, Max Hörmann, and Kai Phillip Schmidt — Department Physik, Staudtstraße 7, Friedrich-Alexander Universität Erlangen-Nürnberg, D-91058 Erlangen, Germany

We derive effective block-diagonal Hamiltonians $H_{\mathrm{eff}} = T^\dagger H T$ using the projective-cluster additive transformation (PCAT) [1]. Numerical linked-cluster expansions (NLCEs) are employed to study the (anti)ferromagnetic transverse-field Ising model (TFIM) on diverse lattice geometries such as chains and various ladders. By calculating energy gaps, we compare the scaling behavior with other methods such as deepCUT [2]. A key challenge arises from the presence of avoided-level crossings (ALCs) [3] which complicates convergence. To probe this issue, we analyze ALCs in the simplified setting of the XXZ model on a chain. A key property of PCAT is the cluster additivity of both H_{eff} and the generator $S = \log(T)$. This allows transforming larger systems via a cluster expansion in S. Using S from clusters up to size N, we compute $\exp(-S)H\exp(S)$ in the thermodynamic limit and compare it with standard NLCE and CUT methods [4]. Notably, S for local clusters generates higher-order terms, mitigating some scaling challenges in traditional cluster expansions.

Computing Excited States in Quantum Many-Body Clusters with Neural Network Support — •Max Kroesbergen[1], Louis Thirion[1], Gianluca Levi[3], Pavlo Bilous[2], Paul Fadler[1], Yorick Schmerwitz[3,4], Elvar Ö. Jónsson[3], Hannes Jónsson[3], and Philipp Hansmann[1] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg — [2]Max Planck Institute for the Science of Light, Erlangen — [3]University of Iceland, Reykjavik — [4]Max Planck Institute for Coal Research, Mühlheim

In this study, we used SOLAX [1], our newly developed Python library for configuration interaction (CI) calculations of fermionic quantum systems, to compute the energies of ground and excited states for various quantum clusters. SOLAX can leverage the power of a neural network (NN) classifier to perform selective CI which mitigates the exponential growth of the many-body Hilbert space. Our benchmarks indicate a significant boost in computational efficiency while maintaining high accuracy. We validate our method for the (discrete) Single Impurity Anderson Model [2] as well as molecular systems, such as N_2 and H_2 [3]. For the latter, we study the dissociation curves of ground- and excited states and their dependence on the underlying single-particle basis, including Hartree-Fock orbitals optimized for excited states. Additionally, SOLAX enables us to simulate spectral functions defined by a transition operator, providing deeper insights into the excitation dynamics of these systems.

Using the Anderson Impurity Model to Look for Particles Beyond the Standard Model — •Vera Butz and Maurits W. Haverkort — Universität Heidelberg, Institut für theoretische Physik, Philosophenweg 19, 69120 Heidelberg

High-precision comparisons between experimental measurements and numerical simulations [1] not only test the accuracy of computational methods but also offer deeper insights into fundamental physics. In this work, we investigate the interaction of charged ions with multiple electrons and continuum states, presenting a generalized Anderson impurity model. The continuum states considered include photons, free electrons, or as-yet-unobserved particles, such as axions. These interactions can be described through the self-energy or hybridization function [2]. The real part of the self-energy induces energy shifts in atomic multiplets, such as the Lamb shift, while the imaginary part results in finite lifetimes for excited states, leading to phenomena like fluorescence or Auger-Meitner decay. When applied to highly charged heavy ions, whether in laboratory settings or astrophysical environments such as the Sun, these enhanced electron-photon (or other particle) interactions provide a platform to probe the Standard Model. Additionally, they may reveal evidence of new physics, including the potential detection of axions, a leading dark matter candidate that could also address the strong CP problem.

TT 37.54 Wed 15:00 P4

Properties of the Density Matrix for Metavalent Materials — •Niklas Penner[1,2], Lucia Reining[1], Matteo Gatti[1], and Matthias Wuttig[2] — [1]ETSF, LSI, CNRS, CEA/DRF/IRAMIS, Ecole Polytechnique, Institut Polytechnique de Paris, France — [2]I. Institute of Physics (IA), RWTH Aachen University, Germany

In the experimental investigation of phase change materials and their unique properties, peculiarities in the bonding character were determined. A corresponding classification of these metavalent materials has so far been carried out on the basis of shared and transferred electrons. The corresponding values were determined using density functional theory (DFT) calculations. Density functional theory has become one of the most universal methods in condensed matter physics and material science to determine and investigate properties of materials. The longer-term goal of the present work is to investigate to which extent the spatial extension of the density matrix is characteristic for metavalent materials, and whether numerical calculations based on the Kohn-Sham formulation of density functional theory can capture this aspect.

TT 37.55 Wed 15:00 P4

Traces of powers of many-body Hamiltonians — •Marcus Kollar — Theoretische Physik III, University of Augsburg

The high-temperature expansion of the partition function for a many-body system of fermions or bosons involves Fock space traces of powers of the Hamiltonian. Here we use algebraic means to evaluate such moments for a fixed number of non-interacting particles with arbitrary discrete spectrum and express them as polynomials of power sums of the single-particle energies. In the fermionic case our expressions agree with those obtained by combinatorial considerations [1]. We discuss possible applications and generalizations of our results.

TT 37.56 Wed 15:00 P4

Ising model on a sphere — •Grigorios Makris[1], Fabian Hassler[2], Stefan Wessel[1], and Ion Cosma Fulga[3,4] — [1]Institute for Theoretical Solid State Physics, RWTH Aachen University, Germany — [2]Institute for Quantum Information, RWTH Aachen University, Germany — [3]Institute for Theoretical Solid State Physics, IFW Dresden, Germany — [4]Würzburg-Dresden Cluster of Excellence ct.qmat, Dresden, Germany

The study of the Ising models is of primary interest in the theory of phase transitions. The models have been extensively studied in flat space and analytical solutions exist in two dimensions. Their scaling behavior is known to substantial precision and confirms the theory of finite-size scaling.

Here, we study Ising models on the surface of a sphere. As it is generally not possible to place a regular lattice on a sphere, for arbitrary number of points, we implement the Fibonacci lattice. The lattice is tested to have a reasonably uniform distribution of points. In order to establish the expected $SO(3)$ symmetry, we first solve the free-particle problem as a tight-binding model and then utilize the hopping coefficients as interaction terms on the Ising model. This is shown to yield better, approximate, $SO(3)$ degeneracies on the low energy levels of the transverse-field Ising model. Having set up the Hamiltonian, we further investigate the critical point of the expected phase transition.

TT 37.57 Wed 15:00 P4

Two site entanglement in the two dimensional Hubbard model — Anna Kauch[1], •Gergo Roosz[2], Frederic Bippus[1], Daniel Wieser[1], Fakher Assaad[3,4], and Karsten Held[1] — [1]Institute of Solid State Physics, TU Wien, 1040 Vienna, Austria — [2]HUN-REN Wigner RCP, Budapest — [3]Universitat Wurzburg, 97074 Wurzburg, Germany — [4]Wurzburg-Dresden Cluster of Excellence ct.qmat, Am Hubland, 97074 Wurzburg, Germany

We calculate the reduced density matrix of two sites in the two-dimensional Hubbard model using the D Gamma A method. We calculate the density matrix by calculating the expectation value of a complete set of hermitian operators in the subspace of the two sites. We can express these eigenvalues with the one- and two-particle Greens functions, and the imaginary time derivatives of these functions. The derivatives are calculated in Matsubara representation. To test convergence we compare our results for the second Renyi entropy with quantum Monte Carlo data. To investigate the entanglement and correlations of the Hubbard model we calculate the mutual information and the entanglement negativity between the two sites.

TT 37.58 Wed 15:00 P4

Thouless time in a spin-1/2 XX ladder — •Kadir Çeven[1], Lukas Peinemann[1], Rohit Patil[2], Marcos Rigol[2], and Fabian Heidrich-Meisner[1] — [1]Institut für Theoretische Physik, Georg-August-Universität Göttingen, Göttingen, Germany — [2]Department of Physics, Pennsylvania State University, University Park, USA

The eigenstate thermalization hypothesis (ETH) offers a powerful framework for understanding many properties of thermalization dynamics in non-equilibrium quantum many-body systems. Here, determining the time scales associated with thermalization is a key focus in the research of nonequilibrium dynamics of such systems. In this study, we investigate a spin-1/2 XX ladder, an experimentally realizable model exhibiting diffusive dynamics, to explore the connections among ETH, transport properties, and measures purely based on its energy spectrum. Specifically, we analyze the spectral form factor and the smooth spectral function, each of which provides a characteristic relaxation time scale potentially linked to the Thouless time–the longest relaxation time defined in terms of the diffusion constant. Using various numerical methods, we compare the time scales obtained from these different measures to identify potential discrepancies and similarities.

We acknowledge funding from the Deutsche Forschungsgemeinschaft (German Research Foundation) within the Research Unit FOR5522 (Project No. 499180199).

TT 37.59 Wed 15:00 P4

Nonequilibrium Phenomena in Strongly Correlated Systems under Structured Fields — •Sajad Mirmohammadi and Jamal Berakdar — Martin-Luther-Universität Halle-Wittenberg Karl-Freiherr-von-Fritsch-Str. 3 06120 Halle/Saale

Strongly correlated systems provide a rich platform for exploring quantum phenomena and understanding nonequilibrium many-body dynamics. A central challenge lies in unraveling the interplay of various interactions that govern the emergence of exotic quantum states. Here, we investigate how phase- and polarization-structured electromagnetic fields interact with strongly correlated materials modeled by the extended Peierls Hubbard Hamiltonian. Using exact diagonalization with the Lanczos algorithm, we demonstrate how structured fields imprint their characteristics onto excitation dynamics, including charge and spin density waves.

TT 37.60 Wed 15:00 P4

Application of the TraSPI Method to Aharonov-Bohm Interferometry with Interacting Quantum Dots — •Alexander Hahn, Jürgen König, and Alfred Hucht — Theoretische Physik, Universität Duisburg-Essen and CENIDE, 47048 Duisburg, Germany

Utilizing the *Transfer-matrix Summation of Path Integrals* (TraSPI) approach, we extend the method's application to the study of quantum transport in an Aharonov-Bohm interferometer housing two parallel quantum dots. Here the usage of TraSPI allows the calculation of the current influenced by the enclosed magnetic flux, in presence of Coulomb interaction. The numerical accuracy and efficiency of the TraSPI method allow for a detailed exploration of the interplay between quantum coherence and dot interactions.

TT 37.61 Wed 15:00 P4

Metastability in Correlated Electron Systems — •Lara Bremer[1], Martin Eckstein[1], Hugo Strand[2], and Tim Wehling[1] — [1]I. Institute of Theoretical Physics, University of Hamburg, Notkestraße 9-11, 22607 Hamburg, Germany — [2]School of Science and Technology, Örebro University, SE-701 82 Örebro, Sweden

The objective of this study is to describe metastable states in correlated electron systems, with a particular focus on numerically accessing unstable solutions within coexistence regions of first-order phase transitions. Our work is based on the well-established phenomenon observed in the Mott transition of the single-orbital Hubbard model, where a coexistence region between a metallic phase and an insulating phase, accompanied by a third unstable solution, has been demonstrated within the framework of Dynamical Mean Field Theory. A Phase Space Extension algorithm is employed to effectively identify and analyse these solutions. By accessing this unstable solution, the double occupancy on this branch can be calculated, thus enabling the Landau free energy to be calculated via a thermodynamic route, as opposed to fitting a Landau free energy functional.

TT 37.62 Wed 15:00 P4

Simulating nonequilibrium systems in the steady-state: GW+EDMFT — •Fabian Künzel — University of Hamburg, 20355 Hamburg, Germany

The Keldysh formalism for nonequilibrium Green's functions provides a versatile theoretical framework for analyzing the dynamics and structure of correlated many-body systems. To address the intrinsic cubic scaling of computational time in the Kadanoff-Baym equations (KBE) for nonequilibrium Green's functions, a truncation of the underlying memory kernel can be incorporated into the time-stepping algorithm of the NESSi simulation package. This reduces the computational cost to linear scaling with respect to the maximum simulation time. For systems where long-time dynamics extend beyond the capabilities of state-of-the-art methods, the KBE can be formulated within the Keldysh steady-state formalism. The resulting equations are then solved using a Fourier transform, enabling the description of systems with exponentially separated timescales. We aim to introduce new methods that extend the reach of the existing NESSi package and present a steady-state study of a Mott insulator, incorporating non-local correlations through a steady-state GW+EDMFT formalism.

TT 38: Superconducting Electronics: SQUIDs, Qubits, Circuit QED I

TT 38.1 Wed 16:45 H32

Microwave characterization of planar Josephson junction arrays — •Alexander Kirchner[1], Johanna Berger[1], Simon Feyrer[1], Narges Momeni[1], Matthias Kronseder[1], Michael Prager[1], Dieter Schuh[1], Dominique Bougeard[1], Nicola Paradiso[1], Christoph Strunk[1], and Leandro Tosi[2,1] — [1]Institut für Experimentelle und Angewandte Physik, University of Regensburg, 93040 Regensburg, Germany — [2]Centro Atómico Bariloche and Insitituto Balseiro, CNEA, CONICET, San Charlos de Bariloche, Río Negro 8400, Argentina

We present microwave characterization measurements of Josephson junction arrays (JJAs) based on a proximitized Al-InAs quantum well heterostructure. JJAs can be used to achieve high inductances, suitable for the implementation of quantum circuits. They also provide an excellent test-bed for studying the microscopic excitations of hybrid superconductor-semiconductor devices associated to the presence of Andreev states. By probing the low-energy plasmon modes of these devices, we have been able to derive the Josephson inductance and to demonstrate its tunability in out-of-plane magnetic field, following the Fraunhofer diffraction pattern of planar Josephson junctions. Furthermore, the temperature dependence of the inductance provides information about the induced superconducting gap in the two-dimensional electron gas.

TT 38.2 Wed 17:00 H32

Niobium-trilayer based Dimer Josephson Junction Array Amplifiers — •Bhoomika R Bhat, Asen L Georgiev, Fabian Kaap, Victor Gaydamachenko, Christoph Kissling, Judith Felgner, Mark Bieler, and Lukas Grünhaupt — Physikalisch-Technische Bundesanstalt, Bundesallee 100, 38116 Braunschweig, Germany

Qubit readout and other quantum technologies using microwave signals at low powers of a few fW benefit from amplification with the least possible added noise. Josephson parametric amplifiers are a well-established class of devices meeting this condition. We design a Dimer Josephson Junction Array Amplifier (DJJAA) [1], which has several pairs of modes, so-called dimers, in the 4 GHz to 12 GHz range. In principle, each of these dimers can be used to achieve non-degenerate amplification using the four-wave mixing regime. Our devices, consisting of arrays with 600-1200 dc-SQUIDs, are fabricated in Nb/Al-AlOx/Nb trilayer technology. We present finite element simulations of our design as well as the fabrication process and the first experimental results of our devices.

TT 38.3 Wed 17:15 H32

Towards a traveling-wave parametric amplifier with two-octave bandwidth — •Christoph Kissling, Victor Gaydamachenko, and Lukas Grünhaupt — Physikalisch-Technische Bundesanstalt, Bundesallee 100, 38116 Braunschweig, Germany

Traveling-Wave Parametric Amplifiers (TWPAs) are among the leading technologies for amplifying weak microwave signals. They provide a gain of 15-20 dB over a bandwidth of more than 1 GHz while keeping the added noise close to the quantum limit. Although TWPAs are widely used in quantum computing, certain applications in fields like radio astronomy require amplifiers with broader bandwidth, ranging from e.g. 4 to 12 GHz. In this work, we present a TWPA consisting of ca. 2400 rf-SQUIDs, which operates in the three-wave mixing regime and achieves a 3-dB bandwidth of 3.6 to 8.3 GHz. Our device provides a gain of 20 dB and has a saturation power of around -90 dBm. By incorporating this TWPA as the first amplifier in our readout chain, we attain a total system noise of 2-3 photons across the entire bandwidth. Finally, we discuss strategies to extend the bandwidth to two octaves and improve the flatness of the gain profile.

TT 38.4 Wed 17:30 H32

Mitigating phase velocity mismatch in flux-pumped Josephson traveling wave parametric amplifiers — •Daniil Bazulin[1,2], Lars Aaron Anhalt[1,2], Kevin Kiener[1,2], Matthias Grammer[1,2], Niklas Bruckmoser[1,2], Leon Koch[1,2], Matthias Althammer[1,2], Stephan Geprägs[1,2], Stefan Filipp[1,2,3], and Kirill G. Fedorov[1,2,3] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany — [2]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany

Josephson traveling wave parametric amplifiers (JTWPAs) play a key role in enabling fast readout of multiple qubits in scalable superconducting quantum processors. These amplifiers utilize wave-mixing processes in extended nonlinear media, to achieve broadband amplification with noise performance close to the standard quantum limit. Flux-pumped JTWPAs, employing the SNAIL-based nonlinear media, are particularly interesting due to their potential to eliminate the problem of pump depletion and mitigate upconversion losses. However, these devices exhibit a phase velocity mismatch between pump and signal modes, which suppresses a maximum achievable amplification gain. This issue can be addressed by using materials with high dielectric constant or kinetic inductance, like $SrTiO_3$ and NbTiN, respectively. Here, we present our progress in millikelvin characterization of these materials and their prospects in the flux-pumped JTWPAs.

TT 38.5 Wed 17:45 H32

Towards superconducting quantum-accurate arbitrary waveform generators for microwave frequencies — •Michael Haas, Abdulrahman Widaa, Oliver Kieler, Shekhar Priyadarshi, Marco Kraus, Ralf Behr, Johannes Kohlmann, and Mark Bieler — Physikalisch Technische Bundesanstalt, Braunschweig, Germany

The Josephson Arbitrary Waveform Synthesizer (JAWS) consists of an array of Josephson Junctions being driven by electrical pulses to produce quantum-accurate output signals with high spectral purity and low noise [1]. It has been subject of research for many years and is well established at output frequencies in the kHz and low MHz range. However, the extension to GHz frequencies, which could prove to be very important for quantum applications and metrology, has just recently started [2, 3]. This effort requires completely new circuit designs. Moreover, at high frequencies part of the input signal is fed through to the output signal and it is essential to accurately determine and minimize this so-called feedthrough error. We will present the status of the GHz-JAWS development at PTB, including new approaches to circuit design and feedthrough reduction.

TT 38.6 Wed 18:00 H32

Characterization of stacked Josephson junction arrays for the Josephson Arbitrary Waveform Synthesizer with integrated on-chip power dividers — •Omar M. Aladdin[1], Oliver Kieler[1], Abdulrahman Widaa[1], Hannes Preissler[1], Erasmus Wolf[2], Marco Schubert[2], Johannes Kohlmann[1], and Mark Bieler[1] — [1]Physikalisch-Technische Bundesanstalt, Bundesallee 100, 38116 Braunschweig, Germany — [2]Supracon AG, An der Lehmgrube 11, 07751 Jena, Germany

The Josephson Arbitrary Waveform Synthesizer (JAWS) is based on pulse-driven Josephson junction (JJ) arrays and provides precisely controlled, spectrally pure quantum-based AC voltages with low noise and no drift. Being widely used at National Metrology Institutes, increasing the output voltage of JAWS might significantly expand its application range. In this contribution, we describe our current efforts towards reaching JAWS output voltage of 1 V RMS. We are improving the existing on-chip RF power dividers enabling up to 8 parallel JJ arrays to operate simultaneously per chip with sufficient operation margins. Additionally, we are increasing the number of active junctions by means of fabricating of up to 5-stacked SNS-type JJ with Nb_xSi_{1-x} as barrier material. The target is to integrate about 50 000 to 60 000 JJ per chip. The circuit layout with integrated on-chip power dividers, the fabrication technology and first measurement results will be presented at the conference.

TT 38.7 Wed 18:15 H32

High-temperature superconducting Josephson junctions for optical neuromorphic computing — •Elena Vinnemeier[1], Sebastian Schaper[1], Malik Ayachi[2], Vincent Humbert[2], Javier Villegas[2], and Ursula Wurstbauer[1] — [1]Institute of Physics, University of Münster, Münster, Germany — [2]Laboratoire Albert Fert, CNRS, Thales, Université Paris-Saclay, Palaiseau, France

Josephson Junctions (JJ) offer a promising platform for neuromorphic computing, owing to their inherent ability to emulate key neuronal behaviours such as spiking and bursting. When coupled with high-temperature superconductors and reconfigurable interconnects, these junctions present a viable alternative to traditional CMOS-based approaches, providing a low-power solution that is both faster and more efficient. The integration of high-temperature superconductors into the JJs enhances energy efficiency while exploiting their sensitivity to external stimuli. The currently missing integrated memory element is addressed by replacing passive interconnections with active links, which can be tuned by external stimuli. Our goal is to achieve optical modulation of the critical current I_C through light irradiation. To explore this capability, we characterize semiconducting materials from the transition metal dichalcogenide (TMDCs) family in combination with superconducting JJs using Raman spectroscopy and photoluminescence (PL), contrasting their properties as a function of environmental conditions.

This project was supported by the EIC pathfinder grant No. 101130224 'JOSEPHINE'.

TT 39: Twisted Materials / Systems (joint session TT/HL)

Time: Wednesday 17:00–18:30 Location: H31

TT 39.1 Wed 17:00 H31

Formation, persistence and ordering of local moments in magic angle twisted bilayer graphene — •Lorenzo Crippa[1,2], Gautam Rai[1], Dumitru Călugăru[3,13], Haoyu Hu[4], Luca de' Medici[5], Antoine Georges[6,7,8,9], Bogdan Andrei Bernevig[3,4,10], Roser Valentí[11], Giorgio Sangiovanni[2], and Tim Wehling[1,12] — [1]University of Hamburg — [2]University of Würzburg — [3]Princeton University — [4]DIPC, Donostia-San Sebastian — [5]ESPCI, Paris — [6]Collège de France, Paris — [7]Flatiron Institute, New York — [8]École Polytechnique, Palaiseau Cedex — [9]Université de Genève — [10]IKERBASQUE, Bilbao — [11]Goethe University Frankfurt — [12]Hamburg CUI — [13]University of Oxford

The physics of magic angle twisted bilayer graphene (MATBLG) is remarkably diverse across a wide range of dopings and temperatures.

By means of a Dynamical Mean-Field Theory (DMFT) approach, we study the effect of electronic correlations in MATBLG, with particular focus on the physics of local spin and valley isospin moments. We analyze their magnitude and screening across a broad temperature range, discuss the limits of very low and infinite temperature, and obtain two different scales for their formation (around 100 K) and ordering (around 10 K).

We discuss their implications in terms of transport properties of the system (e.g. resistivity) and of spectral features (resonance peaks) and contextualize our findings with recent experimental results.

TT 39.2 Wed 17:15 H31

Nematic versus Kekulé phases in twisted bilayer graphene under hydrostatic pressure — Miguel Sánchez Sánchez[1], Israel Díaz[1], José González[2], and •Tobias Stauber[1] — [1]Instituto de Ciencia de Materiales de Madrid, CSIC — [2]Instituto de Ciencia de Materiales, CSIC

We address the precise determination of the phase diagram of magic angle twisted bilayer graphene under hydrostatic pressure within a self-consistent Hartree-Fock method in real space, including all the remote bands of the system. We further present a novel algorithm that maps the full real-space density matrix to a 4x4 density matrix based on a SU(4) symmetry of sublattice and valley degrees of freedom. We find a quantum critical point between a nematic and a Kekulé phase, and show also that our microscopic approach displays a strong particle-hole asymmetry in the weak coupling regime. We arrive then at the prediction that the superconductivity should be Ising-like in the hole-doped nematic regime, with spin-valley locking, and spin-triplet in the electron-doped regime [1].

TT 39.3 Wed 17:30 H31

Quantum diffusion in sheared bilayer graphene — •Taher Rhouma[1], Florie Mesple[2], Vincent Renard[3], and Guy Trambly de Laissardière[1] — [1]LPTM, CY Cergy Paris Univ., CNRS, Cergy-Pontoise, France. — [2]Dept. Physics, Univ. of Washington, USA — [3]CEA, Univ. Grenoble Alpes, IRIG, PHELIQS, Grenoble, France

The identification of correlated insulators and superconductivity in magic-angle twisted bilayer graphene (MATBG) has sparked significant interest in its electronic properties [1]. When examining the MATBG moiré patterns along the line with alternating regions of AA, AB, and BA, we observe striking similarities to those found in a 1D moiré of a sheared bilayer graphene, where one layer is laterally displaced. That may lead to a localization of the electronic states [2]. In this study, we investigate numerically the electronic and quantum transport properties in sheared bilayer graphene, focusing on how the degree of shear influences these characteristics.

TT 39.4 Wed 17:45 H31

Ab-initio fRG study on $tWSe_2$ — •Hannes Braun — Max Planck Institut für Festkörperforschung — Technische Universität München

The recent experimental reports on superconductivity in twisted WSe_2 have served to justify the already considerable interest in twisted TMD systems. From a theoretical standpoint, there have been numerous attempts to describe these systems. To study the phase diagram and analyse the governing physics, we employ the functional renormalisation group method. This approach allows us to gain an unbiased understanding of the interplay between fluctuations leading to symmetry-broken phases. To develop a model capable of describing the material, we integrate *ab-initio* results as initial conditions. In this talk, we present method developments for a more efficient momentum integration and results on the interplay between magnet and pairing instabilities.

TT 39.5 Wed 18:00 H31

Mott transitions and doping asymmetry in twisted bilayer WSe_2 — •Siheon Ryee[1], Lennart Klebl[2,1], Valentin Crépel[3], Ammon Fischer[4], Lede Xian[5,6], Angel Rubio[6,3], Dante Kennes[4,6], Andrew Millis[3,7], Antoine Georges[8,3], Roser Valentí[9], and Tim Wehling[1] — [1]University of Hamburg, Hamburg, Germany — [2]University of Würzburg, Würzburg, Germany — [3]Flatiron Institute, New York, USA — [4]RWTH Aachen University, Aachen, Germany — [5]Tsientang Institute for Advanced Study, Zhejiang, China — [6]Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — [7]Columbia University, New York, USA — [8]Collège de France, Paris, France — [9]Goethe Universität Frankfurt, Frankfurt am Main, Germany

The recent discovery of superconductivity in twisted bilayer WSe_2 ($tWSe_2$) at two distinct twist angles (3.65 deg and 5 deg) along with previous reports of metal-insulator transitions, spin density wave states, and fractional Chern insulators raises deep questions in correlated electron physics. We present results of a dynamical mean-field theory-based investigation of a model that faithfully captures the band structure and topology of twisted transition metal dichalcogenides as functions of twist angle and displacement field. We find good agreement with several key aspects of the experimental data. Focusing further on the twist angle of 3.65 deg, we discuss the nature of the electric-field-induced metal-insulator transition, the experimentally observed coherence temperature, and the origin of the observed doping asymmetry in resistivity.

TT 39.6 Wed 18:15 H31

Twisted bilayer MoS_2 under electric fields: A system with tunable symmetry — •Aitor Garcia-Ruiz[1,2] and Ming-Hao Liu[1] — [1]National Cheng Kung University, Tainan, Taiwan — [2]National Graphene Institute, University of Manchester, Manchester, United Kingdom

Gate voltages take full advantage of two-dimensional systems, making it possible to explore novel states of matter by controlling their electron concentration or applying perpendicular electric fields. Here, we study the electronic properties of small-angle twisted bilayer MoS_2 under a strong electric field. We show that the transport across one of its constituent layers can be effectively regarded as a two-dimensional electron gas under a nanoscale potential. We find that the band structure of such system reconstructs following two fundamentally different symmetries depending on the orientation of the external electric field, namely, hexagonal or honeycomb. By studying this system under magnetic fields, we demonstrate that this duality not only translates into two different transport responses, but also results in having two different Hofstadter's spectra. Our work opens up a new route for the creation of controllable artificial superlattices in van der Waals heterostructures.

TT 40: Spin Transport and Orbitronics, Spin-Hall Effects II (joint session MA/TT)

Time: Wednesday 17:30–19:00 Location: H19

TT 40.1 Wed 17:30 H19

Orbital torques and orbital pumping in two-dimensional rare-earth dichalcogenides — •Mahmoud Zeer[1,2,3], Dongwook Go[3], Mathias Kläui[3,4], Wulf Wulfhekel[5], Stefan Blügel[1], and Yuriy Yuriy Mokrousov[1,3] — [1]Peter Gr *unberg Institute, Forschungszentrum J *ulich, 52425 J *ulich, Germany — [2]Department of Physics, RWTH Aachen University, 52056 Aachen, German — [3]Institute of Physics, Johannes Gutenberg-University Mainz, 55099 Mainz, Germany — [4]Centre for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology, 7491 Trondheim, Norway — [5]5Physikalisches Institut, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany

The design of spin-orbit torque (SOT) properties in two-dimensional (2D) materials represents a key challenge in modern spintronics. We now explore ferromagnetic Janus H-phase monolayers of 4f-Eu rare-earth dichalcogenides

EuSP, EuSSe, and EuSCl using first-principles calculations. Our findings reveal that these compounds exhibit substantial SOT, primarily driven by the colossal current-induced orbital response of Eu f-electrons. Additionally, the resulting orbital torques can generate strong in-plane currents of orbital angular momentum with non-trivial orbital polarization directions. These results establish f-based 2D materials as a highly promising platform for in-plane orbital pumping and SOT applications, positioning f-based 2D materials as a promising platform for next-generation orbitronic and spintronic technologies with 2D materials.

TT 40.2 Wed 17:45 H19

Orbital Topology of Chiral Crystals for Orbitronics — •Ying-Jiun Chen[1], Kenta Hagiwara[1,2], Dongwook Go[3], Xin Liang Tan[1,2], Sergii Grytsiuk[1], Kui-Hon Ou Yang[4], Guo-Jiun Shu[5], Jing Chien[4], Yi-Hsin Shen[4], Xiang-Lin Huang[5], Iulia Cojocariu[1], Vitaliy Feyer[1,2], Minn-Tsong Lin[4,6], Stefan Blügel[1], Claus Michael Schneider[1,2], Yuriy Mokrousov[1,3], and Christian Tusche[1,2] — [1]Forschungszentrum Jülich — [2]University of Duisburg-Essen — [3]Johannes Gutenberg University Mainz — [4]National Taiwan University, Taiwan — [5]National Taipei University of Technology, Taiwan — [6]Academia Sinica, Taiwan

Chirality is ubiquitous in nature and manifests in a wide range of phenomena including chemical reactions, biological processes, and quantum transport of electrons. In quantum materials, the chirality of fermions, given by the relative directions between the electron spin and momentum, is connected to the band topology of electronic states. Here, we show that in structurally chiral materials like CoSi, the orbital angular momentum (OAM) serves as the main driver of a nontrivial band topology in this new class of unconventional topological semimetals, even when spin-orbit coupling is negligible. A nontrivial orbital-momentum locking of multifold chiral fermions in the bulk leads to a pronounced OAM texture of the helicoid Fermi arcs at the surface. Our findings highlight the pivotal role of the orbital degree of freedom for the chirality and topology of electron states, in general, and pave the way towards the application of topological chiral semimetals in orbitronic devices.

TT 40.3 Wed 18:00 H19

Vectorial flow of the Berry curvature and its relation to the transport and band structure — •Jaroslav Hamrle[1,2], Ondřej Stejskal[1], Milan Vrána[2,1], and Martin Veis[2] — [1]Czech Technical University, Prague, Czechia — [2]Charles University, Prague, Czechia

Berry curvature expresses the curvature of the reciprocal space, in a similar manner as magnetic field express curvature of the real space, resulting in a curved transport of electrons in solids. Therefore, Berry curvature is a base of various lossless transport phenomena such as anomalous Hall effect, anomalous Nerst effect, orbital magnetization or electric polarization. Here, in model materials bcc Fe and Fe_3Ga, we demonstrate details of the vectorial flow of the Berry curvature (monopole source, 1-dimensional flow, 2-dimensional flow), and its relations to the band structure, orbital magnetization as well as anomalous Hall and Nerst effects.

[1] O. Stejskal, M. Veis, J. Hamrle, Sci Rep **12**, 97 (2022) [doi: 10.1038/s41598-021-04076-z]

TT 40.4 Wed 18:15 H19

Finite-temperature transport properties of magnetic/non-magnetic alloys: trends in the longitudinal and in the transverse charge and spin currents — •Alberto Marmodoro[1], Yang Wang[2], Yuqing Lin[3], and Ilja Turek[4] — [1]Institute of Physics (FZU), Czech Academy of Sciences, Prague, Czech Republic — [2]Pittsburgh Supercomputer Center (PSC), Carnegie Mellon University, Pittsburgh, USA — [3]Mellon College of Science, Carnegie Mellon University, Pittsburgh, USA — [4]Institute of Physics of Materials, Czech Academy of Sciences, Brno, Czech Republic

Alloys composed of magnetic and non-magnetic metals exhibit non-trivial transport trends as a function of composition and temperature. The stoichiometry controls not only the Curie point, but also the slope of resistivity vs. temperature. Beside affecting longitudinal currents, this has further implications also for transverse charge and spin currents, i.e. on anomalous Hall effects [1]. We report first-principles results based on density functional theory (DFT), relativistic linear response and Green function methods based on the multiple scattering Korringa-Kohn-Rostoker (KKR) or linear muffin tin orbitals (LMTO) frameworks.

TT 40.5 Wed 18:30 H19

Impact of the substrate on angular momentum transport between separated ferromagnets — •Fiona Sosa Barth[1,2], Matthias Grammer[1,2], Richard Schlitz[3], Tobias Wimmer[1,2], Janine Gückelhorn[1,2], Luis Flacke[1,2], Sebastian T.B. Goennenwein[3], Rudolf Gross[1,2,4], Hans Huebl[1,2,4], Akashdeep Kamra[5], and Matthias Althammer[1,2] — [1]Walther-Meißner-Institut, BAdW, Garching, Germany — [2]School of Natural Sciences, TUM, Garching, Germany — [3]Department of Physics, University of Konstanz, Konstanz, Germany — [4]Munich Center for Quantum Science and Technology, München, Germany — [5]RPTU Kaiserslautern-Landau, Kaiserslautern, Germany

Spintronics relies on the transfer of angular momentum between electrons and solid state excitations such as magnons and phonons. In our recent work, we demonstrate angular momentum transfer between two ferromagnetic strips on diamagnetic substrates [1] by converting a DC current at one of the electrodes to a non-equilibrium magnon accumulation. Due to dipolar and potentially phononic coupling, angular momentum is transferred to the magnonic system of the second FM electrode and measured by the inverse processes. In this work, we investigate the substrate influence on the angular momentum transport by comparing our results for SiOx and SiN layers on Si substrates. As a next step, we investigate substrate-supported strips versus freestanding strings to separate phononic contributions from dipolar coupling. [1] R. Schlitz et al., Phys. Rev. Lett. 132, 256701 (2024)

TT 40.6 Wed 18:45 H19

Orbital Edelstein contribution to the spin-charge conversion in Germanium Telluride — •Sergio Leiva-Montecinos[1], Libor Vojáek[2], Jing Li[2], Mairbeck Chshiev[2], Ingrid Mertig[1], and Annika Johansson[3] — [1]Martin Luther University Halle-Wittenberg, Halle (Saale), Germany — [2]Université. Grenoble Alpes, CEA, CNRS, SPINTEC, Grenoble, France — [3]Max Planck Institute of Microstructure Physics, Halle (Saale), Germany

The Edelstein effect (EE) is a promising mechanism for generating spin and orbital polarization from charge currents in systems without inversion symmetry. In ferroelectric materials, such as Germanium Telluride (GeTe), the combination of bulk Rashba splitting and voltage-controlled ferroelectric polarization provides a pathway for reversible spin-charge interconversion [1, 2].

In this work, we investigate current-induced spin and orbital magnetization in bulk GeTe using Wannier-based tight-binding models derived from DFT calculations and semiclassical Boltzmann theory. Employing the modern theory of orbital magnetization (MTOM), we demonstrate that the orbital Edelstein effect (OEE) entirely dominates its spin counterpart (SEE). This difference is visualized through the spin and orbital textures at the Fermi surfaces, where the orbital moment surpasses the spin moment by one order of magnitude. Moreover, the OEE remains largely unaffected when we suppress the spin-orbit coupling, highlighting its distinct physical origin compared to the SEE.

TT 41: Quantum-Critical Phenomena (joint session TT/DY)

Time: Thursday 9:30–12:45 Location: H31

TT 41.1 Thu 9:30 H31

Missing Spectral Weight in a Paramagnetic Heavy-Fermion System — •Debankit Priyadarshi[1], Jingwen Li[1], Chia-Jung Yang[1], Ulli Pohl[2], Oliver Stockert[3], Hilbert von Löhneysen[4], Shovon Pal[5], Manfred Fiebig[1], and Johann Kroha[2,6] — [1]ETH Zurich, Switzerland. — [2]University of Bonn, Germany — [3]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [4]Karlsruhe Institute of Technology, Germany — [5]NISER, HBNI, Jatni, India. — [6]University of St. Andrews, UK

Time-resolved terahertz spectroscopy (THz-TDS) has proven to be a powerful method to study the correlation dynamics in many-body systems, particularly heavy-fermions [1]. The competition between the Kondo screening effect and the Ruderman-Kittel-Kasuya-Yosida (RKKY) interaction in these materials drives a quantum phase transition (QPT) between a magnetically ordered and a liquid-like ground state of heavy Kondo quasiparticles. These quasiparticles disintegrate near a quantum critical point (QCP). Using THz-TDS, we report a suppression in the quasiparticle spectral weight in $CeCu_{6-x}Au_x$ on the antiferromagnetic side of the QPT at temperatures much higher than the Neel temperature, which has a different origin from the suppression at QCP [2]. We study the paramagnetic phase of $CeCu_{6-x}Au_x$ with x = 0.2, 0.3, and 0.5 samples, and show that the suppression results from a quantum frustration effect induced by the temperature-independent RKKY interaction, which may influence material properties at QCP.

TT 41.2 Thu 9:45 H31

Terahertz Crystal Electric Field Transitions in a Kondo-Lattice Antiferromagnet — •Payel Shee[1], Chia-Jung Yang[2], Shishir Kumar Pandey[3], Ashis Kumar Nandy[1], Ruta Kulkarni[4], Arumugam Thamizhavel[4], Manfred Fiebig[2], and Shovon Pal[1] — [1]NISER, HBNI, Jatni, India. — [2]ETH Zurich, Switzerland. — [3]Artificial Intelligence for Science Institute, Beijing, China. — [4]Tata Institute of Fundamental Research, Mumbai, India.

The interplay between the Kondo effect and Ruderman-Kittel-Kasuya-Yosida (RKKY) leads to the emergence of many intriguing phenomena in strongly correlated systems. Metallic materials doped with magnetic impurities are ideal for such studies. These impurities interact with the crystal electric field (CEF) produced by neighboring ions, lifting the degeneracy of their energy levels and creating CEF states. Given that CEF excitations occur in the millielectronvolt (meV) range, the terahertz (THz) frequency range is particularly suited for these investigations. Using time-domain THz reflection spectroscopy, we show the first direct evidence of two low-energy CEF transitions at 0.6 THz (2.5 meV) and 2.1 THz (8.7 meV) in $CeAg_2Ge_2$, a prototype Kondo-lattice antiferromagnet. In addition, we also observe that the lower CEF transition peak undergoes a blue-shift once the sample enters into the antiferromagnetic phase. The temporal spectral weights obtained directly from the THz time traces corroborate the corresponding CEF energy scales of the compound [2].

[2] P. Shee *et al.*, Phys. Rev. B 109, 075133 (2024).

TT 41.3 Thu 10:00 H31

Tuning a ferromagnetic quantum phase transition by interface engineering in artificial heterostructures — Robin Heumann[1], Robert Gruhl[1], Ludwig Scheuchenpflug[1], Leonard Schüler[2], Vasily Moshnyaga[2], and •Philipp Gegenwart[1] — [1]Lehrstuhl für Experimentalphysik VI, Universität Augsburg — [2]Erstes Physikalisches Institut, Georg-August-Universität-Göttingen

The substitution series $Sr_{1-x}Ca_xRuO_3$ between the itinerant ferromagnet $SrRuO_3$ (SRO) and the non-Fermi liquid paramagnetic metal $CaRuO_3$ (CRO) constitutes a broadly smeared quantum phase transition (QPT) between $x = 0.7$ and 1. To avoid the impact of structural disorder we explore the possibility of tuning ferromagnetism by confining SRO to thin layers placed in between those of CRO. Ordered epitaxial $[SRO_n/CRO_m]_K$ superlattices, with n ranging from 8 down to the monolayer limit, keeping $m/n = 2$ and 3 with $K = 32/n$, were grown on $SrTiO_3$ (100) substrates, characterized and investigated by electrical transport and Hall effect measurements. We observe stable ferromagnetism from SRO layers for $n \geq 3$ and fragile low-temperature ferromagnetism due to the SRO/CRO interfaces. The latter survives down to the monolayer limit $n = 1$, explaining the difficulty to cross a ferromagnetic QPT in $Sr_{1-x}Ca_xRuO_3$. We also find that the effective interface density $K/(n+m)$ is a new suitable control parameter and construct the T_C vs $K/(n+m)$ phase diagram.

TT 41.4 Thu 10:15 H31

Interplay of nematic fluctuations and transverse phonons near a nematic quantum critical point — •Morten H. Christensen[1], Michael Schütt[2], Avraham Klein[3], and Rafael M. Fernandes[4] — [1]Niels Bohr Institute, University of Copenhagen — [2]University of Minnesota — [3]Ariel University — [4]University of Illinois Urbana-Champaign

In an electronic fluid absent an atomic lattice, an electronic nematic transition can be described as a consequence of a Pomeranchuk instability of the Fermi surface with an associated critical nematic mode. As a coupling to an atomic lattice is introduced, the nematic transition is accompanied by a structural distortion of the lattice. Here, we study the fluctuation spectra near such a coupled nematic-structural transition driven primarily by the electronic nematic fluctuations. This requires coupling the nematic fluctuations to transverse phonons which implies that the transition is no longer accompanied by a critical nematic mode, but rather by the vanishing of the transverse phonon velocity along a certain direction. To understand how, e.g., superconductivity is affected by this, knowledge of the dynamic behaviour of the hybrid nematic/phonon soft excitation is crucial. The purpose of this presentation is to elucidate the properties of this mode. We find that the low-energy fluctuations are generally overdamped except near the soft lattice directions where they become underdamped. How the transition from overdamped to underdamped takes place depends on the proximity to the nematic quantum critical point.

TT 41.5 Thu 10:30 H31

Chiral Heisenberg Gross-Neveu-Yukawa criticality: Honeycomb vs. SLAC fermions — •Thomas C. Lang[1] and Andreas M. Läuchli[2,3] — [1]Institute for Theoretical Physics, University of Innsbruck, Austria — [2]Laboratory for Theoretical and Computational Physics, Paul Scherrer Institute, Switzerland — [3]Institute of Physics, École Polytechnique Féedérale de Lausanne, Switzerland

We perform large scale quantum Monte Carlo simulations of the Hubbard model at half filling with a single Dirac cone close to the critical point, which separates a Dirac semi-metal from an antiferromagnetically ordered phase where SU(2) spin rotational symmetry is spontaneously broken. We discuss the implementation of a single Dirac cone in the SLAC formulation for eight Dirac components and the influence of dynamically induced long-range super-exchange interactions. The finite size behavior of dimensionless ratios and the finite size scaling properties of the Hubbard model with a single Dirac cone are shown to be superior compared to the honeycomb lattice. We extract the critical exponents believed to belong to the chiral Heisenberg Gross-Neveu-Yukawa universality class which coincide for the two lattice types once honeycomb lattices of sufficient linear dimension are considered.

TT 41.6 Thu 10:45 H31

Fractionalized multicriticality in Kitaev spin-orbital liquids — •Max Fornoville[1,2] and Lukas Janssen[3] — [1]Max Planck Insti- tute for Solid State Research, 70569 Stuttgart, Germany — [2]School of Natural Sciences, Technische Universität München, 85748 Garching, Germany — [3]Institut für Theoretische Physik and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, 01062 Dresden, Germany

Two-dimensional spin-orbital magnets with Kitaev-like exchange frustration realize spin-orbital liquid ground states that are characterized by the appearance of gapless Majorana fermions and a static $\mathbb{Z}_2$ gauge field. It has been shown that the introduction of an antiferromagnetic Heisenberg interaction between nearest-neighbor spin degrees of freedom facilitates a transition towards a partially ordered spin-orbital liquid state with a spontaneously broken spin-rotation symmetry. The associated quantum critical point belongs to the fractionalized fermionic Gross-Neveu-SO(3)* universality class and only partially gaps out the fermionic spectrum. Here, we consider an enlarged theory space, introducing an anisotropic XXZ interaction in the spin sector. The explicit breakdown of spin-rotation symmetry allows for two types of antiferromagnetic order, depending on the nature of the anisotropy. By means of Majorana mean-field theory and ε-expansion to leading order, we uncover the phase diagram of the model and characterize its multicritical behavior. Additionally, we present evidence for the appearance of a symmetry-enhanced first-order transition between the two ordered phases.

15 min. break

TT 41.7 Thu 11:15 H31

One-loop perturbative structure of a (2+1)D bosonized non-Fermi liquid — •Parasar R. Thulasiram[1,2], Chris Hooley[3], and Roderich Moessner[1] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [3]Centre for Fluid and Complex Systems, Coventry University, Coventry, United Kingdom

Non-Fermi liquids are a class of metals with no quasiparticle excitations often arising from the interaction of slow collective modes, such as an emergent critical boson, with a Fermi surface. Minimal models of this type are called Hertz-Millis-Moriya models and historically suffer from uncontrolled approximations in perturbation theory and patchy treatments of the Fermi surface, preventing the study of global-Fermi surface physics. Delacrétaz et al. (2022) recast Fermi liquid theory in any dimension via a bosonic field that parametrizes macroscopic particle-hole excitations about the whole Fermi surface. This bosonized field theory is suggested to reduce the order in perturbation theory necessary to calculate important quantities and is considerate of whole Fermi surface fluctuations, potentially providing the first robust results of a Hertz-Millis-Moriya theory when coupled to a critical boson. We present initial results of the one-loop critical boson self-energy in 2+1D for calculating the dynamical critical exponent and discuss the benefits and challenges of this theory.

TT 41.8 Thu 11:30 H31

Exotic quantum criticality in Luttinger semimetals — •David Moser and Lukas Janssen — TU Dresden, Deutschland

Luttinger semimetals are three-dimensional strongly-spin-orbit-coupled systems, in which valence and conduction bands touch quadratically at the Fermi level. They provide a rich playground for highly unconventional physics and serve as a parent state to a number of exotic states of matter, such as Weyl semimetals, topological insulators, or spin ice. Here, we discuss various quantum critical phenomena beyond standard quantum criticality, including quasiuniversality, fixed-point annihilation scenarios, and large-N aspects. Our results are relevant for the low-temperature behavior of rare-earth pyrochlore iridates, such as $Pr_2Ir_2O_7$ or $Nd_2Ir_2O_7$.

TT 41.9 Thu 11:45 H31

Examination of the antiferromagnetic superradiant intermediate phase and the effects of geometrical frustration in the Dicke-Ising model — •Jonas Leibig, Anja Langheld, Andreas Schellenberger, and Kai Phillip Schmidt — Chair for Theoretical Physics V, FAU Erlangen-Nürnberg, Germany

We map the Dicke-Ising model to a self-consistent matter Hamiltonian in the thermodynamic limit [1, 2] and solve it using a variety of methods, including ex-

act diagonalization, perturbative and numerical linked-cluster expansions, and density matrix renormalization group. In one dimension, we explore the intermediate phase in the antiferromagnetic model and the multi-critical point in the ferromagnetic model, comparing our results with complementary quantum Monte Carlo simulations [2]. Additionally, we investigate the antiferromagnetic model on the frustrated geometry of the sawtooth chain. We employ high-order series expansions in the strong coupling limit, where the mapping to the self-consistent matter Hamiltonian is definitively valid. Independently, we analyze in greater detail whether the mapping also holds in the specific regime emerging from the frustrated Ising limit induced by an infinitesimal light-matter perturbation.

[1] K. Lenk, J. Li, P. Werner, M. Eckstein, arXiv:2205.05559;

TT 41.10 Thu 12:00 H31

Critical behavior of the 1d superconductor in the FLEX approximation — •Šimon Kos[1], Sunil D'Souza[1], Jan Gebel[1], Ján Minár[1], and Václav Janiš[2] — [1]University of West Bohemia, Univerzitní 8, CZ-301 00 Plzeň, Czech Republic — [2]Institute of Physics, The Czech Academy of Sciences, Na Slovance 2, CZ-18200 Praha 8, Czech Republic

The dynamical quantum fluctuations below the lower critical dimension push the superconducting critical point to zero temperature. We study the quantum critical behavior of the 1d superconductor with one-particle self-consistency provided by the FLEX approximation within the canonical Baym-Kadanoff scheme. We use the non-interacting singlet electron-electron bubble in the two-particle vertex of the Schwinger-Dyson equation, allowing for a qualitatively correct and tractable treatment of the low-energy critical behavior compatible with the Mermin-Wagner theorem. We use a polar approximation to transform the convolutive Schwinger-Dyson equation into an algebraic one that can be solved semi-analytically. We confirm the position of the critical point and assess the low-temperature behavior of the Hubbard model with attractive interaction.

TT 41.11 Thu 12:15 H31

Tunable criticality and pseudo-criticality in a quantum dissipative spin system — •Manuel Weber — Institut für Theoretische Physik and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, Germany

The study of competing orders in two-dimensional quantum magnets was strongly motivated by the prediction of non-Landau quantum phase transitions, but often we found symmetry-enhanced first-order transitions or pseudocriticality with a logarithmic drift of critical exponents. Here we present results for a (0+1) dimensional spin-boson model where all of these phenomena occur due to a fixed-point annihilation within the critical manifold. Our recently-developed wormhole quantum Monte Carlo method for retarded interactions allows us to study the critical properties of this model with unprecedented precision. We find a tunable transition between two ordered phases that can be continuous or first-order, and even becomes weakly first-order in an extended regime close to the fixed-point collision. We provide direct numerical evidence for pseudo-critical scaling on both sides of the collision manifesting in an extremely slow drift of critical exponents. We also find scaling behavior at the symmetry-enhanced first-order transition as described by a discontinuity fixed point. Our study motivates future work in higher-dimensional quantum dissipative spin systems.

TT 41.12 Thu 12:30 H31

Universality of the quantum Heisenberg model with sub-volume long-range couplings — •Daniel Resch and Thomas C. Lang — Institute for Theoretical Physics, University of Innsbruck, Austria

We investigate the critical properties of effective spin models which emerge from low energy band structures, or momentum space patches of strongly interacting fermions. As representative worst case scenario we present quantum Monte Carlo simulations of phase transitions in the major-axis coupled, long-range quantum Heisenberg model in two spatial dimensions at finite and zero temperature. We quantify the effects of sub-volume anisotropic long range spin-coupling with power-law form $1/r^{\alpha}$ on the critical exponents of the transitions where SU(2) spin symmetry is spontaneously broken for at low, finite temperatures in accordance with the Mermin Wagner Hohenberg theorem. Performing finite-size scaling analyses for different α we determine the extent of the regimes where the (quantum) phase transitions are represented by Gaussian fixed point, short-range Wilson-Fisher, or continuously varying long-range non-Gaussian critical exponents.

Extraction of the Density of States and the Gap Function on a Temperature Smearing Scale from the Tunneling Conductance Data — •Lucia Geleneky-ová and František Herman — Comenius University in Bratislava

The aim of our work is to extract the density of states (DOS) and the gap function from the tunneling conductance data at higher temperatures. It is known that if the temperature approaches zero, the DOS function is proportional to the tunneling conductance, and therefore, it can be easily extracted. However, with increasing temperature, the temperature smearing causes that this approximation can no longer be used. Thus, we have developed an algorithm that was designed to extract the details of the DOS function and the gap function on a typical temperature scale, which can be used approximately up to 1/2 of T_c. Moreover, knowledge of the DOS in its normal state plays an important role. Hence, we present the results of the testing data sets and also the outcome from experimentally measured tunneling conductance data of the NbN superconductor.

This work has been supported by the Slovak Research and Development Agency under the Contract no. APVV-23-0515, by the European Union's Horizon 2020 research and innovation program under the Marie Skłodowska-Curie Grant Agreement No. 945478.

TT 42.2 Thu 9:45 H32

Superconductivity of α-Gallium Probed on the Atomic Scale by Normal and Josephson Tunneling — Corinna Fohn[1], David Wander[1], Danilo Nikolic[2,3], Stéphanie Garaudée[1], Hervé Courtois[1], Wolfgang Belzig[3], Claude Chapelier[4], Vincent Renard[4], and •Clemens B. Winkelmann[1,4] — [1]Université Grenoble Alpes, CNRS, Grenoble INP, Institut Néel, F-38000 Grenoble, France — [2]Institut für Physik, Universität Greifswald, Felix-Hausdorff-Strasse 6, D-17489 Greifswald, Germany — [3]Fachbereich Physik, Universität Konstanz, D-78457 Konstanz, Germany — [4]Université Grenoble Alpes, CEA, Grenoble INP, IRIG/DEPHY/PHELIQS, F-38000 Grenoble, France

We investigate superconducting gallium in its α phase using scanning tunneling microscopy and spectroscopy at temperatures down to about 100 mK. High-resolution tunneling spectroscopies using both superconducting and normal tips show that superconducting α-Ga is accurately described by Bardeen-Cooper-Schrieffer theory, with a gap $\Delta_{\mathrm{Ga}} = 163\ \mu$eV on the α–Ga(112) facet, with highly homogeneous spectra over the surface, including atomic defects and step edges. Using a superconducting Pb tip, we furthermore study the low-bias conductance features of the Josephson junction formed between tip and sample. The features are accurately described by dynamical Coulomb blockade theory, highlighting α–Ga as a possible platform for surface science studies of mesoscopic superconductivity.

TT 42.3 Thu 10:00 H32

Current Phase Relation of HgTe Nanowire Josephson Junctions in an Axial Magnetic Field — •Niklas Hüttner[1], Wolfgang Himmler[1], Ralf Fischer[1], Dmitriy Kozlov[1], Michael Barth[2], Jacob Fuchs[2], Andreas Costa[2], Klaus Richter[2], Leandro Tosi[1], Nicola Paradiso[1], Dieter Weiss[1], and Christoph Strunk[1] — [1]Institute for Experimental and Applied Physics, University of Regensburg — [2]Institute for Theoretical Physics, University of Regensburg, 93053 Regensburg, Germany

Proximitized semiconductor nanowires are expected to show Anomalous Josephson effect by spin-orbit interaction and Zeeman effect in a magnetic field parallel to the wire direction [1]. The φ_0 shift is accompanied by a direction dependent critical current (Superconducting diode effect).[1] We directly probe the current phase relation (CPR) of HgTe nanowires proximitized by niobium leads via an asymmetric SQUID measurement. The topological surface states additionally pick up an Aharanov Bohm phase for $B_{\parallel}$ in wire direction [2]. We observe an highly tunable φ_0 shift, a 0-π transition, and a superconducting diode effect from the corresponding CPRs. Additionally a strong modulation of both the critical current and the content of higher harmonics is observed for magnetic flux between 0 and $1.5\Phi_0$.

TT 42.4 Thu 10:15 H32

Theory of Josephson Scanning Tunneling Microscopy with s-Wave Tip on a Cuprate Surface — •Peayush Kumar Choubey[1] and Peter Hirschfeld[2] — [1]Indian Institute of Technology Roorkee, Roorkee 247667, Uttarakhand, India — [2]University of Florida, Gainesville, Florida 32611, USA

The Josephson scanning tunneling microscopy (JSTM) is a direct local probe of superconducting gap order parameter (SCOP). JSTM studies have been largely limited to the cases where superconducting sample and superconducting tip,

both, have the same gap symmetry- either s-wave or d-wave. It has been generally assumed that in an s-to-d SJTS study of cuprates the critical current would vanish everywhere owing to the orthogonality of tip and sample SCOPs. We show here that this is not the case. Using first-principles Wannier functions for $Bi_2Sr_2CaCu_2O_8$, we develop a scheme to compute Josephson critical current (I_c) measured by a JSTM setup employing an s-wave tip with sub-angstrom resolution. We show that I_c remains finite everywhere in the unit cell except along Cu-Cu directions, changes sign under four-fold rotation, and attains largest magnitude above O sites, which can be regarded as a hallmark of the d-wave gap symmetry. Further, we find that I_c is suppressed near a strong scatterer like Zn and modulations in I_c around an impurity occur at wavevectors distinct from quasi-particle interference (QPI). Our work provides a theoretical foundation for probing unconventional superconductivity using JSTM set-up with s-wave tip.

TT 42.5 Thu 10:30 H32

Optimal Parametric Control of Transport Across a Josephson Junction — •Hannah Victoria Kleine-Pollmann, Guido Homann, and Ludwig Mathey — Zentrum für Optische Quantentechnologien and Institut für Quantenphysik, *Universität Hamburg, 22761 Hamburg, Germany

We present optimal control strategies for the DC transport across a Josephson junction. Specifically, we consider a junction in which the Josephson coupling is driven parametrically, with either a bichromatic or a trichromatic driving protocol, and optimize the prefactor of the $1/\omega$ divergence of the imaginary part of the conductivity. We demonstrate that for an optimal bichromatic protocol an enhancement of 70 can be reached, and for an optimal trichromatic protocol an enhancement of 135. This is motivated by pump-probe experiments that have demonstrated light-enhanced superconductivity along the c-axis of underdoped YBCO, where the junction serves as a minimal model for the c-axis coupling of superconducting layers. Therefore, the significant enhancement of superconductivity that we show for multi-frequency protocols demonstrates that the advancement of pump-probe technology towards these strategies is highly desirable.

TT 42.6 Thu 10:45 H32

Gate-Controlled Superconductivity: Mechanisms, Parameters and Technological Potential — Leon Ruf, Jennifer Koch, Elke Scheer, and •Angelo Di Bernardo — University of Konstanz, Universitätsstraße 10, 78464 Konstanz

Over the past few years, several research groups have demonstrated the reversible control of the superconducting current flowing through a nanoscale-size constriction under the application of a gate voltage (V_G) - currently known as gate-controlled supercurrent (GCS) [1].

The numerous differences between fabrication protocols, device parameters and measurement setups adopted by these groups, however, have made it difficult to find universal features of the GCS effect.

In this talk, I will discuss the results of systematic studies carried by our group [2-4] that have allowed us to identify parameters that are key for the GCS observation and to achieve high reproducibility in the functioning of GCS devices [4]. In addition, I will review the progress that we have made towards the optimization of performance parameters that are important for the future development of technological applications based on the GCS.

Gate-Controlled Supercurrents in Three-Terminal Devices Made on Industrial Grade SiO_2 and Al_2O_3 — •Leon Ruf, Jennifer Koch, Elke Scheer, and Angelo Di Bernardo — University of Konstanz, Universitätsstraße 10, 78457 Konstanz

Gate-controlled supercurrent (GCS) is a growing, highly debated field of research. It was found that in gated three-terminal devices made of Ti and Al the supercurrent could be modulated by the application of a gate voltage [1]. The authors attribute their observation to a direct electric field effect, which would pave the way for future CMOS compatible transistors. Contrary, other works reported about a leakage related effect: high-energy quasiparticle emission through vacuum [2], phonon-induced heating of the electronic system [3], out-of-equilibrium state induced by phonons and/or high energy electrons without sizeable heating [4]. Here we are studying the GCS in Nb and NbRe Dayem bridges on industrial grade SiO_2 and Al_2O_3. Our results reveal a strong correlation between the substrate material and the GCS parameters, such as suppression voltage and stability. Herby, SiO_2 and Al_2O_3 show major differences. Further, our results suggest that for both SiO_2 and Al_2O_3 the leakage current is mediated via defects giving rise to trap-assisted tunneling. We discuss our results in the light of the above-mentioned mechanism [1-4].

TT 42.8 Thu 11:30 H32

Transport Measurements on Arrays of Four-Terminal Nb-Pt-Nb Josephson Junctions — •Justus Teller[1,2], Christian Schäfer[1,2], Benjamin Bennemann[1], Matvey Lyatti[1,2], Kristof Moors[1,2], Detlev Grützmacher[1,2], Roman-Pascal Riwar[1], and Thomas Schäpers[1,2] — [1]Peter Grünberg Institut (PGI-9, PGI-10, PGI-2), Forschungszentrum Jülich, 52425 Jülich, Germany — [2]JARA-Fundamentals of Future Information Technology, Jülich-Aachen Research Alliance, Forschungszentrum Jülich and RWTH Aachen University, Germany

Arrays of interconnected two-terminal Josephson junctions have been investigated since the 1980's. Usually, the array is realized as a square lattice with four two-terminal Josephson junctions connected in a square unit cell. Recently, Graziano et al. [1] showed that a multi-terminal Josephson junction can be described as a network of interconnected two-terminal Josephson junctions. Based on that concept, we present an array made of 30×30 four-terminal Nb-Pt-Nb Josephson junctions. The in-situ fabrication of large networks of Josephson junctions, using molecular beam epitaxy, is described. For this process, a periodically patterned shadow mask of Si_3N_4 has been developed. The physical concept of a multi-terminal Josephson junction array is introduced. Its theoretical explanation is based on a lattice of interconnected two-terminal Josephson junctions, each described as a resistively-capacitively-shunted junction. Critical current and resistance of the array show oscillations connected to its unit cell.

TT 42.9 Thu 11:45 H32

Superconducting Atomic Contacts under Microwave Irradiation, Photon-Assisted Tunneling and Fractional Shapiro Steps — •Oliver Irtenkauf[1], Patrick Raif[1,2], Carlos Cuevas[1,3], and Elke Scheer[1] — [1]University of Konstanz, Germany — [2]University of Basel, Switzerland — [3]Universidad Autónoma de Madrid, Spain

We form an atomic contact from a mechanically controlled aluminum break junction and irradiate it with microwaves in its superconducting state [1]. In the dI/dV spectra, we observe the well-known structures caused by photon-assisted tunneling, which, in the case of tunnel contacts, are fully explained by the Tien-Gordon (TG) model [2]. However, for higher-order transport processes, the model requires extensions, as shown in simulations based on the TG model [3,4]. Shapiro steps, i.e., replicas of the supercurrent, reveal deviations from the theoretical predictions described in references [5,6]. Fractional Shapiro steps, which we observe in atomic contacts with high-transmission channels at high frequencies, differ from traditional Shapiro steps and represent a new phenomenon.

TT 42.10 Thu 12:00 H32

High-Frequency Irradiation of Single-Atom Josephson Junctions — •Martina Trahms[1,2], Bharti Mahendru[2], Clemens B. Winkelmann[1], and Katharina J. Franke[2] — [1]University Grenoble Alpes, LATEQS, 38042 Grenoble, France — [2]Fachbereich Physik, Freie Universität Berlin, 14195 Berlin, Germany

Understanding superconducting junctions on the atomic scale yields significant insights for the prospect of using superconducting circuits in future technological applications. Here, we investigate the influence of single magnetic adatoms (Mn) on the phase dynamics of current-biased Pb-Pb Josephson junctions in a scanning tunneling microscope (STM) in the presence of high-frequency (HF) irradiation that is applied via an antenna close to the junction. We observe Shapiro steps that indicate coherent absorption of the irradiation while at the same time phase diffusion is enhanced due to incoherent absorption. In the presence of a magnetic adatom, phase diffusion is more prominently enhanced compared to the pristine junction which indicates that the quantum spin of the magnetic impurity influences the coherence of the tunneling processes in the junction.

TT 42.11 Thu 12:15 H32

Amplification Schemes for Single Microwave Photons — •Lukas Danner[1,2], Hanna Zeller[2], Ciprian Padurariu[2], Joachim Ankerhold[2], and Björn Kubala[1,2] — [1]Institute for Quantum Technologies, German Aerospace Center (DLR), Ulm (Germany) — [2]Institute for Complex Quantum Systems and IQST, University of Ulm, Ulm (Germany)

The detection of single microwave photons plays a crucial role in a wide range of envisioned technological applications of quantum microwaves. However, this is challenging because of the large thermal background and the low energy of a single photon. Here, we investigate schemes to amplify single itinerant mircowave photons using Josephson photonics devices [1, 2]. These devices consist of a

dc-voltage biased Josephson junction, connected in series with two microwave cavities. By tuning the dc voltage, various resonances can easily be accessed, such that e.g. a Cooper pair tunneling through the junction enables a coherent transfer between one excitation in the first cavity and n excitations in the second cavity. We show that a single photon pulse absorbed by the device effectively triggers the emission of multiple photons from the second cavity that can subsequently be detected. To study such processes theoretically, we use a recently developed formalism [3] to describe arbitrary traveling photon pulses interacting with a quantum system in a cascaded manner.

TT 42.12 Thu 12:30 H32

Tunneling in Altermagnet/Superconductor/Altermagnet Junctions — •Marcel Polák[1], František Herman[1], Andreas Costa[2], and Jaroslav Fabian[2] — [1]Comenius University Bratislava, Slovakia — [2]University of Regensburg, Germany

Their unprecedented spectral characteristics—particularly their large local magnetic exchange splittings in momentum space without rising an overall net spin polarization—make altermagnets promising candidates for engineering strongly spin-polarized currents in superconducting heterostructures.

In this talk, we will focus on lateral altermagnet/superconductor/ altermagnet junctions in the ballistic limit to theoretically explore the ramifications of their d-wave-like spin-split Fermi surfaces on superconducting transport. We will demonstrate that the subgap interplay of Andreev and quasiparticle tunnelings, and thereby the experimentally accessible tunneling conductance, is tunable through the absolute and relative orientations of the altermagnets' Fermi surfaces, recovering the two important limiting cases in which the altermagnets behave either rather like normal metals or ferromagnets. Finally, we will also investigate geometrical conductance oscillations at supergap voltages in the presence of resonant scattering and compare our results against the ferromagnetic junction counterpart.

This work has been supported by Contract no. APVV-23-0515, by the European Union's Horizon 2020 research and innovation program under the Marie Skłodowska-Curie Grant Agreement No. 945478 and by DFG Grants 314695032 (SFB 1277) and 454646522.

TT 42.13 Thu 12:45 H32

Chiral Interference Pattern in Tunneling Junctions and SQUIDs Made of Time-Reversal Invariant Weyl Superconductors — •Anastasiia Chyzhykova[1,2], Vira Shyta[1], Jeroen van den Brink[1], and Flavio Nogueira[1] — [1]Leibniz Institute for Solid State and Materials Research, IFW Dresden, Helmholtzstrasse 20, 01069 Dresden, Germany — [2]Technische Universität Dresden

In recent years a number of experiments have reported superconductivity in various Weyl semimetals. The low-energy electromagnetic response of Weyl semimetals is governed by the axion term in the action arising due to the chiral anomaly. A recent publication [1] demonstrated that the time-reversal invariant Weyl superconductors (SCs) exhibit a chiral Meissner state. In our work we explore the influence of the chiral Meissner state on the tunnel junctions and squids made of time-reversal invariant Weyl SCs. We derive a modified Fraunhofer interference pattern in such a junction and demonstrate how the presence of the axion term affects Josephson energy in asymmetric squids and Berry phase in charge qubits. The effect of the chiral Meissner state manifests as a temperature-dependent deficit flux, which provides a new tuning parameter compared to ordinary squids.

TT 42.14 Thu 13:00 H32

Superconductor-Altermagnet Proximity Effect with Nonmagnetic Impurities — •Christian Wiedemann[1], Danilo Nikolić[2], Matthias Eschrig[2], and Wolfgang Belzig[1] — [1]Universität Konstanz, Konstanz, Germany — [2]Universität Greifswald, Greifswald, Germany

Altermagnetism is a novel magnetic phase with zero net magnetization and momentum-dependent (e.g. d-wave) spin-split Fermi surface which has been recently discovered [1]. Similarly to ferromagnets [2,3], when brought to the proximity of a superconductor (S) an altermagnet (AM) modifies the spectral properties of the former [4,5]. However, most works in the field of superconducting spintronics involving altermagnets have assumed the absence of impurities that are, however, typically unavoidable in experiments. In this talk, we address this question explicitly presenting a systematic analysis of the inverse proximity effect in an S/AM bilayer in the presence of nonmagnetic impurities. Utilizing the quasiclassical Green's function theory, we investigate the effect of impurities on observables, e.g., the self-consistently calculated order parameter and the density of states. We observe interesting phenomena such as the gapless superconductivity and an impurity-enhanced critical temperature.

TT 43: Correlated Electrons: Other Theoretical Topics

Time: Thursday 9:30–13:00 Location: H33

TT 43.1 Thu 9:30 H33

Fragility of local moments for singular hybridizations — •Max Fischer[1,2], Arianna Poli[3], Lorenzo Crippa[1,2], Sergio Ciuchi[3,4], Matthias Vojta[2,5], Alessandro Toschi[6], and Giorgio Sangiovanni[1,2] — [1]Universität Würzburg, Germany — [2]Würzburg-Dresden Cluster of Excellence ct.qmat — [3]Università dell'Aquila, Italy — [4]CNR, Italy — [5]TU Dresden, Germany — [6]TU Wien, Austria

Some transition-metal phtalocyanines on an Ag(001) surface show hybridizations for xz/yz-orbitals with sharp peaks superimposed on a rather constant z^2 contribution. These sharp peaks in the hybridization correspond to an Anderson impurity model with one impurity site hybridized with one bath site. Investigating only a constant hybridization this typically shows rich physics arising from the Kondo effect yielding local moments and screening of them at low temperatures. Expanding the constant hybridization by a peak at the Fermi level, the formation of the local moment is shifted to lower temperatures with increasing weight of the peak. With such a toy model we analyze the vanishing of the local moment at large weights of the peak. Here, we find the evolution from screening of the local moment to the formation of a singlet ground state for the two site AIM.

TT 43.2 Thu 9:45 H33

Inducing strong electronic correlation by charged impurities in weakly interacting two-dimensional electron system — Junho Bang[1], Byeongin Lee[1], João Augusto Sobral[2], Sayan Banerjee[2], Mathias Scheurer[2], •Jianfeng Ge[3], and Doohee Cho[1] — [1]Department of Physics, Yonsei University, Seoul 03722, Korea — [2]Institute for Theoretical Physics III, University of Stuttgart, 70550 Stuttgart, Germany — [3]Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany

When translational invariance is broken, e.g. in the presence of impurities, an ordered state can emerge where the electronic charge density modulates spatially. While conventional charge modulations are explained by weak-impurity scattering of Landau quasiparticles, strong correlations may drive the electrons to depart from the Fermi liquid behavior. Using scanning tunneling microscopy and spectroscopy, we switch the ionization state of individual surface impurities and discover a local phase transition induced by the impurity potential. A nanoscale charge-ordered phase, which breaks the symmetry of the underneath hosting lattice, spontaneously emerges from the otherwise uniform two-dimensional electron system. Further, the charge modulations appear with an anisotropy distinct from that of the Fermi surface, excluding any Fermi-surface-related interpretations for the ordered phase. While the exact origin of the solid-like electronic phase remains a mystery, our work demonstrates a microscopic approach for creating and manipulating strongly correlated electrons in two-dimensional systems even with weak intrinsic interactions.

TT 43.3 Thu 10:00 H33

Anomalous quantum oscillations from boson-mediated interband scattering — •Léo Mangeolle[1,2] and Johannes Knolle[1,2,3] — [1]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 München, Germany — [3]Blackett Laboratory, Imperial College London, London SW7 2AZ, United Kingdom

Quantum oscillations (QO) in metals refer to the periodic variation of thermodynamic and transport properties as a function of inverse applied magnetic field. QO frequencies are normally associated with semi-classical trajectories of Fermi surface orbits but recent experiments challenge the canonical description. We

develop a theory of composite frequency quantum oscillations (CFQO) in two-dimensional Fermi liquids with several Fermi surfaces and interband scattering mediated by a dynamical boson, e.g. phonons or spin fluctuations. Specifically, we show that CFQO arise from oscillations in the fermionic self-energy with anomalous frequency splitting and distinct strongly non-Lifshitz-Kosevich temperature dependencies. Our theory goes beyond the framework of semi-classical Fermi surface trajectories highlighting the role of many-body effects. We provide experimental predictions and discuss the effect of non-equilibrium boson occupation in driven systems.

TT 43.4 Thu 10:15 H33

Disentangling real space fluctuations: The diagnostics of metal-insulator transitions beyond single-particle spectral functions — •Michael Meixner[1], Marcel Krämer[1,2], Nils Wentzell[3], Pietro Bonetti[1,4], Sabine Andergassen[2], Alessandro Toschi[2], and Thomas Schäfer[1] — [1]Max-Planck-Insitut für Festkörperforschung, Stuttgart, Germany — [2]TU Wien, Vienna, Austria — [3]CCQ at Flatiron Institut, New York NY, USA — [4]Harvard University, Cabridge MA, USA

The destruction of metallicity due to the mutual Coulomb interaction of quasiparticles gives rise to fascinating phenomena of solid state physics such as the Mott metal-insulator transition and the pseudogap. A key observable characterizing their occurrences is the single-particle spectral function, determined by the fermionic self-energy. In this paper we investigate in detail how real space fluctuations constitute a self-energy that drives the Mott-Hubbard metal-insulator transition. To this aim we first introduce a real space fluctuation diagnostics approach to the Hedin equation, which connects the fermion-boson coupling vertex λ to the self-energy Σ. Second, by using cellular dynamical mean-field theory calculations for λ we identify the leading physical processes responsible for the destruction of metallicity across the transition. Eventually, to pave the way for relating our findings to the pseudogap phenomenology, we discuss the influence of real space fluctuations on the momentum-dependence of correlations.

TT 43.5 Thu 10:30 H33

Numerical indications for two-channel physics in the lightly doped t-J model — •Pit Bermes[1,2], Lukas Homeier[1,2], Sebastian Paeckel[1,2], Annabelle Bohrdt[2,3], and Fabian Grusdt[1,2] — [1]Department of Physics, Arnold Sommerfeld Center of Theoretical Physics, University of Munich, Theresienstrasse 37, 80333 Munich, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Schellingstrasse 4, 80799 München, Germany — [3]University of Regensburg, Universitätsstr. 31, Regensburg D-93053, Germany

The infamous cuprate superconductors at low doping are effectively described by hole doped antiferromagnets. Due to strong correlations however, standard techniques fail to describe these materials and full understanding of the microscopic mechanism remains elusive. Here we analyze numerical simulations of the lightly doped t-J model in two dimensions and present indications for two effective scattering channels in the simulated pair spectrum. We employ a previously proposed effective model whose degrees of freedom are given by magnetic polarons and bipolarons and show that it qualitatively reproduces the two branches in the pair spectrum. In addition, we propose a scheme to experimentally measure these signatures. The understanding of the effective quasiparticles presents an important step to unravel the elusive phases of high Tc superconductors.

TT 43.6 Thu 10:45 H33

Interplay of local and non-local electronic correlations in the Hubbard model — •Maria Chatzieleftheriou[1], Silke Biermann[2], and Evgeny Stepanov[2] — [1]Goethe University Frankfurt, Germany — [2]Ecole Polytechnique, IP Paris, France

Strongly correlated electronic systems exhibit intriguing properties and highly complex phase diagrams, including metal-to-insulator transitions, magnetic/charge orderings and the field's holy grail: high temperature superconductivity. Their theoretical description is very challenging and various many-body methods have been developed to this direction. I will present results using state-of-the-art numerical techniques that allow for an accurate description of both strong local electronic correlations and spatial fluctuations. I will discuss the application of this approach on the study of the Hubbard model, relevant for a series of materials, where we have analyzed the interplay of Mott physics and magnetic fluctuations at half-filling. We have identified the Slater and Heisenberg regimes in the phase diagram, which are separated by a crossover region of competing spatial and local electronic correlations. This bridging of the two limits (the spin-fluctuation dominated Slater regime at weak coupling and the Mott insulator at strong-coupling) had been a key missing ingredient to our understanding of metal-insulator transitions in real materials. Lastly, I will present recently obtained results on the evolution of the system's magnetic and charge susceptibility as a function of doping.

TT 43.7 Thu 11:00 H33

Fracton and topological order in the XY checkerboard toric code — Max Vieweg and •Kai Phillip Schmidt — Frichdrich-Alexander Universität Erlangen-Nürnberg (FAU), 91058 Erlangen, Germany

Topological and fraction phases are of great importance in current research due to their fascinating physical properties like entangled ground states, exotic excitations with non-trivial particle statistics or restricted mobility as well as potential applications in quantum technologies. The 2D toric code is the most paradigmatic, simplest, and exactly solvable model displaying topological order, which has been proposed as quantum memory and is relevant for quantum error correction. Consequently, the toric code plays an important role in several domains of research covering condensed matter physics, quantum optics, and quantum information.

However, the toric code has so far not been linked to the field of fracton physics. Here we introduce the XY checkerboard toric code (XYTC) connecting for the first time topological and fracton order in two dimensions within the same model. The XYTC represents a generalization of the conventional toric code with two types of star operators and two anisotropic star sublattices forming a checkerboard lattice. The quantum phase diagram is deduced exactly by a duality transformation displaying topological and type-I fracton phases.

15 min. break

TT 43.8 Thu 11:30 H33

Deconfinement Phase Transitions in a nematic two dimensional XY model with Long-range couplings — •Luis Walther[1], Josef Willsher[1,2], and Johannes Knolle[1,2,3] — [1]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Schellingstraße 4, 80799 Munchen, Germany — [3]Blackett Laboratory, Imperial College London, London SW7 2AZ, United Kingdom

The Modified XY model is an illustrative example of the interplay between ferromagnetic and nematic couplings, hosting both vortex and half-vortex excitations. The model gives rise to an exotic second order phase transition driven by the deconfinement of vortices into half-vortices. This transition is in the universality class of the Ising model, displaying features of the 'Deconfined Criticality' scenario. We analyse the effect of long-range algebraically decaying couplings $\sim r^{-2-\sigma}$ on the model. Long-range couplings enrichen the phase diagram and influence the deconfinement phase transition. We find that the transition persists for long-range couplings decaying fast enough so that $\sigma > 2 - \eta$ holds, where η is the the correlation function exponent of the short-range XY model. Our results are based on Landau Peierls type arguments as well as Renormalisation Group flow techniques. Long-range couplings appear in many experimental setups including 2D Rydberg simulators. Therefore we hope our work contributes to enable the experimental observation of the deconfinement phase transition present in the model.

TT 43.9 Thu 11:45 H33

Mapping out Localization Phases in Bond-Disordered XXZ Models — Adrian Braemer[1], •Javad Vahedi[2], and Martin Gärttner[2] — [1]Physikalisches Institut, Universität Heidelberg, Im Neuenheimer Feld 226, 69120 Heidelberg, Germany — [2]Institut für Festkörpertheorie und -optik, Friedrich-Schiller-Universität Jena, Max-Wien-Platz 1, 07743 Jena, Germany

Historically, the phenomenon of many-body localization (MBL) has been studied in spin systems subject to random, local magnetic fields. At strong disorder, the system is found to be localized, with the local integrals of motion (LIOMs) consisting of single spins. However, this is not the only type of MBL: in bond-disordered Heisenberg models, the LIOMs have been shown to involve pairs of spins.

In this talk, we show that the bond-disordered XXZ model also exhibits a single-spin localized phase at strong anisotropy and map out the transitions between these three phases. To this end, we generalize the notion of occupation distance introduced by Hopjan et al. [1] to different observables, enabling us to characterize all three phases.

TT 43.10 Thu 12:00 H33

Melting of Devil's Staircases in the Long-Range Dicke-Ising Model — •Jan Alexander Koziol and Kai Phillip Schmidt — Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Staudtstraße 7, 91058 Erlangen, Germany

We present ground-state phase diagrams of the antiferromagnetic long-range Ising model under a linear coupling to a single bosonic mode on the square and triangular lattice. In the limit of zero coupling the ground state magnetization forms a Devil's staircase structure of magnetization plateaux as a function of an applied longitudinal field in Ising direction. The linear coupling to a single bosonic mode melts this structure to a so-called superradiant phase with a finite photon density in the ground state. The long-range interactions lead to a plethora of intermediate phases that break the translational symmetry of the lattice, as well as having a finite photon density. To study the ground-state phase diagram we apply an adaption of the unit-cell-based mean-field calculations [1,2], which capture all possible magnetic unit cells up to a chosen extent. Further, we exploit a mapping of the non-superradiant phases to the Dicke model in order to calcu-

late upper bounds for phase transitions towards superradiant phases [3]. In the case of second-order phase transitions, these bounds agree with the boundaries determined by the mean-field calculations.

TT 43.11 Thu 12:15 H33

Anyonic phase transitions in the 1D extended Hubbard model with fractional statistics — •Sebastian Eggert[1], Martin Bonkhoff[2], Kevin Jägering[1], Shi-Jie Hu[3], Axel Pelster[1], and Imke Schneider[1] — [1]University of Kaiserslautern-Landau — [2]Theoretische Physik, Univ. Hamburg — [3]Beijing Computational Science Research Center

Recent advances in quantum technology allow the realization of "lattice anyons", which have enjoyed large interest as particles which interpolate between bosonic and fermionic behavior. We now study the interplay of such fractional statistics with strong correlations in the one-dimensional extended Anyon Hubbard model at unit filling by developing a tailored bosonization theory and employing large-scale numerical simulations. The resulting quantum phase diagram shows several distinct phases, which show an interesting transition through a multicritical point. As the anyonic exchange phase is tuned from bosons to fermions, an intermediate coupling phase changes from Haldane insulator to a dimerized phase. Detailed results on the universality classes of the phase transitions are presented.

TT 43.12 Thu 12:30 H33

Nonlinear effects on the transport of fractional charges in quantum wires — •Imke Schneider[1], Flavia Braga Ramos[1], Rodrigo Gonçalves Pereira[2], and Sebastian Eggert[1] — [1]Physics Department and Research Center OPTIMAS, University of Kaiserslautern-Landau, Kaiserslautern, Germany — [2]International Institute of Physics and Departamento de Física Teórica e Ex- perimental, Universidade Federal do Rio Grande do Norte, Natal, Brazil

We investigate the transport properties of one-dimensional systems be- yond linear response, focusing on the fractionalization of propagating charges. Starting from a right-moving unit charge, we predict its evo- lution into at least three distinct stable parts: a fractionally charged particle with freeparticle dynamics, a left-moving signal, and a right- moving low-energy excitation, which can carry positive or negative charge depending on the interaction strength and energy regime. Our findings provide deep insights into the universal correlated nature of these emergent particles and pave the way for out-of-equilibrium transport measurements, offering a direct method to extract the interaction parameters governing correlations in the system.

TT 43.13 Thu 12:45 H33

To Infinity and Back - $1/N$ Graph Expansion of Light-Matter Systems — •Andreas Schellenberger and Kai Phillip Schmidt — FAU Erlangen-Nürnberg, Erlangen, Deutschland

We present a method for performing a full graph expansion for light-matter systems, utilizing the linked-cluster theorem. This enables us to explore $1/N$ corrections to the thermodynamic limit $N \to \infty$, giving us access to the mesoscopic regime. This region is yet largely unexplored, as it is challenging to tackle with established solid-state methods. However, it hosts intriguing features, such as entanglement between light and matter that vanishes in the thermodynamic limit [1-3]. We calculate physical quantities of interest for paradigmatic light-matter systems like generalized Dicke models by accompanying the graph expansion by both exact diagonalization (NLCE [4]) and perturbation theory (pcst++ [5]), benchmarking our approach against other techniques.

TT 44: Focus Session: Ising Superconductivity in Monolayer Transition Metal Dichalcogenides (joint session TT/HL/MA)

Superconducting monolayer transition metal dichalcogenides (TMDs) like $NbSe_2$, TaS_2, and gated WSe_2 or MoS_2, have attracted lot of interest in recent years. On the one hand Ising spin-orbit coupling pins the electron's spin out of plane, and hence is responsible for critical in-plane magnetic fields by far exceeding the Pauli limit. On the other hand, while the underlying pairing mechanism is still under debate, recent experiments provide strong evidence for its unconventional, multiband, nature. The Focus Session will feature experimental and theoretical advances on the superconductivity in monolayer TMDs, with focus on universal features, a possible Luttinger-Kohn mechanism, a nodal or even chiral nature of the gap functions, and their phase diagram.

Organizers: Milena Grifoni (Universität Regensburg), Julian Siegl (Universität Regensburg)

Time: Thursday 9:30–12:45 Location: H36

Topical Talk TT 44.1 Thu 9:30 H36

Evidence of Unconventional Superconductivity in Monolayer and Bulk van der Waals Material TaS_2 — •Somesh Chandra Ganguli[1], Viliam Vano[1,2], Yuxiao Ding[1], Maryam Khosravian[1], Jose Lado[1], and Peter Liljeroth[1] — [1]Department of Applied Physics, Aalto University FI-00076 Aalto, Finland — [2]Joseph Henry Laboratories and Department of Physics, Princeton University, Princeton, NJ, USA

Unconventional superconductors are at the forefront of modern quantum materials' research. Even though unconventional superconductivity has been discovered in a large number of bulk systems, intrinsic unconventional superconductivity in the monolayer limit has remained elusive.

In our work, we demonstrate the evidence of nodal f-wave superconductivity in monolayer 1H-TaS_2. We also observe the emergence of many-body excitations potentially associated to its unconventional pairing mechanism. Furthermore, the nodal f-wave superconducting state in the pristine monolayer 1H-TaS_2 is driven to a conventional gapped s-wave state by the inclusion of non-magnetic disorder. I will also briefly describe our recent results on bulk layered superconductor 6R-TaS_2 where alternating metallic and Mott insulating layers gives rise to unconventional superconductivity.

Our results demonstrate the emergence of unconventional superconductivity in van der Waals (vdW) materials and therefore opens possibilities to create designer unconventional superconductivity in vdW heterostructures.

Topical Talk TT 44.2 Thu 10:00 H36

Signatures of Unconventional Superconductivity in Transition Metal Dichalcogenides — •Miguel Ugeda — Donostia International Physics Center, San Sebastián, Spain

Lowering the dimensionality of a material is an effective strategy to boost electronic correlations that fail to be captured by conventional pictures. In this arena, two-dimensional (2D) materials provide an ideal platform for the exploration of quantum collective phenomena arising from such strong interactions due to their simple synthesis and modelling. In this talk, I will review the rich physics that emerges in the family of transition metal dichalcogenide (TMD) metals in the superconducting state in the 2D limit. While many of these TMD metals exhibit superconductivity in both the bulk form down to the monolayer, the latter limit stores exciting surprises beyond the BCS frameworks that have been revealed in the last years. I will focus on our $NbSe_2$, the most representative TMD superconductor, where I will describe our recent STM/STS experiments. Lastly, I will briefly describe our current efforts to induce unconventional superconductivity in more complex TMD heterostructures.

Topical Talk TT 44.3 Thu 10:30 H36

Friedel Oscillations and Chiral Superconductivity in Monolayer $NbSe_2$ — •Magdalena Marganska[1,2], Julian Siegl[1], Anton Bleibaum[1], Marcin Kurpas[3], Wen Wan[4], John Schliemann[1], Miguel M. Ugeda[4,5], and Milena Grifoni[1] — [1]Institute for Theoretical Physics, University of Regensburg, 93 053 Regensburg — [2]Institute for Theoretical Physics, Wrocław University of Science and Technology, Wyb. Wyspiańskiego 27, 50-370 Wrocław, Poland — [3]Institute of Physics, University of Silesia in Katowice, 41-500 Chorzów, Poland — [4]Donostia International Physics Center, Paseo Manuel de Lardizábal 4, 20018 San Sebastián, Spain — [5]Ikerbasque, Basque Foundation for Science, Bilbao 48013, Spain

In 1965 Kohn and Luttinger proposed a mechanism for superconductivity, based on the electronic Coulomb interaction alone. The screening effects, which cause

Friedel oscillations of charge density around impurities, modulate also the interaction between moving electrons. If it has attractive regions, superconductivity can arise by exploiting them. This mechanism, negligible in 3D metals, can become much stronger in 2D electronic systems. In a monolayer of $NbSe_2$ the screening is further suppressed, due to the multi-orbital nature of the electronic band at the Fermi level. We show how this, and the presence of K/K' Fermi surfaces, leads to superconducting pairing. The dominant gap solution at $T = 0$ has the chiral p+ip symmetry. It evolves with increasing temperature, turning from fully chiral at T=0 to a nematic solution with p-like symmetry close to the critical temperature. Our results are also consistent with our tunneling spectroscopy measurements in $NbSe_2$.

15 min. break

Topical Talk TT 44.4 Thu 11:15 H36

Unconventional Pairing in Ising Superconductors — •Andreas Kreisel[1], Subhojit Roy[2,3,4], Brian M. Andersen[1], and Shantanu Mukherjee[2,3,4] — [1]Niels Bohr Institute, University of Copenhagen, DK-2100 Copenhagen, Denmark — [2]Department of Physics, Indian Institute of Technology Madras, Chennai, 600036, India — [3]Center for Atomistic Modelling and Materials Design, IIT Madras, Chennai 600036, India — [4]Quantum Centers in Diamond and Emergent Materials (QCenDiem)-Group, IIT Madras, Chennai, 600036 India

Ising spin orbit coupling arises in materials with non-centrosymmetric crystal structure in conjunction of an in-plane mirror symmetry and is realized in some two dimension transition metal dichalcogenides. Example materials are monolayer $NbSe_2$, MoS_2, TaS_2, and $PbTe_2$, where signatures of unconventional superconductivity are found in contrast to their three dimensional bulk counterparts. In this talk, I present a microscopic formalism to calculate the superconducting instability from a momentum-dependent spin- and charge-fluctuation-mediated pairing interaction in presence of spin orbit coupling that induces a spin splitting. This pairing is then applied to the electronic structure of transition metal dichalcogenides. We provide a quantitative measure of the mixing between the even- and odd-parity superconducting states which varies with Coulomb interaction. The pairing scenario from spin fluctuations together with the mixing of the odd-parity superconducting state gives rise to an enhancement of the critical magnetic field.

Topical Talk TT 44.5 Thu 11:45 H36

High-Field Study of Ising Superconductivity in TMDs — •Oleksandr Zheliuk[1,2], Xiaoli Peng[3], Andrew Ammerlaan[1,2], Puhua Wan[3], Yulia Kreminska[3], Steffen Wiedmann[1,2], Uli Zeitler[1,2], and Jianting Ye[3] — [1]High Field Magnet Laboratory (HFML-EMFL), Radboud University, Toernooiveld 7, Nijmegen 6525 ED, The Netherlands — [2]Radboud University, Institute for Molecules and Materials, Nijmegen 6525 AJ, The Netherlands — [3]Zernike Institute for Advanced Materials, University of Groningen, 9747 AG Groningen, The Netherlands

Semiconducting transition metal dichalcogenides are known for their strong spin-orbit coupling, the possibility of hosting a variety of quantum phases such as two-dimensional superconductivity with upper critical fields that by far bypasses the Pauli limit, Josephson coupled states, and high mobility electron gasses accessed in electric double-layer transistor (EDLT) configuration. Despite its well-established electronic structure, the dome-shaped superconducting phase diagram where the critical temperature T_c can be modulated by carrier concentration is yet to be understood. This talk will sharpen the understanding of the electronic structure of the electron-doped MoS_2, covering recent insights into superconductivity in MoS_2 probed via the multivalley transport phenomena accessed in high magnetic field.

TT 44.6 Thu 12:15 H36

Unconventional Pairing in Ising Superconductors: Application to Monolayer $NbSe_2$ — •Subhojit Roy[1], Andreas Kreisel[2], Brian Andersen[3], and Shantanu Mukherjee[4] — [1]Indian Instititute of Technology Madras, Chennai, 600036, India — [2]Niels Bohr Institute, University of Copenhagen, DK-2100 Copenhagen, Denmark — [3]Niels Bohr Institute, University of Copenhagen, DK-2100 Copenhagen, Denmark — [4]Indian Instititute of Technology Madras, Chennai, 600036, India

The presence of a non-centrosymmetric crystal structure and in-plane mirror symmetry allows an Ising spin-orbit coupling to form in some two-dimensional materials, where a nontrivial nature of the superconducting state is currently being explored. In this study(1), we develop a microscopic formalism for Ising superconductors that captures the superconducting instability arising from a momentum-dependent spin- and charge-fluctuation-mediated pairing interaction. We apply our pairing model to the electronic structure of monolayer $NbSe_2$, where first-principles calculations reveal the presence of strong paramagnetic fluctuations. Our calculations provide a quantitative measure of the mixing between the even- and odd-parity superconducting states and its variation with Coulomb interaction. Further, numerical analysis in the presence of an external Zeeman field reveals the role of Ising spin-orbit coupling and mixing of odd-parity superconducting state in influencing the low-temperature enhancement of the critical magnetic field.

TT 44.7 Thu 12:30 H36

Emergence of Unconventional Superconductivity and Doped Mott Physics in 6R-TaS_2 — •Yuxiao Ding[1], Amritroop Achari[2], Jonas Bekaert[3], Jose Lado[1], Rahul R. Nair[2], Peter Liljeroth[1], and Somesh C. Ganguli[1] — [1]Aalto University, Finland — [2]University of Manchester, UK — [3]University of Antwerp, Belgium

Discovery of Unconventional superconductivity in van der Waals (vdW) materials have brought about a paradigm shift in modern condensed matter research for their tunability and potential application in quantum computing. Among these, most prevalent are 4Hb-TaS_2 and 6R-TaS_2. They comprise of alternating Mott insulating and metallic layers and give rise to exotic quantum states such as topological superconductivity, anomalous Hall effect potentially associated with hidden magnetism etc. We have studied, using low temperature STM/STS, the newly discovered vdW superconductor 6R-TaS_2. For the 1T phase, a doped Mott phase was observed with potential charge order occurring due to hybridisation between 1T and underlying 1H layer. We also observe Kondo sites in the half-filled regime, which unlike 4Hb-TaS_2, were more robust under the application of tip-induced electric field. This indicates significantly different interlayer interactions in these two systems. We also observe evidence of unconventional superconductivity in the 1H phase, indicated by the presence of V-shaped superconducting gap and many-body excitations. Our results pave a new direction in understanding the role of interplay between magnetism and superconductivity in layered unconventional superconductors.

TT 45: 2D Materials: Electronic Structure and Exitations III (joint session O/HL/TT)

Time: Thursday 10:30–12:30 Location: H11

TT 45.1 Thu 10:30 H11

Charge ordered phases in the hole-doped triangular Mott insulator 4*Hb*-TaS_2 — •Byeongin Lee[1], Junho Bang[1], Hyungryul Yang[1], Sunghun Kim[2], Dirk Wulferding[3], and Doohee Cho[1] — [1]Department of Physics, Yonsei University, Seoul 03722, Republic of Korea — [2]Department of Physics, Ajou University, Suwon 16499, Republic of Korea — [3]Center for Correlated Electron Systems, Institute for Basic Science, Seoul 08826, Republic of Korea

4*Hb*-TaS_2 has a unique layered structure, featuring a heterojunction between a 2D triangular Mott insulator and a charge density wave metal. Since a frustrated spin state in the correlated insulating layer is susceptible to charge ordering with carrier doping, it is required to investigate the charge distribution driven by interlayer charge transfer to understand its various phases. In this study, we utilize scanning tunneling microscopy and spectroscopy (STM/S) to examine the charge-ordered phases of 1*T*-TaS_2 layers within 4*Hb*-TaS_2, explicitly focusing on the non-half-filled regime. Our STS findings reveal an energy gap that exhibits an out-of-phase relation of the charge density. We attribute the emergence of the charge-ordered insulating phase in a doped triangular Mott insulator to the interplay between on-site and nonlocal Coulomb repulsion.

TT 45.2 Thu 10:45 H11

Superlattice engineering in graphene and 1T-$NbSe_2$ heterostructures — •Keda Jin[1,2], Lennart Klebl[3], Junting Zhao[1,2], Tobias Wichmann[1,5], F. Stefan Tautz[1,5], Felix Lüpke[1], Dante Kennes[4], Jose Martinez-Castro[1,2], and Markus Ternes[1,2] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, 52425 Jülich, Germany — [2]Institut für Experimentalphysik II B, RWTH Aachen, 52074 Aachen, Germany — [3]I. Institute for Theoretical Physics, Universität Hamburg, 22607 Hamburg, Germany — [4]Institut für Theorie der statistischen Physik, RWTH Aachen, 52074 Aachen — [5]Institut für Experimentalphysik IV A, RWTH Aachen, 52074 Aachen, Germany

Superlattice engineering has become a major branch of condensed matter research, not at least due to the variety of exotic states observed twisted in van der Waals heterostructures. We here present a new method to periodically modulate graphene by stacking it on 1T/2H-$NbSe_2$. By tuning the twist angle, we realized two near-commensurate superlattices: $\sqrt{3}\times\sqrt{3}$ and 2×2 aligned with the charge density wave (CDW) of 1T-$NbSe_2$. Using scanning tunnelling microscopy, we visualized local stacking configurations for these two superlattices. We applied a newly developed symmetry analysis method to track rotational symmetry breaking as a function of bias. In the 2×2 superlattice, C_3 rotational symmetry was

preserved. However, in the $\sqrt{3} \times \sqrt{3}$, a strong strip phase occurs. This symmetry breaking is explained by our tight-binding model. Our findings highlight a mechanism for superlattice-induced symmetry breaking that hints towards exotic states of matter.

TT 45.3 Thu 11:00 H11

Influence of Edge Termination on the Electronic Structure of Single Layer MoS_2 on Graphene/Ir(111) — •Alice Bremerich[1], Marco Thaler[2], Thais Chagas[1], Borna Pielic[1], Laerte Patera[2], and Carsten Busse[1] — [1]Universität Siegen, Deutschland — [2]Universität Innsbruck, Österreich

MoS_2 is the prototypical semiconducting single-layer transition-metal dichalcogenide (TMDC). It exhibits a metallic edge state that induces partial charge accumulation at its edges, resulting in band bending effects. This 1D state acts as a barrier to electron transport across the edge and contributes significantly to quantum confinement effects in TMDC islands. In this study, we tune the edge state and the associated band bending by altering the edge termination of MoS_2/gr/Ir(111) and investigate the resulting changes in the electronic structure by Scanning Tunneling Microscopy and Spectroscopy (STM and STS) at 8 K.

Quasi-freestanding MoS_2 is grown on gr/Ir(111) by Molecular Beam Epitaxy (MBE). We prepare hexagonal islands that exhibit two geometrically different edge types (Mo- and S-type). We vary the chemical potential of sulfur and thereby modify the chemical environment of the boundaries. The partial charge at the perimeter depends on edge type as well as edge chemistry. In consequence, also the upward bending of both valence and conduction band shows distinct variations.

TT 45.4 Thu 11:15 H11

magnetic-field-induced dimensionality transition of charge density waves in strained 2H-NbSe2 — •Ryo Ichikawa[1], Yukiko Takahashi[2], Eiichi Inami[3], and Toyo Kazu Yamada[1,4] — [1]Department of Material Science, Chiba University — [2]National Institute for Material Science, Tsukuba — [3]School of system Engineering, Kochi University of Technology — [4]Molecular Chirality Research center, Chiba University

Layered transition metal dichalcogenides (TMDs) exhibit various correlated phases, including charge density waves (CDW), superconductivity, and magnetic orders. Bulk 2H-NbSe2 (2H niobium diselenide) is one of the most extensively studied TMDs, showing a triangular (3Q) incommensurate CDW with a 3a period in real space (3 * 3, TCDW ~ 33 K). Electric and magnetic fields have been used to manipulate spatial or time inversion symmetry, while the CDW in 2H-NbSe2 remains robust even under large magnetic fields on the order of tens of Tesla. However, magnetic-field-sensitive CDWs have been reported in few-layer NbSe2, where a weak magnetic field of approximately 30 mT can switch the electronic phase within the thin film, resulting in a supercurrent diode effect. This study investigates the strained 2H-NbSe2 exhibiting the 2*2 CDW phase. We utilize low-temperature (4.3 K) scanning tunneling microscopy and spectroscopy (STM/STS) in ultrahigh vacuum (UHV). STS maps reveal the coherence of the 2*2 CDW patterns. However, applying an out-of-plane magnetic field induces a dramatic transformation akin to that observed in 1T-NbSe2, shifting the metallic 2D CDW pattern to a 1D CDW pattern.

TT 45.5 Thu 11:30 H11

Ultrafast phonons dynamics of monolayer transition metal dichalcogenides — •yiming pan and fabio caruso — Kiel University, Germany

Valley degrees of freedom in transition-metal dichalcogenides influence thoroughly electron-phonon coupling and its nonequilibrium dynamics. Here we present a time-resolved ab-initio study of the ultrafast dynamics of chiral phonons following carrier excitation with circularly-polarized light. By investigating the valley depolarization dynamics of monolayer MoS_2 and WS_2, we find that a population imbalance of carriers distributed at K and K' can lead to valley polarized phonons persisting beyond 10 ps, and characterized by a distinctive chirality [1]. Additionally, we find that strain can be exploited as a tool to control the phonon emission and the relaxation channels of hot carriers [2]. Finally, we briefly discuss available opportunities for experimental detection of these phenomena

[2] Y. Pan and F. Caruso, npj 2D Mater. Appl. 8, 42 (2024)

TT 45.6 Thu 11:45 H11

Probing Excitonic Properties and Structural Effects in WS_2-Graphene Heterostructures Using EELS and DFT-BSE Modeling — •Max Bergmann, Jürgen Belz, Oliver Massmeyer, Robin Günkel, Badrosadat Ojaghi Dogahe, Andreas Beyer, Stefan Wippermann, and Kerstin Volz — Department of Physics, Philipps-Universität Marburg, Germany

This study investigates the excitonic properties of WS_2 epitaxially grown on graphene by metal-organic chemical vapor deposition. We focus on understanding the effects of structural changes, such as variations in the number of WS_2 layers. Using monochromatic electron energy loss spectroscopy (EELS) in a scanning transmission electron microscope (STEM), we observe in the monolayer region of WS_2 an excitonic spectrum with excitonic peaks at 2.0 eV and 2.4 eV, as well as additional spectral features at higher energies. Measurements in the bilayer region show a small redshift of these features due to the additional layer. Complementary density functional theory and Bethe-Salpeter calculations show that this redshift in the K-valley excitons is due to both a change in quantum confinement and a change in the WS_2 lattice constant, with the latter being the dominant effect. Using STEM, this lattice distortion can be attributed to the heteroepitaxial alignment of the lower WS_2 layer to the graphene substrate, while the upper layer is relaxed. This study provides valuable insights into the relationship between atomic structure and optical properties in complex material systems, providing essential knowledge for the design and optimization of 2D heterostructures for advanced device applications.

TT 45.7 Thu 12:00 H11

Optical excitations in 2H-MoS_2 bilayers under pressure — •Jan-Hauke Graalmann[1], Paul Steeger[2], Rudolf Bratschitsch[2], and Michael Rohlfing[1] — [1]University of Münster, Institute of Solid State Theory, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany — [2]University of Münster, Institute of Physics and Center for Nanotechnology, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany

Theoretical and experimental investigations have shown several changes in the optical spectrum of the 2H-MoS_2 bilayer under pressure [1].

By using density functional theory (DFT) and many-body perturbation theory in combination with linear elasticity, our computational investigations show an effective shift of the A exciton under pressure. It is strongly connected to the behavior of the direct band gap at the K point, which shifts in energy under pressure. The direction of this shift depends on the stress condition. While a hydrostatic pressure leads to a blueshift, a suppression of the in-plane contraction, as it appears in diamond anvil cell-experiments due to the interaction between the sample and the substrate, shows a redshift.

Moreover, we observe a similar behavior for the interlayer exciton, whereas the shift rate is smaller than that of the A exciton, which results in a decreasing A-IL splitting for an increasing pressure.

[1] P. Steeger, J. Graalmann et al., Nano Lett., 23, (2023)

TT 45.8 Thu 12:15 H11

Visualizing and controlling charge states of metal nanoislands on a two dimensional semiconductor — •Junho Bang[1], Byeongin Lee[1], Jian-Feng Ge[2], and Doohee Cho[1] — [1]Department of Physics, Yonsei University, Seoul, Korea — [2]Department of Topological Quantum Chemistry, Max Planck Institute for Chemical Physics of Solids, München ,Germany

Nanoscale objects show unique electronic behaviors when weakly coupled to electrodes. Coulomb blockade (CB) can occur in such systems, where the repulsive Coulomb interaction between electrons prevents additional electrons from entering the quantum dots, hindering their flow. Single electron tunneling occurs by these correlated electron transports, leading to the discrete charge states of objects in double barrier tunneling junctions. Despite enormous progress, challenges remain in precisely controlling the interplay between objects' charge states and tunneling dynamics under varying conditions. Here, we visualize the charge states and their spatial variation on the random array of the indium islands on two-dimensional semiconductor black phosphorus using scanning tunneling microscopy and spectroscopy. Our spatially resolved tunneling spectra reveal that the junction capacitance varies across the islands. Furthermore, we find that the CB features are visible outside the islands, which is attributed to the remote gating of the islands. Our work advances the manipulation of electron transport at the nanoscale, which will be helpful in the application of nanoscale object-based single-electron devices.

TT 46: Transport Properties (joint session HL/TT)

Time: Thursday 15:00–17:15 Location: H13

TT 46.1 Thu 15:00 H13

Quasi-Ballistic Transport in Phase-Pure GaAs/InAs Core/Shell Nanowires — •Farah Basarić[1,2], Vladan Brajović[1,2], Gerrit Behner[1,2], Kristof Moors[1], William Schaarman[1], Raghavendra Juluri[3], Ana M. Sanchez[3], Hans Lüth[1,2], Detlev Grützmacher[1,2], Alexander Pawlis[1,2], and Thomas Schäpers[1,2] — [1]Peter Grünberg Institut (PGI9), Forschungszentrum Jülich, 52425 Jülich, Germany — [2]JARA-Fundamentals of Future Information Technology, Jülich-Aachen Research Alliance, Forschungszentrum Jülich and RWTH Aachen University, Germany — [3]Department of Physics, University of Warwick, Coventry CV4 7AL, UK

Core/shell GaAs/InAs nanowires represent tubular conductors due to their insulating core and confined conducting states in the InAs shell. We investigate nanowires with a crystalline phase purity of the InAs shell, where reduced scattering in electronic transport is expected. Low-temperature gate-dependent transport measurements give us insight into different contributions to the oscillatory behavior in the magnetoconductance, as well as the possibility to probe non-local transport phenomena due to large phase coherence length. With temperature-dependent measurements, we resolved the quasi-ballistic transport regime, and estimate the phase coherence length. Both measurements indicate superior transport properties of phase-pure GaAs/InAs nanowires in contrast to previous reports on non-phase pure nanowires. Our findings are an important optimization step for further development of nanowire-based hybrid devices.

TT 46.2 Thu 15:15 H13

Influence of defects and shape of thin InAs nanowires on their thermal conductivity, assessed via machine-learning potentials — •Sandro Wieser[1], Yujie Cen[1], Georg K. H. Madsen[1], and Jesús Carrete[2] — [1]Institute of Materials Chemistry, TU Wien, Wien, Austria — [2]Instituto de Nanociencia y Materiales de Aragón (INMA), CSIC-Universidad de Zaragoza, Zaragoza, Spain

Nanowires (NWs) grown from the zincblende (ZB) phase of InAs in the (111) direction commonly contain twin boundary defects consisting of narrow wurtzite (WZ) (001) phase regions between ZB sections. To investigate the impact of these and other defects on heat transport, we employ Green-Kubo equilibrium molecular dynamics simulations utilizing cepstral analysis to efficiently process the noise, and an accurate MACE model trained via active learning strategies to achieve transferability for a wide range of surface conditions.

We show that these twin boundaries reduce the thermal conductivity with respect to that of defect-free WZ-phase (001) NWs by a factor of more than two and that surface conditions lead to lower thermal conductivity values for defect-free ultrathin InAs ZB NWs. Analysis of the shape of twinning NWs reveals that structures mimicking experimentally measured surface configurations can enhance heat transport compared to strictly hexagonal NWs. Additional insights are gained from an analysis of line-group symmetries and vibrational properties for various NW shapes. Furthermore, experimentally motivated symmetric and symmetry-breaking surface defects are studied to reveal more and less influential defect sites.

TT 46.3 Thu 15:30 H13

Ab-initio heat transport in defect-laden quasi-1D systems from a symmetry-adapted perspective — •Yujie Cen[1], Sandro Wieser[1], Georg Kent Hellerup Madsen[1], and Jesús Carrete Montaña[2] — [1]Institute of Materials Chemistry, TU Wien, A-1060 Wien, Austria — [2]Instituto de Nanociencia y Materiales de Aragón (INMA), CSIC-Universidad de Zaragoza, Zaragoza, Spain

Due to their aspect ratio and wide range of thermal conductivities, nanotubes hold significant promise as heat-management nanocomponents. However, one major limitation preventing their widespread use is the typically high thermal resistance that arises from defects or contact with other materials. An intriguing question is the role that structural symmetry plays in thermal transport through those defect-laden sections. However, the ab-initio study of lattice thermal transport is hindered by factors such as the large number of atoms involved and the artifacts introduced by formalism designed for 3D systems.

We employ an Allegro-based machine learning potential to calculate the force constants and phonons of single and multi-layer MoS_2-WS_2 nanotube with near-DFT accuracy and efficient scaling. Subsequently, we combine representation theory with the mode-resolved Green's function method to calculate detailed phonon transmission profiles across defects, and connect the transmission probability of each mode to structural symmetry. while more drastic symmetry breakdowns might be expected to increase scattering and thermal resistance, our results show they actually reduce it by the suppression of selection rules and opening more phonon transmission channels.

TT 46.4 Thu 15:45 H13

Analysis of the electrical transport properties of MBE grown cubic Galliumnitride (c-GaN) sample structures — •Hannes Hergert[1,2], Mario F. Zscherp[1,2], Silas A. Jentsch[1,2], Jörg Schörmann[1,2], Sangam Chatterjee[1,2], Peter J. Klar[1,2], and Matthias T. Elm[1,2,3] — [1]Center for Materials Research, Heinrich-Buff-Ring 16, 35392 Giessen — [2]Institute of Experimental Physics I, Heinrich-Buff-Ring 16, 35392 Giessen — [3]Institute of Physical Chemistry, Heinrich-Buff-Ring 17, 35392 Giessen

Due to its lack of internal polarization fields cubic gallium nitride (c-GaN) is a promising semiconductor system for 'more-than-Moore' applications such as high-power electronics or optoelectronic devices. The analysis of its electrical transport properties is challenging since the molecular beam epitaxy (MBE) growth of high-quality c-GaN thin films requires a complex substrate architecture in order to accommodate the lattice mismatch between c-GaN and the 3C-SiC template. However, a reliable characterization of the electrical transport properties of c-GaN is crucial for the design of advanced functional devices. Here we analyze the electrical transport properties of the whole sample structure (MBE grown c-GaN/c-AlN thin films onto a 3C-SiC/Si template) with different c-GaN thicknessses using electrochemical impedance spectroscopy (EIS) as well as angle- and temperature-dependent magnetoresistance (MR) measurements. MR measurements reveal the existence of a highly conductive channel while EIS measurements allow the determination of the position of the channel between the c-AlN thin film and the 3C-SiC layer.

TT 46.5 Thu 16:15 H13

Fabrication and Characterisation of Short-channel Junctionless Nanowire Transistors — •Alessandro Puddu — Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

The downscaling limitations of conventional planar transistors require the investigation of alternative device configurations. Because of their excellent electrostatic control and intrinsic scalability, junctionless nanowire transistors (JNTs) present a feasible solution and are highly desirable for next-generation electronics. The key factor that characterizes the JNTs is the absence of pn-junctions. This provides several benefits, such as an easier fabrication process since the devices do not require abrupt doping profiles within the nanowire channel, which is now uniformly doped.

This work focuses on the fabrication and characterisation of short-channel Si JNTs. A top-down approach based on e-beam lithography (EBL) and inductively coupled plasma reactive ion etching (ICP-RIE) was used to fabricate the Si nanowires. The device characterisation showed improved performances due to the channel length shrinking.

TT 46.6 Thu 16:30 H13

***Ab initio* investigation of drag effect in germanium** — •Dwaipayan Paul and Nakib Protik — Humboldt-Universität zu Berlin, Zum Großen Windkanal 2, 12489 Berlin, Germany

In a system of interacting electrons and phonons, the transport of one induces transport in the other. This phenomenon is known as the electron-phonon drag effect [1]. Now, an important milestone in the history of drag physics is the first recorded measurement of this phenomenon in germanium [2]. Here we present the results of our *ab initio* computations of the thermoelectric transport coefficients of germanium for various temperatures and charge carrier concentrations using the `elphbolt` code [3]. We investigate how the various scattering channels in the system enable this material to exhibit strong drag phenomena.

TT 46.7 Thu 16:45 H13

Anomalous Knudsen effect signaling long-lived modes in 2D electron gases — •Grigorii Starkov and Björn Trauzettel — Institute for Theoretical Physics and Astrophysics, University of Würzburg, D-97074 Würzburg, Germany

Careful analysis of electron collisions in two spatial dimensions leads to the conclusion, that the odd harmonics of the electron distribution function decay much slower in comparison to the even ones at finite temperatures. Focusing on a channel geometry with boundary scattering, we show, that such behaviour of

the odd decay rates leads to a characteristic behaviour of the resistance that we dub anomalous Knudsen effect: increasing temperature leads to decreasing resistance, that quickly slows down and turns into growth. The further increase of temperature exhibits the usual Gurzhi peak in the resistance related to the crossover from ballistic to hydrodynamic transport. The simultaneous observation of the Gurzhi peak preceded by an anomalous Knudsen dip can serve as a concrete signature of the long-lived modes in the 2D electron transport at low temperatures.

TT 46.8 Thu 17:00 H13

Quantum confinement and stoichiometry fluctuations in nm-thin SiGe layers — •Daniel Dick[1,2,3,4], Florian Fuchs[1,2,3], Sibylle Gemming[2,4], and Jörg Schuster[1,2,3] — [1]Center for Micro- and Nanotechnology, TU Chemnitz, Germany — [2]Center for Materials, Architecture and Integration of Nanomembranes, TU Chemnitz, Germany — [3]Fraunhofer Institute for Electronic Nanosystems (ENAS), Chemnitz, Germany — [4]Institute of Physics, TU Chemnitz, Germany

We simulate biaxially strained SiGe layers of varying thickness in the range of a few nanometers, as found in the base layer of heterojunction bipolar transistors (HBTs). At this length scale, local fluctuations in atomic concentrations can strongly influence the electronic properties of the device, especially the distribution of dopants like e.g. boron. Even at high doping concentrations, only a single atom is present at a 1 nm^2 cross section of the layer on average.

Employing a new parameterization of silicon and germanium in the framework of extended Hückel theory (EHT), we calculate the local band gap for different permutations of the atomic structure. Various distributions of boron atoms are simulated. We study the impact of locally increased and decreased concentrations on the band gap. By varying layer thickness, we evaluate the effects of quantum confinement and how it impacts transport properties of the thin layer in contrast to bulk material.

TT 47: Fluctuations, Noise and Other Transport Topics (joint session TT/DY)

TT 47.1 Thu 15:00 H31

Noise and reliability characterization of ferroelectric field-effect transistors under cryogenic conditions — •Yannick Raffel[1], Shouzhuo Yang[1], Oliver Ostien[1], Maik Simon[1], Thomas Kämpfe[1], Konrad Seidel[1], Maximilian Lederer[1], and Johannes Heitmann[2] — [1]Fraunhofer Institute IPMS-CNT, Dresden, Germany — [2]TU Bergakademie Freiberg, Freiberg, Germany

This study explores the impact of defects in the ferroelectric (FE) hafnium oxide (HfO_2) layer on the low-frequency noise (LFN) characteristics of HfO_2-based ferroelectric field-effect transistors (FeFETs), which show great potential as memory devices for quantum computing applications under cryogenic conditions. The investigation focuses on device degradation and material-dependent changes under various temperature conditions, including cryogenic temperatures as low as 2 K. A clear link between device reliability and flicker noise was identified. Initially, the endurance of the devices was evaluated across a range of temperatures, including cryogenic conditions. Subsequently, their data retention behavior was characterized, revealing a notably prolonged electron detrapping time at 2 K. In addition, flicker noise trends were analyzed and discussed, shedding light on key factors influencing device optimization and reliability.

TT 47.2 Thu 15:15 H31

Charge dissipation in Josephson systems and its impact on phase diffusion — •Johannes Hauff, Joachim Ankerhold, and Dominik Maile — Institut für komplexe Quantensysteme, Universität Ulm

We theoretically investigate the dynamics of the Josephson phase for different quantum circuits in the presence of dissipative couplings. Thereby, we study the environmental assisted quantum tunneling of the superconducting phase in a current-biased Josephson junction and consider Ohmic resistors inducing dissipation both in the phase and in the charge of the quantum circuit. We find that the charge dissipation leads to an enhancement of the quantum escape rate, which is strongly dependent on the shape of the potential. This effect appears already in the low Ohmic regime and also occurs in the presence of phase dissipation that favors localization [1]. Inserting realistic circuit parameters, we address the question of its experimental observability, the impact of temperature and discuss suitable parameter spaces for the observation of the enhanced rate. Furthermore, we show how the interplay of thermal and quantum fluctuations in such nonlinear systems can lead to an interesting stochastic cooling process. In this context, we also discuss the relevance of dissipative couplings for quantum annealing procedures.

TT 47.3 Thu 15:30 H31

Thermodynamic and energetic constraints on out-of-equilibrium tunneling rates — Ludovico Tesser[1], •Matteo Acciai[2,1], Christian Spånslätt[3,1], Inès Safi[4], and Janine Splettstoesser[1] — [1]Department of Microtechnology and Nanoscience (MC2), Chalmers University of Technology, Göteborg, Sweden — [2]Scuola Internazionale Superiore di Studi Avanzati, Trieste, Italy — [3]Department of Engineering and Physics, Karlstad University, Karlstad, Sweden — [4]Laboratoire de Physique des Solides, CNRS-Université Paris-Sud and Paris-Saclay, Orsay, France

We consider a bipartite quantum system, where the two parts are kept at different temperatures and are connected by a tunnel coupling. In this setup, we show that the out-of-equilibrium tunneling rates between the two subsystems (depending on the applied temperature bias) are bounded by two constraints. The derived bounds are related to the dissipated heat and the absorbed energy neede to establish and deplete the temperature bias, thus providing a thermodynamic and energetic constraint on the tunneling rates.

Except for the restriction to the tunneling regime, our results are valid for arbitrary Hamiltonians of the two subsystems, that can include generic many-body interactions. The derived bounds thus apply to a large class of systems, such as molecular junctions and coupled cavities, and can be tested by measuring the out-of-equilibrium tunneling current and its fluctuations.

TT 47.4 Thu 15:45 H31

Colored noise Langevin equation for photon counting — •Steven Kim and Fabian Hassler — Institute for Quantum Information, RWTH Aachen, Germany

For open quantum systems, obtaining the photon counting statistics of the emitted radiation is central to obtain insights into phenomena such as entanglement and correlations, in particular super- and anti-bunching. Typically, these systems are described by a Lindblad master equation, which allows the counting statistics to be derived from normal-ordered number operators. However, the Lindblad equation relies on the rotating wave approximation (RWA), which assumes that the dissipation rate is much smaller than the characteristic photon frequency. While this requirement is always fulfilled at optical frequencies, microwave cavities can have broader linewidths, making the RWA inaccurate. Alternatively, such systems can be effectively described by an equivalent Langevin equation with correlated (colored) noise, which bypasses the need for the RWA. In this work, we derive the photon counting statistics directly from the Langevin equation, providing a broader framework for understanding photon emission in open quantum systems.

TT 47.5 Thu 16:00 H31

Quantum stochastic resonance in a periodically-driven quantum dot — •Johann Zöllner[1], Hendrik Mannel[1], Eric Kleinherbers[2], Marcel Zöllner[1], Nico Schwarz[1], Fabio Rimek[1], Andreas Wieck[3], Arne Ludwig[3], Axel Lorke[1], Martin Geller[1], and Jürgen König[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen — [2]Department of Physics and Astronomy, University of California, Los Angeles — [3]Faculty of Physics and Astronomy, Ruhr University Bochum

The combination of periodic driving and fluctuations in a system with an inherent noise source leads to stochastic resonance, where the synchronization of the system dynamics with the external drive leads to an enhanced signal-to-noise ratio. This phenomenon has been found in many different noisy systems in palaeoclimatology, biology, medicine and physics. The classical stochastic resonance with thermal noise has recently been experimentally extended to the quantum regime, where the fundamental randomness of individual quantum events is the noise source [1]. Here we demonstrate quantum stochastic resonance in the single-electron tunneling dynamics of a periodically driven single self-assembled quantum dot, tunnel-coupled to an electron reservoir [2]. We extend the statistical evaluation to factorial cumulants to gain a deeper understanding of the transition between stochastic and deterministic transport through the quantum dot.

Curvature-assisted high harmonic generation in strongly-driven superconductors — •Björn Niedzielski and Jamal Berakdar — Institut für Physik, Martin-Luther Universität Halle-Wittenberg, Halle/Saale 06099, Germany

Superconductors (SCs) under strong driving fields show inherently nonlinear dynamics, offering potential for nonlinear optics and high harmonic generation. However, the weak coupling of SCs to homogeneous transverse fields limits their efficiency. Here, we show that introducing curvature to mesoscopic type-II SC structures enables enhanced coupling to strong THz fields. Applied transport currents further allow for controlled emission of even and odd-order harmonic light modes.

The enhanced coupling of SCs and light arises from geometric and finite-size effects steering supercurrents while preserving the coherence of the SC state. Using the time-dependent Ginzburg-Landau framework, we simulate the dynamics of the superconducting order parameter in nanostructures with large coherence lengths under near-gap driving frequencies. Our simulations reveal the time-dependent supercurrents and their contributions to dipole radiation and high harmonic generation.

Our results highlight the role of the SC geometry and finite-size effects for amplifying nonlinear optical responses, offering a new method to use SCs for nonlinear THz optics.

Quantum oscillations in magneto-thermoelectrical conductivities of 2DEG: The Keldysh field-theoretical approach — •Kitinan Pongsangangan — Mahidol University, Bangkok, Thailand

The purpose of this work is to formulate a kinetic theory describing transport properties of interacting electrons in a uniform magnetic field of arbitrary magnitude. Exposing an electronic system to a constant magnetic field quenches its energy bands into a series of discrete energy levels, known as Landau levels. Following Keldysh formalism, we derive the quantum kinetic equation with the Landau-level basis. The Landau-level states, exact solutions of the Schroedinger equation in a constant background magnetic field, are natural and suitable basis to use, especially, for the investigation of strong-magnetic-field phenomena. In the weak-field limit, the lowest order approximation of the quantum kinetic equation reduces to a Boltzmann equation into which the magnetic field enters as the Lorentz force. As an application of our quantum transport equation, we calculate magneto-thermoelectric coefficients of a disordered two-dimensional electron gas (2DEG) in the quantum hall regime interacting with acoustic phonons.

TT 47.8 Thu 17:00 H31

Typical medium theory for disordered electronic systems on simple lattices with Cauchy distribution of on-site potentials — Andreas Ostlin[1], Hanna Terletska[2], Dylan Jones[1], and •Liviu Chioncel[1,3] — [1]Institute of Physics, University of Augsburg, Augsburg, Germany — [2]Middle Tennessee State University, Murfreesboro, Tennessee, USA — [3]ACIT, University of Augsburg, Augsburg, Germany

Effective medium approaches using single-site averaging procedures of various kinds contributed substantially in understanding the density of states of electronically disordered systems in models and materials. The nature and the conditions for appearance of single-particle (Anderson) localization seems to be qualitatively understood, yet discussions concerning special applied methods and quantitative results for the critical conditions are still ongoing. Here we present results using the typical medium theory for the one-particle and two-particle Green's function (conductivities) for the special case of Cauchy-distribution.

TT 47.9 Thu 17:15 H31

Dynamical current as tool to distinghuish degenerate spin states in open-shell graphene nanoribbons — •Nico Leumer, Thomas Frederiksen, and Geza Giedke — Donostia International Physics Center

The recent advances of surface synthesis unlocked the potential of open-shell physics in graphene nanoribbons (GNRs) which ever since have gained significant attention. Normally chemically unstable, these structures feature unpaired, localized p_z-electrons pinned at zero energy, giving rise to the unique phenomenon of π-magnetism. Intrinsically low spin-orbit/hyperfine interactions suppress spin relaxation, making GNRs ideal for tunable spin physics and spintronics applications. Although scanning probe techniques provide the necessary access to electron's spins and their interactions, state preparation, manipulation and detection remains an open challenge. Our ambition addresses the latter.

At half-filling certain GNRs host quasi degenerate spin singlets/triplets states with a vanishing energy gap for long ribbons. Without significantly increasing the gap, e.g., via magnetic fields, conventional current-based measurements hardly distinguish these spin textures. However, and even for absent gap, we demonstrate that in our setup $I(t)$ discriminates between the responsible states by exploiting the states's distinct spatial profiles. To probe the spatial information, we apply a constant bias between two STM tips. The scheme is suitable for single shot measurements and a quantum master equation (Hubbard model) accounts for the time evolution (GNR).

TT 47.10 Thu 17:30 H31

Josephson force in a vibrating carbon nanotube Josephson junction — •Andreas K. Hüttel[1,2], Jukka-Pekka Kaikkonen[2], Keijo Korhonen[2], and Pertti Hakonen[2] — [1]Institute for Experimental and Applied Physics, Universität Regensburg, Regensburg, Germany — [2]Low Temperature Laboratory, Dept. of Applied Physics, Aalto University, Espoo, Finland

A single carbon nanotube suspended between superconducting electrodes acts simultaneously as nanomechanical resonator and as Josephson junction. Its energy-dependent density of states and thus displacement-dependent Josephson energy couple electronics and mechanics. Measurements on such a system display complex behaviour of the vibrational resonance with respect to junction biasing; strikingly, the resonance frequency decreases in a distinct parameter region where the bias is similar in size to the junction switching current.

We numerically solve the coupled differential equation system of the driven (via an ac gate voltage and an ac bias) system for realistic device parameters, using highly parallelized Julia code, and characterize the evolving steady state. Specific attention is given to the effect of the Josephson junction behaviour on the mechanical resonance frequency and the vibration amplitude. In the numerical results, we observe a clear impact of superconductivity on the mechanical response, with a rather counterintuitive dependence on externally tunable parameters.

TT 47.11 Thu 17:45 H31

Tunable nonlinear Duffing response of a driven carbon nanotube nanomechanical resonator — •Akong Loh, Furkan Özyigit, Fabian Stadler, Katrin Burkert, Niklas Hüttner, and Andreas K. Hüttel — Institute for Experimental and Applied Physics, University of Regensburg, 93040 Regensburg, Germany

Extremely lightweight and with very high quality factors, Carbon nanotube nanomechanical resonators have been used as ultrasensitive force, mass, and charge sensors [1-5]. When suspended on source and drain leads and gated, a CNT nanomechanical resonator can also be operated as a quantum dot. The motion of the nanotube is strongly coupled to single electron tunneling, dominating the nonlinear response [1-5]. Control of the strong nonlinear dynamics of a CNT will be useful for engineering mechanical qubits with information stored in the vibrations and mechanical Schrödinger's cat states [3]. Here, we analyze the nonlinear vibrational response of a driven CNT quantum dot, at ~10mK in a dilution refrigerator and with opaque tunnel barriers to minimize dissipation. We demonstrate how the nonlinearity parameters of the coupled system can be controlled via Coulomb blockade and the associated gate voltage, leading to a rich interplay of frequency, damping, and Duffing behavior.

Vibrational instabilities in molecular nanojunctions: A mixed quantum-classical analysis — •Martin Mäck, Samuel Rudge, Riley Preston, and Michael Thoss — Institute of Physics, University of Freiburg

Understanding the current-induced vibrational dynamics in molecular nanojunctions is critical for gaining insight into the stability of such systems. While it is well known that Joule at higher bias voltages plays an important role for the stability of the nanojunction, a different mechanism caused by current-induced nonconservative forces has been reported to cause vibrational instabilities already at much lower voltages [1].

In this contribution, we apply a mixed quantum-classical approach based on electronic friction and Langevin dynamics [2,3] to a model system for which vibrational instabilities have previously been reported. Such a mixed quantum-classical description has the benefit of giving valuable insight into the electronic forces acting on the molecular vibrations. We analyze the possible occurrence of vibrational instabilities and compare our results to previous approaches, which were limited to small amplitude motion of the vibrational degrees of freedom [1].

Invited Talk TT 48.1 Thu 15:00 H32

Optical Conductivity as a Probe for Chiral Majorana Edge Modes — •Lina Johnsen Kamra[1,2,3], Bo Lu[4], Jacob Linder[1], Yukio Tanaka[5], and Naoto Nagaosa[6] — [1]Norwegian University of Science and Technology, Trondheim, Norway — [2]Universidad Autónoma de Madrid, Madrid, Spain — [3]Massachusetts Institute of Technology, Cambridge, USA — [4]Tianjin University, Tianjin, China — [5]Nagoya University, Nagoya, Japan — [6]RIKEN, Saitama, Japan

Recent years have seen considerable progress towards realizing nonabelian particles for topological quantum devices. A prominent example is the chiral Majorana mode at the edge of topological superconductors. It introduces the possibility of using wave packets propagating at high speed as an alternative to the braiding of zero-dimensional Majorana bound states. However, a weak spot in detecting them lies in reliably capturing quantitative measures such as a quantized conductivity. Recent advances in microwave microscopy [1] have opened a promising new avenue for observing distinct qualitative signatures in their optical conductivity [2,3]. These emerge due to the unique dispersion of the Majorana edge mode that allows photons to break up Cooper pairs into propagating Majorana fermions [2]. As a guide to future experiments, we have shown how the local optical conductivity presents distinct and tunable qualitative features that depend on the symmetry of the superconductivity [3].

TT 48.2 Thu 15:30 H32

Interedge backscattering in time-reversal symmetric quantum spin Hall Josephson junctions — •Cajetan Heinz[1], Patrik Recher[1,2], and Fernando Dominguez[1,3] — [1]Technische Universität Braunschweig, D-38106 Braunschweig, Germany — [2]Laboratory for Emerging Nanometrology, D-38106 Braunschweig, Germany — [3]University of Würzburg, D-97074 Würzburg, Germany

Using standard tight-binding methods, we investigate a novel backscattering mechanism taking place on quantum spin Hall N'SNSN' Josephson junctions in the presence of time-reversal symmetry. This extended geometry allows for the interplay between two types of Andreev bound states (ABS): the usual phase-dependent ABS localized at the edges of the central SNS junction *and* phase-independent ABS localized at the edges of the N'S regions. Crucially, the latter arise at discrete energies E_n and mediate a backscattering process between opposite edges on the SNS junction, yielding gap openings when both types of ABS are at resonance. In this scenario, a 4π-periodic ABS decouples from the rest of the spectrum, and thus, it can be probed preventing the emission to the quasicontinuum. Interestingly, this backscattering mechanism introduces a new length scale, determining the ratio between 4π- and 2π-periodic supercurrent contributions and distorts the superconducting quantum interference (SQI) pattern. Finally, to prove the participation of these ABS, we propose to use a magnetic flux to tune E_n to zero, resulting in the selective lifting of the fractional Josephson effect.

TT 48.3 Thu 15:45 H32

Geometric measure of entanglement in systems with poor man's Majorana modes — •Vimalesh Vimal and Jorge Cayao — Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden

The physical realization of minimal Kitaev chains has recently opened an alternative avenue for engineering Majorana physics with interesting applications in quantum computing. Central to these applications is the utilization of the Majorana-like quasiparticles in these systems, known as poor man's Majorana modes, for realizing qubits and highly entangled states. In this work we consider a minimal Kitaev chain hosting poor man's Majorana modes and investigate the generation of maximally entangled quantum states by using an entirely geometric approach [1]. In particular, for pure states, the geometric measure of entanglement is quantified by its distance from the nearest separable state and provides an advantageous approach for quantifying entanglement in multipartite mixed states, in contrast to conventional bipartite measures. We characterize regimes with maximally entangled states, which surprisingly emerge with and without poor man's Majorana modes. We also discuss the generation and control of maximally entangled states by the Josephson effect in a Josephson junction based on minimal Kitaev chains. Our work thus demonstrates the potential of minimal Kitaev chains for applications in quantum information.

TT 48.4 Thu 16:00 H32

Emerging Majorana bound states in superconducting Haldane nanoribbons — •Simone Traverso[1], Niccolò Traverso Ziani[1], Maura Sassetti[1], and Fernando Dominguez[2] — [1]Physics Department, University of Genoa and CNR-SPIN, 16146 Genoa, Italy — [2]Faculty of Physics and Astrophysics and Würzburg-Dresden Cluster of Excellence ct.qmat, University of Würzburg, 97074 Würzburg, Germany

In the rapidly evolving field of quantum technologies, topological superconductors are promising platforms for topologically protected quantum computation. In this context, manipulating Majorana bound states (MBSs) would be a significant breakthrough.

We introduce a novel approach to designing MBSs, based on the geometric confinement of 2D nodal topological superconductors. We illustrate this mechanism in a superconducting extension of the Haldane model. In 2D, the model displays a nodal topological superconducting phase with chiral Majorana modes. However, by confining one of the dimensions the bulk bands gap out faster than the edge states, allowing for their hybridization and potentially resulting in Majorana zero modes. We assess their emergence by computing the topogical invariant for the quasi-1D setup and inspecting the energy spectrum of open flakes. Their topological nature is confirmed by the zero bias conductance in a normal-superconducting junction, precisely quantized to $2\frac{e^2}{h}$ in presence of an MBS. Our findings indicate quantum confinement as a crucial ingredient for developing quasi-1D topological superconducting phases starting from 2D nodal topological superconductors.

TT 48.5 Thu 16:15 H32

Absence of gapless Majorana edge modes in few-leg bosonic flux ladders — •Felix A. Palm[1,2], Cécile Repellin[3], Nathan Goldman[2,4], and Fabian Grusdt[1] — [1]LMU Munich & MCQST, Munich, Germany — [2]Université Libre de Bruxelles, Brussels, Belgium — [3]Université Grenoble-Alpes, Grenoble, France — [4]Laboratoire Kastler Brossel, Collège de France, Paris, France

Non-Abelian phases of matter, such as certain fractional quantum Hall states, are a promising framework to realize exotic Majorana fermions. Quantum simulators provide unprecedented controllability and versatility to investigate such states, and developing experimentally feasible schemes to realize and identify them is of immediate relevance. Motivated by recent experiments, we consider bosons on coupled chains, subjected to a magnetic flux and experiencing Hubbard repulsion. At magnetic filling factor $\nu = 1$, similar systems on cylinders have been found to host the non-Abelian Moore-Read Pfaffian state in the bulk.

Here, we address the question whether more realistic few-leg ladders can host this exotic state and its chiral Majorana edge states. We perform extensive DMRG simulations and determine the central charge of the ground state. While we do not find any evidence of gapless Majorana edge modes in systems of up to six legs, exact diagonalization of small systems reveals evidence for the Pfaffian state in the entanglement structure. By systematically varying the number of legs and monitoring the appearance and disappearance of this signal, our work highlights the importance of finite-size effects for the realization of exotic states in experimentally realistic systems.

Magnetotransport of the Radial Rashba Spin-Orbit Coupling in Proximitized Graphene — •Wun-Hao Kang[1,2], Ming-Hao Liu[1,2], and Denis Kochan[2,3] — [1]Department of Physics, National Cheng Kung University, Tainan 70101, Taiwan — [2]Center for Quantum Frontiers of Research and Technology (QFort), National Cheng Kung University, Tainan 70101, Taiwan — [3]Institute of Physics, Slovak Academy of Sciences, 84511 Bratislava, Slovakia

Graphene-based van der Waals heterostructures take advantage of tailoring spin-orbit coupling (SOC) in the graphene layer by the proximity effect. The proximity effect can be effectively modeled by the tight-binding Hamiltonian involving novel SOC terms[1] and allows for an admixture of the tangential and radial spin-textures[2]. Taking such effective models we perform realistic large-scale magnetotransport calculations–transverse magnetic focusing–and show that there are unique qualitative and quantitative features allowing for an unbiased experimental disentanglement of the conventional Rashba SOC from its novel radial counterpart, called here the radial Rashba SOC. Along with that, we propose a scheme for a direct estimation of the Rashba angle by exploring the magneto response symmetries when swapping an in-plane magnetic field[3].

Nonequilibrium Spin Transport in Graphene Proximitized by WSe_2 — •Ming-Hao Liu — Department of Physics, National Cheng Kung University, Tainan 70101, Taiwan

Spin-orbit coupling (SOC) in graphene is known to be negligibly weak, on the order of 0.1 meV, due to its composed atom, carbon, a light element of atomic number only 6. A decade ago, it was found that the SOC in graphene can be significantly enhanced simply by attaching it to a transition metal dichalcogenide of strong SOC, known as the spin-orbit proximity effect. Our recent theoretical work in collaboration with a transport experiment on graphene proximitized by WSe_2 reported a supporting number for the SOC as strong as 12.6 meV [1]. Inspired by this finding, here I present numerical results on nonequilibrium spin Hall accumulation in graphene/WSe_2 heterostructures based on the Landauer-Keldysh formalism [2]. Combined with the recently discussed radial Rashba SOC [3], nonequilibrium spin precession will be shown, paving an alternative way to realize the Datta-Das spin transistor.

TT 49.3 Thu 15:30 H33

Resistively Detected Electron Spin Resonance and g Factor in Few-Layer Exfoliated MoS_2 Devices — •Chithra H. Sharma[1,2], Appanna Parvangada[2], Lars Tiemann[2], Kai Rossnagel[1,3], Jens Martin[4], and Robert H. Blick[2,5] — [1]Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany — [2]Universität Hamburg, Luruper Chaussee 149, 22761 Hamburg, Germany — [3]Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany — [4]Leibniz Institut für Kristallzüchtung, 12489 Berlin, Germany — [5]University of Wisconsin-Madison, University Ave. 1550, Madison, 53706, Wisconsin, USA

MoS_2 has recently emerged as a promising material for enabling quantum devices and spintronic applications. In this context, the demonstration of resistively detected electron spin resonance (RD-ESR) and the determination and improved physical understanding of the g factor are of great importance. However, its application and RD-ESR studies have been limited so far by Schotttky or high-resistance contacts to MoS_2. Here, we exploit naturally n-doped few-layer MoS_2 devices with ohmic tin (Sn) contacts that allow the electrical study of spin phenomena. Resonant excitation of electron spins and resistive detection is a possible path to exploit the spin effects in MoS_2 devices. Using RD-ESR, we determine the g factor of few-layer MoS_2 to be ≈1.92 and observe that the g factor value is independent of the charge carrier density within the limits of our measurements.

TT 49.4 Thu 15:45 H33

Unifying Recent Experiments on Spin-Valley Locking in TMDC Quantum Dots — Aakash Shandilya[1], Sundeep Kapila[2], Radha Krishnan[3], Bent Weber[3], and •Bhaskaran Muralidharan[2] — [1]Department of Physics, IIT Bombay, Powai, Mumbai-400076, India — [2]Department of Electrical Engineering, IIT Bombay, Powai, Mumbai-400076, India — [3]Division of Physics and Applied Physics, School of Physical and Mathematical Sciences, Nanyang Technological University, Singapore 637371, Singapore

The spin-valley qubit promises significantly enhanced spin-valley lifetimes due to strong coupling of the electrons* spin to their momentum (valley) degrees of freedom. Very recently, few experiments on TMDC quantum dots have, for the first time, shared evidence for spin-valley locking at the few-electron limit. Employing quantum transport theory, we numerically simulate the ground- and excited-state transport spectroscopy signatures of these experiments under diverse conditions through a unified theoretical framework, and reveal the operating conditions, based on intrinsic properties, for spin- valley locking. We thus provide a method to experimentally deduce the degree of spin-valley locking based on the SOC strength, inter-valley mixing, and the spin and valley g-factors. Our theoretical analysis provides an important milestone towards the next challenge of experimentally confirming valley-relaxation times using single-shot projective measurements.

TT 49.5 Thu 16:00 H33

Estimation of Relaxation Parameters of Spin-Valley Qubits Via Readout Simulations — •Sundeep Kapila, Aparajita Modak, and Bhaskaran Muralidharan — Department of Electrical Engineering, IIT Bombay, Powai, Mumbai-400076, India

Two dimensional (2D)-material quantum dot systems, can host multiple qubit possibilities, namely, spin, valley and the spin-valley qubits. The spin-valley qubit, often referred to as the Kramers qubit, is of special interest due to the possibility of long relaxation and coherence times. Experimentally, such long relaxation times (T_1) have been demonstrated in the bilayer graphene (BLG) platform via Elzerman single-shot readout techniques [1-3]. However, there is a lack of comprehensive synergy in explaining the experimental trends in the relaxation times of different types of qubit possibilities, especially at low magnetic fields [1-3]. Here, we present a detailed master equation-based simulation approach to mimic the Elzerman readout schemes to understand the experimental data presented and to characterize the relaxation processes. Our approach allows us to directly extract from the experimental data, the relaxation rates for individual decay processes. We then extend our analysis to unify various experimental data observed across varying conditions in the BLG platform [1-3]. Our analysis backed up by dedicated machine learning algorithms also enables the extension of the model to qubit systems in the transition metal dichalcogenide platform.

TT 49.6 Thu 16:15 H33

Quantum transport in graphene-based Chern mosaics — •Patrick Wittig[1], Fernando Dominguez[1,2], and Patrik Recher[1,3] — [1]Institute of Mathematical Physics, TU Braunschweig, 38106 Braunschweig, Germany — [2]Faculty of Physics and Astrophysics and Würzburg-Dresden Cluster of Excellence ct.qmat, University of Würzburg, 97074 Würzburg, Germany — [3]Laboratory of Emerging Nanometrology, 38106 Braunschweig, Germany

Chern mosaics [1] are systems composed of domains with different Chern numbers within the bulk of the material. Here, the difference in the Chern number between neighboring domains leads to the emergence of chiral boundary modes that propagate along their interface. In our research, we construct a phenomenological scattering network theory based on the symmetries of the system to model the propagation of these chiral modes in triangular and kagome lattice structures, which can arise in graphene-based systems with characteristic valley-chiral edge modes. In particular, we investigate effects such as energy-dependent scattering [2] and spin-orbit coupling [3] within these networks to analyze the spectrum and transport properties.

TT 49.7 Thu 16:30 H33

Effects of relaxation in deformed graphene structures — Jan Verlage[1], Thomas Stegmann[2], and •Nikodem Szpak[1] — [1]Fakultät für Physik, Universität Duisburg-Essen, Duisburg, Germany — [2]Instituto de Ciencias Físicas, Universidad Nacional Autónoma de México, Cuernavaca, Mexico

It is known that locally deformed graphene creates strong pseudomagnetic fields (of over 100 T) giving rise to Landau levels and being crucial elements of various valleytronic devices. However, taking into account the atomic relaxation of such structures may lead to reduction and regularization of the strain. Here, we revise these effects in various previously studied setups, including membranes and bumps. Our numerical simulations indicate that the atomic relaxation induces a reduction of the pseudomagnetic field by a factor of $5 \div 10$. It may have several consequences for applications.

TT 49.8 Thu 17:00 H33

Landau level mixing in moderately disordered graphene junctions — •Yu-Ting Hsiao and Ming-Hao Liu — Department of Physics,National Cheng Kung University,Tainan 70101,Taiwan

Landau levels are quantized eigenenergy levels in two-dimensional (2D) systems in the presence of an applied perpendicular magnetic field. They are the basic origin of the (integer) quantum Hall effect (QHE). To observe the QHE, i.e., electrical conductance quantized into a sequence of an integer multiple of the universal conductance quantum $\nu * \frac{e^2}{h}$, the sample quality and the strength of the magnetic field typically play the most decisive roles. The cleaner the sample, the weaker the magnetic field required to form the Landau levels. Collaborating with the experiment group led by Prof. Wei Yang from the Institute of Physics(CAS), China, who observed phase shifts of quantized conductance plateaus in ultra-clean two-terminal, single-gated graphene devices. From our quantum transport simulations with a systematic tuning of different parameters that could influence the conductance behavior of the graphene device, we found that the experimentally observed phase shift shall arise from the mixing of Landau levels across two neighboring regions with slightly different doping concentrations. Interestingly, we found that the Landau level mixing occurs only when the graphene sample is moderately disordered. In the purely ballistic regime or under strong disorder, the Landau levels mixing fails to form. Our finding reveals a counter-intuitive role played by disorder, possibly also required in other fundamental transport phenomena, such as the Shubnikov-de Haas oscillation.

TT 49.9 Thu 17:15 H33

Dirac meets flat bands: Topological Mottness swap over through hybridization control — Siheon Ryee[1], •Niklas Witt[2,1,3], Lennart Klebl[2,1], Jennifer Cano[4,5], Giorgio Sangiovanni[2], and Tim Wehling[1,3] — [1]Universität Hamburg — [2]JMU Würzburg — [3]Hamburg Centre for Ultrafast Imaging — [4]Stony Brook University — [5]CCQ

Graphene-based multilayer systems provide a versatile platform to explore the interplay between correlation physics and topology. These systems' unique electronic properties arise from their low-energy bands, characterized by significant Berry curvature originating from graphene's Dirac bands, which is believed to play a crucial role in stabilizing emergent correlated states such as superconducting order and various pseudomagnetic states. In this work, we investigate single-site functionalized graphene, where the Dirac bands hybridize with a correlated flat band of localized orbitals. Our findings based on dynamical mean-field theory (DMFT) calculations reveal a hybridization-driven transition between two symmetry-distinct Mott insulators with a protected metallic state emerging in between. Density functional theory (DFT) calculations suggest that the topological transition observed in our model system is achievable in real materials, specifically through the proximity coupling of epitaxial graphene on SiC with group IV intercalants. Unlike phenomena in other correlated graphene-based platforms, such as twisted bilayer graphene and rhombohedral graphene multilayers, the topology-enforced Mottness swap over occurs at a much higher energy scale of electron-volts.

TT 49.10 Thu 17:30 H33

Magnetism in monolayer graphene near 1/4 doping — •Maxime Lucas, Andreas Honecker, and Guy Trambly de Laissardière — Laboratoire de Physique Théorique et Modélisation, CY Cergy Paris Université / CNRS, France

Recent studies of twisted bilayer graphene (or other 2D materials) have been stimulated by the discovery of correlations between electronic flat-band states due to a moiré pattern [1]. It is shown experimentally and theoretically that the filling of the flat bands affects their magnetic properties significantly. On the other hand, the effect of doping on a simple graphene layer is still unclear. Indeed, its half-filled case is well known [2], but unlike other lattices [3] its magnetic properties beyond half filling are mostly unexplored, except at 1/4 doping [4]. Here, we present our analysis of graphene magnetism using a combination of the Hubbard model and Hartree-Fock mean-field theory. We work at density values around 1/4 doping (average number of electron per site N_e=0.75) as it puts the system right into one of the Van Hove singularities found in graphene's density of states, giving rise to interesting magnetic properties. We present an interaction-density phase diagram and its associated magnetic orders, described by their band structure and spin structure factor.

TT 49.11 Thu 17:45 H33

Electronic transport and anti-super-Klein tunneling in few-layer black phosphorus — •Jorge Alfonso Lizarraga Brito[1], Yonatan Bentancur Ocampo[2], and Thomas Stegmann[1] — [1]Instituto de Ciencias Físicas, Universidad Nacional Autónoma de México, Cuernavaca, México — [2]Instituto de Física, Universidad Nacional Autónoma de México, Ciudad de México, México

The electronic transport of few-layer black phosphorus is analyzed theoretically. This work was performed using recent experimental results obtained by μ-ARPES, where tight-binding parameters up to the 4th nearest neighbors within and between the layers were estimated. It is confirmed that the anisotropic band structure of few-layer black phosphorus leads to highly anisotropic transport properties. Most prominently, it is found that the electrons can pass through a potential barrier aligned in a certain crystallographic direction, while for potential barriers rotated by 90 degrees, the transport is completely blocked (anti-super-Klein tunneling). Finally, the study was extended to the case where the top layer of the system is oxidized, showing that the electronic transport is significantly reduced in the oxidized layers, whereas it can be largely unaffected in the central layers.

TT 49.12 Thu 18:00 H33

Pressure-induced structural phase transitions in the van der Waals multiferroic $CuCrP_2S_6$ — •Swarnamayee Mishra[1] and Jochen Geck[1,2] — [1]Institute for Solid State and Materials Physics, TU Dresden, D-01062 Dresden, Germany — [2]Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, D-01062 Dresden, Germany

Two-dimensional (2D) crystals with strong in-plane covalent bonds and weak van der Waals (vdW) interlayer interactions have garnered significant attention following the discovery of graphene and its remarkable properties. $CuCrP_2S_6$ (CCPS) is a promising 2D material exhibiting antiferromagnetic behavior due to the collective ordering of Cr^{3+} spins and antiferroelectric properties driven by Cu+ ion ordering. As a type-I multiferroic, CCPS is particularly notable for its coexistence of antiferroelectricity and antiferromagnetism, coupled with strong polarization-magnetization interactions. These ferroic properties arise from spin-orbit coupling associated with crystal symmetry breaking. Despite its potential, a detailed pressure-dependent crystallographic study of CCPS remains unexplored. In this work, we address this gap using high-pressure single-crystal X-ray diffraction (XRD) to investigate the interplay between structural changes and the material's ferroic behaviors. Our study reveals a phase transition from the low-pressure monoclinic Pc phase to the high-pressure monoclinic C2/c phase at low temperatures, providing new insights into the structure-property relationships of this promising 2D vdW material.

TT 49.13 Thu 18:15 H33

^{31}P NMR studies of quasi-two-dimensional (2D) magnetic correlations in $ACrP_2S_6$ (A = Cu, Ag) — •Saramgi Sivan[1,2], Kizhake Malayil Ranjith[1], Lukas Prager[1,2], Saicharan Aswartham[1], Bernd Büchner[1,2], and Hans-Joachim Grafe[1] — [1]Leibniz IFW Dresden, D-01069 — [2]Institute for Solid State and Materials Physics, TU Dresden, D-01062

The $AA'P_2S_6$ (A, A' = transition metal ions) family of quasi-2D van der Waals materials has proven to be a model system for low-dimensional magnetism. Here we present detailed ^{31}P NMR measurements on the single crystals of $ACrP_2S_6$. The high-temperature single narrow NMR line shows a splitting at about 160 K for $CuCrP_2S_6$, which is attributed to the antiferroelectric (AFE) transition, while a pake-doublet NMR spectrum is observed for $AgCrP_2S_6$ at room temperature, but no AFE transition at lower temperatures. In $CuCrP_2S_6$, we observed further line splitting below 30 K, reflecting the antiferromagnetic (AFM) order. At T_N = 30 K, the NMR spin-lattice relaxation rate $T_1^{-1}(T)$ in $CuCrP_2S_6$ measured at 2.5 T shows a sharp peak due to the critical fluctuations. The T_N is suppressed towards lower temperatures when measured at higher magnetic fields. The $(T_1T)^{-1}(T)$ measured at 7 T shows a broad maximum at about 60 K and a critical enhancement at T_N. On the other hand, $AgCrP_2S_6$ exhibits in-plane AFM order at 20 K, as evidenced by the clear splitting of the NMR spectra, the divergence of $T_1^{-1}(T)$ at T_N, and a broad maximum in the NMR Knight shift. In contrast to $CuCrP_2S_6$, the $(T_1T)^{-1}(T)$ shows only a critical enhancement around T_N without a broad anomaly.

TT 50: Superconducting Electronics: SQUIDs, Qubits, Circuit QED II

Time: Thursday 15:00–18:30 Location: H36

TT 50.1 Thu 15:00 H36

Development of ultrasensitive dc SQUIDs with sub-micrometric circuit elements — •Mauro Esattore[1], Michael Paulsen[2], Jörn Beyer[2], Oliver Kieler[1], Mark Bieler[1], Patryk Krzysteczko[2], and Rainer Körber[2] — [1]Physikalisch-Technische Bundesanstalt, Bundesallee 100, 38116 Braunschweig, Germany — [2]Physikalisch-Technische Bundesanstalt, Abbestraße 2-10, 10587 Berlin, Germany

The dc SQUID is one of the most established applications of superconductor technology. Their sensitivity to magnetic flux allows for numerous applications, such as low-temperature thermometry or current sensing for electrical metrology. In this contribution, we present superconducting "fine-pitch" input coils with sub-micrometric parameters to be integrated into existing Nb/Al-AlO_x/Nb-based SQUID sensor designs. The aim is to reduce inductive losses of the signal-to-SQUID coupling, without compromising the overall device layout. In a SQUID current sensor, to maximize the inductive coupling constant k between the signal input coil and the SQUID loop means to achieve a low coupled energy sensitivity $\epsilon_c = (1/k^2)\times\epsilon$ - where ϵ is the SQUID-intrinsic energy sensitivity. Fine-pitch input coils will increase k, as well as extend the range of input coil inductances for our existing devices. The energy sensitivity $\epsilon \propto \sqrt{C}$: reduced Josephson junction (JJ) sizes will lower the capacitance C and improve ϵ_c. Thus, we are refining our JJ definition process to obtain JJs with sub-micrometric lateral size. The contribution will provide details on the fabrication process and design aspect of the sensors, as well as characterization results.

TT 50.2 Thu 15:15 H36

Superconducting Pb stripline resonators: Role of coupling and applications in spectroscopy — Elies Ben Achour, Cenk Beydeda, Gabriele Untereiner, Martin Dressel, and •Marc Scheffler — 1. Physikalisches Institut, Universität Stuttgart, Stuttgart, Germany

Planar superconducting microwave resonators play an important role for various research directions in solid state physics and quantum technologies. Here we investigate superconducting lead (Pb) stripline resonators, which we probe at various harmonics between 0.7 GHz and 6 GHz and at temperatures between 1.5 K and 7 K.

We discuss on general grounds how the loaded quality factor Q_L of a planar microwave resonator made of a conventional superconductor should depend on temperature and frequency. We consider contributions due to dissipation by thermal quasiparticles Q_{QP}, due to residual dissipation Q_{Res}, and due to coupling Q_C. We focus on the role of coupling, and we compare resonators with different coupling capacitance. For the Pb resonators, we find a strongly frequency- and temperature-dependent Q_L, which we can describe by a lumped element model. For certain resonators at the lowest studied temperatures we observe a maximum in the frequency-dependent Q_L when Q_{Res} and Q_C match, and here the measured Q_L can exceed 2×10^5.

We also present the application of such Pb stripline resonators for microwave spectroscopy at temperatures down to the mK range.

TT 50.3 Thu 15:30 H36

Hybrid Microwave Resonators Integrated with van der Waals Superconductors — •Yejin Lee[1], Haolin Jin[1,2], Giuseppe Serpico[1,3], Tommaso Confalone[2,4], Berit Goodge[1], Edouard Lesne[1], Kornelius Nielsch[2,4], Nicola Poccia[3,4], and Uri Vool[1] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]Technische Universität Dresden, Germany — [3]University of Naples Federico II, Italy — [4]Leibniz Institute for Solid State and Materials Science Dresden, Germany

Superconducting microwave resonators are highly coherent devices that are extensively used in quantum circuits. Their robustness and sensitivity also make them excellent probes for exploring novel materials, which are coupled to them in a hybrid system. Particularly good candidates are van der Waals materials, whose microscopic size makes them incompatible with conventional bulk measurement methods. However, such hybrid platforms require the development of a new process to maintain the high quality of the circuit. We present a technique to integrate a microwave resonator with a superconducting thin van der Waals flake with a crystalline-preserved interface. We investigate their microwave response as a function of temperature under various microwave powers and magnetic field. The hybrid resonator exhibits a significant modification in its resonant mode with the presence of the flake while maintaining a high-quality factor. Hybrid superconducting circuits integrated with vdW crystals offer an extensive potential in probing materials' unique properties and for developing high-quality devices for quantum technology.

TT 50.4 Thu 15:45 H36

Two-level system involved nonlinear response in van der Waals hybrid microwave resonators — •Haolin Jin[1,3], Giuseppe Serpico[1,2], Yejin Lee[1], Berit Goodge[1], Edouard Lesne[1], Nicola Poccia[2,3], and Uri Vool[1] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]University of Naples Federico II, Italy — [3]Leibniz Institute for Solid State and Materials Science Dresden, Germany

Two-level system (TLS) bath is considered as the main loss channel in coplanar superconducting microwave resonators and is often associated with an upshift in resonance frequency as the temperature increases. The individual TLS can be saturated at the high input power, improving the quality factor of the resonator. However, the resonance frequency upshift remains unaffected by driving power because all TLS at different energy can contribute to the frequency shift, whereas only those close to the resonance frequency can be saturated. Here, we observed a positive nonlinearity in a van der Waals superconductor integrated hybrid resonator device. The hybrid device exhibited a significant upshift in resonance frequency with increasing temperature, indicating strong coupling to a TLS bath. It maintained a high-quality factor despite this coupling. These findings suggest that the resonance mode in the hybrid device is coupled to an off-resonant TLS bath and the hybrid system provides a new source of lossless nonlinearity unrelated to the Josephson effect. This work opens a path towards high quality hybrid superconducting circuits with vdW materials and highlights the development of new devices for quantum technology.

TT 50.5 Thu 16:00 H36

Dielectric waveguide setup tested with a superconducting millimeter-wave Fabry-Pérot interferometer at milli-Kelvin temperatures — •Jakob Lenschen[1], Hannes Rotzinger[1,2], and Alexey V. Ustinov[1,2] — [1]Physikalisches Institut (PHI), Karlsruher Institut für Technologie — [2]Institut für Quantenmaterialien und Technologie (IQMT), Karlsruher Institut für Technologie, 76131 Karlsruhe, Germany

Superconducting quantum circuits operating at mm-wave frequencies of around 100 GHz may offer many interesting new possibilities. The order of magnitude higher photon energy compared to current implementations and the wider bandwidth would not only improve the resilience to thermal fluctuations, but could also speed up qubit manipulation. Millimeter-wave measurements at ultra-low temperatures are largely unexplored due to several technical difficulties, such as a difficult signal path isolation and thermalization. We have developed a cryogenic setup consisting of dielectric waveguides and a superconducting Fabry-Pérot cavity located at the dilution cryostat base temperature. We show that the quality of the mm-wave signal guided to and from a temperature of 10 mK is sufficient to measure resonator cavity quality factors of over one million at 110 GHz in the few photon limit.

TT 50.6 Thu 16:15 H36

Resonant escape in Josephson tunnel junctions under millimeter-wave irradiation — •Jonas N. Kämmerer[1], Sergei Masis[1], Karo Hambardzumyan[1], Philipp Lenhard[1], Urs Strobel[1], Jürgen Lisenfeld[1], Hannes Rotzinger[1,2], and Alexey V. Ustinov[1,2] — [1]Physikalisches Institut (PHI), Karlsruher Institut für Technologie, 76131 Karlsruhe, Germany — [2]Institut für QuantenMaterialien und Technologien (IQMT), Karlsruher Institut für Technologie, 76131 Karlsruhe, Germany

Operating superconducting quantum circuits at mm-wave frequencies around 100 GHz promises several advantages. For example, it may allow for much higher operating temperatures above 1 K and faster qubit manipulation. We study the microwave-driven dynamics of a superconducting phase qubit made of Nb/AlO_x/Nb junction. In particular, we have measured the switching current distributions at radiation frequencies above 100 GHz and observed clear double-peak structures. The data indicate a resonant escape of the phase as well as an irradiation-induced suppression of the potential barrier. This behavior is well described by the strong-driving model of the resonant escape[1]. While being measured in the quasi-classical regime of thermally activated escape, our results point towards a feasibility of operating phase qubits at mm-wave frequencies.

TT 50.7 Thu 16:45 H36

Heat transport in the quantum Rabi model: Universality and ultrastrong coupling effects — Luca Magazzu[1], Elisabetta Paladino[2,3], and •Milena Grifoni[1] — [1]University of Regensburg — [2]Università di Catania, Italy — [3]INFN, Sez. Catania, Italy

Heat transport in a qubit-oscillator junction weakly coupled to heat baths displays a rich variety of effects depending on the junction parameters. Signatures of

the transition to the regime of ultrastrong qubit-oscillator coupling appear in the thermal conductance, current, and rectification. For example, upon increasing the coupling, the conductance as a function of a bias applied to the qubit undergoes a transition from a resonant to a broadened, zero-bias peak behavior. At low temperatures, coherent heat transfer via virtual processes yields a universal power-law behavior in the linear conductance as a function of the temperature. In addition, the low-temperature conductance is modulated by a prefactor which unravels the multilevel nature of the junction: A coherent suppression arises in the presence of quasi-degeneracies in the spectrum. At higher temperatures, sequential processes dominate heat transfer and a scaling regime is found when quantities are scaled with a coupling-dependent Kondo-like temperature.

TT 50.8 Thu 17:00 H36

Gauging away the ground-state photon content of the quantum Rabi model — •Arka Dutta, Daniel Braak, and Marcus Kollar — Theoretische Physik III, University of Augsburg

The quantum Rabi model (QRM) features the simplest type of coupling between a single cavity light mode and an atomic electron. It is integrable if the electronic degree of freedom is truncated to just two states [1]. The derivation of the effective Hamiltonian leads to different forms depending on the chosen gauge [2]. In the dipole gauge, the ground state of the QRM exhibits non-zero photon number in contrast to its weak coupling approximation, the Jaynes-Cummings model. We compute the exact photon content for all eigenstates in an arbitrary gauge and obtain a gauge for which the ground state contains no photons. Thus only this gauge fits the intuitive understanding that the cavity should be empty in the lowest energy state even for strong light-matter interaction.

TT 50.9 Thu 17:15 H36

Dispersive and dissipative interactions in niobium-based photon-pressure circuits — •Zisu Emily Guo, Mohamad el Kazouini, Janis Peter, Kevin Uhl, Dieter Koelle, Reinhold Kleiner, and Daniel Bothner — Physikalisches Institut, Center for Quantum Science (CQ) and LISA$^+$, Universität Tübingen

Photon-pressure (PP) circuits consist of one superconducting microwave resonator in the GHz range and one low-frequency (LF) circuit in the MHz range and are the cQED analog of cavity optomechanics. The LC circuits in a PP device are coupled to each other via a superconducting quantum interference device (SQUID), emulating an optomechanical interaction and offering access to sensing and control of MHz photons with potential applications in axion dark matter detection and quantum information technologies. Here, we report the realization of niobium- and nanoconstriction-based photon-pressure circuits operated in the thermal regime. In contrast to previous implementations, we observe in our experiments both dispersive and dissipative PP coupling - meaning that not only frequency but also linewidth modulations contribute significantly to the overall interaction. We investigate dynamical backaction effects with these dissipative contributions as well as sideband-cooling of the LF mode, measured through photon-pressure-induced transparency and output noise thermometry, respectively. Additionally, our circuit design with on-chip flux-bias line allows the parametric modulation of the LF mode resonance frequency, which may be used for LF squeezing and (phase-sensitive) amplification of the PP coupling rate.

Exact and Dispersive Models for Superconducting Networks — •Adrian Parra-Rodriguez — Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany — Institute of Fundamental Physics IFF-CSIC, Calle Serrano 113b, 28006 Madrid, Spain — Institut Quantique and Département de Physique, Université de Sherbrooke, Sherbrooke, Quebec J1K 2R1, Canada

In this presentation, I will address the construction of exact quantum mechanical models for quasi-lumped electrical networks [1,2], comprising (nonlinear) capacitors, inductors, nonreciprocal elements (circulators), and transmission lines (TLs). Traditional quantization methods, such as node-flux or loop-charge approaches, often lead to singularities and unphysical predictions, stemming from incorrect identification of the TLs' infinite-dimensional Hilbert space. Using a geometrical description [1] and the Faddeev-Jackiw method, we resolve these issues via a mixed charge-flux first-order quantization. I will also introduce a systematic method to construct effective dispersive Lindblad master equations for weakly anharmonic superconducting circuits coupled by generic linear nonreciprocal systems, deriving coupling parameters and decay rates from the coupler's immittance parameters [3]. Extending the work of Solgun et al. (2019) on reciprocal couplers, this approach includes nonreciprocal elements, stray coupling, and collective dissipative effects from external environments, while avoiding potential singularities.

TT 50.11 Thu 17:45 H36

Nonlinear High-Kinetic-Inductance Microstrips for Integrated Non-Reciprocal Devices — •Niklas Gaiser[1], Ciprian Padurariu[1], Björn Kubala[1,2], Nadav Katz[3], and Joachim Ankerhold[1] — [1]ICQ and IQST, University of Ulm, Ulm, Germany — [2]Institute of Quantum Technologies, German Aerospace Center (DLR), Ulm, Germany — [3]The Racah Institute of Physics, The Hebrew University of Jerusalem, Israel

Superconducting microwave circuits offer a rich platform for many quantum information devices and quantum-technological applications. Recently, nonlinear properties of circuit elements have become of increasing interest as they allow new functionalities, such as frequency mixing or self-interaction of waves. Microstrip waveguides with high-kinetic-inductance, as experimentally realized in [1], possess strong nonlinear features. Moreover, they yield a greatly reduced phase velocity which addresses the challenge of long wavelengths in the microwave regime and enable highly compact and integrated on-chip solutions.

Here, we present a theoretical proposal for a devices that utilizes a nonlinear high-kinetic-inductance to achieve a non-reciprocal effect. Diode-like behaviour is proven with markedly dissimilar transmission spectra for signals propagating through the device in different directions. We discuss the nonlinearities' power dependence as well as the special boundary conditions posed by the nonlinear propagation problem.

TT 50.12 Thu 18:00 H36

Observation and Modelling of Self-Sustained Oscillations in Non-Linear Cavity-Optomechanics — •Korbinian Rubenbauer[1,2], Shivangi Dhiman[4], Thomas Luschmann[1,2], Achim Marx[1,2], Rudolf Gross[1,2,3], Anja Metelmann[4,5], and Hans Huebl[1,2,3] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]School of Natural Sciences, Technical University of Munich, Garching, Germany — [3]Munich Center for Quantum Science and Technology, Munich, Germany — [4]Institute for Theory of Condensed Matter and Institute for Quantum Materials and Technology, Karlsruhe Institute of Technology, Karlsruhe, Germany — [5]Institut de Science et d'Ingénierie Supramoléculaires, University of Strasbourg and CNRS

Quantum sensing uses quantum elements or quantum principles to detect an external stimulus. In this context, cavity-electromechanics focuses on mechanical sensor elements dispersively coupled to a microwave resonator. This setting typically uses linear mechanical elements and linear microwave cavities. Here, we discuss the case of a non-linear or Kerr microwave resonator as a readout circuit. Our device integrates a mechanically compliant nanostring into a superconducting quantum interference device (SQUID), which is part of a flux-tunable superconducting resonator. This enables large tunable single-photon optomechanical coupling. We present an experimental and theoretical study investigating the impact of the Kerr nonlinearity on the device performance, particularly in the context of mechanical instabilities. We find excellent quantitative agreement.

TT 50.13 Thu 18:15 H36

Engineering Cooper Pair Bunching Using an Anharmonic Environment — •Surangana Sengupta[1], Björn Kubala[1,2], Joachim Ankerhold[1], and Ciprian Padurariu[1] — [1]ICQ and IQST,Ulm University,Germany — [2]Institute of Quantum Technologies, German Aerospace Center (DLR), Ulm, Germany

The electromagnetic environment of superconducting circuits provides exciting opportunities to engineer the tunneling of Cooper pairs. The simplest example is a dc biased Josephson junction in series with a microwave cavity. There has been extensive work showing that when the dc bias is chosen to be resonant with a well-defined cavity mode, the transport of Cooper pairs has the same statistics in the long time limit as that of the photon emission from the cavity mode [1].

In my talk, I extend this study to the case when the cavity mode is anharmonic. I investigate the case when the voltage bias is detuned from the transition between Fock states 0 and 1. Due to the anharmonicity however, this voltage can be resonant with half the transition between Fock states 0 and 2. Therefore, the process of coherent two-Cooper pair tunneling accompanied by two-photon creation is favored compared to single Cooper pair tunneling and single photon creation. This results in bunched Cooper pair tunneling, with Fano factor approaching $F = 2$, and in a squeezed cavity state. I will compare this effect to a similar and competing inelastic co-tunneling process arising from second-order rotating wave approximation.

TT 51: Topological Superconductors

Time: Thursday 16:45–18:15 Location: H32

TT 51.1 Thu 16:45 H32

Disentangling the Individual Junctions in Multi-Terminal Devices — •Josua Thieme[1,2], Nisha Shahi[1], Abdur Rehman Jalil[1], Benedikt Frohn[1], Detlev Grützmacher[1,2], and Peter Schüffelgen[1] — [1]Forschungszentrum Jülich, Germany — [2]RWTH Aachen, Germany

One avenue towards building a topological qubit, is by creating and manipulating Majorana zero modes in a hybrid device made from s-wave superconductors and 3D topological insulators (TIs). Such hybrid multi-terminal devices possess an increased number of interfaces and the coupling between all electrodes needs to be assured. We present low-temperature measurements of a TI-based three-terminal Josephson device fabricated by a combination of selective-are growth of $(BiSb)_2Te_3$ and shadow evaporation of Nb. This approach allows for the in-situ fabrication of Josephson devices with an exceptional interface quality, which is important for obtaining a strong proximity effect. In our measurements, we find quartet resonances, formed by two entangled Cooper pairs. Additionally, we present a method on how to disentangle the contributions of individual junctions in a multi-terminal device.

TT 51.2 Thu 17:00 H32

Non-Hermitian Topology in Multi-Terminal Superconducting Junctions — •Valentin Wilhelm, David Christian Ohnmacht, Hannes Weisbrich, and Wolfgang Belzig — Universität Konstanz, Konstanz, Germany

Recent experimental advancements in dissipation control have yielded significant insights into nonhermitian Hamiltonians for open quantum systems. Of particular interest are the topological characteristics exhibited by these non-hermitian systems, that arise from exceptional points–distinct degeneracies unique to such systems. In this study, we focus on Andreev bound states in multiterminal Josephson junctions with non-hermiticity induced by normal metal or ferromagnetic leads [1]. By investigating several systems of different synthetic dimensions and symmetries, we predict fragile and stable non-hermitian topological phases in these engineered superconducting systems.

TT 51.3 Thu 17:15 H32

Localized Edge States in Antiferromagnet-Superconductor Hybrid Structures — •Ignacio Sardinero[1,2], Yuriko Baba[1,2], Rubén Seoane-Souto[3], and Pablo Burset[1,2,4] — [1]Department of Theoretical Condensed Matter Physics, Universidad Autónoma de Madrid, 28049 Madrid, Spain — [2]Condensed Matter Physics Center (IFIMAC), Universidad Autónoma de Madrid, 28049 Madrid, Spain — [3]Instituto de Ciencia de Materiales de Madrid (ICMM-CSIC), Sor Juana Inés de la Cruz, 3, 28049 Madrid, Spain — [4]Instituto Nicolás Cabrera, Universidad Autónoma de Madrid, 28049 Madrid, Spain

Topological superconductors (TSCs) are promising building blocks for robust and reliable quantum information processing [1]. Most approaches to implement TSCs focus on materials with intrinsic spin-orbit coupling (SOC). However, a recent alternative strategy relies on synthetically engineering spin orbit using spatially varying magnetic fields [2]. Such proximitized structures need to be carefully designed so that the magnetic and superconducting orders coexist, avoiding stray fields detrimental for superconductivity. Here, we circumvent this challenge by investigating the role of antiferromagnetic (AF) textures in proximity to 2-dimensional superconducting surfaces. Our results reveal that the interplay between AF order and the SC coherence length impacts the density of states at the Fermi level. We show that lattice symmetry plays a crucial role for emerging topological phases, with higher-order phases arising when interlayer SOC is considered.

TT 51.4 Thu 17:30 H32

Proximity-Induced Superconductivity into Thin Films of Magnetic Topological Insulators — •Daniele Di Miceli[1,2], Eduárd Zsurka[1,3], and Thomas Schmidt[1] — [1]Department of Physics and Materials Science, University of Luxembourg, L-1511 Luxembourg, Luxembourg — [2]Department of Physics, University of the Balearic Islands, E-07122 Palma, Spain — [3]Peter Grünberg Institute (PGI-9), Forschungszentrum Jülich, D-52425 Jülich, Germany

Inducing superconducting (SC) correlations into magnetic topological insulators (MTIs) is becoming a promising route toward topological superconductivity and the realization of topologically protected Majorana bound states. However, a detailed understanding of the proximity effect in such MTI-SC heterostructures is still missing.

To address this question, we have developed a theory for the SC pairing induced by a conventional BCS superconductor on top of a 3D MTI thin film. By performing a perturbation series expansion in the electron tunneling between the SC and the MTI, we computed the corrections to the normal and anomalous Green's functions in the MTI in terms of the unperturbed propagators in the two isolated materials. Since the latter can be obtained exactly as a solution to the Gor'kov equations, this makes it possible to evaluate the Green's functions in the full MTI-SC heterostructures.

Our results provide a detailed description of the induced pairing, in particular showing the existence of p-wave correlations in the MTI.

TT 51.5 Thu 17:45 H32

Topological Classification of Chiral Symmetric One Dimensional Interfaces — •Harry MullineauxSanders and Bernd Braunecker — University of St. Andrews, St. Andrews, United Kingdom

Low dimensional topological phases can be engineered by placing a scattering interface into a higher dimensional bulk where the in-gap bands of quasi low dimensional interface modes can be tuned to a topologically non-trivial phase. However the classification of such modes cannot be done through low-dimensional conventional methods due to the dimensional mismatch and local nature of the topological bands. We demonstrate that there exists a simple and efficient classification method through the local Green's function at the interface, that sidesteps numerically heavy real space computations. We show that the Green's function maintains the protecting symmetries of the Hamiltonian and produces the correct phase diagram, together with a formula disentangling the contributions to the topological invariant from the substrate and the interface. For illustration we apply our method to a model of a spiral magnetic interface in an s-wave superconductor. Furthermore we compare with an alternative classification scheme derived from the spatially reduced ground state projector and show that it can produce an erroneous topological classification due to gap closures driven by the strong entanglement between the internal and spatial degrees of freedom which are naturally contained in the local Green's function. [arXiv:2407.01223]

TT 51.6 Thu 18:00 H32

Role of Spin-Orbit Coupling on Topological Superconductivity from First Principles — •András Lászlóffy[1], Bendegúz Nyári[2], Levente Rózsa[1], László Szunyogh[2], and Balázs Újfalussy[1] — [1]HUN-REN Wigner Research Centre for Physics, Budapest, Hungary — [2]Budapest University of Technology and Economics, Budapest, Hungary

Recent developments on magnetic structures on superconductors paved the way to explore topological phases in real materials [1,2]. This was achieved by solving the Kohn-Sham-Dirac Bogoliubov-de Gennes equations within the Korringa-Kohn-Rostoker multiple scattering theory. By investigating 1D magnetic chains on superconductors we demonstrate that the spin-orbit coupling plays a key role in the formation of a topological phase, however, it is challenging to scale it up, because SOC is implicitly included in the Dirac equation. To circumvent this, we calculate the superconducting order parameter and the Shiba band structure of magnetic chains on a Ta overlayer on Nb. Ta has a very similar crystal structure and lattice constant to Nb. It is also a superconductor with a much smaller gap size and a considerably larger SOC. With varying the Ta layer thickness SOC can be tuned in a way which is in principle reproducible in experiments. We show that a few layers of Ta has tiny effects on the energy of the Yu-Shiba-Rusinov states of single adatoms, however, varying the SOC can tune the chains into a topologically non-trivial domain.

TT 52: Nickelates and Other Complex Oxides

Time: Friday 9:30–11:15 Location: H31

TT 52.1 Fri 9:30 H31

High-temperature superconductivity and polymorph structures in $La_3Ni_2O_7$ — •Matthias Hepting[1], Pascal Puphal[1], Pascal Reiss[1], Niklas Enderlein[2], Yu-Mi Wu[1], Vignesh Sundaramurthy[1], Peter A. van Aken[1], Hidenori Takagi[1], Bernhard Keimer[1], Y. Eren Suyolcu[1], Björn Wehinger[3], and Philipp Hansmann[2] — [1]Max-Planck-Institute for Solid State Research, Stuttgart, Germany — [2]University of Erlangen-Nürnberg, Erlangen, Germany — [3]ESRF, Grenoble, France

The recent discovery of high-temperature superconductivity in $La_3Ni_2O_7$ under high pressure has drawn considerable interest [1]. Using high-resolution synchrotron x-ray diffraction and scanning transmission electron microscopy, we observed that $La_3Ni_2O_7$ single crystals which show signs of filamentary superconductivity exhibit a crystal structure composed of alternating monolayer (ML) and trilayer (TL) units [2]. This lattice architecture diverges significantly from the previously assumed bilayer configuration [1]. In addition, we employed density functional theory to examine the distinct contributions of the ML and TL structural units to the electronic structure of the $La_3Ni_2O_7$ polymorph. In combination with recent angle resolved photoemission spectroscopy experiments [3], our findings set the stage for future investigations into unique properties of the ML-TL polymorph and the possibility of bulk high-temperature superconductivity.

TT 52.2 Fri 9:45 H31

Theory of potential impurity scattering in pressurized superconducting $La_3Ni_2O_7$ — •Steffen Bötzel[1], Frank Lechermann[1], Takasada Shibauchi[2], and Ilya Eremin[1] — [1]Theoretische Physik III, Fakultät für Physik und Astronomie, Ruhr-Universität Bochum — [2]Department of Advanced Materials Science, The University of Tokyo, Kashiwa, Chiba 277-8561, Japan

We study the effect of the point-like non-magnetic impurities on the superconducting state of La-327 and show that the interlayer $s_{\pm}$-wave and d-wave symmetries show a very different behavior as a function of impurity concentration, which can be studied experimentally by irradiating the La-327 samples by electrons prior applying the pressure. While d−wave superconducting state will be conventionally suppressed, the $s_{\pm}$-wave state shows more subtle behavior, depending on the asymmetry between bonding and antibonding subspaces. For the electronic structure, predicted to realize in La-327, the $s_{\pm}$−wave state will be robust against complete suppression and the transition temperature, T_c demonstrates a transition from convex to concave behavior, indicating a crossover from $s_{\pm}$-wave to s_{++}-wave symmetry as a function of impurity concentration. We further analyze the sensitivity of the obtained results with respect to the potential electronic structure modification.

TT 52.3 Fri 10:00 H31

Surface effects in infinite layer nickelates — •Leonard M. Verhoff[1], Liang Si[1,2], and Karsten Held[1] — [1]Institute of Solid State Physics, TU Wien, Vienna, Austria — [2]School of Physics, Northwest University, Xi'an, China

Nickelates have emerged as a compelling platform for studying high-temperature superconductivity, drawing comparisons to cuprates. Infinite layer rare-earth (R) nickelates, $RNiO_2$, consist of an alternating stacking of NiO_2 layers and rare-earth spacing layers along the crystallographic z-axis. While their bulk structure has been extensively studied computationally, the samples that exhibit superconductivity in experiments are thin nickelate films. They are synthesized through a chemical reduction process that removes apical oxygen from perovskite $RNiO_3$, often grown on substrates such as $SrTiO_3$ (001).

We explore emerging surface effects by studying the formation of various surfaces within the framework of DFT. While perfect stoichiometry favors a NiO_2-terminated surface, the presence of excess apical oxygen in the surface region – possibly a remnant of the chemical reduction process – might favor an RO-terminated surface. The atomic structures of the studied surfaces strongly influence the local electronic structure in the surface region. These surface effects indicate the absence of an electron pocket around the Γ point – even for $NdNiO_2$ surfaces, in contrast to DFT and *dynamical mean field theory* bulk calculations.

We acknowledge support through a joint German and Austrian Science Funds (DFG and FWF) project; IWF project ID I5398.

TT 52.4 Fri 10:15 H31

Uniaxial pressure dependencies of the metal-to-metal transition in $P2_1/a$ and $Bmab$ $La_4Ni_3O_{10}$ single crystals — •Lukas Gries, Jan Arneth, Ning Yuan, Ahmed Elghandour, and Rüdiger Klingeler — Kirchhoff Institut for Physics, Heidelberg, Germany

The $n = 3$ Ruddlesden-Popper nickelate $La_4Ni_3O_{10}$ exhibits an intriguing metal-to-metal transition (MMT) accompanied by the evolution of intertwined charge and spin order [1]. We report report high-resolution capacitance dilatometry and magnetisation data on phase-pure single crystals of $P2_1/a$ and $Bmab$ $La_4Ni_3O_{10}$ grown by the high-pressure floating-zone method [2]. Our data show pronounced magnetoelastic coupling at the MMT for both phases. The extracted uniaxial pressure dependencies are negative for the *ab* plane and positive along the *c* axis. The uniaxial pressure dependencies are quantified and the relevant energy scales are investigated via Grüneisen scaling and Ehrenfest analysis.

[2] N. Yuan, et al., J Cryst. Growth 627, 127511 (2024)

TT 52.5 Fri 10:30 H31

A versatile microscope for simultaneous optical and thermodynamic investigation of $Ca_3Ru_2O_7$ — •Simli Mishra[1], Elena Gati[1], Fei Sun[1], Hilary Noad[1], Dmitry Sokolov[1], Andrew Mackenzie[1,2], and Veronika Sunko[1,3] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]School of Physics and Astronomy, University of St. Andrews, St. Andrews, UK — [3]Department of Physics, University of California, Berkeley, California, USA

Ruddlesden-Popper-type ruthenates are well-known for hosting intriguing phenomena, including unconventional superconductivity, metal-insulator transitions, spin-orbit coupling, and strange metal behavior. Among these, the bilayer ruthenate $Ca_3Ru_2O_7$ is a polar metal that exhibits strong electronic correlations. It undergoes an antiferromagnetic transition at 56 K and a first-order structural phase transition at 48 K at ambient pressure.

In our experiments, we utilize a versatile, optics-based microscope with high spatial resolution, to investigate quantum materials. The setup has been integrated with a uniaxial pressure cell that enables pressure to be used as both a tuning parameter and a thermodynamic probe. Using this technique, we simultaneously measure the optical reflectivity and the elastocaloric effect to understand the behavior of $Ca_3Ru_2O_7$ as a function of temperature and uniaxial pressure.

TT 52.6 Fri 10:45 H31

Designed cleaving planes in ruthenium dioxide for ARPES experiments — •Marieke Visscher[1,2], Lea Richter[1], Sebastian Buchberger[2], Bruno Saika[2], Andy Mackenzie[1,2], and Phil King[2] — [1]Max Planck Institute for Chemical Physics of Solids, Nöthnitzer Straße 40, 01187 Dresden, Germany — [2]Scottish Universities Physics Alliance, School of Physics and Astronomy, University of St Andrews, St Andrews, KY16 9SS, UK

Ruthenium dioxide has a complex band structure, underpinning a variety of phenomena including superconductivity under strain and a Dirac nodal line network. It has also been proposed as a candidate altermagnet, and although recent studies suggest it lacks the requisite magnetic order, it has been shown to host unusual spin-polarised states in its band structure. These phenomena motivate the need for more detailed studies into its electronic structure. Angle-resolved photoemission spectroscopy (ARPES) would be an ideal probe for this, but the three-dimensional structure of ruthenium dioxide makes it difficult to prepare atomically clean and flat surfaces with conventional methods. We have therefore investigated a fabrication method based on Focused Ion Beam (FIB) structuring to stimulate sample cleavage along desired crystallographic planes. With this method, we were able to obtain high quality surfaces, on which we performed ARPES measurements. With this new capability to tailor the sample cleavage, we significantly improve the quality of ARPES data from this compound, opening new perspectives for studying its low-energy electronic structure.

TT 52.7 Fri 11:00 H31

Localized Ti-4s molecular orbitals and correlated 3d states in the bad metal TiO_x — •Daisuke Takegami[1,2], Anna Melendez-Sans[2], Takashi Miyoshino[1], Ryo Nakamura[1], Miguel Ferreira-Carvalho[3,2], Georg Poelchen[2], Chun-Fu Chang[2], Masato Yoshimura[4], Ku-Ding Tsuei[4], Haruka Matsumoto[5], Asuka Yanagida[5], Takuro Katsufuji[5], Liu Hao Tjeng[2], and Takashi Mizokawa[1] — [1]Department of Applied Physics, Waseda University, Japan — [2]Max Planck Institute for Chemical Physics of Solids, Germany — [3]Institute of Physics II, University of Cologne, Germany — [4]National Synchrotron Radiation Research Center, Taiwan — [5]Department of Physics, Waseda University, Japan

We have investigated the electronic structure of the rocksalt TiO_x system using polarizationdependent hard x-ray photoelectron spectroscopy. The spectra showed a vanishingly small intensity at the Fermi level, classifying TiO_x as a bad metal. With the main spectral features attributed to the Ti^{2+} 3d2 configuration, we were able to detect spectroscopically also the co-existence of both Ti and O vacancies. The presence of Ti^{3+} states were identified. It was a surprise not to find signs for Ti1+ entities. Instead a sharp occupied state of Ti 4s origin was unveiled in the valence band, which gave evidence that localized Ti-4s-based

molecular orbitals are formed around the O vacancies. Our findings suggest that a defect free and stoichiometric TiO would have been a strongly correlated a Mott-Hubbard insulator, and that the 4s is an important degree of freedom for low-valent 3d materials.

TT 53: Topology: Other Topics

TT 53.1 Fri 9:30 H32

Quantum Geometric Tensor and Inertial Effects — •Maike Fahrensohn and Richard Matthias Geilhufe — Condensed Matter and Materials Theory Division, Department of Physics, Chalmers University of Technology, 41258 Göteborg, Sweden

The quantum geometric tensor (or Fubini-Study metric), defined on a parametrized quantum state manifold, encodes the full geometric structure of quantum space. The real part of the quantum geometric tensor, known as the quantum metric tensor, is a positive semi-definite Riemannian metric that measures the geometric distance between quantum states. This tensor has recently been shown to play a crucial role in the description of physical phenomena such as quantum transport, quantum noise, and optical conductivity. The antisymmetric part of the quantum geometric tensor, proportional to the Berry curvature, has been extensively studied and is central to the classification of topological insulators through their first Chern number.

While inertial effects have been well explored in classical mechanics, their role in quantum systems remains less understood. We build a connection between the quantum geometric tensor and inertial effects to bridge the geometric and topological properties of quantum systems to their physical response. This relationship may offer new insights into transport phenomena, stability, and collective dynamics in quantum systems.

TT 53.2 Fri 9:45 H32

Theory of Quantum Geometry in Unconventional Magnets — •Johannes Mitscherling, Jan Priessnitz, and Libor Smejkal — Max Plank Institute for the Physics of Complex Systems, Nöthnitzer Str. 38, 01187 Dresden, Germany

Metals with altermagnetic spin-polarisation [1] and non-collinear spin textures [2] are emerging platforms exhibiting rich fundamental physics and spintronics applications. Remarkably, this class of materials intrinsically yields a complex interplay of at least two orbital degrees of freedom besides spin. It was recently noticed that such multiband Hamiltonians host previously overlooked geometric invariants beyond the quantum metric and Berry curvature, especially when more than two bands are involved, making altermagnetic and non-collinear magnetic systems promising candidates for novel quantum geometric responses [3]. In this talk, I will introduce a quantum geometric perspective adequate for multiband systems with both spin and orbital degrees of freedom, which helps us to determine and quantify the properties of the nontrivial Bloch states. With this systematic geometric characterization, I will elaborate on a pathway to identify the most promising observables, model parameter regimes, and tuning parameters, simplifying the search for experimental realizations.

TT 53.3 Fri 10:00 H32

Topological Order in the Spectral Riemann Surfaces of Non-Hermitian Systems — •Anton Montag[1,2], Alexander Felski[1], and Flore Kiki Kunst[1,2] — [1]Max Planck Institute for the Science of Light, 91058 Erlangen, Germany — [2]Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

We show topologically ordered states in the complex-valued spectra of non-Hermitian systems. These arise when the distinctive exceptional points in the energy Riemann surfaces of such models are annihilated after threading them across the boundary of the Brillouin zone. This process results in a non-trivially closed branch cut that can be identified with a Fermi arc. Building on an analogy to Kitaev's toric code, these cut lines form non-contractible loops, which parallel the defect lines of the toric-code ground states. Their presence or absence establishes topological order for fully non-degenerate non-Hermitian systems. Excitations above these ground-state analogs are characterized by the occurrence of additional exceptional points. We illustrate the characteristics of the topologically protected states in a non-Hermitian two-band model and provide an outlook toward experimental realizations in metasurfaces and single-photon interferometry.

TT 53.4 Fri 10:15 H32

Exceptional Points of Any Order in a Generalized Hatano-Nelson Model — •Julius T. Gohsrich[1,2], Jacob Fauman[1,2], and Flore K. Kunst[1,2] — [1]Max Planck Institute for the Science of Light, Staudtstraße 2, 91058 Erlangen, Germany — [2]Department of Physics, Friedrich-Alexander Universität Erlangen-Nürnberg, Staudtstraße 7, 91058 Erlangen, Germany

Exceptional points (EPs) are truly non-Hermitian (NH) degeneracies where matrices become defective. The order of such an EP is given by the number of coalescing eigenvectors. On the one hand, most work focuses on studying Nth-order EPs in ($N \leq 4$)-dimensional NH Bloch Hamiltonians. On the other hand, some works have remarked on the existence of EPs of orders scaling with systems size in models exhibiting the NH skin effect.

In this talk, I introduce a new type of EP and provide a recipe on how to realize EPs of arbitrary order not scaling with system size. Therefore, I introduce a generalized version of the paradigmatic Hatano-Nelson model with longer-range hoppings. The EPs existing in this system show remarkable physical features: Their associated eigenstates have support on a subset of sites and exhibit the NH skin effect, which can be tuned to localize on the opposite end of the chain compared to all remaining states. Furthermore, the EPs are robust against generic perturbations in the hopping strengths as well as against a specific form of on-site disorder.

TT 53.5 Fri 10:30 H32

Topological Properties of the Non-Reciprocal α-Diamond Chain — Carolina Martinez-Strasser[1] and •Dario Bercioux[1,2] — [1]Donostia International Physics Center (DIPC), 20018 Donostia-San Sebastián, Spain — [2]Ikerbasque, Basque Foundation for Science, Plaza Euskadi 5 48009 Bilbao, Spain

This work explores the topological properties of a generalized non-Hermitian quasi-1D lattice, dubbed as the non-reciprocal α-diamond chain. The diamond chain is a tripartite lattice featuring three sites per unit cell, characterized by a flat band at zero energy associated with compact localized states, and topological edges edge states in the Hermitian and non-Hermitian regimes [1,2]. Building upon our previous investigations [2], we extend the analysis to a more general framework by introducing an α-parameter, quantifying the non-reciprocal hopping strength in the lower part of the diamond chain. Our generalization reveals a spectrum of non-Hermitian phenomena, including exceptional points of order 3 (EP3s) under specific parameter tuning. These EP3s, where three eigenvalues and their eigenvectors coalesce, offer valuable insights into the behavior of three-band non-Hermitian systems. The α-diamond chain thus serves as an effective 1D platform for exploring such phenomena, particularly in the presence of sublattice symmetries [3].

Topological characterization of carbon nanotubes — •Udo Schwingenschlögl, Xiaoning Zang, and Nirpendra Singh — King Abdullah University of Science and Technology (KAUST), Thuwal 23955-6900, Saudi Arabia

Orbital angular momentum plays a central role in quantum mechanics, from the microscopic interaction between light and matter to the macroscopic behavior of superconductors and superfluids. We show that the topology of carbon nanotubes can be characterized by winding numbers related to the orbital angular momentum. The tight-binding Hamiltonian of any carbon nanotube with C_N symmetry can be represented by N tight-binding Hamiltonians of decoupled molecular chains, for which a pseudospin formulation, characterized by specific paths in a two-dimensional auxiliary space, is developed. The quantum phases are given by the N winding numbers of these paths. The paths rotate in the auxiliary space when a magnetic field of varying strength is applied along the carbon nanotube, which gives rise to quantum phase transitions.

Non-Hermitian Quantum Fractals and Inner Non-Hermitian Skin Effects — Changan Li[1], Junsong Sun[2], Huaming Guo[2], and •Björn Trauzettel[1] — [1]Institute for Theoretical Physics and Astrophysics, University of Würzburg, 97074 Würzburg, Germany — [2]School of Physics, Beihang University, Beijing, 100191, China

The first quantum fractal discovered in physics is the Hofstadter butterfly. It stems from large external magnetic fields. We discover instead a class of non-Hermitian quantum fractals (NHQFs) emerging in coupled Hatano-Nelson models on a tree lattice in the absence of any fields. Based on analytic solutions, we are able to rigorously identify the self-similar recursive structures in the energy spectrum and wave functions. We prove that the complex spectrum of NHQFs bears a resemblance to the Mandelbrot set in fractal theory. We further investigate the non-Hermitian Su-Schrieffer-Heeger (SSH) model on Bethe lattice, revealing a novel localization phenomenon coined inner non-Hermitian skin effect. Our findings open another avenue for investigating quantum fractals in non-Hermitian systems.

TT 53.8 Fri 11:30 H32

Non-Hermitian Dynamics Close to Exceptional Points — •Aisel Shiralieva, Grigorii Starkov, and Björn Trauzettel — University of Würzburg, Würzburg, Germany

Exceptional points (EPs), which are degeneracies occurring in both open classical and quantum systems, play a crucial role across numerous areas of physics. This work examines the behavior of dissipative systems with N levels, with a particular emphasis on non-Hermitian qubits and qutrits. These systems are of interest due to recent experimental studies involving a driven non-Hermitian superconducting qubit embedded within a three-level structure, where the ground state serves as an "effective bath". Although significant progress have been made in understanding EPs, the precise connection between their occurrences in non-Hermitian Hamiltonians and in the Lindblad formalism remains unclear, especially if quantum jumps are treated as perturbations. Our results reveal how EPs in these two frameworks relate to each other and illustrate how perturbations can either lift the degeneracy or eliminate the EPs entirely in the Lindblad formalism.

TT 53.9 Fri 11:45 H32

Polarization-Induced Topology in Quantum Emitter Chains — •Jonathan Sturm and Adriana Pálffy — Julius-Maximilians-Universität Würzburg

Synthetic quantum matter has become a field of strongly growing interest over the past decade due to its versatility, adaptibility, and applicability in areas like quantum simulation and others. One particulary suited platform for engineered quantum systems are arrays of quantum emitters, which can be optically excited and couple by the exchange of virtual photons [1].

We theoretically study a quantum emitter implementation of the Su-Schrieffer-Heeger model. Different from earlier studies [2], we show that for certain chain geometries the topological invariant depends on the polarization of the chain, allowing us to alter the topology without altering the lattice. Moreover, we demonstrate how this mechanism can be used for a topological pumping protocol enabling controlled transport of photons through the chain.

Topological Signatures and Induced Triplet Pairing in Proximitized Quantum Hall - Superconductor Heterostructures — •Yuriko Baba, Rafael Sánchez, Alfredo Levy Yeyati, and Pablo Burset — Department of Theoretical Condensed Matter Physics, Condensed Matter Physics Center (IFIMAC), Universidad Autónoma de Madrid, 28049 Madrid, Spain

In a quantum Hall (QH) state, the proximity to a superconductor (SC) leads to the formation of hybridized electron-hole states called chiral Andreev edge states (CAES). Although the strong magnetic fields required for the QH effect are detrimental to superconductivity, recent experiments have achieved QH-SC hybrid junctions based on InAs 2DEGs [1], graphene [2], and magnetic topological insulators [3]. In this work, we theoretically study the formation of CAES in QH-SC hybrid junctions on a 2DEG. Using numerical simulations in Kwant [4], we study the formation of spin-polarized triplet Cooper pairs induced by Rashba spin-orbit coupling and Zeeman splitting [5], which may be important in 2DEG devices. We also consider the effect of the geometry of nanodevices in planar junctions [6] and in a narrow-finger configuration. In these geometries, the coupling of CAES can induce a topological band inversion and trivial localized states, both of which show particular signatures in non-local electron transport.

Optical Hopfion quantizes inverse Faraday effect — •Emma L. Minarelli and Matthias R. Geilhufe — Chalmers University of Technology, Department of Physics, 412 96 Göteborg, Sweden

Control and manipulation of quantum materials is of paramount significance, both for fundamental characterization and for quantum technologies. Among others, light-matter interaction has recently gained traction because both optical counterpart of solid-state phenomena and emergent effects can be investigated.

We extend this paradigm to 3D topological optical quasiparticle i.e. optical Hopfion (oHop) - a knotted structure presenting robust topological protection, resolution on ultrafast time-scales, localization on nanometer-scale - as novel source to probe and regulate properties and phases of matter.

We show a first instance of OHop-matter coupling: an oHop travelling through a non-magnetic material induces a net effective magnetization, that is now promoted to be topologically quantized in virtue of the linking number (Hopf index) classifying the oHop source. By relating the induced magnetization to the Hopf index, we identify the quantum inverse Faraday effect. This quantized optical response is obtained without constraints on the material but only by introducing topological light. We conclude with a demonstration for a specific material and we give predictions about its promising application in optical protocols for communication and storage of information.

TT 53.12 Fri 12:30 H32

Network Model for Magnetic Higher-Order Topological Phases — Hui Liu[1,2], Ali G. Moghaddam[3,4,5], •Daniel Varjas[1,2,6,7], and Ion Cosma Fulga[1] — [1]IFW Dresden, Dresden, Germany — [2]Stockholm University, Stockholm, Sweden — [3]Institute for Advanced Studies in Basic Sciences (IASBS), Zanjan, Iran — [4]Research Center for Basic Sciences and Modern Technologies (RBST), Zanjan, Iran — [5]Tampere University, Tampere, Finland — [6]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [7]Budapest University of Technology and Economics, Budapest, Hungary

We propose a network-model realization of magnetic higher-order topological phases (HOTPs) in the presence of the combined space-time symmetry $C_4\mathscr{T}$ – the product of a fourfold rotation and time-reversal symmetry. We show that the system possesses two types of HOTPs. The first type, analogous to Floquet topology, generates a total of 8 corner modes at 0 or π eigenphase, while the second type, hidden behind a weak topological phase, yields a unique phase with 8 corner modes at $\pm\pi/2$ eigenphase (after gapping out the counterpropagating edge states), arising from the product of particle-hole and phase-rotation symmetry. By using a bulk $\mathbb{Z}_4$ topological index (Q), we found both HOTPs have $Q = 2$, whereas $Q = 0$ for the trivial and the conventional weak topological phase. Together with a $\mathbb{Z}_2$ topological index associated with the reflection matrix, we are able to fully distinguish all phases. Our work suggests that such phases may find their experimental realization in coupled-ring-resonator networks.

TT 54: Correlated Electrons: Charge Order

Broad-Band Noise at the Different CDW Transitions in $BaNi_2As_2$ — •Julian Beu[1], Marvin Kopp[1], Markus König[2], Amir Haghighirad[3], Matthieu Le Tacon[3], Jure Demsar[4], and Jens Müller[1] — [1]Institute of Physics, Goethe-University Frankfurt, Frankfurt (Main), Germany — [2]MPI CPfS, Dresden, Germany — [3]KIT, Karlsruhe, Germany — [4]Institute of Physics, JGU, Mainz

Ever since collective modes like charge (CDW) and spin density waves (SDW) have been routinely found near to or in direct competition with unconventional superconductivity in many interesting compounds, including high-T_c cuprates and iron-pnictides, the influence of these states on the superconducting phase is of interest. In this work we focus on $BaNi_2As_2$ (BNA), a structurally close analogue of the 122-type iron-based superconductors. In contrast to the iron-pnictides, no magnetic ordering was observed in BNA, and two different CDW phases, one incommensurate (I-CDW) and the other commensurate (C-CDW), replace a SDW phase. We investigate the charge carriers in samples of $BaNi_2(As_{1-3.5\%}P_{3.5\%})_2$ by analyzing the resistance and broad-band noise properties. The samples are structured by a FIB process with a meander current path in order to increase the absolute resistance by two orders of magnitude, making fluctuation spectroscopy possible. Our measurements reveal significant differences in the behavior of the electronic fluctuations at the two CDW formations, that show interesting connections to recent findings regarding the properties of the I-CDW in BNA [1] and our noise measurements performed on the conventional CDW system $K_{0.3}MoO_3$. TT 54.2 Fri 9:45 H33

Visualizing p-Orbital Texture in the Charge Density Wave State of CeSbTe — Xinglu Que[1], Qingyu He[1], Lihui Zhou[1], Shiming Lei[2], Leslie Schoop[3], •Dennis Huang[1], and Hidenori Takagi[1,4,5] — [1]Max Planck Institute for Solid State Research, Stuttgart, Germany — [2]Hong Kong University of Science and Technology, China — [3]Princeton University, USA — [4]University of Stuttgart, Germany — [5]University of Tokyo, Japan

The collective reorganization of electrons into a charge density wave (CDW) inside a crystal has long served as a textbook example of an ordered phase in condensed matter physics. Two-dimensional square lattices with p electrons are well-suited to the realization of CDW, due to the anisotropy of the p orbitals and the resulting one dimensionality of the electronic structure. In spite of a long history of study of CDW in square-lattice systems, few reports have recognized the existence and significance of a hidden orbital degree of freedom. The degeneracy of p_x and p_y electrons inherent to a square lattice may give rise to nontrivial orbital patterns in real space that endow the CDW with additional broken symmetries or unusual order parameters. Using scanning tunneling microscopy, we visualize signatures of p-orbital texture in the CDW state of the topological semimetal candidate CeSbTe, which contains Sb square lattices with $5p$ electrons. We image atomic-sized, anisotropic lobes of charge density with periodically modulating anisotropy, that ultimately can be mapped onto a microscopic pattern of p_x and p_y bond density waves.

TT 54.3 Fri 10:00 H33

Charge Density Wave and Phonon Softening in $EuAl_4$ — •Aleksandr Sukhanov[1], Steven Gebel[1], Artem Korshunov[2], and Marein Rahn[1] — [1]Experimental Physics VI, Center for Electronic Correlations and Magnetism, University of Augsburg, 86159 Augsburg, Germany — [2]Donostia International Physics Center (DIPC), Paseo Manuel de Lardizabal, 20018 San Sebastian, Spain

$EuAl_4$ is a rare earth intermetallic in which competing itinerant and/or indirect exchange mechanisms give rise to a complex magnetic phase diagram, including a centrosymmetric skyrmion lattice. These phenomena arise not in the tetragonal parent structure but in the presence of a charge density wave (CDW), which lowers the crystal symmetry and renormalizes the electronic structure. Microscopic knowledge of the corresponding atomic modulations and their driving mechanism is a prerequisite for a deeper understanding of the resulting equilibrium of electronic correlations and how it might be manipulated.

In my talk, I present inelastic x-ray scattering results, which can clarify the origin of the CDW in $EuAl_4$.

TT 54.4 Fri 10:15 H33

Charge Density Wave Quantum Critical Point under Pressure in 2H-$TaSe_2$ — •Yuliia Tymoshenko[1], Amir-Abbas Haghighirad[1], Rolf Heid[1], Gaston Garbarino[2], Luigi Paolasini[2], and Frank Weber[1] — [1]Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, 76021 Karlsruhe, Germany — [2]2European Synchrotron Radiation Facility, 71 avenue des Martyrs, CS 40220, Grenoble 38043, France

Suppression of the ordered state is one of the ways to increase the superconducting (SC) transition temperatures. Materials characterized by charge density waves (CDW) and SC are promising candidates for such studies, since both states can be associated with electron-phonon coupling. Transition metal dichalcogenides (TMD) are prominent examples of such coexisting phases, however, not all such materials show the expected behavior or possess additional mechanisms that complicate an unambiguous interpretation. Here, we report high-pressure X-ray diffraction (XRD) and inelastic X-ray scattering (IXS) measurements of a prototypical transition metal dichalcogenide 2H-$TaSe_2$ and determine the evolution of the CDW state and its lattice dynamics. We found that the quantum critical point (QCP) of the charge density wave is in close proximity to the reported maximum superconducting transition temperature T_{sc} = 8.2 K. Ab-initio calculations confirm that 2H-$TaSe_2$ is a typical example of enhanced superconductivity with suppressed order and can serve as a textbook example for studying superconductivity near the quantum critical point of the CDW.

TT 54.5 Fri 10:30 H33

Tunable Charge Density Wave Orders in 2H-TaS_2 — •Mihir Date[1,2], Joost Aretz[3], Enrico da Como[4], Marcin Mucha-Kruczynski[4], Malte Roesner[3], Stuart S P Parkin[1], Niels B M Schroeter[1], and Matthew D Watson[2] — [1]Max Planck Institute of Microstructure Physics, Halle, Germany — [2]Diamond Light Source Ltd., Didcot, UK — [3]Radboud University, Nijmegen, The Netherlands — [4]University of Bath, Bath, UK

The charge density wave (CDW) transition is an electronic instability driven by strong electron-phonon coupling, where the parent electronic band is renormalized, and shows a spectral gap. Angle-resolved photoemission spectroscopy (ARPES) has been extremely successful in identifying these spectral features, most prominently in layered van der Waals materials like 2H-$NbSe_2$ and $TaSe_2$. Surprisingly, however, until now there has not been any high-quality data reported on the 2H-TaS_2, presumably due to materials challenges. Making use of spatially resolved ARPES, we were able to overcome these challenges and measure high-quality bandstructures revealing the 3x3 commensurate charge density waves (CCDW) ground state in 2H-TaS_2. We further find variation of the stoichiometry between samples prepared by different routes, and incredibly, at a different band filling we find evidence of a new CDW order that is commensurate, but not the 3x3 reconstruction as observed in previous experiments. Our results are compared with tight-binding and ab-initio modelling which show that TaS_2 is prone to multiple instabilities that can be tuned by the band filling, with an important role played by a van Hove singularity.

TT 54.6 Fri 10:45 H33

Resistance of Vapor-Grown $NbSe_2$ Single Crystals under Strain — •Maik Golombiewski, Tianyi Xu, Simon Knudsen, Michael Paul, Sven Graus, Teslin R. Thomas, Andreas Kreyssig, and Anna E. Böhmer — Experimentalphysik IV, Ruhr-Universität Bochum, 44801 Bochum, Germany

$NbSe_2$ shows a charge density wave (CDW) transition upon cooling below T_{CDW} = 32 K and becomes superconducting at T_c = 7.2 K. Large $NbSe_2$ single crystals were grown via chemical vapor transport with iodine as transport agent. Growth conditions, such as temperature gradient, were optimized resulting in an increase in RRR. Samples were shown to have a 1:2 stoichiometry via energy-dispersive x-ray spectroscopy and the 2H-structure was confirmed by powder x-ray diffraction measurements. Temperature-dependent resistance was measured while simultaneously straining the samples using cryogenic strain and force cells. This so-called elastoresistance exhibits a minimum around T_{CDW}. Using the force cell, large strains were applied and investigated.

We acknowledge support by the Mercator Research Center Ruhr (MERCUR), under project number Ko-2021-0027.

TT 54.7 Fri 11:00 H33

Fingerprints of a Charge Ice State in the Doped Mott Insulator Nb_3Cl_8 — •Evgeny Stepanov — CNRS, Ecole Polytechnique

Monolayer Nb_3Cl_8 is a textbook example of a Mott insulator [1,2]. However, little is known about its characteristics, particularly in doped regimes where the strong local correlations responsible for the Mott state are competing with significant spatial collective electronic fluctuations.

Our many-body calculations suggest that monolayer Nb_3Cl_8 undergoes phase separation (PS) upon doping, driven by the emergence of a charge ice state [3]. In close proximity to the PS, the charge susceptibility dramatically increases and displays a distinctive bow-tie pattern in momentum space, resembling the form of magnetic susceptibility observed in spin ice states. At the same time, the effective exchange interaction between charge densities undergoes a striking transformation, acquiring a power-law dependence in real space. This dependence is reminiscent of hydrogen bonding interactions in water and serves as a hallmark of spin ice states when applied to spin degrees of freedom. These findings allow us to associate the observed PS with a charge ice state, characterized by a remarkable power-law dependence of correlations between electronic densities in real space.

While spin ice states were first experimentally realized in 1997 by Harris et al. [4], an analogue for charge degrees of freedom has remained elusive until now. Our work not only provides a theoretical description of the charge ice state but also offers compelling evidence that this novel phase can be realized in a real material.

Non-Thermal Cavity Control of Order in Electronic Systems — •Md Mursalin Islam[1], Michele Pini[2,1], Rafael Flores-Calderón[1], and Francesco Piazza[2,1] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]University of Augsburg, Augsburg, Germany

Cavity quantum materials have emerged as a platform to study non-thermal many-body physics with applications to the control of collective electron behavior. In an electronic system coupled to cavity photons, the superconducting gap has been predicted previously to be enhanced, due to a 'Eliashberg effect' taking place due to electromagnetic fluctuations as instead of a coherent laser source [1,2]. We extend this idea for the case of charge-density-wave order and systematically derive a generalized gap equation for the non-thermal situation using field theoretical methods. This allows us to compare the modified gap equations for superconductors and charge density waves: we find that while the two equations are exactly equivalent in thermal equilibrium, they assume different forms in non-thermal settings. Our formalism also allows us to systematically investigate the role of disorder in the non-thermal enhancement of the gap in both the cases.

Disorder in Photoexcited Charge Density Wave Systems: Insights from Stochastic Resonance in Impurity Models. — •Francesco Valiera and Martin Eckstein — Department of Physics, University of Hamburg, D-22607 Hamburg, Germany

Photoexcitation in charge density wave (CDW) systems can potentially lead to inhomogeneously disordered phases [1], where ions are displaced locally but do not achieve global ordering. In these phases, each ion moves within a local double-well potential and settles in one of the two equilibrium positions with equal probability. Similar behaviours have also been observed experimentally in VO_2 through scattering experiments [2]. A fundamental question in understanding these disordered states is identifying their signatures beyond X-ray scattering. In order to explore this, we have developed a model of a single ion embedded in a metallic host and use the semiclassical stochastic approach [3] to compute its linear response to an external probe. At low frequencies, the system exhibits a peak in the response amplitude as a function of temperature, which we attribute to stochastic resonance. The latter is typical of bistable systems that experience both periodic driving and noise and it can provide insights into the features of the local double-well potentials and the fluctuations to which the ions are subject.

Kinetic Magnetism and Stripe Order in the Antiferromagnetic Bosonic t-J Model — •Timothy J. Harris[1,2], Ulrich Schollwöck[1,2], Annabelle Bohrdt[1,2,3], and Fabian Grusdt[1,2] — [1]Ludwig Maximilian University of Munich, Munich, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany — [3]University of Regensburg, Regensburg, Germany

Understanding the microscopic mechanisms governing the physics of doped quantum magnets is a central challenge in strongly correlated many-body physics. In this talk, I will present results that disentangle the role of particle statistics from the intrinsic physics of strong correlations in the antiferromagnetic (AFM) bosonic t-J model. Using large-scale density matrix renormalization group (DMRG) calculations, we map out the T=0 phase diagram on the 2D square lattice [1]. At low doping, we find evidence of partially-filled stripe structures, reminiscent of those observed in high-T_c cuprates. As doping increases, a transition occurs to a partially-polarized ferromagnetic (FM) phase, driven by formation of Nagaoka polarons as mobile holes bind to localized FM regions. At high doping or large t/J, these polarons overlap, and the system evolves into a full-polarized ferromagnet. Our findings shed new light on the role of particle statistics in strongly correlated quantum matter, revealing connections to stripe formation and the physics of kinetic ferromagnetism. I will also discuss experimental realizations of this model using state-of-the-art quantum simulators, paving the way for future studies of doped bosonic quantum magnets.

SU(2) Gauge Theory for Fluctuating Stripes in the Pseudogap Regime — •Mark Henrik Müller-Groeling, Pietro Maria Bonetti, Paulo Forni, and Walter Metzner — Max Planck Institute for Solid State Research, Heisenbergstraße 1, D-70569 Stuttgart, Germany

We investigate the role of charge order in a pseudogap described by an SU(2) gauge theory of fluctuating magnetic order.

The theory is based on a fractionalization of electrons into a fermionic chargon pseudospinor and a bosonic spinon, which leads to an emergent SU(2) pseudospin symmetry. In the mean-field solution of the 2D Hubbard model, which we use to describe the electrons in the copper-oxygen planes, Néel, spiral, or stripe order were observed below a density dependent transition temperature T^* [1].

Fluctuations of the spin orientation are described by a non-linear sigma model obtained from a gradient expansion of the spinon action. The spin stiffnesses are computed from a random phase approximation for the chargon susceptibility. The spinon fluctuations prevent magnetic long-range order of the electrons at any finite temperature. The phase with magnetic chargon order exhibits the most salient features characterizing the pseudogap regime in high-T_c cuprates: a strong reduction of charge carrier density, a spin gap, and Fermi arcs [2], and we set out to observe the effects of charge order in this context.

Combined Cluster and Diagrammatic Method for Symmetry Broken Phases in Correlated Electron Systems — •Félix Fossati and Evgeny Stepanov — Ecole Polytechnique

In this work, we investigate dynamical symmetry breaking in correlated electron systems. To achieve this, we refine a theoretical approach called D-TRILEX [1-3], which constructs a diagrammatic expansion based on an interacting reference system, using a cluster problem as a reference. Traditional cluster methods account for short-range correlation effects within the cluster exactly but neglect correlations beyond the cluster size. Our approach addresses this limitation by self-consistently combining the non-perturbative treatment of short-range correlations with a diagrammatic description of long-range collective electronic fluctuations. We demonstrate the effectiveness of this method by applying it to the one-dimensional Hubbard model. Our results show that the cluster extension of D-TRILEX accurately captures the transitions to the charge density wave (CDW) and bond-ordered wave (BOW) phases, which are associated with local and non-local order parameters, respectively, across various regimes of electronic interactions. This implementation provides new insights into the role of non-local interactions in dynamical symmetry breaking, establishing D-TRILEX as a promising tool for investigating complex phases in strongly correlated systems.

Simultaneous locking and operation of gradiometric fluxonium qubits — •Denis Bénâtre[1], Mathieu Féchant[1], Nicolas Gosling[1], Nicolas Zapata[1], Patrick Paluch[1], Martin Spiecker[1], and Ioan Pop[1,2,3] — [1]IQMT, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany — [2]PHI, Karlsruhe Institute of Technology, Karlsruhe, Germany — [3]PI1, Stuttgart University, 70569 Stuttgart, Germany

Gradiometric fluxoniums, introduced by Gusenkova et al. (Appl. Phys. Lett. 120, 2022), have the ability to be flux-locked at the sweet spot of operation by trapping a persistent current in their most external loop. We demonstrate the reliability of the procedure by simultaneously locking several fluxoniums sitting in the same waveguide and show that the locking in stable in time. We engineer devices with varying asymmetries and exhibit samples with close-to-zero asymmetry, allowing them to be used with little additional flux-biasing. Such devices could thus help reduce cross-talk between flux lines addressing flux qubits.

TT 55.4 Fri 10:15 H36

Low cross-talk modular flip-chip architecture for coupled superconducting qubits — •Sören Ihssen[1], Simon Geisert[1], Gabriel Jauma[2,3], Patrick Winkel[1,4,5], Martin Spiecker[1], and Ioan M. Pop[1,6,7] — [1]IQMT, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany — [2]Institute of Fundamental Physics IFF-CSIC, Calle Serrano 113b, 28006 Madrid, Spain — [3]Applied Physics Department, Salamanca University, Salamanca 37008, Spain — [4]Departments of Applied Physics and Physics, Yale University, New Haven, CT 06520, USA — [5]Yale Quantum Institute, Yale University, New Haven, CT 06520, USA — [6]PHI, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany — [7]Physics Institute 1, Stuttgart University, 70569 Stuttgart, Germany

We introduce a novel flip-chip architecture designed for an array of coupled superconducting qubits, where each circuit component is housed within its own microwave enclosure. Unlike traditional flip-chip designs, our approach features electrically floating qubit chips, enabling a straightforward and fully modular assembly of capacitively coupled components, including qubits, control systems, and coupling structures. This design minimizes crosstalk among components. We validate our concept using a chain of three nearest-neighbor coupled generalized flux qubits, with the central qubit functioning as a frequency-tunable coupler. Through this coupler, we achieve a transverse coupling on/off ratio of approximately 50, zz-crosstalk below 1.4 kHz between resonant qubits, and over 70 dB of isolation between the qubit enclosures.

TT 55.5 Fri 10:30 H36

Optically mediated control for superconducting qubits — •Kevin Kiener[1,2], Gleb Krylov[1,2], Florian Wallner[1,2], Max Werninghaus[1,2], Nadeem Akhlaq[2,3], Frederik Pfeiffer[1,2], Johannes Schirk[1,2], and Stefan Filipp[1,2] — [1]Walther-Meißner-Instiut, Bayerische Akademie der Wissenschaften — [2]Technical University of Munich, TUM School of Natural Sciences, Department of Physics — [3]Walter Schottky Institut

In superconducting quantum computers, scaling control and readout wiring infrastructure presents significant challenges. Optical fibers offer a promising alternative to microwave cables by providing lower passive heat load, reduced footprint per channel, reduced crosstalk and the potential for multiplexing control channels. Here, we explore the conversion of microwave- to optical signals via amplitude modulation and the subsequent reconversion to microwave signals at millikelvin (mK) temperatures. Two fiber coupling strategies are experimentally evaluated in a cryogenic environment, focusing on their practicality for qubit control. We theoretically investigate methods to reduce the power dissipation of the photodiode at mK temperatures, focusing on two approaches: utilizing an impedance converter and employing high-impedance transmission lines. We investigate the validity of the signal generation for different frequencies and identify suitable frequency ranges to control different qubit architectures and coupling elements.

TT 55.6 Fri 10:45 H36

Spectroscopic characterization of noise and decoherence mechanisms in superconducting qubits — •Julian Englhardt[1,2], Emily Wright[1,2], Niklas Glaser[1,2], Leon Koch[1,2], Ivan Tsitsilin[1,2], Christian Schneider[1,2], Max Werninghaus[1,2], and Stefan Filipp[1,2] — [1]Technical University of Munich, TUM School of Natural Sciences, Department of Physics — [2]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften

Dynamical decoupling sequences during free evolution time have proven effective in suppressing the impact of environmental noise in superconducting qubits, thereby increasing coherence times towards the theoretical 2T1 limit. While primarily used for error suppression during quantum computation, these sequences can also serve as a diagnostic tool for noise characterization by revealing the qubit's response across specific frequency ranges. Beyond standard dynamical decoupling sequences, here we employ additional methods such as time resolved single-shot Ramsey measurements to probe low-frequency noise sources and the signature noise spectra of specific decoherence events. Specifically, we investigate charge parity jumps in superconducting Transmon qubits induced by quasiparticle tunneling across the Josephson junction. We believe that the combined toolkit for noise spectroscopy can contribute to the understanding of decoherence mechanisms in superconducting qubits.

We acknowledge financial support from GeQCoS, MUNIQC-SC, MCQST, OpenSuperQPlus100, the Munich Quantum Valley and the Deutsche Forschungsgemeinschaft.

TT 55.7 Fri 11:00 H36

Suppressing chaos with mixed superconducting qubit devices — •Ben Blain[1,2], Giampiero Marchegiani[1], Luigi Amico[1,3,4], and Gianluigi Catelani[5,1] — [1]Quantum Research Center, Technology Innovation Institute, Abu Dhabi 9639, UAE — [2]School of Physics and Astronomy, University of Kent, Canterbury CT2 7NH, United Kingdom — [3]Dipartimento di Fisica e Astronomia, Via S. Sofia 64, 95123 Catania, Italy — [4]INFN-Sezione di Catania, Via S. Sofia 64, 95127 Catania, Italy — [5]JARA Institute for Quantum Information (PGI-11),Forschungszentrum Jülich, 52425 Jülich, Germany

In quantum information processing, a tension between two different tasks occurs: while qubits' states can be preserved by isolating them, quantum gates can be realized only through qubit-qubit interactions. In arrays of qubits, weak coupling leads to states being spatially localized and strong coupling to delocalized states. Here, we study the average energy level spacing and the relative entropy of the distribution of the level spacings to analyze the crossover between localized and delocalized (chaotic) regimes in linear arrays of superconducting qubits. We consider both transmons as well as capacitively shunted flux qubits, which enables us to tune the qubit anharmonicity. Arrays with uniform anharmonicity display remarkably similar dependencies of level statistics on the coupling strength. In systems with alternating anharmonicity, the localized regime is found to be more resilient to the increase in qubit-qubit coupling strength in comparison to arrays with a single qubit type. This result supports designing devices that incorporate different qubit types to achieve higher performances.

15 min. break

TT 55.8 Fri 11:30 H36

Higher Josephson harmonics in superconducting qubits — •Abbas H. Hirkani[1,2], Giampiero Marchegiani[1], Luigi Amico[1,3,4], and Gianluigi Catelani[1,5] — [1]QRC, TII, Abu Dhabi, UAE — [2]SISSA, Trieste, Italy — [3]Dipartimento di Fisica e Astronomia, Catania, Italy — [4]INFN-Catania, Catania, Italy — [5]Forschungszentrum Jülich, Jülich, Germany

Measurements of higher-level spectra of transmon cannot be explained using the standard $I = I_0 \sin\phi$ current-phase relation, and a more accurate description of the Josephson element, with non-negligible contributions from higher harmonics, is needed [1]. Stray inductances can also lead to similar corrections to the spectrum; here we investigate the Fraunhofer effect in transmons comprising thin-film Al/AlO_x/Al junctions under parallel magnetic field [2] as a tool to discriminate between contributions from inductances and from intrinsic higher harmonics of the junctions. The magnetic field modulates each harmonic on a different field scale; this results in a field dependence of the qubit spectrum measurably different from the one due to a stray inductance alone. We also examine how the presence of a few percent higher harmonic contributions affects various qubit designs, and comment on the implications for accurate targeting of qubit parameters.

[2] J. Krause et al., Phys. Rev. App. 22, 044063 (2024).

TT 55.9 Fri 11:45 H36

Impact of infrared photons on superconducting qubits — •Markus Griedel[1,2], Jonathan Huschle[2], Hannes Rotzinger[1,2], and Alexey V. Ustinov[1,2] — [1]Institut for Quanten Materials and Technologies (IQMT), Karlsruhe Institut for Technology (KIT), Karlsruhe, Germany — [2]hysikalisches Institut (PHI), Karlsruhe Institut for Technology (KIT), Karlsruhe, Germany

Low-noise superconducting quantum circuits are manipulated by microwave photons with energies below the superconducting energy gap. However, the impact of photons with much higher energies may break Cooper pairs and result in an increase in the noise level. Stray infrared (IR) radiation, e.g. transmitted through the dielectrics of coaxial cables, must be blocked by a low-pass filter to avoid this additional noise. The coherence of superconducting qubits is particularly sensitive to this influence and can be used as a detector. In the qBriqs project, we focus on studying the impact of far-infrared photons and present the results of a detailed experimental study. We propose materials to suppress the IR radiation, e.g. with an in-line filter, while maintaining good microwave properties.

TT 55.10 Fri 12:00 H36

Investigation of parasitic two-level systems in merged-element Transmon qubits — •Etienne Daum[1], Benedikt Berlitz[1], Alexey V. Ustinov[1,2], and Jürgen Lisenfeld[1] — [1]PHI, Karlsruher Institut für Technologie, 76131 Karlsruhe, Deutschland — [2]IQMT, Karlsruher Institut für Technologie, 76131 Karlsruhe, Deutschland

In conventional transmon qubits, decoherence is dominated by large numbers of parasitic two-level systems (TLS) residing at the edges of its large area coplanar shunt capacitor. Avoiding these defects by improvements in design, fabrication and materials proved to be a significant challenge that so far led to limited progress. The merged-element transmon qubit, a recently proposed paradigm shift in transmon design, attempts to address these issues by engineering the Josephson junction to act as its own parallel shunt capacitor. Incorporating an additional aluminium deposition and oxidation into the *in-situ* bandaged Niemeyer-Dolan technique, we were able to fabricate flux-tunable mergemon qubits in the low transmon regime ($E_J/E_C \approx 34$). A mean T_1 relaxation time of about $20\mu s$ ($Q \approx 5.4 \times 10^5$) has been observed over a six hour time period. TLS spectroscopy under applied strain and electric fields revealed that the majority of coherence limiting TLS (~ 60%) still reside on the interfaces of exposed qubit electrodes, despite their drastically reduced surface area. This indicates that ma-

terial and fabrication improvements, in combination with optimized electrode geometries, are still necessary before the advantages of the "mergemon" approach can be exploited.

TT 55.11 Fri 12:15 H36

Demonstration of a Solid-State Random Defect Maser — •Christian Ständer, Jan Blickberndt, Andreas Fleischmann, Andreas Reiser, and Christian Enss — Kirchhoff Institute for Physics, Heidelberg University

The low temperature properties of amorphous solids are governed by atomic tunneling systems, which can be described as two-level systems (TLS) with a distribution of their energy splitting E, as assumed by the phenomenological standard tunnelling model. Recent interest in these systems due to their deteriorative effects on the performance of superconducting quantum devices lead to experimental investigations of atomic tunnelling systems.

We designed and microfabricated a superconducting LC-resonator to study the dielectric rf-response of an amorphous sample in the presence of a slowly varying electric bias field and two symetrically detuned pump tones. A novel method of applying this electrical bias field was introduced to the resonators. By shifting the energy splitting of the inverted TLS with the external bias, to match the resonators frequency we found a paramterspace of negative dielectric loss, hence gain. In this way we demonstrate that a media containing random TLS could be transformed from an inertially lossy system to a system that features no significant dielectric loss, up to a point of coherent gain.

TT 55.12 Fri 12:30 H36

Two-qubit entangling quantum gates in a 2D ring resonator architecture — •Anirban Bhattacharjee[1,2], Panya Jain[1], Jay Deshmukh[1], Srijita Das[1], Madhavi Chand[1], Meghan Patankar[1], and Rajamani Vijayaraghavan[1] — [1]Tata Institute of Fundamental Research, Mumbai, India — [2]Walther Meissner Institute, Garching b Muenchen, Germany

A novel ring resonator [1] design allows interqubit connectivity beyond nearest neighbours, which has always been a topological constraint in present state-of-art quantum architectures. In this work, we demonstrate connectivity between three fixed-frequency transmon qubits coupled to a ring resonator in a planar 2D architecture. We have also demonstrated two-qubit entangling gates between two fixed-frequency qubits in this geometry. Our results show the ability to demonstrate quantum entanglement using the ring resonator and opens up the possibility of exploring various gate implementations in this architecture.

TT 55.13 Fri 12:45 H36

Study of the quarton-quarton qubits interaction — •Hossam Tohamy[1], Alex Kreuzer[1], Andras Di Giovanni[1], Thilo Krumrey[1], Hannes Rotzinger[1,2], and Alexey V. Ustinov[1,2] — [1]Physikalisches Institut (PHI), Karlsruhe Institute of Technology (KIT) — [2]Institute for Quantum Materials and Technologies (IQMT), Karlsruhe Institute of Technology (KIT)

Tunable qubits are a useful resource in superconducting quantum processors to enable high-performance quantum gates. While much of the recent focus has been on the exploration of transmon multiqubit architectures, the quarton qubit [1] offers a three- to five-times higher and, in addition, positive anharmonicity. In this work, we experimentally study the interaction between two quarton qubits. We have performed spectroscopy and time-domain measurements on these qubits system, and compared the experimental results with theoretical model.

TT 56: Quantum Dynamics, Decoherence, and Quantum Information (joint session DY/TT)

Time: Friday 9:30–11:15 Location: H37

TT 56.1 Fri 9:30 H37

Entanglement phase transitions in unitary circuit games with free fermions — •Raúl Morral-Yepes[1,2], Marc Langer[1,2], Adam Smith[3,4], Barbara Kraus[1,2], and Frank Pollmann[1,2] — [1]Technical University of Munich, TUM School of Natural Sciences — [2]Munich Center for Quantum Science and Technology (MCQST) — [3]School of Physics and Astronomy, University of Nottingham — [4]Centre for the Mathematics and Theoretical Physics of Quantum Non-Equilibrium Systems

In the recently introduced framework of unitary circuit games, two competing parties an entangler and a disentangler can induce an entanglement phase transition, distinct from measurement-induced transitions. In this work, we study such games within the context of matchgate dynamics, which correspond to free fermion systems. First, we investigate the entanglement properties of fermionic Gaussian states (FGS) and explore different methods for their disentangling. We propose a representation of FGS using a minimal matchgate circuit in a standard form, and introduce algorithms for updating this representation as unitary operations are applied. Within this framework, we define a natural disentangling procedure that reduces the number of gates in the circuit, thereby decreasing the system's entanglement. We then analyze the unitary game using this gate disentangler, observing a phase transition between a volume-law and area-law entanglement phase. The nature of this transition differs depending on whether we examine Rényi-0 or other entanglement entropies.

TT 56.2 Fri 9:45 H37

Measurement Induced Entanglement Transitions in Random Qudit Clifford Circuits — •Aamod Vinayak Atre, Raúl Morral Yepes, and Frank Pollmann — Department of Physics, Technical University of Munich

Random quantum circuits with local projective measurements uncover the universal dynamical properties of generic chaotic quantum many-body systems, as their unitary evolution is independent of the microscopic features of Hamiltonians. Entanglement measures characterize these universal dynamics into volume-law and area-law regimes, which exhibit bipartite entropy scaling proportional to the system volume and system boundary respectively. This continuous entanglement scaling transition, driven by the rate of measurement, has been extensively studied in spin-1/2 (qubit) systems of various spatial geometries. In this talk, we discuss the characterization the entanglement transitions in 1D random quantum circuits of spins (qudits) with arbitrary local Hilbert-space dimension d. This work employs the generalized stabilizer formalism, taking advantage of the Clifford group which forms a unitary 2-design on the space of unitaries. We find the nature of the entanglement transition, from volume-law to area-law regimes, to be preserved for $d > 2$. The critical measurement density increases, converging to 1/2 in the limit $d \to \infty$. Lastly, we describe the stabilizer dynamics in the limit $d \to \infty$, by a dynamical classical model.

TT 56.3 Fri 10:00 H37

Entanglement phases, localization and ergodicity of monitored free fermions in 2D — •Karim Chahine and Michael Buchhold — Institut für Theoretische Physik, Universität zu Köln, D-50937 Cologne, Germany

Monitored quantum systems, characterized by the interplay between unitary evolution and mid-circuit measurements, have recently emerged as a novel expression of quantum dynamics. Despite their inherently out-of-equilibrium nature, these systems can host robust quantum phases and display measurement-induced phase transitions (MIPT) in the entanglement entropy. Remarkably, they are also unique in providing a link between quantum dynamics in D dimensions and quantum statistical mechanics in $D + 1$ dimensions. In this talk, I will present our recent work on a new arena with a rich phenomenology: continuously monitored, $U(1)$-symmetric free fermions in 2D. I will address the emerging MIPT and its similarities and differences with Anderson-type localization transitions. Some emphasis will be put on the low-measurement regime, where intriguing features in the entanglement structure and ergodic properties emerge, revealing a richer phenomenology than previously anticipated.

TT 56.4 Fri 10:15 H37

Spectral Properties and Magic generation of T-doped Random Clifford Circuits — •Dominik Szombathy — Budapest University of Technology and Economics

We investigate the spectral properties and magic generation of T-doped random Clifford circuits. There is a direct relation between the structure of Pauli string orbits and the eigenvalue spectrum of a Clifford circuit. Operatively, we sample the closed trajectories with brick-wall circuits and determine the distribution of the eigenvalues $\lambda = e^{i\Theta}$. The autocorrelation function of the phases of the eigenvalues displays peculiar properties: extreme degeneracies as well as some level-repulsion, and features reminiscent of a fractal pattern.

To investigate the stability of orbits and head towards universal quantum computation, we introduce $\pi/4$ phase shift gates (T-gates). We find that even a single T-gate completely changes the properties of the circuit. By increasing the number of T-gates (N_T), the correlation function rapidly approaches that of the random unitary circuits. Nevertheless, some statistically significant fraction of non-trivial orbits persists at low T-gate densities (N_T/N).

We observe a similar phenomenology in the magic generation as a function of T-gate density. In particular, we find universal scaling of the maximum and mean magic as a function of N_T/N . We also highlight the structure of magic generated by these circuits. Injecting a few T-gates the distribution is discrete but becomes continuous as N_T increases. At large densities N_T/N , most of the weight is found in a sharp peak well below the theoretical maximum.

TT 56.5 Fri 10:30 H37

Magic transition in measurement-only circuits — •Poetri Sonya Tarabunga[1,2] and Emanuele Tirrito[3,4] — [1]Technical University of Munich, Physics Department, 85748 Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), 80799 München, Germany — [3]The Abdus Salam International Centre for Theoretical Physics (ICTP), 34151 Trieste, Italy — [4]Dipartimento di Fisica "E. Pancini", Università di Napoli "Federico II", 80126 Napoli, Italy

Magic quantifies the distance of a quantum state to the set of stabilizer states, and it serves as a necessary resource for potential quantum advantage over classical computing. In this work, we study magic in a measurement-only quantum circuit with competing types of Clifford and non-Clifford measurements, where magic is injected through the non-Clifford measurements. This circuit can be mapped to a classical model that can be simulated efficiently, and the magic can be characterized using any magic measure that is additive for tensor product of single-qubit states. Leveraging this observation, we study the magic transition in this circuit in both one- and two-dimensional lattices using large-scale numerical simulations. Our results demonstrate the presence of a magic transition between two different phases with extensive magic scaling, separated by a critical point in which the mutual magic exhibits scaling behavior analogous to entanglement. We further show that these two distinct phases can be distinguished by the topological magic. In a different regime, with a vanishing rate of non-Clifford measurements, we find that the magic saturates in both phases.

TT 56.6 Fri 10:45 H37

Developing a Framework for Predicting Useful Quantum Advantage in the Calculation of Molecular NMR Spectra — •Keith Fratus, Andisheh Khedri, Juha Leppäkangas, Michael Marthaler, and Jan Reiner — HQS Quantum Simulations GmbH, Karlsruhe, Germany

Demonstrating useful quantum advantage remains a primary goal of quantum computing efforts in the NISQ era. Key to such efforts is the ability to estimate the accuracy and performance of competing classical approximation methods when exact comparisons are not available. In this talk we report on our efforts to develop and understand the behaviour of various classical approximation methods which aim to solve a specific class of chemical simulation problems. In particular, we develop classical simulation methods designed to predict molecular NMR spectra, with the aim of being able to quantify the accuracy and computational requirements of performing these simulations, even for parameter regimes which we do not directly simulate. Using such methods, we work towards a framework for predicting in which parameter regimes, system sizes, and target accuracies one can expect the failure of classical methods for this class of systems, thus allowing for the possibility of quantum advantage.

TT 56.7 Fri 11:00 H37

Linear differential equation approach to the Loschmidt amplitude — •Michael Vogl — King Fahd University of Petroleum and Minerals, Dhahran, Saudi Arabia

The Loschmidt amplitude is a popular quantity that allows making predictions about the stability of quantum states under time evolution. We present an approach that allows us to find a linear differential equation that can be used to compute the Loschmidt amplitude. This approach, while in essence perturbative, has the advantage that it converges at finite order. We demonstrate that the approach for generically chosen matrix Hamiltonians often offers advantages over Taylor and cumulant expansions even when we truncate at finite order. Even in low dimensional systems such as two band Hamiltonians (multi-Weyl semimetals and AB bilayer graphene) it can be used to obtain general formulas for the Loschmidt amplitude after a quench. Results readily generalize to find transmission amplitudes and specific contributions of the partition function, too. Our method can also be applied to many body spin and fermionic Hamiltonians. Here, while the approach still offers advantages, more care has to be taken than in a generic case. We also provide an estimate for a breakdown time of the approximation.

TT 57: Topology and Symmetry-protected Materials (joint session O/TT)

Time: Friday 10:30–12:15 Location: H25

TT 57.1 Fri 10:30 H25

Topological material in the III–V family: heteroepitaxial InBi on InAs — •L. Nicolaï[1], J. Minár[1], M.C. Richter[2,3], O. Heckmann[2,3], J.-M. Mariot[4], U. Djukic[2], J. Adell[5], M. Leandersson[5], J. Sadowski[6], J. Braun[7], H. Ebert[7], J.D. Denlinger[8], I. Vobornik[9], J. Fujii[9], P. Šutta[1], G.R. Bell[10], M. Gmitra[11,12], and K. Hricovini[2,3] — [1]Univiversity of West Bohemia — [2]CY Cergy-Paris Université — [3]Université Paris-Saclay — [4]Sorbonne Université — [5]Lund University — [6]Polish Academy of Sciences — [7]LMU München — [8]ALS — [9]Istituto Officina dei Materiali, CNR — [10]University of Warwick — [11]Pavol Jozef Šafárik University in Košice — [12]Slovak Academy of Sciences

InBi(001) is formed epitaxially on InAs(111)-A by depositing Bi on to an In-rich surface. ARPES measurements reveal topological electronic surface states, close to the $\overline{\mathrm{M}}$ high symmetry point. InBi surprisingly shows coexistence of Bi and In surface terminations. For the Bi termination, the study gives a consistent physical picture of the topological surface electronic structure of InBi(001) terminated by a Bi bilayer rather than a surface formed by splitting to a Bi monolayer termination. Theoretical calculations based on relativistic DFT and the one-step model of photoemission clarify the relationship between the InBi(001) surface termination and the topological surface states, supporting a predominant role of the Bi bilayer termination. Furthermore, a tight-binding model based on this Bi bilayer termination with only Bi–Bi hopping terms gives a deeper insight into the spin texture[1]. [1] Nicolaï *et al.* Phys. Rev. Research 6.4 (2024): 043116.

TT 57.2 Fri 10:45 H25

Hidden spin-texture in an inversion-symmetric Dirac crystal — Kenta Hagiwara[1,2], Peter C. Schmitz[1], Philipp Rüssmann[1], Xin Liang Tan[1,2], Ying-Jiun Chen[3], Kui-Hon Ou Yang[4], Raman Sankar[5], Chien Jing[4], Yi-Hsin Shen[4], Mahmoud Zeer[1], Dongwook Go[6], Iulia Cojocariu[1], Daniel Baranowski[1], Vitaliy Feyer[1], Minn-Tsong Lin[1,6], Stefan Blügel[1], Claus M. Schneider[1,2], Yuriy Mokrousov[1,5], and •Christian Tusche[1,2] — [1]Peter Grünberg Institut, Forschungszentrum Jülich, — [2]Faculty of Physics, University of Duisburg-Essen — [3]Ernst Ruska-Centre, Forschungszentrum Jülich — [4]Department of Physics, National Taiwan University, Taipei, Taiwan — [5]Academia Sinica, Taipei, Taiwan — [6]Johannes-Gutenberg University Mainz

A hidden spin polarization refers to a local spin polarization caused by apparent symmetry breaking and offers new perspectives for spintronics applications. Transition metal dichalcogenides can host various topological phases depending on the symmetry of their crystal structure. Here, by means of spin-resolving momentum microscopy, we reveal the spin texture of both topologically and symmetrically distinct surface and bulk Dirac cones in the inversion symmetric Dirac semimetal $NiTe_2$. We discovered a "hidden" spin polarization the bulk Dirac cone, localized at the different Te layers of the inversion symmetric bulk unit cell, such that the overlap of the two states results in a topologically trivial Dirac cone enforced by the global crystal symmetry. This work establishes a link between topology, spin-texture, and symmetry, enabling control by external perturbations.

TT 57.3 Fri 11:00 H25

Edge spectroscopy of the quantum spin Hall insulator indenene — •Jonas Erhardt[1,2], Mattia Ianetti[3], Gianni Profeta[3], Domenico Di Sante[4], Giorgio Sangiovanni[2,5], Simon Moser[1,2], and Ralph Claessen[1,2] — [1]Physikalisches Institut, Universität Würzburg — [2]Würzburg-Dresden Cluster of Excellence ct.qmat — [3]Department of Physical and Chemical Sciences, University of L'Aquila — [4]Department of Physics and Astronomy, University of Bologna — [5]Institut für Theoretische Physik und Astrophysik, Universität Würzburg

The non-trivial topology of the quantum spin Hall insulator indenene was recently demonstrated through bulk probes that reveal its topological band ordering [1,2]. According to the bulk-boundary correspondence, this ensures the existence of robust metallic states confined to the edge of this triangular indium monolayer. In this study, we employ scanning tunneling spectroscopy to investigate all three edge types of indenene for this correspondence. Our results demonstrate metallic edge density of states with suppressed backscattering near the bulk band gap, providing strong evidence for the existence of topologically protected edge states in indenene.

TT 57.4 Fri 11:15 H25

Bismuthene at the Graphene/SiC Interface: A Protected Quantum Spin Hall Insulator — •Niclas Tilgner[1], Susanne Wolff[1], Serguei Soubatch[2], Andres D. P. Unigarro[1], Sibylle Gemming[1], F. Stefan Tautz[2], Christian Kumpf[2], Thomas Seyller[1], Fabian Göhler[1], and Philip Schädlich[1] — [1]Institute of Physics, Chemnitz University of Technology, Germany — [2]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, Germany

Quantum spin Hall insulators (QSHIs) hold the potential to revolutionize next-generation technologies. Kane and Mele identified 2D honeycomb structures of heavy atoms with strong spin-orbit coupling as promising candidates for these materials. To realize this potential, however, the QSHI must be shielded from environmental influences. Previous research has demonstrated the intercalation of 2D Bi layers beneath graphene on SiC, resulting in the formation of two distinct phases. Among those, the β-phase exhibits a $(\sqrt{3}\times\sqrt{3})R30^\circ$ periodicity relative

to the substrate. We identify the Bi adsorption site using x-ray standing wave imaging, a method which deterimes the element specific, 3D atomic distribution with respect to the bulk unit cell. After subsequent hydrogen intercalation, the Bi position changes significantly from hollow to top site adsorption. Further measurements with angle-resolved photoelectron spectroscopy reveal the band structure of the QSHI bismuthene with a pronounced Rashba splitting and slight p-type doping. We propose that the initial β-phase has to be considered as an electronically inactive layer of bismuthene, whose electronic structure can be established by subsequent hydrogen intercalation.

TT 57.5 Fri 11:30 H25

Probing the Electronic Structure at the Boundary of Topological Insulators in the Bi2Se3 Family by Combined STM and AFM — •Christoph S. Setescak[1], Irene Aguilera[2], Adrian Weindl[1], Matthias Kronseder[1], Andrea Donarini[1], and Franz J. Giessibl[1] — [1]University of Regensburg, Regensburg, Germany — [2]University of Amsterdam and European Theoretical Spectroscopy Facility (ETSF), Amsterdam, The Netherlands

We develop a numerical scheme for the calculation of tunneling current I and differential conductance dI/dV of metal and CO terminated STM tips on the topological insulators Bi2Se3, Bi2Te2Se and Bi2Te3 and find excellent agreement with experiment. The calculation is an application of Chen's derivative rule, whereby the Bloch functions are obtained from Wannier interpolated tightbinding Hamiltonians and maximally localized Wannier functions from first-principle DFT+GW calculations. We observe signatures of the topological boundary modes, their hybridization with bulk bands, Van Hove singularities of the bulk bands and characterize the orbital character of these electronic modes using the high spatial resolution of STM and AFM. Bare DFT calculations are insufficient to explain the experimental data, which are instead accurately reproduced by many-body corrected GW calculations.

TT 57.6 Fri 11:45 H25

Revealing higher-order topological bulk-boundary correspondence in Bi crystals with spin-helical hinge state loop and proximity superconductivity — •Dongming Zhao[1], Yang Zhong[1], Tian Yuan[1], Haitao Wang[1], Tianxing Jiang[1], Yang Qi[1], Hongjun Xiang[1,2,3], Xingao Gong[1,2,3], Donglai Feng[2,3,4], and Tong Zhang[1,2,3,4] — [1]Fudan University, Shanghai, China — [2]Collaborative Innovation Center for Advanced Microstructures, Nanjing, China — [3]Shanghai Research Center for Quantum Sciences, Shanghai, China — [4]Hefei National Laboratory, Hefei, China

Topological materials are typically characterized by gapless boundary states, known as bulk-boundary correspondence. Recently, this concept has been generalized in higher-order topological insulators (HOTIs). E.g., a 2nd-order 3D TI hosts 1D topological hinge states winding around the crystal. A complete verification of HOTI will require probing all crystal boundaries. Here we studied a promising candidate of 2nd-order TI, Bi, in the form of mesoscopic crystals grown on superconducting V3Si. Using low-temperature STM, we directly observed dispersive 1D states on various hinges. Upon introducing magnetic scatterers, new scattering channels emerged selectively on certain hinges, revealing their spin-helical nature. Combining first-principle calculation and global symmetry analysis, we find these hinge states topological and formed a closed loop encircling the crystal. This provides direct evidence on the HOTI in Bi. Moreover, proximity superconductivity is observed in the topological hinge states serving as a promising platform for realizing topological superconductivity.

TT 57.7 Fri 12:00 H25

Simultaneous Atomic-Scale Imaging and Electronic Characterization of Wet-Chemically Prepared Bi_2Se_3 Nanoplatelets — •Auke Vlasblom, Victor Wesselingh, Jara Vliem, Daniel Vanmaekelbergh, and Ingmar Swart — Utrecht University, Utrecht, The Netherlands

Colloidal semiconductor nanoparticles are of great interest for various optoelectronic applications, such as integration in displays, solar cells and electronics. For applications, the surface of nanoparticles is of critical importance. However, until now, no technique exists to simultaneously investigate the atomic structure (e.g. the presence of defects) and the electronic properties of a nanoparticle, foremost limited by the presence of ligands that prevent direct access to the surface with a local probe. Here, we present a new and widely applicable procedure that allows investigation of the surface of a nanoparticle with a local probe. Using this method, nanoparticles are transferred to an atomically clean substrate under ultra-high vacuum conditions. We demonstrate the procedure for topological two-dimensional Bi_2Se_3 nanoplatelets deposited on Au(111). We reveal the atomic and electronic structure of the surface of colloidally synthesised Bi_2Se_3 nanoplatelets with scanning tunneling microscopy and spectroscopy measurements. In this talk, I will highlight the various types of defects that occur at the (sub-)surface of Bi_2Se_3 nanoplatelets and I will show their influence on the electronic structure.

TT 58: f-Electron Systems and Heavy Fermions

Time: Friday 11:30–13:00 Location: H31

TT 58.1 Fri 11:30 H31

The in-plane magnetic anisotropy of the coupled antiferromagnetic and charge-multipolar orders in $CeRh_2As_2$ — •Konstantin Semeniuk[1], Seunghyun Khim[1], and Elena Hassinger[1,2] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]Dresden University of Technology, Institute for Solid State and Materials Physics, Dresden, Germany

The heavy-fermion superconductor $CeRh_2As_2$ displays multiple intriguing electronic orders (1,2). Besides two superconducting phases, the material also hosts a state called Phase I at temperatures below $T_0 = 0.5$ K. Phase I exhibits magnetism (3), but the response of T_0 to a magnetic field H along the *ab* plane of the tetragonal lattice is incompatible with conventional magnetic orders. In particular, while $T_0(H)$ is rather stable in Phase I, at a critical field H_{cr} the material transitions into Phase II, in which T_0 rapidly increases with field.

We conducted a detailed investigation of the H-T phase diagram of $CeRh_2As_2$ for various in-plane field orientations. The behaviour of $T_0(H)$ is remarkably different for $H||[100]$ and $H||[110]$, with, respectively, suppression and enhancement of T_0 in Phase I, as well as strong anisotropy of H_{cr}. In line with recent theoretical work (4), we regard Phase I as a unique case of coupled antiferromagnetic and charge-multipolar orders, and use our results to constrain the model.

TT 58.2 Fri 11:45 H31

Complex magnetic order from multiple Ce–sites in $CeRhSn_2$. — Petr Opletal[1], Jan Fikáček[1], Arumugam Thamizhavel[2], Zakir Hossain[3], Róbert Tarasenko[4], Vladimír Tkáč[4], and •Jeroen Custers[1] — [1]Charles University, MMF DCMP, Prague, Czech Republic — [2]DCMP & MS, Tata Institute of Fundamental Research, Mumbai, India — [3]Dept. of Physics, Indian Institute of Technology, Kanpur, India — [4]Institute of Physics, Faculty of Science, P.J. Šafárik University, Košice, Slovak Republic

Previous reports on polycrystalline $CeRhSn_2$ reveal different magnetic ground states being ferromagnetic ($T_C = 4$ K) or antiferromagnetic ($T_N = 3.5$ K). To elucidate we have grown a single crystal and conducted measurements of the magnetization (M), specific heat (C_p/T), and electrical resistivity (ρ). The compound crystallizes in the orthorhombic lattice structure with space group *Cmcm* characterized by the cell parameters $a = 4.5905(10)$Å, $b = 16.9758(5)$Å and $c = 9.5924(3)$Å. Moreover, it exhibits two crystallographic inequivalent Ce–sites with a zigzag chain of Ce–atoms running along the c–axis. Our measurements reveal an AFM phase transition at $T_{M1} = 3.6$ K manifesting by a strong decrease of the orthorhombic c–axis magnetization, while only a tiny cusp is notable along the other directions, a sharp discontinuity in C_p/T and a kink in ρ and a subsequent ferrimagnet–like (FIM) ordering at $T_{M2} = 1.7$ K visible by a λ-shape of peak in C_p/T and a sudden drop in the resistivity. We map out a B–T phase diagram for field $B \parallel b$–axis and follow the evolution of the transitions under hydrostatic pressure up to 3 GPa.

TT 58.3 Fri 12:00 H31

Anderson impurity model calculations for line shape analyses of core to valence RIXS spectra of Ce Kondo materials — •Michelangelo Tagliavini[1], Federico Mazza[2], Xinlin Yan[2], Andrey Prokofiev[2], Kurt Kummer[3], Maurits W. Haverkort[1], and Silke Paschen[2] — [1]*Institute for Theoretical Physics (ITP), Heidelberg University*, Philosophenweg 19, 69120, Heidelberg, Germany — [2]*Institute of Solid State Physics, Vienna University of Technology*, Wiedner Hauptstr. 8-10/138 A 1040 Vienna, Austria — [3]*European Synchrotron Radiation Facility*, 71 Avenue des Martyrs, CS40220, F-38043 Grenoble Cedex 9, France

In rare-earth-containing heavy-fermion compounds, the interaction of continuum electrons with 4f local moments can give rise to a Kondo screened ground state. Crystal-field excited states can be probed using Resonant Inelastic X-ray Scattering (RIXS). Interaction between localized 4f states and continuum electrons transforms the crystal-field excitations into resonances with hybridization-dependent asymmetric line shapes. In this study, we present results for two heavy-fermion compounds: $CeBa_7Au_6Si_{40}$ and $CeRu_4Sn_6$, which exhibit low (≈1 K) and high (≈ 200 K) Kondo temperatures, respectively. Using density-functional-theory-based Anderson impurity model calculations implemented in Quanty (www.Quanty.org), we link the f-f transition line shapes to the hybridiza-

tion function in these materials. Our findings reveal a direct relationship between the hybridization function, the Kondo temperature, and the crystal fields, offering new insights into the underlying physics of these complex systems.

TT 58.4 Fri 12:15 H31

Emergent in-plane anisotropic elastoresistance in $YbRh_2Si_2$ — •Soumendra Nath Panja, Jacques Gounelle-Pontanel, Anton Jesche, and Philipp Gegenwart — Experimental Physics VI, Center for Electronic Correlations and Magnetism, University of Augsburg, 86159 Augsburg, Germany

We have shown recently that the Kondo interaction in the tetragonal heavy-fermion metal $YbRh_2Si_2$ can be efficiently tuned by tensile and compressive uniaxial strain along the [100] axis [1]. Here, we present a detailed investigation of the temperature dependent elastoresistance $d\rho/d\epsilon_i$ of $YbRh_2Si_2$, for both i=[100] and [110] directions. Remarkably, elastoresistance develops a pronounced in-plane strain anisotropy at low temperatures that is analyzed with respect to the influence of uniaxial strain on the crystal electric field splitting and Kondo interaction. Furthermore, we investigate the combined impact of magnetic field and strain on the low-temperature elastoresistance behavior in $YbRh_2Si_2$.

TT 58.5 Fri 12:30 H31

Anisotropic antiferromagnetic order in $EuPd_3Si_2$ — •Michelle Ocker[1], Nour Marayatta[2], Michael Merz[2], Kristin Kliemt[1], and Cornelius Krellner[1] — [1]Physikalisches Institut, Goethe Universität Frankfurt, 60438 Frankfurt/Main, Germany — [2]Karlsruhe Institute of Technology, 76021 Karlsruhe, Germany

The magnetic order of a rare earth compounds is determined by the RKKY exchange interaction. In case of Eu compounds small changes in the growth method or the initial composition can potentially lead to small composition changes which than modify the physical properties [1]. For example, the compound $EuPd_3Si_2$, which crystallises in the orthorhombic space group Imma, shows a ferromagnetic transition at T_{C1} = 78 K and a spin reorientation at T_{C2} = 5 K according to Ref. [2]. Whereas our $EuPd_3Si_2$ samples show an antiferromagnetic transition at T_{N1} = 61 K and a possible reorientation at T_{N2} = 40 K. With field aligned along the three main symmetrie directions, our samples show different degrees of anisotropy, as has been observed for related compounds [3]. In this presentation, we report about the crystal growth and our evaluation of the physical properties, from which we constructed a magnetic phase diagram.

TT 58.6 Fri 12:45 H31

Coherent valence dynamics in UAl_3 — •Vinicius Estevo Silva Frehse[1], Hlynur Gretarsson[2], Eric Bauer[3], Atsushi Hariki[4], Filip Ronning[3], and Marein Rahn[1] — [1]Center for Electronic Correlations and Magnetism, Augsburg, Germany — [2]P01 High Resolution Dynamics Beamline, Hamburg, Germany — [3]Institute for Materials Science, Los Alamos, USA — [4]Department of Physics and Electronics, Osaka, Japan

The interaction between itinerant and localized electrons, as proposed by the Kondo model, enables the formation of heavy fermions, and unconventional superconductivity. In f-electron intermetallics with a large Kondo temperature, the emergence of lattice-coherent valence dynamics can be resolved by resonant inelastic x-ray scattering (RIXS). In the simple cubic, strongly valence fluctuating compound UAl_3, a coherent Fermi surface of Kondo quasiparticles emerges around $T_{coh} \sim 200$ K. We study the excitations of these quasiparticles using the newly available RIXS instrumentation for the tender x-ray range. The spectra indeed reveal dispersive trends of the 5f interband excitations at low temperatures, reminiscent of the isostructural 4f compound $CePd_3$[1]. [1] M.C.Rahn, *et al.*, Nat. Comm. **13**, 6129 (2022).

TT 59: Quantum Chaos (joint session DY/TT)

Time: Friday 11:30–13:00 Location: H37

TT 59.1 Fri 11:30 H37

Semiclassical foundation of universality in many-body quantum circuits — •Maximilian Kieler[1], Felix Fritzsch[2], and Arnd Bäcker[1] — [1]TU Dresden, Institut für Theoretische Physik, Dresden, Germany — [2]Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Straße 38, 01187 Dresden, Germany

For single particle systems the fundamental equivalence of quantum chaotic systems and random matrix theory is well-understood by means of semiclassical periodic orbit theory. We propose an extension to spatially local many-body systems by incorporating the concept of symmetry-breaking. Using this we show that random matrix behavior arises generically in quantum chaotic many-body systems in the form of a symmetry breaking of local time-translation symmetries. This general framework is applied to quantum circuits where an explicit correspondence to the random matrix result for the spectral form factor can be shown.

TT 59.2 Fri 11:45 H37

Distribution of resonance poles of chaotic scattering systems — •Jan Robert Schmidt, Florian Lorenz, and Roland Ketzmerick — TU Dresden, Institute of Theoretical Physics, Dresden, Germany

The distribution of resonance poles of chaotic scattering systems is investigated in the semiclassical limit at unprecedented small wavelengths. For the paradigmatic three-disk scattering system, we study the spectral gap towards the real axis, the fractal Weyl law, which counts the number of resonance poles, and the distribution of decay rates. These properties are compared to previous analytical results, e.g. from random matrix theory. In contrast to this system with full escape, systems with partial escape have significantly different properties. For the example of a dielectric cavity, we show that results from random matrix theory cannot explain the distribution of decay rates.

TT 59.3 Fri 12:00 H37

Solved after 60 years: Exact Derivation of the Ericson Transition in Quantum Chaotic Scattering — •Simon Köhnes and Thomas Guhr — University of Duisburg-Essen, Lotharstr. 1, 47048 Duisburg, Germany

Scattering experiments are the prime source of information on the quantum world. Scattering theory nowadays has numerous applications in various branches of physics and beyond, even including classical wave phenomena. We analyze chaotic scattering systems in the framework of Random Matrix Theory. The distribution of the scattering matrix elements is the key quantity. A strong sign of chaos in complex quantum systems is the Ericson regime of strongly overlapping resonances in which the cross sections exhibit random behavior. We apply the Supersymmetry Method. For the three Wigner-Dyson symmetry classes, we analytically calculate the transition to the Ericson regime, facilitating direct comparison with experimental results. In the course of doing so, we also gather new information on features of the underlying supersymmetric non-linear sigma model.

TT 59.4 Fri 12:15 H37

Chaotic Quantum Scattering: Exact Solutions for Systems with Spin — •Nils Gluth and Thomas Guhr — Universität Duisburg-Essen, Duisburg, Germany

Scattering experiments facilitate access to quantum systems. Scattering theory is needed to fully describe the involved experimental situations. Over the years, it became a powerful tool with applications to a large variety of different systems, such as for example compound nuclei, atoms, molecules, quantum graphs or even microwave networks and cavities. These systems are typically complex or in a broad sense chaotic, calling for statistical approaches, in particular Random Matrix Theory. Considerably extending our previous work, we calculate the distribution of scattering matrix elements and cross sections using Supersymmetry. We focus on the symplectic symmetry class which had not yet been solved, because a theoretical understanding is needed in view of recent experiments. We provide a comparison of our results with experimental data.

TT 59.5 Fri 12:30 H37

Phase-space representations and exceptional points of coupled polarized modes in cylindrical cavities — •Tom Rodemund[1], Shilong Li[2], Síle Nic Chormaic[3], and Martina Hentschel[1] — [1]Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany — [2]College of Information Science and Electronic Engineering, Zhejiang University, Hangzhou, China — [3]Okinawa Institute of Science and Technology Graduate University, Okinawa, Japan

% Optical microcavities are often assumed to be two-dimensional (2D). This allows a convenient phase-space representation in 2D, where Poincaré surface of section for particle dynamics and the Husimi function for their wave counterpart are prominent methods. Here we extend the concept of Husimi functions for open systems [1] to three-dimensional (3D) optical microcavities of arbitrary shape. In particular we study deformed cylindrical cavities and illustrate their mode dynamics in terms of generalized Husimi functions.

The coupling between the two different polarizations (TE and TM) is a new feature in realistic 3D optical cavities that is not present in 2D. We find the interaction of polarized modes to be governed by a network of exceptional points that reflects the openness, or non-Hermiticity, of the system. The mode coupling is analyzed using the extended Husimi formalism that we find to be a comprehensive and useful way to represent the mode structure of 3D microcavities [2].

TT 59.6 Fri 12:45 H37

The classical Maldacena-Shenker-Standford bound — •Gerrit Caspari, Fabian Haneder, Juan-Diego Urbina, and Klaus Richter — University of Regensburg, Regensburg, Deutschland

The Maldacena-Shenker-Stanford (MSS) bound [1] is a condition on a system's quantum Lyapunov exponent, defined as half the growth rate of the regularised out-of-time-ordered correlator (OTOC), which states that said exponent is bounded by the system's temperature, with, e.g., black holes as characteristic systems saturating the bound.

From the perspective of classical chaos, this is surprising, since the classical Lyapunov exponent seems not to be bounded. We study chaotic quantum systems in a hyperbolic geometry with and without cusps and magnetic fields [2][3] via Selberg's Trace Formula (STF). Through this we derive bounds on the classical Lyapunov exponent from analyticity conditions in the trace formula and relate them to the MSS bound.

We report our progress in studying these bounds using the STF, which entails an investigation of the analyticity condition needed to prove the STF for the partition function of our systems and its relation to possible phase transitions.

Reshaping the History of Quantum Physics: Paths to Gender Equality — •Andrea Reichenberger — TU Munich

We are all familiar with gender dynamics, biases, and stereotypes on the online platforms we visit, use, and co-create every day. They are ubiquitous in large language models (LLMs) and other generative AI technologies trained on large amounts of data. Their spillover effects are now well studied in scientific research. There is comparatively little research on how the history of physics is represented and practiced in today's online spaces. This talk will take you on a journey through the history of quantum physics, exploring new avenues for a gender-sensitive future of the history of physics. And it offers a critical insight into how expertise in the history of physics, science communication and public opinion influence and reinforce each other in the practice of digital history. Drawing on a series of case studies on women in the history of quantum physics, we examine the Matilda effect on online platforms and offer perspectives on how to successfully counteract this effect, which gives a name to the systematic misrecognition of women's contributions to science and technology.

Invited Talk AKC 1.2 Fri 11:15 H2

Prevention and protection against sexual harassment, discrimination and violence (SBDG): A private matter or how much does it concern us as a university? — •Michael Tunç — Katholische Hochschule für Sozialwesen, Berlin, Deutschland

Universities have the obligation to implement measures to prevent sexual harassment in the workplace according to AGG paragraph 12. But there are people reporting assaults and sexual harassment against physicists occur repeatedly.

In this lecture, participants will get brief informations how they can effectively support/protect themselves and others at universities. The lecture would like to sensitize by presenting the following basic informations:

- What is sexual harassment at the university (facts and figures)?
- What are the causes and consequences of sexual harassment for employees and the university organization?
- What are the rights of those affected and the obligations of those involved?

The topic of being/becoming a bystander includes sensitization as well as hits on concrete options for action, both for male and female participants. First ideas will be given how a complaint procedure to prosecute sexual harassment can be established. Relevant questions are:

- How can a professional protection of victims succeed?
- How do you deal with your fears of hierarchical, legal consequences?
- How can you protect dependent people from hierarchically superior people?

30 min. discussion

AKC 2: Women in Physics Lunch

Time: Friday 12:15–13:15 Location: H2

Female physicists of all career stages are cordially invited to join our meet-and-greet networking lunch or snack. Diverse and all kinds of interested colleagues are also welcome!

AIW 1: Quantencomputing

Time: Wednesday 14:00–15:30 Location: H4

Willkommen und Grußwort durch AIW und AKPIK - Hans-Georg Grothues, John Kettler, Tim Ruhe

AIW 1.1 Wed 14:10 H4

Von Quantenwinter bis Quantensprung - Wo stehen Quantentechnologien heute? — •Carina Kiessling — Roland Berger

Von Quantenwinter bis Quantensprung - Wo stehen Quantentechnologien heute?", gibt einen Einblick in die Markt-Entwicklung von Quantentechnologien und in den Fortschritt kommerzieller Anwendungen. Darüber hinaus werden Zukunftspotenziale hinsichtlich Zeithorizont, Kollaboration zwischen Forschung und Wirtschaft sowie geopolitische Schwachstellen diskutiert.

AIW 1.2 Wed 14:30 H4

Der Weg zum praktischen Quantencomputing - Potenziale und Use-Cases — •Nico Piatkowski — Fraunhofer-Institut für Intelligente Analyse- und Informationssysteme

Auch wenn nahezu monatlich neue Durchbrüche berichtet werden, steckt die praktische Anwendung von Quantencomputern noch in den Kinderschuhen. Für die meisten produktiven Anwendungen sind Quantenalgorithmen nicht bekannt, und wenn doch, sind die praktischen Probleminstanzen oft zu groß für die derzeit verfügbaren Quantencomputer. Daher ist es heute wichtig, sich mit generellen Fragen der Anwendbarkeit auseinanderzusetzen. In meinem Vortrag erkläre ich, welche Berechnungsprobleme vom Quantencomputing profitieren können, und stelle drei Use-Cases aus den Bereichen Erdbeobachtung, Chipdesign und Flugplanmanagement vor. Experimentelle Ergebnisse zeigen, was heute möglich ist und wo noch Forschungsbedarf besteht.

AIW 1.3 Wed 14:50 H4

Wie verbinden wir die Quanten- mit unserer klassischen Welt? — •Claudius Riek — Zurich Instruments Germany

Die Nutzung der Quantenphysik ermöglicht Anwendungen, die über das hinausgehen, was auf der Grundlage der klassischen Physik möglich ist. Modernste Technologien wie Elektronik, Kryogenik oder Photonik erlauben es uns erst, dieses Potenzial auszuschöpfen. Zurich Instruments bietet Messtechnik und Steuerelektronik für Quantencomputer an, um Qubits zu kontrollieren, auszulesen und eine Quantenfehlerkorrektur durchzuführen und so die Quantenwelt effektiv mit unserer klassischen Welt zu verbinden. Die Umsetzung von Technologien aus dem Labor in innovative Produkte erfordert ein tiefes Verständnis der wissenschaftlichen Anwendungen. - Wie und wo Physiker auf dieser Reise ihren Beitrag leisten, ist oft nicht so offensichtlich, wie es vielleicht aussieht.

Podiumsdiskussion: Quantencomputing - Perspektiven für die Industrie

AIW 2: Quantenkommunikation

AIW 2.1 Wed 16:00 H4

Introduction to quantum cryptography and related use-cases — •Mathieu Bozzio — Universität Wien

Harnessing the quantum properties of light can boost the security of communication networks by relying on physical assumptions instead of computational assumptions. This talk will provide a brief introduction to the principles of quantum cryptography and present use-cases in which its security features may be desirable such as message encryption, leader election and centralized digital payments

AIW 2.2 Wed 16:20 H4

Quantenkommunikation in der Raumfahrt — •Stephan Seidel — Airbus Defence \& Space

Das Aufkommen von Quantencomputern stellt eine Bedrohung für die derzeit verwendeten asymmetrischen Verschlüsselungsalgorithmen dar, da Quantencomputer die klassisch rechenintensiven mathematischen Probleme, auf denen diese Algorithmen basieren, in deutlich kürzerer Zeit lösen können. Dies eröffnet nicht nur die Möglichkeit Nachrichten zu entschlüsseln, die nach einer breiten Verfügbarkeit von Quantencomputern gesendet wurden, sondern auch solcher die vorher aufgezeichnet wurden.

Die Quanten-Schlüsselverteilung (Quantum Key Distribution, QKD) ist ein Mittel, um diese Bedrohung zu neutralisieren. Sie nutzt die Prinzipien der Quantenmechanik, um Schlüssel für die Verschlüsselung sicher zwischen zwei Parteien zu verteilen. Daten werden in Quantenzuständen von Licht codiert, und da jede Messung an einem Quantenzustand diesen verändert, kann ein Abfangen des Schlüssels erkannt werden. In Kombination mit symmetrischer Verschlüsselung, beispielsweise durch One-Time-Pad-Verschlüsselung, bei der jedes Bit des Schlüssels direkt ein Bit der Nachricht verschlüsselt, kann eine sichere Kommunikation hergestellt werden. Diese Kommunikation ist sowohl gegen Angriffe klassischer als auch Quantencomputer resistent.

In Zukunft könnte eine europäischen Quantenkommunikationsinfrastruktur neben terrestrische Glasfasernetzwerken ein weltraumbasiertes System umfassen, um eine vollständige Abdeckung in der EU und auf anderen Kontinenten zu gewährleisten.

Airbus arbeitet an der Entwicklung der Quanten-Schlüsselverteilung in verschiedenen nationalen und europäischen Programmen, die von der Technologieentwicklung bis hin zur Architektur einer europäischen Quantenkommunikationsinfrastruktur reichen. In dieser Präsentation geben wir einen Überblick über den aktuellen Stand der Arbeiten.

AIW 2.3 Wed 16:40 H4

Small is beautiful: Leading innovation in miniaturizing quantum sensors — •Binh Tran — Bosch Quantum Sensing

After almost ten years of research in the field of quantum sensing, Bosch is taking the next step in transforming tabletop experiments into portable sensor solutions. In this talk, I will give you an introduction into our sensor technology based on nitrogen-vacancy (NV) centers in diamond. This technology provides many advantages over conventional sensors, such as a high magnetic field sensitivity with the ability to operate at ambient conditions. Finally, I will present how these unique properties open up exciting applications ranging from detecting tiny signals in medical diagnosis to improving airplane navigation.* I joined Bosch after finishing my PhD in experimental quantum physics. As a research engineer at Bosch, I am able to readily apply knowledge from physics lectures and laboratory experience into an emerging technology.

Podiumsdiskussion: Quantenkommunikation - Chancen für globale Anwendungen

AIW 3: Get Together bei Bier und Brezeln

Time: Wednesday 17:20–18:30 Location: H4

Im Anschluss an die Sitzungen lädt der Arbeitskreis Industrie und Wirtschaft zu Bier und Brezeln ein. In diesem Rahmen kann die Diskussion mit den Referenten und weiteren anwesenden Mitgliedern des AIW im persönlichen Gespräch vertieft werden.

Sessions

– Invited Talks, Tutorials, Contributed Talks, and Posters –

AKPIK 1: Hands-on Tutorial: AI Fundamentals for Research (joint session BP/TUT/DY/AKPIK)

Artificial intelligence (AI) has become an essential tool in modern physics, enabling new approaches to data analysis, modeling, and prediction. This hands-on tutorial provides an accessible introduction to key AI concepts, emphasizing their practical applications in physics research.

Please bring your laptop. There will be limited power outlets in the room, so come with a fully charged battery.

Materials will be made available from 10.03.2025, accessible via the following options:

GitHub repository:

https://github.com/RedMechanism/DPG-SKM-2025-Tutorial-AI-Fundamentals-for-Research

ZIP file download:

https://jlubox.uni-giessen.de/getlink/fiAGRzcGTiCL3GZxk8WAjom4/

Participants are encouraged to download them ahead of time.

Organized by Jan Bürger (Aachen), Janine Graser (Duisburg), Robin Msiska (Duisburg/Ghent), and Arash Rahimi-Iman (Gießen), with support from Stefan Klumpp (Göttingen) and Tim Ruhe (Dortmund).

Time: Sunday 16:00–18:15 Location: H2

Tutorial AKPIK 1.1 Sun 16:00 H2

Introduction — Jan Bürger[1], •Janine Graser[2], Robin Msiska[2,3], and Arash Rahimi-Iman[4] — [1]ErUM-Data-Hub, RWTH Aachen University, Aachen, Germany — [2]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Duisburg, Germany — [3]Department of Solid State Sciences, Ghent University, Ghent, Belgium — [4]I. Physikalisches Institut and Center for Materials Research, Justus-Liebig-University Gießen, Gießen, Germany

The session begins with an overview of essential AI concepts, including neural networks, training methodologies, and key distinctions between AI models. Participants will gain a foundational understanding of AI principles and how these tools can be leveraged for various research challenges.

5 min. break

Tutorial AKPIK 1.2 Sun 16:40 H2

Hands-On Session 1 – Function Approximation — •Jan Bürger[1], Janine Graser[2], Robin Msiska[2,3], and Arash Rahimi-Iman[4] — [1]ErUM-Data-Hub, RWTH Aachen University, Aachen, Germany — [2]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Duisburg, Germany — [3]Department of Solid State Sciences, Ghent University, Ghent, Belgium — [4]I. Physikalisches Institut and Center for Materials Research, Justus-Liebig-University Gießen, Gießen, Germany

In the first half of the interactive session, participants will work with Jupyter Notebooks to explore practical applications of machine learning. They will train simple neural networks to predict a mathematical function, gaining hands-on experience in tuning key parameters. Since neural networks can typically be considered universal function approximators, this concept is effectively illustrated using a one-dimensional function, making it easy to visualize and understand.

5 min. break

Tutorial AKPIK 1.3 Sun 17:30 H2

Hands-On Session 2 – Classification and More — Jan Bürger[1], Janine Graser[2], •Robin Msiska[2,3], and Arash Rahimi-Iman[4] — [1]ErUM-Data-Hub, RWTH Aachen University, Aachen, Germany — [2]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Duisburg, Germany — [3]Department of Solid State Sciences, Ghent University, Ghent, Belgium — [4]I. Physikalisches Institut and Center for Materials Research, Justus-Liebig-University Gießen, Gießen, Germany

The session demonstrates how pre-trained models can simplify tasks such as classification, making them readily applicable to research. Typical examples include recognizing handwritten digits, which showcase the power of pretrained models in solving common challenges. As a preview of advanced topics, the tutorial concludes with brief examples of large language models (LLMs) and generative AI.

AKPIK 2: Machine Learning Prediction and Optimization Tasks

Time: Tuesday 9:30–10:30 Location: H5

AKPIK 2.1 Tue 9:30 H5

Attention space geometry — •Claudius Gros — Institute for Theoretical Physics, Goethe University Frankfurt

Attention involves comparing query and key vectors in terms of a scalar product, $\mathbf{Q} \cdot \mathbf{K}$, together with a subsequent softmax normalization. Classicaly, parallel/orthogonal/anti-parallel queries and keys lead to large/intermediate/small attention weights. Here we study expressive attention (EA), which is based on $(\mathbf{Q} \cdot \mathbf{K})^2$, the squared dot product. In this case attention is enhanced when query and key are either parallel or anti-parallel, and suppressed for orthogonal configurations. For a series of auto-regressive prediction tasks, we find that EA performs at least as well as the standard mechanism, dot-product attention (DPA). Increasing task complexity, EA is observed to outperform DPA with increasing margins, which also holds for multi-task settings. For a given model size, EA manages to achieve 100% performance for a range of complexity levels not accessible to DPA.

AKPIK 2.2 Tue 9:45 H5

Global Opimization of Atomic Structures in Extra Dimensions — •Casper Larsen[1], Sami Kaappa[2], Andreas Vishart[3], Thomas Bligaard[4], and Karsten Jacobsen[5] — [1]Technical University of München — [2]Tampere University — [3]Technical University of Denmark — [4]Technical University of Denmark — [5]Technical University of Denmark

This work formulates an approach to global optimization of atomic structures by use of an atomic descriptor extending the atoms with additional nonphysical degrees of freedom. These include chemical identity coordinates, atomic existence, and hyperspatial coordinates, all of which can be energetically minimized separately or simultaneously. The minimization is performed on a surrogate potential energy surface generated by Gaussian process regression trained on DFT calculations as part of a Bayesian optimization algorithm, where it is assured that all relaxational end states and training points are physically valid. The method is shown to successfully interpolate energy and force predictions from a training set of physically valid structures to structures with nonphysical coordinates. The inclusion of extra degrees of freedom significantly improves the efficiency of optimization of both clusters and bulk materials by circumventing energy barriers encountered in the conventional potential energy surface.

AKPIK 2.3 Tue 10:00 H5

Co-orchestration of multiple instruments for automated exploration of structure-property relationships in combinatorial libraries — •Boris Slautin[1], Utkarsh Pratiush[2], Ilia Ivanov[3], Yongtao Liu[3], Rohit Pant[4],

Xiaohang Zhang[4], Ichiro Takeuchi[4], Maxim Ziatdinov[5], and Sergei Kalinin[2,5] — [1]University of Duisburg-Essen, Essen, Germany — [2]University of Tennessee, Knoxville USA — [3]Oak Ridge National Laboratory, Oak Ridge, USA — [4]University of Maryland, College Park, USA — [5]Pacific Northwest National Laboratory, Richland, USA

The advancement of combinatorial synthesis techniques has significantly accelerated the development of novel materials. However, closing the loop in materials design requires powerful approaches for characterizing the synthesized libraries. This is a non-trivial task, as characterization often involves revealing multiple methods.

We present a multimodal co-orchestration framework for autonomous combinatorial library characterization through the simultaneous coordination of various tools (e.g., Raman spectroscopy, SPM). The multimodal co-orchestration enables the real-time utilization of acquired knowledge about one property to accelerate the exploration of other properties measured by different methods. The capabilities of the proposed framework were validated by the co-orchestrating of the SPM and Raman techniques in the Sm-BiFeO3 combinatorial library. The workflow confirms its effectiveness in optimizing the exploration trajectory. The proposed framework is general and can be extended to multiple modalities and arbitrary dimensionality of signals.

AKPIK 2.4 Tue 10:15 H5

Data nexus vista: A research assistance framework for physics-informed descriptor engineering — •Kanchan Sarkar and Axel Gross — Institute of Theoretical Chemistry, Ulm University, 89069 Ulm, Germany

In today's fast-paced world, accurate modeling and prediction of complex systems are more crucial than ever, particularly for advancing modern technologies. In energy storage, for example, the design of materials with tailored properties for sustainable, next-generation devices is a critical goal. However, the vast materials space and intricate nature of materials data poses serious challenges for experimental and computational explorations, often likened to searching for a needle in a haystack. To address this, we present "Data Nexus Vista," a flexible framework for descriptor engineering. The framework offers four core functionalities: (1) adaptive preprocessing protocols for defining physically meaningful data transformations; (2) a feature selection interface that incorporates physics-based rules for improved interpretability; (3) diverse correlation analysis tools to uncover underlying physical mechanisms; and (4) workflows for developing interpretable models that balance physical validity with statistical robustness. By enabling thorough exploration of data-physical phenomena connections, this user-guided, modular approach ensures scientific rigor while addressing uncertainties in complex systems. Moreover, its adaptable design allows seamless application across diverse domains, from energy storage, surface science to nonlinear optical properties, advancing both scientific discovery and practical innovation.

AKPIK 3: Research with AI: Hardware, Software, Tools

Time: Tuesday 11:00–12:30 Location: H5

Invited Talk AKPIK 3.1 Tue 11:00 H5

3D Integration Towards Autonomous Optical Neural Networks — •Adrià Grabulosa, Anas Skalli, and Daniel Brunner — Institute Femto-ST, Université Marie et Louis Pasteur, CNRS UMR6174, 15B Avenue des Montboucons, Besançon, France.

In the last decades, modern electronic integrated circuits has reached a fundamental limit at 2 nm feature sizes. At the same time, emerging computing concepts such as neural networks (NNs), which are already playing a major role in modern societies, further amplifying this challenge. Adopting the third dimension is a promising strategy for achieving scalability of connections over the microchip's dimensions. Here, based on additive one- (OPP) and two-photon polymerization (TPP) processes and combined with direct-laser writing (DLW) settings, a complete toolbox comprising photonic waveguides, splitters and bends towards three-dimensional (3D) photonic integration is presented. The concept CMOS is validated by printing 3D photonic waveguides onto semiconductor (GaAs) substrates and silicon-on-insulator (SOI) platforms. Finally, we show first steps towards the 3D integration of a fully autonomous NN using spatially multiplexed modes of an injection locked large area vertical cavity surface emitting laser (LA-VCSEL) capable of performing NN tasks with >98% accuracy, fully realized in hardware using off-the-shelf, low energy consumption components. Overall, these building blocks are highly appealing for realizing fully-parallel and efficient communication throughout a densely-connected network, which are pivotal concepts for future NN computing topologies.

AKPIK 3.2 Tue 11:30 H5

Brain-inspired Computing with Gold Nanoparticle Networks: A Kinetic Monte Carlo Model — •Jonas Mensing and Andreas Heuer — Institute of physical Chemistry, University of Münster, Germany

Nanoparticles interconnected by insulating organic molecules exhibit nonlinear switching behavior at low temperatures. By assembling these nonlinear switches into a network and manipulating the inner charge transport dynamics via surrounding electrodes, the network can be functionalized to approximate functions such as Boolean Logic or model dynamical systems given the temporal dependence of input data. This makes nanoparticle networks promising candidates for neuromorphic computing and eventually bring machine learning applications on hardware.

We developed a kinetic Monte Calo simulation tool that applies established principles of single-electronics to model charge transport dynamics in nanoparticle networks. We demonstrate the network*s capability to approximate functions such as Boolean logic, perform nonlinear transformation of time dependent input signals, and forecast time series. These applications are evaluated using fitness metrics, enabling the optimization of surrounding electrode voltages to train the internal charge transport for a given task. The fitness measures are further analyzed in relation to system sizes, network disorder, or temporal scales. Furthermore, newly derived metrics enable us to link these design parameters to general nonlinear properties of the network.

AKPIK 3.3 Tue 11:45 H5

Discovery of the data structure as a way for prediction accuracy improvement — •Aliaksei Mazheika — independent researcher, Berlin, DE

High prediction accuracy of machine learning (ML) models is the main figure of merit of models efficiency. Usually this is achieved by choosing an optimal ML method, discovering the hyperparameters space, augmenting the data, etc. However, if a data set contains the data subsets significantly varying in their properties, addressing such heterogeneity can be pretty challenging task. Herewith a new method is presented in which improvement of prediction accuracy is achieved by discovering the heterogeneity of the data sets. This is done using a data mining method the subgroups discovery, in which the subsets of data are generated and discovered in terms of prediction accuracy improvement of local models in comparison to the global model within certain ML formalism. The application of this method showed its efficiency for classical data sets allowing for instance to solve the XOR problem staying on the level of logistic regression. Applying developed method for building ML models for a range of perovskite materials properties (lattice vector, tolerance factor) showed improvement of prediction accuracy for up to 50% for regression tasks, and up to 10% for classification. Also the new method was found to provide improved domains of applicability for ML models compared to previously proposed ones.

AKPIK 3.4 Tue 12:00 H5

Calculating the electronic structure of GaAs using Variational Quantum Algorithms — •Ivana Miháliková[1,2], Michal Krejčí[1,2], and Martin Friák[1] — [1]Institute of Physics of Materials, Czech Academy of Sciences, Brno, Czech Republic — [2]Department of Condensed Matter Physics, Faculty of Science, Masaryk University, Brno, Czech Republic

Simulating and characterizing physical systems is one of the most promising applications of quantum computing. In our research, we focused on electronic structure calculations of GaAs using quantum computer simulator. This work explores the binary crystal gallium arsenide, employing Variational Quantum Deflation (VQD) and the Subspace-Search Variational Quantum Eigensolver (SSVQE) to access the full energy spectrum. A tight-binding Hamiltonian is used to investigate the effects of optimization methods, hyperparameter tuning, and quantum circuit architecture on the performance of these variational quantum algorithms. Our findings show that higher-energy states require more iterations for accurate evaluation, with the Constrained Optimization BY Linear Approximation (COBYLA) method proving to be the most effective. Notably, SSVQE demonstrates robustness to hyperparameter settings, while VQD is highly sensitive requiring precise hyperparameter tuning for optimal performance.

AKPIK 3.5 Tue 12:15 H5

Photonics and A.I. Education Supported by Virtual Reality and Unreal Engine Contents — •Arash Rahimi-Iman — I. Physikalisches Institut and Center for Materials Research, Justus-Liebig-Universität Gießen, 35392 Gießen, Germany

3D interactive elements visualized in computer game engines combined with virtual or mixed reality (VR/XR) offer many possibilities to reach younger people. Here, we present one example of a virtual reality environment for gamification in

the field of photonics and AI, created in the Unreal Engine UE5 for own teaching and training activities.

Thanks to modern information technologies, a plethora of ways exist which allow promoting topics of interest to a wider audience - among them digital games on platforms such as PCs and phones. While modern simulation software and sophisticated 3D visualization tools from all around typically address advanced users with a much more accurate science representation, simplified exploration spaces and toy experiments can create excitement at different age levels and attract potentially new students towards natural science topics based on fun and fascination.

AKPIK 4: Focus: Applications of Deep Neural Networks

Time: Tuesday 14:00–15:30 Location: H5

Invited Talk AKPIK 4.1 Tue 14:00 H5

The Scaling of Intelligence: From Transformers to Agentic AI — •Oliver Mey — Vodafone Tech Innovation Center, Dresden, Germany

The 2024 Nobel Prize in Physics recognized fundamental contributions to artificial intelligence and highlighted its profound impact on all disciplines, including physics. Generative AI has become a central tool in science and beyond, and understanding its underlying principles, the forces driving its rapid progress, and its emerging applications opens the door to new scientific breakthroughs and transformative innovations. We trace the evolution from Moore's Law to the scaling principles that enable today's large-scale AI models. At the heart of this transformation lies the Transformer architecture, the foundation of large-scale language models (LLMs) that generate coherent, context-aware text. These models are evolving into multimodal systems that seamlessly integrate text, images and other data types, greatly expanding their capabilities. Retrieval-augmented generation (RAG) extends LLMs with dynamic memory, enabling access to external information. In parallel, new concepts for task-dependent scaling of computations allow LLMs to distribute computational effort based on task complexity, increasing their efficiency in reasoning and adaptive problem solving. These advances pave the way for AI systems that act as collaborative agents and are capable of context-aware, goal-oriented interactions. In this talk, I will provide an overview of these developments and discuss them in the context of their broader implications, setting the stage for further specialized discussions.

Invited Talk AKPIK 4.2 Tue 14:30 H5

Inverse Design in Electromagnetics with Artificial Intelligence — •Willie Padilla — Duke University, Durham, North Carolina, USA

Artificial electromagnetic materials (AEMs) have enabled exotic electromagnetic responses that are difficult or impossible to achieve with naturally occurring materials. However, as AEMs have become more complex, the relationship between their structure and resulting properties is increasingly less understood, or sometimes completely unknown. Deep neural networks (DNNs) have been shown to effectively infer the relationship between AEM geometry and their electromagnetic properties, using simulated training data. More recently, a type of DNN * termed a large language model (LLM) * has shown a remarkable ability to respond to complex prompts. This presentation explores the potential of DNNs and LLMs for the inverse design of AEMs. I present a LLM fine-tuned on simulated data that can predict electromagnetic spectra over a range of frequencies given a text prompt that only specifies the AEM geometry. In view of the great potential of deep learning for the future of AEM research, we review the status of the field, focusing on recent advances, open challenges, and future directions.

Invited Talk AKPIK 4.3 Tue 15:00 H5

Inverse design of lateral hybrid metasurfaces with machine learning — •Rui Fang[1], Amir Ghasemi[1], Dagou Zeze[1], Koen Valk[2], Yuqing Jiao[2], Peter Zijlstra[2], and Mehdi Keshavarz Hedayati[1] — [1]Durham University — [2]Eindhoven Technology University

The development of metasurface structural colour typically depends on laborious and time-consuming simulations such as Finite Element Method (FEM) or Finite-Difference Time-Domain (FDTD) simulation, along with human intuition for parameter adjustments, rendering it impractical for design optimization. In this context, we have introduced an innovative AI-assisted design process that circumvents the intricate simulations, allowing for a swift and precise correlation between metasurface parameters and colour coordinates. In this study, we have applied the model to the lateral hybrid design, a novel concept in metasurfaces proposed by our research group and demonstrated that the model can predict a structure tailored to achieve continuous colour coordinates with an accuracy of up to 97%. A noteworthy aspect of our discovery is that the model is capable of predicting the range of colours that can be generated from a single design of an active metasurface. Our deep learning approach proves to be a valuable tool in designing active metasurfaces for structural colours. This advancement contributes to the development of highly sensitive sensors, bringing tunable metamaterials closer to practical applications.

AKPIK 5: Poster

Time: Thursday 15:00–16:30 Location: P2

AKPIK 5.1 Thu 15:00 P2

Photonic Matrix-Vector Multiplication at the Quantum Limit of single photons — •Mingwei Yang[1,2], Okan Akyüz[2], Felix Kübler[2], Konrad Tschernig[1], Xavi Barcons[1,3], Enrico Stoll[2], and Janik Wolters[1,2] — [1]Deutsches Zentrum für Luft- und Raumfahrt, Institute of Optical Sensor Systems, Berlin, Germany. — [2]Technische Universität Berlin, Berlin, Germany. — [3]Humboldt-Universität zu Berlin, Berlin, Germany.

Photonic integrated circuits (PICs) have emerged as a promising solution for performing energy-efficient matrix multiplication and addition operations (MACs) in neural networks [1]. In this work, we demonstrate a 4x4 optical matrix-vector multiplication (MVM) using a mesh of Mach-Zehnder interferometers (MZIs), operating with attenuated laser pulses at the single-photon level. Using this as an example, we analyze the quantum limit of energy consumption of optical systems for classical machine learning. [1] Wetzstein, Gordon, et al. "Inference in artificial intelligence with deep optics and photonics." Nature 588.7836 (2020): 39-47.

AKPIK 5.2 Thu 15:00 P2

Machine Learning Optimization of Chiral Photonic Nanostructures — •Davide Filippozzi[1], Nicolas Roy[2], Alexandre Mayer[2], and Arash Rahimi-Iman[1] — [1]I. Physikalisches Institut and Center for Materials Research, Justus-Liebig-Universität Gießen, 35392 Gießen, Germany — [2]NaXys, Namur Institute for Complex Systems, University of Namur, Belgium

Deep learning (DL) and evolutionary algorithms (EA) as part of the machine learning (ML) domain have recently been well utilized for optimization purposes, such as for nanostructure design. Particularly, unintuitive problems can benefit from the potential abstraction levels that artificial Neural Networks (NNs) can achieve based on sufficient training and proper data. Reinforcement learning approaches promise to boost inference of solutions for complicated design requirements and specific functionalities.

We present a study that discusses the nano-pattern design optimization with a combination of DL and EA for a dielectric surface's preference for single-handed circularly polarized light in reflection or transmission. Advancing our previous simulations and algorithms [O. Mey and A. Rahimi-Iman, Phys. Status Solidi RRL 2022, 16, 2100571], the optimization in chiral dichroism and reflectivity for our metasurface's design is discussed. Such ML optimization can improve desirable features of unintuitive metamaterials and photonic nanostructures, as increasingly highlighted in up-to-date literature.

AKPIK 5.3 Thu 15:00 P2

Towards an ontology-based digital twin for graphene-based conductor materials — •Fabian Teichert[1,2,3], Leonhard Niemann[4,5], Florian Fuchs[1,2,3], Jörg Schuster[1,2,3], and Martin Köhne[4] — [1]Fraunhofer Institute for Electronic Nano Systems (ENAS), Chemnitz, Germany — [2]Center for Microtechnologies, Chemnitz University of Technology, Chemnitz, Germany — [3]Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Chemnitz University of Technology, Chemnitz, Germany — [4]Department of Advanced Technologies and Micro Systems, Robert Bosch GmbH, Renningen, Germany — [5]Faculty of Natural Sciences, Chemnitz University of Technology, Chemnitz, Germany

The „Platform Material Digital" (www.materialdigital.de) advances digital twins within material science, based on a semantic description using ontologies. The aim is to digitally represent (new) materials, their properties and crucial processing steps. We are actively involved in this endeavour by digitalizing graphene-based conductor materials. An ontology is created and enriched with simulation data and experimental data, covering various aspects such as model parameters, preparation processes, and measurement processes. We create the fol-

lowing demonstrator use cases with a semantic data description: (1) the integration of our simulation methods as workflows within the „Platform Material Digital", (2) an App to store, filter, and post-process our production and measurement processes and material properties of the graphene-based conductor materials.

AKPIK 5.4 Thu 15:00 P2

Machine learning to resolve the structure: Perovskites and related materials — •Ekaterina Kneschaurek, Vladimir Starostin, Valentin Munteanu, Constantin Völter, Damian Balaz, Mikhail Romodin, Maik Hylinski, Dmitry Lapkin, Ivan Zaluzhnyy, Alexander Hinderhofer, Alexander Gerlach, and Frank Schreiber — University of Tübingen, Tübingen, Germany

Recent advances in synthesis of novel materials used in solar cells, such as perovskites, are supported by structural analysis, using X-rays. To unravel the complexity of such materials, we utilize both *in situ* (studying crystallization kinetics) and *ex situ* (accessing phase composition) X-ray diffraction. The high-resolution scattering patterns are recorded by large 2D detectors, resulting in enormous amounts of data, which are difficult to analyze manually [1]. In some cases, there are no crystallographic information files (.cif) for the newly synthesized materials. An initial guess, based on the composition of the studied material, can estimate ranges of expected scattering signals from distinct phases. The deep learning (DL) model can detect Bragg peaks within the diffraction pattern, while the application of clustering and 2D Gaussian fitting enables the processing of complex data to be conducted more effectively. Preliminary data analysis of 2D patterns in real time can increase the efficiency of beamtimes and provide a feedback loop to optimize the parameters of the experiment.

[1] Hinderhofer, A., Greco, A., Starostin, V., Munteanu, V., Pithan, L., Gerlach, A., Schreiber, F. (2023). J. Appl. Cryst. **56**, 3-11.

AKPIK 5.5 Thu 15:00 P2

Balancing the Cart-Pole: Deep Q-Networks vs. Echo State Networks — •Igor Polonskiy, Atreya Majumdar, and Karin Everschor-Sitte — Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, 47057 Duisburg, Germany

Balancing a pole on a moving cart by applying directional forces is a standard benchmark problem in reinforcement learning. Deep Q-Networks [1], which integrate reinforcement learning with neural networks, have been highly effective in solving this problem. However, their reliance on multiple hidden layers makes them computationally intensive and energy-demanding. Replacing these hidden layers with an Echo State Network reduces trainable parameters and energy consumption. In this study, we compare the performance of Deep Q-Networks and Echo State Networks on the Cart-Pole problem. We show that an Echo State Network-Q-Network combination, with sufficient size and runtime, can not only match but also surpass Deep Q-Networks in cumulative rewards and control success rates.

[1] V. Mnih et al., Nature 518, 529 (2015)

AKPIK 5.6 Thu 15:00 P2

Latent Measures of Memory and Stochasticity in Dynamical Systems: Murphy's Law of Tumbling Toast — •Janine Graser, Atreya Majumdar, Kübra Kalkan, Ross Knapman, and Karin Everschor-Sitte — Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of DuisburgEssen, 47057 Duisburg, Germany

Murphy's Law, which suggests that "anything that can go wrong will go wrong," is often exemplified by toast landing butter-side down. In reality, a toast falling from a table can be described by Newtonian mechanics and is bound to fall on the butter side under standard conditions [1]. Here, the fall is modelled through its seemingly hidden aspects (table height and toast asymmetry because of the butter).

We revisit the tumbling toast problem using the data-driven machine learning tools - latent entropy and latent dimension -introduced by Horenko et al. [2]. We develop a Python-based implementation that characterizes the fall using these latent measures. This approach has broader applications in other dynamical systems, such as predicting and optimizing magnetic material properties.

[1] R. A. J. Matthews, Eur. J. Phys. 16 172 (1995)
[2] I. Horenko et al., Commun. Appl. Math. Comput. Sci. 16 267-297 (2021).

AKPIK 5.7 Thu 15:00 P2

Measurement of thermal conductivity and thermal diffusivity through spatial and temporal temperature gradients — •Junsheng Zhuo[2] and Stephanie Lippmann[1,2] — [1]Institute of Applied Physics, Friedrich Schiller University Jena, Jena, Thuringia, 07745, Germany — [2]Otto Schott Institute of Materials Research, Friedrich Schiller University Jena, Jena, Thuringia, 07743, Germany

To address the challenges of measuring thermal properties of metal, a new device is being developed to measure both thermal conductivity and thermal diffusivity quickly and accurately. The sample is heated directly using an electromagnetic induction furnace, avoiding thermal resistance issues. High-resolution infrared cameras capture temperature distribution with ultra-short time and space intervals, allowing for precise thermal conductivity and diffusivity measurements. Mineral oil is used for cooling, enabling rapid heat transfer. This device calculates temperature-dependent thermal conductivity using spatial temperature gradients and heat flow, based on Fourier's law assisted by fitting, statistics, and machine learning, while thermal diffusivity is derived from real-time transient temperature gradients using the inverse method. Specific heat capacity is then calculated from these two values.

AKPIK 5.8 Thu 15:00 P2

Deterministic Model of Multi-Agent Boltzmann Q-Learning: Transient Dynamics, Feedback Loops, and Non-Convergence — •David Goll[1], Jobst Heitzig[2], and Wolfram Barfuss[3] — [1]Humboldt University of Berlin — [2]Potsdam Institute of Climate Impact Research — [3]University of Bonn

Multi-Agent Reinforcement Learning involves interacting agents whose learning processes are indirectly coupled through their shared environment, giving rise to emergent, collective dynamics that are sensitive to initial conditions and parameter variations. A Complex Systems approach, which examines dynamic interactions in multi-component systems, can uncover the underlying dynamics by constructing deterministic, approximate models of stochastic algorithms. In this work, we show that even in the simplest case of independent Q-learning with a Boltzmann exploration policy, previous models fail to capture actual learning behaviour. Specifically, the dynamics of the Q-space—representing agents' state-action value estimates—cannot be directly reduced to the lower-dimensional policy space representing their strategies, as assumed in earlier models. By explicitly incorporating agents' update frequencies, we propose a new discrete-time model that captures the observed behaviours and uncovers a fundamentally more complex dynamical landscape. We demonstrate the utility of this approach by applying it to the Prisoner's Dilemma, where our model distinguishes transient states, which might be mistaken for equilibria, from true equilibria. Furthermore, we show that varying hyperparameters, such as the discount factor, can prevent convergence to a joint policy.

AKPIK 5.9 Thu 15:00 P2

Noisy quantum computing of electronic structure of crystals — •Vojtěch Vašina[1,2], Ivana Miháliková[1], and Martin Friák[1] — [1]Institute of Physics of Materials, Czech Academy of Sciences, Brno, Czech Republic — [2]Brno University of Technology, Brno, Czech Republic

Quantum computing is currently emerging as a useful paradigm for solving highly complex computational problems. Current quantum computers are unfortunately too noisy to provide sufficient accuracy, and quantum-classical hybrid algorithms emerged as a solution. Variational Quantum Eigensolver (VQE) has gained significant attention for addressing challenges in quantum chemistry, material science, etc. VQEs typically use multiple optimization methods, and the correct choice of optimization method can significantly impact performance. In our study, we focused on the comparison of multiple optimization methods used in VQE when applied to the electronic structure of crystals. The quantum part of VQE ran on a classical simulator with imported noise models from real quantum computers from the IBM Quantum Platform.

AKPIK 5.10 Thu 15:00 P2

Advancing Digital Transformation in Research on Universe and Matter in Germany — Martin Erdmann[1], •Jan M. Bürger[1], Banjamin Fischer[1], Stefan Fröse[2], Judith Steinfeld[1], and Angela Warkentin[1] — [1]RWTH Aachen University — [2]TU Dortmund University

Research on Universe and Matter (ErUM) at major infrastructures such as CERN or large observatories, jointly conducted with university groups, is an important driver for the digital transformation. In Germany, about 20,000 scientists are working on ErUM-related sciences and can benefit from actual methods of artificial intelligence. The central networking and transfer office ErUM-Data-Hub provides support by designing, organizing and performing schools and workshops for young and expert scientists in the areas of big data, machine learning, sustainable computing and many more. We present the actual achievements of the ErUM-Data-Hub in the German ErUM community.

AKPIK 5.11 Thu 15:00 P2

The graphene resonant metasurface substrate in near-zero refractive index regime to control the surface plasmon-polariton propagation length — •Zoya Eremenko — Leibniz-Institut für Festkörper- und Werkstoffforschung, Dresden, Deutschland

The study goal is to identify and investigate conditions for controlling the propagation length of graphene surface plasmon-polaritons (SPP) through the utilization of hybrid graphene-dielectric metasurfaces. We study the spectral characteristics of resonant multipole modes in all-dielectric metasurface using the photonic crystal approach, metasurface unit cell modelling approach and implement these approaches by the commercial software Comsol Multiphysics 6.2. For controlling the propagation length of graphene SPPs we used all-dielectric metasurface as a substrate of graphene layer in a near-zero refractive index regime. The determined the parameters of the near-zero refractive index regime for the studied metasurface, which is crucial for achieving the main project goal of con-

trolling SPP propagation length in the graphene layer. Knowing the effective refractive index of the metasurface unit cell in the near-zero regime, these values are used in Comsol modeling the hybrid metasurface as a graphene layer substrate to calculate the SPP propagation length.

Development of a Parametric Design Program for Building Construction Elements using Artificial Intelligence — •Artem Burdin — Moscow, Russia

Thesis: The aim of this research is to develop a parametric design program for building construction elements using artificial intelligence, focusing on the application of modern IT and artificial intelligence in physics-based modeling and simulation. The program will enable the creation of complex building structures, such as bridges, tunnels, and high-rise buildings, with increased accuracy and efficiency. Key objectives: * Analyze the current state of parametric design in building construction * Develop a parametric design program using artificial intelligence and machine learning algorithms * Implement the program using a suitable programming language and software * Test and validate the program using real-world examples * Evaluate the program's performance and potential applications in the construction industry Expected outcomes: * A parametric design program capable of generating complex building structures with increased accuracy and efficiency * A comprehensive analysis of the current state of parametric design in building construction * A detailed evaluation of the program's performance and potential applications in the construction industry * Contributions to the development of artificial intelligence and modern IT in physics-based modeling and simulation Keywords: parametric design, building construction, artificial intelligence, machine learning, physics-based modeling, simulation, computer-aided design (CAD), construction industry.

AKPIK 5.13 Thu 15:00 P2

Working group on physics, modern Information technologies and artificial Intelligence — •Adam Barakhoev — Moscow, Russia

Artificial intelligence and modern computer infrastructure are changing the approach to physics, combining powerful computational methods with experiments. These innovations help scientists process large amounts of data, automate complex tasks, and make accurate predictions. One of the important achievements is the use of artificial intelligence to improve physical experiments, especially in quantum mechanics and optical systems. Machine learning algorithms can predict results based on incomplete data and help set up experiments in real time, which significantly increases their efficiency and accuracy. Also, modern OT technologies, such as cloud services and high-performance computing, are important for managing the large-scale modeling needed in modern physics research.

AKPIK 5.14 Thu 15:00 P2

Autonomous Vehicles: Technologies and Challenges — •Nikita Timoshin — Moscow, Russia

Autonomous vehicles are transforming transportation with technologies such as artificial intelligence (AI), machine learning, and advanced sensor systems like LiDAR, radar, and cameras. These vehicles rely on AI to make real-time decisions, using data from various sensors through sensor fusion for accurate environmental perception. Communication networks like V2X (Vehicle-to-Everything) and 5G enable vehicles to interact with infrastructure and other vehicles.

The benefits include enhanced safety by reducing human error, improved traffic efficiency, and increased mobility for people with disabilities. However, challenges such as sensor limitations in adverse conditions, high computational demands, and ethical dilemmas about decision-making in critical situations remain. Additionally, regulatory and privacy concerns need to be addressed. As autonomous vehicles integrate with smart cities, they could significantly reshape urban mobility.

AKPIK 5.15 Thu 15:00 P2

Experimental examination of the validity of the Turing test for considering Artificial Intelligence as having subjectivity — •Lev Gelbart and Alexey Iakovlev — Moscow, Russia

The speed of development of Artificial Intelligence (AI) raises questions about its subjectivity and thinking. Alan Turing, who set the criteria for thinking, did not consider subjectivity. There are sharp discussions on this topic, for example, Doctor of Law Valery Zorkin, professor at MSU, opposes endowing AI with subjectivity, emphasising humanism.

It should also be taken into account that the Turing test may be invalid if we consider people, who are not capable of passing it. For example, a study by Alan Ropper (2010) showed that patients in a vegetative state can demonstrate brain activity, but are clearly unable to pass the Turing test, which does not detract from their human value.

We have considered, whether a machine can pass a test designed for humans. Machines are thought to not be able to adequately mimic emotions, so we tested three chatbots (Lily, AI Chat, ChatGPT) for emotional intelligence using the IDRlabs test. All chatbots performed above the average of humans (77.27%, 68.87%, 64.6%), but this, obviously, does not make them subjects of law.

Conclusion: the Turing test is not valid for assessing the subjectivity of AI.

Unmanned transportation in the field of cargo transportation and its contribution to industry. — •Alexey Platonov — Moscow, Russia

In recent years, the transportation industry has witnessed a transformative shift towards automation and innovation, with unmanned transportation systems emerging as a pivotal force in cargo logistics.

Unmanned transportation significantly improves safety in cargo movement. By reducing the reliance on human drivers, the industry can mitigate the risks associated with human error, a leading cause of accidents in transportation.

The integration of LiDAR into cargo transportation also opens up new avenues for delivery services.

It is worth considering that the active introduction of unmanned vehicles in cargo transportation is beginning. Several test shipments of real orders were made on KamAZ-5490 trucks without direct driver control. There was only a mechanic controller in the cockpit, who checked the performance of the systems.

By enhancing efficiency, improving safety, and fostering innovation, these technologies are set to revolutionize the logistics landscape, proving that the future of transportation is indeed unmanned.

AKPIK 5.17 Thu 15:00 P2

Crawler-motor grader — •Vyacheslav Kharchevnikov — Moscow, Russia

An overview of the relevance and necessity of developing a crawler-mounted motor grader. A description of the problems that this equipment solves in the construction and road sector. An analysis of existing models of motor graders, including wheeled and tracked versions, their advantages and disadvantages. Defining the main goal of the project - to create an effective crawler-mounted motor grader. Setting the tasks necessary to achieve the goal, such as improving the cross-country ability and stability of the equipment. A detailed description of the design of a crawler-mounted motor grader, including the features of the chassis, control system and attachments.

An analysis of the economic feasibility of introducing a crawler-mounted motor grader, a comparison with traditional models, an assessment of production and operating costs. An assessment of the environmental impact of using a crawler-mounted motor grader, measures to reduce emissions and reduce noise. Summarizing the research, assessing the results achieved and prospects for further development and implementation of a crawler-mounted motor grader.

Acceleration of crystal structure relaxation with Deep Reinforcement Learning — •Elena Trukhan, Efim Mazhnik, and Artem R. Oganov — Moscow, Russia

We introduce a Deep Reinforcement Learning (DRL) model for the structure relaxation of crystal materials and compare different types of neural network architectures and reinforcement learning algorithms for this purpose. Experiments are conducted on Al-Fe structures, with potential energy surfaces generated using EAM potentials. We examine the influence of hyperparameter settings on model performance and benchmark the best-performing models against classical optimization algorithms. Additionally, the model's capacity to generalize learned interaction patterns from smaller atomic systems to more complex systems is assessed. The results demonstrate the potential of DRL models to enhance the efficiency of structure relaxation compared to traditional methods.

AKPIK 6: AI Methods for Materials Science

Time: Thursday 16:30–18:00 Location: H5

AKPIK 6.1 Thu 16:30 H5

Bayesian Optimization for High-Resolution Transmission Electron Microscopy — •Xiankang Tang[1], Lei Jin[2], Yixuan Zhang[1], Rafal Dunin-Borkowski[2], and Hongbin Zhang[1] — [1]Institute of Materials Science, TU Darmstadt, 64287 Darmstadt, Germany — [2]Ernst Ruska-Centrum für Mikroskopie und Spectroskopie mit Elektronen, FZ Jülich, 52428 Jülich, Germany

Advances in machine learning technologies make it possible to automatize material characterizations, indispensable for the near-future implementation of autonomous experimentation for solid-state materials. High-resolution transmission electron microscopy (HRTEM) allows the study of the atomic structure of solid materials with sub-Angstrom resolution. By matching experimental and simulated images, unknown experimental parameters and crystal structures can be determined. However, this process entails strong domain expertise and can be time-consuming. In this work, we implement a Bayesian optimization-based approach to automatize the image analysis processes. Combined with some prior information, such as the experimentally measured aberration, the 3D crystal structure of the specimen can be reconstructed from a single HRTEM image. Specifically, by defining the mean square error(MSE) of pixel intensity values between experimental and simulated images, our method effectively captures both global and local image features. This approach not only achieves an exact match in absolute image contrast but also identifies unknown experimental parameters, optimizes atomic positions, and reveals surface morphology at atomic resolution.

AKPIK 6.2 Thu 16:45 H5

Synthetic Data Generation for Enhanced Segmentation of Electron Microscopy Images — •Amir Omidvarnia[1], Ali Ghaznavi[2], Junbeom Park[1], Shibabrata Basak[1], and Simone Köcher[1] — [1]Institute of Energy Technologies - Fundamental Electrochemistry (IET-1), Forschungszentrum Jülich GmbH, 52428 Jülich, Germany — [2]Federal Institute for Materials Research and Testing (BAM), 12205 Berlin, Germany

Monitoring structural changes in materials via operando electron microscopy (EM) is crucial for understanding the material's changes under operating conditions, which directly impacts its durability and performance. However, accurate segmentation of features such as cracks or pores in EM time-series data requires extensive labeled datasets, which are challenging to produce due to the labor-intensive, subjective nature of manual annotation. Our research addresses this limitation by exploring different synthetic data generation techniques that can effectively supplement scarce annotated data and improve segmentation outcomes. We evaluate multiple synthetic image generation approaches to enhance the training dataset for U-Net models aimed at segmenting EM time-series data: (1) deep convolutional generative adversarial networks (DCGAN) to produce realistic textures; (2) time-varying image synthesis that mimics the temporal development of features and introduces artificial features to simulate structural imperfections; and (3) standard data augmentation methods. These methods are evaluated in generating training data for EM image segmentation from a limited set of EM images.

AKPIK 6.3 Thu 17:00 H5

Neural Networks in Surface Crystallography: A New Paradigm for GIWAXS Analysis — •Erwin Pfeiler[1], Vladimir Starostin[3], Alexander Hinderhofer[3], Roland Resel[2], Frank Schreiber[3], and Stefan Kowarik[1] — [1]University of Graz, Austria — [2]TU Graz, Austria — [3]University of Tübingen, Germany

Thin film materials are essential to modern technology, with grazing incidence X-ray diffraction (GIWAXS) being the primary method for resolving their crystal structure. However, the current data analysis process is often slow and labor-intensive, frequently requiring more time and resources than the GIWAXS measurements themselves. Accelerating this bottleneck is critical for enabling automated materials discovery.

In this work, we present an AI-driven approach utilizing neural networks to streamline and enhance GIWAXS analysis. Our model predicts unit cell dimensions (a, b, c) and angles (α, β, γ) directly from the positions of Laue reflections. Additionally, it identifies the Miller indices of the contact plane, providing insights into the film texture.

Using both simulated GIWAXS data and real-world examples, we demonstrate the neural network's potential to significantly accelerate the analysis process, delivering accurate structural predictions with sub 0.01 Å precision.

AKPIK 6.4 Thu 17:15 H5

Reflectivity Analysis with AI: The LISA Data Pipeline at P08/DESY — •Julia Kobus[1,2], Lukas Petersdorf[1,2], Svenja Hövelmann[1,2], Alexander Hinderhofer[3], Vladimir Starostin[3], Chen Shen[4], Florian Bertram[4], Linus Pithan[4], Frank Schreiber[3], and Bridget Murphy[1,2,4] — [1]Institute of Experimental and Applied Physics, Kiel University, Leibnizstr. 19, 24118 Kiel, Germany — [2]Ruprecht-Haensel Laboratory, Olshausenstr. 40, 24098 Kiel, Germany — [3]University of Tübingen, 72076 Tübingen, Germany — [4]Deutsches Elektronen-Synchrotron DESY, Notkestraße 85, 22607 Hamburg, Germany

We present a data analysis pipeline that is under development within TA3 of DAPHNE4NFDI for the LISA instrument at the P08 beamline at DESY. This pipeline is adapted from the development on solid surface XRR AI analysis to be used for liquid surfaces and interfaces. The pipeline aims at performing data reduction and subsequent analysis for reflectivity measurements using AI-based models. This approach increases measurement efficiency by processing data in real time, allowing flexible adjustments during the experiment and providing immediate insights. This will help users make better-informed decisions for subsequent measurements. The pipeline also will make advanced data analysis accessible to less experienced users. Our work will demonstrate the potential of AI to transform experimental workflows and data interpretation, and provides a blueprint for similar developments in the scientific community.

AKPIK 6.5 Thu 17:30 H5

Prediction of Infrared Spectra of organic molecules with Active Learning — •Gusein Bedirkhanov[1], Nitik Bhatia[1], Ondrej Krejci[2], and Patrick Rinke[1,2] — [1]Department of Physics, Technical University of Munich, Germany — [2]Department of Applied Physics, Aalto University, Finland

Infrared (IR) spectroscopy is a valuable tool for understanding catalytic processes, but interpreting experimental spectra is challenging due to the strong influence of the species environment. Ab initio molecular dynamics (AIMD) offers accurate theoretical spectra, accounting for anharmonic effects, but at a high computational cost. Machine-learned interatomic potentials (MLIPs), such as MACE [1], provide an alternative to AIMD, enabling accurate and fast IR spectra predictions. To reduce the amount of training data, we have established the active learning method PALIRS [2] (a Python-based active learning code for infrared spectroscopy). PALIRS predicts IR spectra of organic molecules essential in catalytic processes accurately, with peak positions matching experiment within 20cm^{-1}. We aim to further improve the efficiency of PALIRS, using only a hundredth of DFT data in comparison with AIMD, through optimization of MACE training strategies. We will inspect various combinations of transfer learning and conventional iterative training to find the ideal match between training time and final MLIP accuracy.

Towards AI-assisted high-throughput thin film research workflow — •Dmitry Lapkin, Roody Nasro, Constantin Völter, Valentin Munteanu, Alexander Hinderhofer, Alexander Gerlach, and Frank Schreiber — University of Tübingen

The compositional optimization of new materials necessitates the high-throughput screening of a multitude of compositions, which must be investigated to elucidate the non-linear and non-monotonic structure-property-composition dependencies. In this regard, data-driven material science enables researchers to accelerate the identification of new materials with desired properties for specific applications by efficiently exploring vast material spaces. Such high-throughput data-driven studies comprise two key elements: the combinatorial preparation of suitable sample libraries spanning wide compositional ranges, and the high-throughput screening of the structure and properties of the synthesized samples.

In this work, we present a complete workflow for high-throughput studies of thin films. A specially designed vacuum deposition chamber enables the production of gradient thin films suitable for high-throughput screening. Surface-sensitive X-ray scattering methods available at modern X-ray sources comprise a convenient tool for resolving the thin film structure with ultimate resolution and high speed, while the developed AI-based approaches provide on-the-fly analysis of the collected X-ray scattering data.

Index of Exhibitors Regensburg 2025

Exhibition venue
University of Regensburg
Universitätsstraße 31
93053 Regensburg

Exhibition areas
Foyer Audimax, H6, (A)
Economy Building (E)
Tent (T)

	Area	Stand No.
ADDITIVE Soft- und Hardware für Technik und Wissenschaft GmbH Max-Planck-Straße 22 b, 61381 Friedrichsdorf *ADDITIVE steht für Berechnen, Visualisieren, Automatisieren für Statistik und Wissensmanagement im Qualitäts-/Ingenieurwesen mit den Produkten Minitab, Origin, Mathematica und ADDITIVE-Cloud-Services.*	**H6**	**A54**
ADL Analoge & Digitale Leistungselektronik GmbH Bunsenstraße 30, 64293 Darmstadt *ADL is developer and manufacturer of various power supplies for thin film coatings and plasma etching as DC Plasma Power supplies, Uni- and Bipolar pulse generators and Power supplies for Ion Sources.*	**Economy Bldg.**	**E04**
Agilent Technologies Deutschland GmbH Hewlett-Packard-Straße 8, 76337 Waldbronn *Vakuumpumpen, Vakuummessgeräte, Lecksucher.*	**H6**	**A51**
AHF analysentechnik AG Kohlplattenweg 18, 72074 Tübingen *Optical filters (also custom-specific), LED microscopy light sources, image splitters, fluorescence quality monitoring tools, patterned illumination systems for science and research.*	**H6**	**A53**
AIP Publishing 1305 Walt Whitman Road, Suite 300, Melville NY 11747-4300, *APL Quantum, AVS Quantum Science, Journal of Applied Physics, Applied Physics Letters, and more.*	**Foyer Audimax**	**A41**
Allectra GmbH Traubeneichenstr. 62-66, 16567 Schönfließ *Vakuumkomoponenten, el. Durchführungen, Kabel.*	**H6**	**A59**
AMT Andreas Mattil - Technischer Vertrieb Talstraße 33, 67737 Frankelbach *UHV Komponenten und Systeme, Plasma Systeme und Beschichtungsanlagen.*	**Tent**	**T04**
ANFATEC Instruments AG Melanchthonstraße 28, 08606 Oelsnitz (V) *Nano-IR, Rastersonden-Mikroskope, LockIn-Verstärker.*	**Tent**	**T14**

attocube systems AG — **Foyer Audimax** — **A07+A08**

Eglfinger Weg 2, 85540 Haar

Nanopositioners, low-vibration cryostats, low-temperature scanning probe and nanoscale imaging & spectroscopy systems.

Avenir Photonics GmbH & Co. KG — **Economy Bldg.** — **E11**

Franz-Mayer-Straße 1, 93053 Regensburg

Kompakte optische Spektrometer für Wellenlängenbereiche zwischen 185 und 2100 nm.

Bluefors — **Foyer Audimax** — **A42+A43**

Arinatie 10, 003700 Helsinki, Finland

Bluefors is the world leader in manufacturing cryogenic measurement systems, cryocoolers and other cryogenic product lines for quantum technology and fundamental physics research.

Bruker Nano GmbH — **Economy Bldg.** — **E02**

Am Studio 2D, 12489 Berlin

Bruker Nano Surfaces & Metrology.

CAEN ELS S.R.L. — **Foyer Audimax** — **A24**

AREA Science Park - SS14 km 163,5, 34149 Basovizza, Trieste, Italy

High performance power supplies, high precision 0-FLUCS current measurement devices, Beamline electronic instrumentation, Components for FMC and MicroTCA applications.

CLASS 5 PHOTONICS GmbH — **Foyer Audimax** — **A40**

Notkestraße 85, 22607 Hamburg

Ultrafast Lasersystems, High Harmonic Sources, High Power OPCPAs, Complete Beamline Solutions, Customized Lasersystems, Nonlinear Compression, Attodriver, White Dwarf, Supernova

CreaTec Fischer & Co. GmbH — **Tent** — **T17**

Industriestraße 9, 74391 Erligheim

Manufacturer of customized LT-STM/AFM, MBE, RTA and molecular spray systems including associated electronics with software solutions as well as a wide range of equipment for use in (ultra-high) vacuum.

Cryoandmore Budzylek GbR — **Foyer Audimax** — **A11+A12**

Hermann-Cossmann-Straße 19, 41472 Neuss

4 K / 77 K Wet and Dry Cryostats, Closed Cycle Ultra Low Vibration Cryostats 3-5 nm, PulseTube Cryocooler, Custom Cryostats, UHV, Cryogenic Temperature Sensors, Stinger Cryostat, Helium Recovery Solutions, Helium Reliquefier, GM Cryocooler up to 2.2 W@ 4.2 K

Cryogenic Ltd. — **Foyer Audimax** — **A06**

Action Park Estate, London, W3 7QE, United Kingdom

Cryogenic, Helium, cryogen free, magnets, superconducting magnets, Beam Line magnets, NMR Magnets, cold temperature insert, vector magnets, cryocooled magnets.

CryoVac GmbH & Co. KG — **Economy Bldg.** — **E08**

Langbaurghstraße 13, 53842 Troisdorf

Helium-, Bad- und Verdampferkryostate, Temperaturmess- und -regelgeräte.

DCA Instruments Oy — **Economy Bldg.** — **E20**

Aerotie 6, 20360 Turku, Finland

Advanced MBE, PVD and PLD systems for research, optimized for III-VI, III-V, Oxide and Nitride growth.

Deutsche Forschungsgemeinschaft (DFG) — **Foyer Audimax** — **A31**

53170 Bonn

Information und Beratung zu den Förderprogrammen der DFG.

Dr. Eberl MBE-Komponenten GmbH — **Economy Bldg.** — **E06**

Josef-Beyerle-Straße 18/1, 71263 Weil der Stadt

MBE-Systeme, Effusionszellen, Elektronenstrahlverdampfer, Dotierquellen, kundenspezifische Verdampfer.

Edwards GmbH — **Foyer Audimax** — **A39**

Philipp-Hauck-Straße 2, 85622 Feldkirchen

Edwards offers the full range of vacuum pumps and gauges — from atmosphere to ultra-high vacuum (UHV) and extreme high vacuum (XHV). The portfolio ranges from mechanical to ion getter vacuum pumps.

Entropy GmbH — **Tent** — **T09**

Gmunder Straße 37 a, 81379 München

Entropy GmbH is a cryostat manufacturer based in Munich, Germany. The product range offers various types of closed-cycle cryostats for the temperature range of Kelvin and Millikelvin.

FAIRmat c/o Humboldt-Universität zu Berlin — **Foyer Audimax** — **A25**

Zum Großen Windkanal 2, 12489 Berlin

FAIRe Dateninfrastruktur für die Physik der kondensierten Materie und die Chemische Physik von Stoffen.

FEMTO Messtechnik GmbH — **Economy Bldg.** — **E05**

Klosterstraße 64, 10179 Berlin

Rauscharme Signalverstärker, Kompakte Lock-In Verstärkermodule, Empfindliche Photoreceiver.

Fermiologics — **Tent** — **T01**

George-Bähr-Straße 20, 01069 Dresden

ARPES analyzers FeSuMa, cryomanipulators NorFi, complete systems mini-ARPES.

Ferrotec Europe GmbH — **H6** — **A57**

Seerosenstraße 1, 72669 Unterensingen

Ferrotec provides customers with manufacturing products and materials for semiconductor, electronics and high-power applications. EB-PVD equipment, Peltier modules and cooling units will be displayed.

Forschungszentrum Jülich Ernst-Ruska-Centrum (ER-C) — **Economy Bldg.** — **E14**

Wilhelm-Jonen-Straße, 52425 Jülich

The Ernst Ruska-Centre (ER-C) offers external users access to advanced electron microscopy, including state-of-the-art aberration-corrected TEMs, cutting-edge tools and expert support.

GVL Cryoengineering Dr. George V. Lecomte GmbH — **Economy Bldg.** — **E13**

Aachener Straße 89, 52223 Stolberg

Kryotechnisches Zubehör, 3He/4He Kryostate.

Hamamatsu Photonics Deutschland GmbH — **Foyer Audimax** — **A38**

Arzbergerstraße 10, 82211 Herrsching

To improve life through photonic technologies, we continuously develop new products for the generation and measurement of a broad spectrum of wavelengths from x-rays, UV light, visible and infrared.

Heidelberg Instruments Mikrotechnik GmbH — **Tent** — **T02**

Mittelgewannweg 27, 69123 Heidelberg

With more than 1,300 systems installed worldwide, Heidelberg Instruments is a world leader in high-precision laser lithography systems, maskless aligners, and nanofabrication tools.

Helmholtz-Zentrum Dresden-Rossendorf e. V. (HZDRI)
Hochfeld-Magnetlabor Dresden (HLD) — **Tent** — **T19**

Bautzner Landstraße 400, 01328 Dresden

Tensormeter, Tiefsttemperatur-Probenhalter ROTAX, Portable Pulsed Micro Magnetometer PPMM, TeraSED.

HORIBA Jobin Yvon GmbH — **Foyer Audimax** — **A26+A27**

Hans-Mess-Str. 6, 61440 Oberursel

Raman-Mikroskop LabRAM Soleil, Raman-AFM, Signature-SPM.

Hositrad Deutschland — **Foyer Audimax** — **A21**

Lindnergasse 2, 93047 Regensburg

CF, KF, ISO-K, ISO-F, UHV-Vakuumbauteile, Elektrische Durchführungen, Membranbälge, Vakuumkammern, Turbomolekularpumpen, Manipulatoren, Viewports, Sonderanfertigungen.

Hübner Photonics — **H6** — **A49**

Heinrich-Hertz-Straße 2, 34123 Kassel

Manufacturer of high performance lasers and THz systems.

ICEoxford — **Foyer Audimax** — **A33**

Avenue 4, Station Lane, Witney, Oxon, OX28 4BN, United Kingdom

Cryostats

Incienta Technologie GmbH — **Foyer Audimax** — **A09**

Pommernstraße 22, 63110 Rodgau-Weiskirchen

Closed Cycle Cryostats, Helium Flow Cryostats, Cryogenic Probe Stations, Piezo-& Ferro-electric Test Systems, UHV Components, Thin Film Deposition, Hot-plates, Wire Bonder, Die Bonder.

JUST VACUUM GmbH — **Foyer Audimax** — **A45**

Daimlerstraße 17, 66849 Landstuhl

Vakuumtechnik

Kashiyama Europe GmbH — **Foyer Audimax** — **A16**

Leopoldstraße 244, 80807 München

Kashiyama bietet zuverlässige, wartungsarme Multi-Stage Roots Vakuumpumpen (7–300 m³/h), wie die NeoDry-Serie, für die Halbleiter- und Beschichtungsindustrie. Seit 1951 Marktführer in Japan, seit 2018 auch in Europa.

Kleindiek Nanotechnik GmbH — **Foyer Audimax** — **A48**

Aspenhaustraße 25, 72770 Reutlingen

Micromanipulators, nanopositioners, nanoprobing, cryo TEM sample liftout, nano-assembly, manipulators for UHV, force measurement, etc. Give your microscope a hand! www.kleindiek.com.

Leiden Probe Microscopy B.V. — **H6** — **A55**

J.H. Oortweg 19, 2333 CH Leiden, Netherland

EC-STM, ReactorSTM, Onnes Technologies, CryoWalkers.

Leybold GmbH — **Foyer Audimax** — **A46**

Bonner Straße 498, 50968 Köln

Vakuumpumpen

magnitude GmbH — **Economy Bldg.** — **E01**

Am Viertelbach 5, 85464 Finsing

Magnitude is a manufacturer of superconducting magnets based near Munich, Germany. Our focus is on European manufacturing, high quality, reliable delivery performance, and customer satisfaction. We provide a range of Solenoids and Vectormagnets, based on NbTi and Nb3Sn technology.

MaTeck - Material-Technologie & Kristalle GmbH — **H6** — **A52**

Im Langenbroich 20, 52428 Jülich

Einkristalle, Sputtertargets, Substrate, hochreine Materialien, Isotope, Halbleiterkristalle.

mechOnics AG — **Economy Bldg.** — **E17**

Unnützstraße 2 b, 81825 München

Mikropositionierer mit Piezoträgheitsantrieb und Schrittmotor, Piezo- und Schrittmotorsteuerungen.

Menlo Systems GmbH — **Foyer Audimax** — **A17+A18**

Bunsenstraße 5, 82152 Martinsried

Frequency Combs, Quantum Systems, Ultrastable Lasers, FS Lasers, THz Systems.

Munich Quantum Valley — **Tent** — **T15**

Leopoldstraße 244, 80807 München

Munich Quantum Valley promotes quantum science and quantum technologies in Bavaria and offers various research positions, especially in connection to quantum computing.

Nanomagnetics Instruments Suite 290 — **Tent** — **T13**

266 Banbury Road, Oxford OX2 7DL, United Kingdom

NanoMagnetics Instruments, Producer of Scanning Hall Probe Microscope and Atomic Force Microscope

nanoscore tech GmbH — **Economy Bldg.** — **E19**

Zum Greifenstein 5, 65594 Runkel

nanoscore is the European distributor for UNISOKU Scanning Probe Microscope products.

Nanoscribe GmbH — **Economy Bldg.** — **E09**

Hermann-von-Helmholtz-Platz 1, 76021 Karlsruhe

Laserlithografie-Systeme zur 3D Mikro- und Nanostrukturierung, PIC und Probenerstellung.

Nanosurf GmbH — **Foyer Audimax** — **A19**

Rheinstraße 5, 63225 Langen

Atomic Force Microscopes, AFM, Scanning Probe Microscopes, SPM, Rasterkraft-mikroskope.

Oxford Instruments GmbH — **Foyer Audimax** — **A44**

Borsigstraße 15 a, 65205 Wiesbaden

Mikroskope und Analysengeräte.

Park Systems Europe GmbH — **Foyer Audimax** — **A29+A30**

Schildkrötstraße 15, 68199 Mannheim

Atomic Force Microscopy, Imaging Spectroscopic, Ellipsometry.

Pfeiffer Vacuum GmbH — **Tent** — **T20+T21**

Berliner Straße 43, 35614 Asslar

With our product portfolio, we offer solutions for all vacuum applications. We are not only driven by highest quality standards. It is our vision to be the most sustainable and fastest growing market player to drive technology for a sustainable future.

Physik Instrumente (PI) GmbH & Co. KG — **Tent** — **T03**

Auf der Römerstraße 1, 76228 Karlsruhe

Lösungen für präzise Bewegung und Positionierung.

PINK GmbH Vakuumtechnik — **Economy Bldg.** — **E16**

Gyula-Horn-Straße 20, 97877 Wertheim

Vakuum- u. UHV-Kammern, Beschleunigerkomponenten, Vakuumtechnische Anlagen u. Systeme, Manipulatoren.

PREVAC sp.z.o.o. — **Foyer Audimax** — **A03**

Raciborska Str. 61, 44362 Rogów, Poland

UHV and HV components, electronics, software and complete customized measurement systems.

pureions GmbH — **H6** — **A50**

Zeppelinstraße 16, 82205 Gilching

Mass selected ion beam deposition systems for STM, AFM and components. Electrospray (ESI), clusters, ion guides, mass spectrometers, quadrupoles, ion traps, paul traps, digital square wave RF supplies.

Qioptiq Photonics GmbH & Co. KG — **H6** — **A58**

Königsallee 23, 37081 Göttingen

Excelitas, Qioptiq ist der internationale Marktführer in den Bereichen Life Sciences, Advanced Industrial, Halbleiter der nächsten Generation, Luft- und Raumfahrt und Verteidigung.

Qlibri GmbH — **Foyer Audimax** — **A35**

Karlsplatz 3, 80335 München

Cavity-based microscopes for absorption microscopy, fiber-based micromirrors, and quantum optics at ambient and cryogenic temperatures.

Quantum Design GmbH — **Foyer Audimax** — **A13+A14**

Breitwieserweg 9, 64319 Pfungstadt

Quantum Design will exhibit systems and components for magnetometry, cryogenic, electric measurements, spectroscopy and material science.

Quantum Machines — **Tent** — **T05**

Fruebjergvej 3, 2100 Copenhagen, Denmark

Founded in 2018, Quantum Machines vast portfolio includes state-of-the-art control systems and cryogenic electronic solutions that support multiple quantum processing unit technologies.

robeko GmbH & Co. KG — **Foyer Audimax** — **A47**

An der Heide 3 B, 67678 Mehlingen

Kathoden, Generatoren, Targets, Mikrowellen.

Schaefer Technologie GmbH — **Foyer Audimax** — **A04**

Robert-Bosch-Straße 31, 63225 Langen

Scanning Probe Microscopy (UHV, Cryo, Ambient, Liquid), Cryo-XYZ-Positioners and Scanners, Capacitance Bridges, Electron Microscopy.

Schäfter + Kirchhoff GmbH Optics, Metrology and Photonics — **Foyer Audimax** — **A10**

Kieler Straße 212, 22525 Hamburg

Polarization-maintaning fiber optic components including laser beam coupler, fiber collimators, fiber cables, polarization analyzers and fiber port clusters.

Scienta Omicron GmbH — **Economy Bldg.** — **E21**

Limburger Straße 75, 65232 Taunusstein

Systems and Instruments for Surface Science and Thin Film Technology.

SEKELS GmbH — **Economy Bldg.** — **E12**

Dieselstraße 6, 61239 Ober-Mörlen

Magnetwerkstoffe, Magnetische Abschirmungen, Magnetsysteme, Induktive Bauelemente, Magnetische Messtechnik.

SENTECH Instruments GmbH — **Foyer Audimax** — **A01**

Schwarzschildstraße 2, 12489 Berlin

Plasma Prozesstechnologie, Ellipsometer.

SmarAct GmbH — **Foyer Audimax** — **A37**

Schütte-Lanz-Straße 9, 26135 Oldenburg

High precision positioning and metrology solutions.

SOLITON Laser- und Meßtechnik GmbH — **Economy Bldg.** — **E10**

Talhofstraße 32, 82205 Gilching

Laser, APT Atom Probe Tomography, SLM, Messtechnik, Sensoren, Laserzubehör, Spektroskopie

Specialised Imaging Limited — **Tent** — **T18**

6 Harvington Park, Pitstone Green Business Park, Pitstone, Bucks LU7 9GX, United Kingdom

Design, Manufacture, Consultancy and Service of Ultra-High Speed Imaging Systems. Cameras up to 1 Billion frames per second.

SPECS Surface Nano Analysis GmbH — **Foyer Audimax** — **A19+A20**

Voltastraße 5, 13355 Berlin

Photoelektronenspektroskopie, Rastersondenmikroskopie, winkelaufgelöste Photoemission, Elektronenmikroskopie.

Springer-Verlag GmbH — **Foyer Audimax** — **A34**

Europaplatz 3, 69115 Heidelberg

Wissenschaftliche Bücher, Zeitschriften, Datenbanken.

Staib Instrumente GmbH — **Tent** — **T11**

Hagenaustraße 22, 85416 Langenbach

In situ growth monitoring for MBE, RHEED, TorrRHEEDTM, AUGERProbeTM, AES, XPS, UPS, REELS, electron and ion sources, complete surface analysis systems, STAIB MultitecTM.

Sumitomo (SHI) Cryogenics of Europe GmbH — **Foyer Audimax** — **A28**

Daimlerweg 5 a, 64293 Darmstadt

Cryocoolers: @4K: GMJT (9watt); RDK-101D(L); RDE-412D4; RDK-415D2; RDE-418D4; RP-062B2(S); RP-082B2(S); RP-182B2S @10K: CH-204; CH-210 @20K: RDK-500B2 @77K: CH-110; CH-160D2; New compressor: E77A.

Surface Concept GmbH — **Economy Bldg.** — **E18**

Am Sägewerk 23 a, 55124 Mainz

MCP based detectors, ToF momentum microscopes, Fast analoge readout electronics.

SweepMe! GmbH — **Tent** — **T12**

Bienertstraße 18, 01187 Dresden

Messtechniksoftware

Technische Informationsbibliothek Hannover (TIB) — **Tent** — **T16**

Welfengarten 1B, 30167 Hannover

Wissenschaftliche Fachliteratur.

Technische Universität München Forschungs-Neutronenquelle — **Economy Bldg.** — **E15**

Lichtenbergstraße 1, 85747 Garching

As a cooperation between TU München, Forschungszentrum Jülich, and Helmholtz-Zentrum hereon, the Heinz Maier-Leibnitz Zentrum is a user facility for cutting-edge research with neutrons and positrons.

tectra GmbH — **Foyer Audimax** — **A36**

Reuterweg 51-53, 60323 Frankfurt/M.

UHV Komponenten, Dünnschichttechnik, Plasmaquellen.

THORLABS GmbH — **Foyer Audimax** — **A02+A05**

Münchner Weg 1, 85232 Bergkirchen

Optische & optomechanische Komponenten, Test & Measurement Systeme, optische Tische und Vibrationskontrolle, Nanopositionierungen, Lichtquellen sowie Imaging, Mikroskopie und Life Science Komponenten.

TOPAG Lasertechnik GmbH — **H6** — **A56**

Nieder-Ramstädter Straße 247, 64285 Darmstadt

Laser und optische Messtechnik.

TOPTICA Photonics AG — Tent — T06

Lochhamer Schlag 19, 82166 Gräfelfing / München

New Tunable Diode Lasers, New Laser Frequency Stabilization, Femto Fiber Lasers, Wavelength Meters.

VACOM Vakuum Komponenten und Messtechnik GmbH — **Foyer Audimax** — **A23**

In den Brückenäckern 3, 07751 Großlöbichau

Vakuumkammer

vakuumfinder.de c/o CompoNext GbR — **Tent** — **T10**

Freiligrathstraße 35, 07743 Jena

Vakuumkomponenten, Vakuummesstechnik, Vakuumkammern, Kryotechnik, Critical Design Review, Vakuumpumpenservice, Auftragsfertigung.

Vaqtec-scientific Mario Melzer — **Economy Bldg.** — **E07**

Thulestraße 18B, 13189 Berlin

Komponenten der UHV- und HV-Technik: u.a. Stromdurchführungen, Schaugläser, Schichtdicken-Messgeräte

VASTA PTE. LTD. — **Tent** — **T08**

Blk 81 Ayer, Singapore 139967, Singapore

VASTA offers advanced solutions for cryogenic RF connectivity, single-photon detection, portable spectroscopy and Raman analysis, and low-temperature electrical transport measurement.

Wiley-VCH GmbH — **Foyer Audimax** — **A15**

Boschstraße 12, 69469 Weinheim

Verlag - Fachzeitschriften und Fachbücher.

Zurich Instruments Germany GmbH — **Foyer Audimax** — **A22**

Mühldorfstraße 15, 81671 München

Lock-in Amplifier, Impedance Analyzer, Arbitrary Waveform Generator, Quantum Control System, Oscilloscope.
